*Hanford Site Waste Management Units Report*
February 2015
The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

</tbody>
</table>
Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.
Inactive

The waste site has been remediated and Interim Closed Out. The site consisted of a burned area with glass, cinders, slag, metal and the underlying soil.

The site was located 12 meters (39 feet) north east of sitecode 600-171 - White Bluffs Office. The center point coordinates for the site are E578208.20, N148209.90.

Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Remnants of the burned debris included nails and tar like roofing material. The site appeared to be next to an area where a building had once been located.

**Location:** The site was located 138 meters (452 feet) southeast of WIDS sitecode 600-200, on the north side of a White Bluffs Office. Center point coordinates for the site are E578238.91, N147691.25.

**Closure Info:** Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was
determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.
### Code: 600-316  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (8/7/2013)

### Names: 600-316; Dry Cell Batteries  
### Type: Unplanned Release  
### Status: Inactive

### Description:
The waste site has been remediated and Interim Closed Out. It was described as six areas with dry cell battery debris lying on the ground surface near Route 2 North. The six areas (subsites) were evaluated in the same document and Interim Closed Out on a single Reclassification form.

Area 1 consisted of debris from a dry cell battery pack in an area less than 1 meter (3 ft) in diameter.

Area 2 consisted of farmstead debris including items such as cans and bottles and included four dry cell batteries in a 5 meters (16 ft) diameter area.

Area 3 consisted of debris from a dry cell battery pack. The affected area was less than 1 meters (3 ft) in diameter.

Area 4 consisted of debris from a dry cell carbon core battery pack in an area less than 1 meter (3 ft) in diameter.

Area 5 consisted of debris from dry cell carbon core batteries in an area less than 1 meter (3 ft) in diameter.

Area 6 consisted of debris from a single dry cell battery that was found during the site visit conducted on 02/20/2008.

### Location:
The six debris areas were located west of the Hanford Construction Camp and along three miles of Route 2 North.

Area 1 was located approximately 86 meters (282 ft) north of Route 2 North and 1.8 kilometers (1.1 miles) southeast of the intersection of F Avenue and Route 2 North.

Area 2 was located approximately 848 meters (0.5 miles) west of Route 2 North and 3.2 kilometers (2 miles) north of Route 11A.

Area 3 was located approximately 725 meters (0.5 miles) west of Route 2 North and 1.2 kilometers (0.75 miles) north of Route 11A.

Area 4 was located approximately 235 meters (771 feet) west of Route 2 North and 1.6 kilometers (1.0 miles) north of Route 11A.

Area 5 was located approximately 58 meters (186 feet) west of Route 2 North and 941 meters (0.6 miles) north of Route 11A.

Area 6 was located approximately 61 meters (200 ft) north of Route 2 North and 688 meters (0.4 miles) southeast of the intersection of F Avenue and Route 2 North.

### Closure Info:
Site visits and geophysical surveys were done in June and November 2011. The results determined that remediation was required. Remediation activities began in July 2011 and continued through February 2013.

The waste site boundaries were re-defined during the remediation process. The excavation extent removed all the debris associated with the battery waste sites.
No anomalous material or stained soil was discovered during remediation activities of either the 600-316 or 600-318 waste sites. All material was direct loaded for disposal to the Environmental Restoration and Disposal Facility (ERDF).

</tbody>
</table>
The six areas (subsites) were evaluated in the same document and Interim Closed Out on a single Reclassification form. Area 2 consisted of farmstead debris including items such as cans and bottles and included four dry cell batteries in a 5 meters (16 ft) diameter area.

Area 2 was located approximately 848 meters (0.5 miles) west of Route 2 North and 3.2 km (2 miles) north of Route 11A.

Site visits and geophysical surveys were done in June and November 2011. The results determined that remediation was required. Remediation activities began in July 2011 and continued through February 2013.

The waste site boundaries were re-defined during the remediation process. The excavation extent removed all the debris associated with the battery waste sites.

No anomalous material or stained soil was discovered during remediation activities of either the 600-316 or 600-318 waste sites. All material was direct loaded for disposal to the Environmental Restoration and Disposal Facility (ERDF).

The six areas (subsites) were evaluated in the same document and Interim Closed Out on a single Reclassification form. Area 3 consisted of debris from a dry cell battery pack. The affected area was less than 1 meters (3 ft) in diameter.

Area 3 was located approximately 725 meters (0.5 miles) west of Route 2 North and 1.2 km (0.75 miles) north of Route 11A.

Site visits and geophysical surveys were done in June and November 2011. The results determined that remediation was required. Remediation activities began in July 2011 and continued through February 2013.

The waste site boundaries were re-defined during the remediation process. The excavation extent removed all the debris associated with the battery waste sites.

No anomalous material or stained soil was discovered during remediation activities of either the 600-316 or 600-318 waste sites. All material was direct loaded for disposal to the Environmental Restoration and Disposal Facility (ERDF).
Description: The six areas (subsites) were evaluated in the same document and Interim Closed Out on a single Reclassification form. Area 4 consisted of debris from a dry cell carbon core battery pack in an area less than 1 meter (3 ft) in diameter.

Location: Area 4 was located approximately 235 meters (771 feet) west of Route 2 North and 1.6 kilometers (1.0 miles) north of Route 11A.

Closure Info: Site visits and geophysical surveys were done in June and November 2011. The results determined that remediation was required. Remediation activities began in July 2011 and continued through February 2013.

The waste site boundaries were re-defined during the remediation process. The excavation extent removed all the debris associated with the battery waste sites.

No anomalous material or stained soil was discovered during remediation activities of either the 600-316 or 600-318 waste sites. All material was direct loaded for disposal to the Environmental Restoration and Disposal Facility (ERDF).

The SubSite is Part Of:

Code: 600-316
Names: 600-316; Dry Cell Batteries

Description: The six areas (subsites) were evaluated in the same document and Interim Closed Out on a single Reclassification form. Area 5 consisted of debris from dry cell carbon core batteries in an area less than 1 meter (3 ft) in diameter.

Location: Area 5 was located approximately 58 meters (186 feet) west of Route 2 North and 941 meters (0.6 miles) north of Route 11A.

Closure Info: Site visits and geophysical surveys were done in June and November 2011. The results determined that remediation was required. Remediation activities began in July 2011 and continued through February 2013.

The waste site boundaries were re-defined during the remediation process. The excavation extent removed all the debris associated with the battery waste sites.

No anomalous material or stained soil was discovered during remediation activities of either the 600-316 or 600-318 waste sites. All material was direct loaded for disposal to the Environmental Restoration and Disposal Facility (ERDF).

</table>

Description: The waste site has been remediated and Interim Closed Out. The site consisted of a 20 meter (66 ft) diameter area that contained discarded radiological protective clothing.

Location: This site was located 521 meters from "Susie" railroad junction and 140 meters west of waste site 600-38 (Railroad Siding Susie). The clothing debris was located approximately 8 meters southwest of the rail line.

Closure Info: The contaminated clothing was found in December 2008 in an area measuring approximately 20 meters (66 feet) in diameter. It was located at coordinates N140562/E566665. The radiological control personnel surveyed the clothing and properly disposed of the clothing. The area where the clothing had been located was radiologically surveyed. No contamination was detected.

The 600-342 waste site was remediated as a "plug-in" site in accordance with the Remaining Sites ROD (EPA 1999) and associated Explanation of Significant Difference (ESD) (EPA 2009). Per the 2009 ESD, plug-in sites are documented in the Administrative Record, and an annual fact sheet will be published by DOE identifying sites that have been added to the Remaining Sites ROD. The addition of plug-in waste sites will not have a significant impact on the scope, performance, or costs of the Remaining Sites ROD (EPA 1999). No RSVP document was written. The activity was documented on Reclassification form 2010-008.

Description: This site has been remediated and Interim Closed Out. It consisted of residual ash from burned material and a trench containing pieces of asphalt.

Location: The site was located approximately 481 meters (0.3 miles) WNW of Susie railroad junction (Gable Butte).

Process Description: The site was discovered on December 10, 2008 while the WCH Inter-Area Segment 1 Orphan Site Evaluation (WCH OSR-2009-0002; 147807) was being conducted. The feature was described as a 6 by 6 square meter (387 sq. ft.) stain resembling ash and asphalt dumped in a trench.

Closure Info: Remediation of the waste site occurred on February 9, 2010. Approximately 1 meter (3 ft) of fly ash and asphalt material were removed from the trench area. All excavated material was
directly loaded into containers for shipment to the Environmental Restoration Disposal Facility. The excavation depth was 1 meter (3 ft) below ground surface. The vadose beneath the excavation was approximately 45 meters (148 ft) thick. A total of approximately 135 BCM (177 BCY) of material was removed from the waste site.

| Names: 600-344; Inter Areas Stain Site #1 | Reclassification: Interim Closed Out (10/21/2010) |
| Type: Unplanned Release | Start Date: |
| Status: Inactive | End Date: |

Description: This site has been remediated and Interim Closed Out. It consisted of an area of stained soil with pre-Hanford, metal container lids.

Location: The site was located in the southeast portion of Section 4 in Township 13N Range 25E, approximately 2.7 km (1.7 miles) northwest of the 100-B/C Area. It was approximately 0.5 km (0.34 miles) south of the Columbia River and 23 meters (75 ft) west of an unmarked road. (E561662.68; N145734.47)

Closure Info: A site walkdown was done in October 2008. One characterization sample was collected in December 2009. Remediation of the site occurred on April 26, 2010. Approximately 1 meter (3 ft) of stained soil and metal debris was removed from the area. All excavated material was directly loaded into containers for shipment to the Environmental Restoration Disposal Facility. The excavation depth was 1 meter (3 ft) below ground surface. The vadose beneath the excavation is approximately 15 meters (51 ft) thick, based on well data in the area. A total of approximately 120 bank cubic meter (BCM) (157 bank cubic yards [BCY]) of material was removed.

| Code: 600-345 | Classification: Accepted |
| Names: 600-345; 100-BC Vicinity Oil Stain and Filter Area | Reclassification: Interim Closed Out (10/21/2010) |
| Type: Unplanned Release | Start Date: |
| Status: Inactive | End Date: |

Description: This site has been remediated and Interim Closed Out. It consisted of an area of stained soil with oil filters littered around.

Location: The site was located on the south side of Route 6 approximately 450 meters (0.28 miles) west of the curve where Route 6 goes from a North/South to an East/West road. The site is approximately 28 meters (92 ft) south of 600-253 at coordinates E563569.11/N145087.08.

Closure Info: Remediation occurred on February 10, 2010. All the oil filters and stained soil were removed. The excavated area measured approximately 4 by 5 meters (12 by 15 ft) and was approximately 46 cm (18 in.) deep. A total of approximately 22 bank cubic meters (BCM) (29 bank cubic yards [BCY]) of material was removed from the waste site.

Following remediation, verification sampling was conducted in May 2010. Due to levels of total petroleum hydrocarbons (TPH) in the Quadrant 4 verification sample that exceeded cleanup criteria, this quadrant was further remediated August 2010. An additional 0.6 meters (2 ft.) of material was removed from Quadrant 4, bringing the total excavation depth to 1.06 meters (3.5 feet). The area was re-sampled. The results of all verification sampling indicated that the waste removal action achieved compliance with the remedial action objectives (RAOs)
and remedial action goals (RAGs) for the 600-345 waste site.

<tr>
<td>Description:</td>
<td>The waste site was remediated and Deleted from the NPL. It was an abandoned military site. All surface structures have been removed or leveled. Remaining features include a building foundation, roadways, parking areas, and drainage structures. The underground structure has been backfilled with 29-cubic yards of slurry. A 55-gallon drum buried to its rim, presumed to be a drywell, was also backfilled. Its function is unknown.</td>
</tr>
<tr>
<td>Location:</td>
<td>The site was located north of 100-F Area, on the opposite side of the Columbia River. (NW 1/4 Section 34, T 15N R 27E; one mile north of Highway 24 at mile marker 62 1/2).</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>One underground storage tank had been placed at this site during military operations. While the approximate location was known during the remedial activities, no evidence remained of the tank. It was assumed to have been removed during excess operations in the 1970s. A 208 liter (55 gallon) barrel, now backfilled, is buried to the rim at the perimeter of the site. An underground structure has also been filled in with slurry.</td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Process Effluent</td>
</tr>
</tbody>
</table>
Waste Description: The unit contained miscellaneous debris including: paint cans, construction materials, asbestos siding and brake pads, and exposed re-bar associated with structure foundations.

Closure Info: In 1974 the Atomic Energy Commission initiated a cleanup. Two missile magazines were demolished with explosives in June 1974. In 1993, the debris was removed and the underground bunker was filled with 29 cubic yards of slurry.

The 55-gallon drum "drywell" and a rock filled pit were sampled during the Expedited Response Action investigations (Sample numbers B07KQ2 and B07KQ3). No environmental hazards were identified.

As reported in the interim closeout report (DOE-RL 1994), full characterization of the H-06L landfill began in April 1994 as a confirmation of the sampling results per the Action Memorandum (Ecology and EPA 1994). Each location identified by the geophysical investigation (WHC 1992) as having an anomaly was excavated with a bulldozer or backhoe. Suspect waste was sampled for characterization by an offsite laboratory.

Table 4.1 of CDM (1994) details the wide variety of debris found at the anomalies excavated, including construction debris, oil filters, light bulbs, batteries, car frames, 208-liter (55 gallon) drums, transite, sheet metal, roofing tar, empty insecticide cans, bottles, dried paint, wood, shoes, rags, paper, food cans, silverware, auto engines, and a toilet bowl. A small cistern was backfilled. Table 4-4 of CDM (1994) describes the media and location of each of the samples taken from the landfills.

Approximately 459 cubic meters (600 cubic yards) of DDT-contaminated soil was discovered and disposed of at the Chemical Waste Management Hazardous Waste Landfill in Arlington, Oregon. More than 153 cubic meters (200 cubic yards) of petroleum-contaminated soil were found and disposed of in Pasco. Six 208-liter (55-gallon) drums of soil contaminated with metals from paint, tar-like waste, and soil from beneath several pesticide cans were designated and sent to the Hanford 616 waste facility. No ordnance or explosive waste was found.

Based on these discoveries, the U.S. Environmental Protection Agency (EPA) and Washington State Department of Ecology (Ecology) asked that the remaining North Slope disposal areas also be characterized and remediated as needed (DOE-RL 1994). Each of 10 potential landfill sites received a geophysical investigation to identify and excavate anomalies (Smith and Rhoades 1994). Because this site served as an analogous site for all the other military landfills, and because of the elevated levels of contamination found at this site, Ecology and EPA requested that all the military landfills be characterized and remediated as necessary (DOE-RL 1994).

This site was assumed to have an acid neutralization pit, based on facility drawings, but field investigators were unable to locate it at this site. Using the analogous approach, the pit at Site H 12L (600-6) was sampled. No areas of contamination above regulatory limits were detected (CDM 1994).

The waste site has been remediated and Deleted from the Nation Priority List. It was a burial trench, approximately 122 meters (400 feet) by 18.3 meters (60 feet), used for disposal eleven empty tanks and soil contaminated with 2,4-Dichlorophenoxyacetic acid (2,4-D). The disposal

Hanford Site Waste Management Units Report
February 2015
593
The 2,4-D burial site is located across the Columbia River from 100 F Area. It is approximately 0.5 miles east of the Columbia River and south of the old White Bluffs townsite at the toe of an encroaching sand dune. (Section 35T, 14N, R27 E)

In 1966, the U.S. Bureau of Reclamation (USBR) used this site to bury 46 meters (50 yards) of soil contaminated with 3,407 liters (900 gallon) of 2,4-D that had leaked from storage tanks from a USBR station in Eltopia, Washington (Roos 1990). In 1967, the USBR flattened and buried a reported eleven 2,4-D storage tanks (3.7 meters [12 feet] long with 1.2-meters [4-feet] diameters) in the same excavation as the contaminated soil (Ecology and DOE-RL 1997). The site has not been used since 1967, but the specific location of the burial trench and the dates the items were disposed on are not documented (Ecology and DOE-RL 1997). The half-life of 2,4-D in the soil under dry conditions is usually between 9.4 and 254 days with the average typical half-life under normal application conditions being about 10 days (Cramer 1985, DOE-RL 1994).

In 1966, 2,4-D contaminated soil was generated from leaking storage tanks at a USBR Station in Eltopia, WA. The burial consisted of 900 gallons of 2,4-D that had leaked into 50 cubic yards of soil. A second burial in 1967 consisted of the ten storage tanks, which were flattened and buried in the same location.

Samples were collected from eight evenly spaced auger-rig borehole locations at the site in February 1993. Locations 1, 2, 3, and 4 showed less than detection limit results for field analysis of 2,4-D, so these samples were composited into sample number B07KQ6. Locations 5, 6, and 7, also less than the detection limit for field analysis, were composited into sample B07KQ7. Sample B07KQ5 was taken from location 8, which showed a positive (but near detection limit) field analysis result for 2,4-D (Lucas 1993). The laboratory samples showed no detectable levels of 2,4-D. (DOE/RL-2002-74).

Based on the 1993 sampling results and expected life span of the 2,4-D in the environment, only verification sampling (characterization) and hazard mitigation (if justified) was required for the site. In February and March 1994, geophysical surveys were conducted at the site to more precisely locate the buried tanks so angle borings could be drilled close to the edges of the tanks for the verification sampling. In July 1994, the U.S. Army Corps of Engineers drilled four exploratory holes at an incline under the buried tanks. Four samples were collected per borehole, plus two duplicate samples and one split provided to Ecology for a total of 19 samples. No 2,4 D or breakdown products were detected. The samples were analyzed for chlorinated herbicides with a method detection limit for 2,4-D of 0.2 ppm (Shannon & Wilson 1994c, Ecology and DOE-RL 1997).

In 1997, a hunter reported to the Fish and Wildlife Commission that he had seen the weathered, 2,4 D Burial Site warning signs and he believed there was still contamination at the site. The EPA toured and investigated the site on May 3, 1997 with the hunter and conducted cursory sampling by digging four small pits that were 0.9 meters (3 feet) in diameter and 0.6 meters (2 feet) deep at locations that showed stressed vegetation. These pits were located 1.5 to 3 meters (5 to 10 feet) from the base of the sand dune and at random locations 6.1 to 61 meters (20 to 200 feet) north of the buried tanks. During the investigation, strong chemical odors were encountered (Ecology and DOE-RL 1997).

Four samples were collected, one of which had a detectable level of 2,4-D higher than the cleanup standard of 800 ppm. This "hot spot" had 2,4-D concentrations of 2,500 ppm (Ecology and DOE RL 1997). The "hot spot" was estimated as 7.6 meters long by 4.6 meters wide by 1.5 meters deep (25 feet long by 15 feet wide by 5 feet deep) (Lerch 1998). The results of this "hot
The characterization sampling data showed 2,4-D as high as 17,000 ppm and approximately 15 cubic meters (20 cubic yards) of contaminated soil that were above the cleanup standards. In addition, the 2,4-D sample contained dioxin levels that exceeded the MTCA standards of 0.00000667 ppm. The contamination ranged from 0.6 to 2.4 meters (2 to 8 feet) deep in the soil. Additional hand auger samples to depths of 1.5 meters (5 feet) taken by EPA indicated further 2,4-D levels ranging from 1,000 to 1,300 ppm (Ecology and DOE-RL 1997).

Contamination was considered to potentially go 3 meters (10 feet) deep and all across the area, based on the sampling data. There is no impact on the groundwater in the area as the groundwater is over 90 meters (300 feet) below the surface of the site and, hence, is not contaminated or impacted by the 2,4-D at this location (Ecology and DOE-RL 1997).

The site was reopened and remediated under a CERCLA Action Memorandum issued in 1997 (Ecology and DOE-RL 1997). In August and September 1997, the bioremediation efforts were underway at this site. Excavated soil was placed on a plastic liner 30 mm thick, and composted manure was tilled into the soil and irrigated regularly (Lerch 1998). Random samples were periodically collected until the results fell within the allowable limits for 2,4-D, which marked the end of the bioremediation process for this waste site (Lerch 1998). The 2,4-D and dioxin-contaminated soil from the "hot spot" identified in May 1997 was excavated and shipped as U240-listed waste to the Laidlaw, Deer Park Treatment, Storage, and Disposal Facility in Texas. About 25 cubic meters (80 cubic yards) of contaminated material was shipped to Texas. Ten crushed tanks were found and removed as well (the eleventh tank was not found). They were shipped as U240-listed waste to the Laidlaw, Grassy Mountain Treatment, Storage, and Disposal Facility in Utah (Lerch 1998). As reported in Lerch (1998, sample numbers, cleanup criteria, and results on pages A-1 and A-2 of DOE/RL-2002-74), five confirmation samples were collected from the excavated tank pit, 20 from the excavated trench, and 11 from the bioremediation area. All results were below the cleanup criteria.

All the objectives established in the 1997 Action Memorandum were met as stated in the closure document 100-IU-3 Waste Site 600-104 Remediation Summary (Lerch 1998).
100-IU-4

**Code:** 600-105 **Classification:** Accepted

**Names:** 600-105; SDBDL; Sodium Dichromate Barrel Disposal Landfill **Reclassification:** Final Closed Out (2/12/1996)

**Type:** Burial Ground **Start Date:** 1/1/1945

**Status:** Inactive **End Date:** 1/1/1945

**Description:** The site has been remediated. It contained approximately 5000 crushed 55 gallon drums. The 1993 Sodium Dichromate Expedited Response Action removed the crushed barrels and small amounts of other waste.

**Location:** The site was located in a small depression between 100-D and 100-H areas. It was approximately 130 meters north of the access road that runs between where the 100-D Badge House and the 100-H Badge House were located.

**Process Description:** There is very little historical information documented about this site. The landfill was used during the reactor operation years as a disposal site for crushed, empty Sodium Dichromate barrels. Sodium Dichromate was used as a corrosion inhibitor in the reactor cooling water systems.

**Waste Type:** Steam Condensate

**Waste Description:** The wastes disposed of at this site were empty, crushed drums containing sodium-dichromate residue. It is estimated, assuming that 1% of the original quantity of sodium dichromate remained in the drum on disposal, that 30.9 tons of sodium dichromate were disposed. The sodium dichromate was used for water treatment in the 100 Areas. This disposal technique was used only once at this site.

**Closure Info:** The crushed drums were removed between March 17, 1993 and April 26, 1993. Conventional earth moving equipment was used exhumed the barrels and to transport them to the Central Landfill. During the removal activities, small quantities of asbestos, waste oil and batteries were found. These items were disposed of as hazardous waste.

The area included 144 anomalies located in eleven subsurface zones. Four zones contained empty, crushed sodium dichromate barrels. The areas were excavated to a maximum depth of 7 feet. Approximately 5000 crushed barrels and miscellaneous debris (wire fencing and wood posts) were transported to the Central Landfill.

Besides containing crushed drums, the four zones included some loose asbestos, one crushed drum full of asbestos. The drum of asbestos went to the Central Landfill asbestos section for disposal. Other anomalies included two 5 gallon roofing tar cans, one paint can, and used oil and grease (about 0.5 gallons total). These materials were placed in three 55 gallon drums and sent to an offsite disposal facility.

This was the only waste site in Operable Unit 100-IU-4. A 1996 Record of Decision was issued stating that no further remedial actions are necessary in 100-IU-4.
### 100-IU-5

**Code:**  600-106  
**Classification:**  Accepted  

**Names:**  600-106; WBPAC; White Bluff Pickling Acid Cribs; White Bluffs Pickling Acid Cribs  
**Reclassification:**  Final Closed Out (2/12/1996)

**Type:**  Crib  
**Start Date:**  1/1/1943

**Status:**  Inactive  
**End Date:**  1/1/1945

**Description:**  The site has been characterized and closed with a No Action alternative. The cribs are located west of 100-F Area, south of the intersection of Route 2 North and Federal Ave. The site consisted of two cribs located side by side. The western crib was 200 feet by 45 feet with a 3 foot diameter riser pipe. The eastern crib was 225 feet by 50 feet. Vent pipes protruded from the surface of each crib at 7 to 9 foot intervals. The surface was covered with large cobbles.

**Process Description:**  It is assumed that the cribs received acid etch solutions from the pipe fabrication facility located northeast of the cribs. Nitric and Hydrofluoric acids were used to "pickle" galvanized pipe before being used in the construction of the 100 Area reactors.

**Waste Type:**  Steam Condensate  
**Waste Description:**  The site was used to dispose spent pickling acid used to pickle galvanized piping for use in the reactor buildings during construction. The process used several thousand gallons of nitric and hydrofluoric acid. Generally, the acid was neutralized prior to disposal, but may not have been completely neutralized prior to disposal. Chromium was also identified as a contaminant of concern.
100-IU-6

**Code:** 600-3  
**Classification:** Accepted

**Names:** 600-3; Hanford Townsite Excess Material Storage Yard/Paint Pit

**Reclassification:** Interim Closed Out (9/14/2011)

**Type:** Dumping Area  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site has been remediated and Interim Closed Out. It consisted of a shallow trench that appeared to be an old borrow pit. The trench was approximately 37 by 27 by 1.2 meters (120 by 90 by 4 feet). The dumping area spread out over an area approximately 280 by 490 meters (925 by 1,600 feet). Both the dumping area and pit showed signs of an attempt to cover the waste with a bulldozer, as tracks were visible throughout the areas. The site also had evidence of burning. The remains of an old railroad spur was just east of the waste site. Debris included metal items, cans, burned wood, transite piping and rubber. Several radioactively contaminated items were found during the remediation activity.

**Location:** The site was located north of Gable Mountain, west of Route 2 North, south of Route 1, and approximately 0.8 kilometers (0.5 miles) south of the intersection of Route 1 and Route 2 North.

**Waste Type:** Process Effluent

**Waste Description:** Dried paint and paint cans can be found on the south side of the pit. Closure rings for 208-liter (55-gallon) drums, roofing paper, and a white fibrous substance suspected of being asbestos are also present. The dumping area contains various solid wastes that include, broken wet cell battery cases and plates, stainless steel pipe and materials, various sizes and types of containers (three which are labeled as containing ethylene glycol), machining operations cuttings, pieces of aluminum, pieces of galvanized sheet, burnt wood, and the remains of dry cell batteries.

**Closure Info:** Based on existing historical information of the 600-3 waste site, the waste site was recommended for remove, treat, and dispose (RTD) in the Remaining Sites ROD (EPA 1999). Remedial action at the 600-3 waste site began in February 2010, and was completed in February 2011.

On February 23, 2010, a piece of 2.5-cm (1-in.) diameter pipe, approximately 5 cm (2 in.) long, was found amid other debris. The pipe had a bright yellow discolored surface and had field radiological readings of approximately 88,000 disintegrations per minute beta/gamma. The radiation was fixed and no dose was coming from the item. This discovery initiated the posting of the area as a contamination area (CA). Work was suspended at 600-3 until a path forward could be determined.

Excavation began again on April 13, 2010, with radiological controls in place. Several beta-gamma contaminated items were found throughout the remediation process, which led to the site being posted as a radiological buffer area (RBA) and soil contamination area (SCA). Other waste items found in concentrated locations at the waste site included paint, pin boxes, drums, crucibles, miscellaneous metal debris, lead sheeting and batteries, and potentially friable asbestos. Several areas of disturbed vegetation, staining, and burning were also found.

The final excavation footprint at the 600-3 waste site consists of a large excavated area divided into the east and west excavations, three waste staging pile area footprints, and smaller areas where concentrated contaminated materials were found, some of which are outside of the main excavation footprint. All of the staged waste was loaded out to the Environmental Restoration Disposal Facility (ERDF). The areas where concentrated lead batteries were found outside of the main excavation also have associated small waste staging pile footprints, which have been
loaded out to the ERDF. Across the main excavation footprint, the depth of excavation ranged from 1 meter (3 ft) to 6 meters (20 ft).

<tr>
<td>Closure Info:</td>
<td>Remedial action at the 600-23 site began on February 1, 2001. More than 16,330 metric tons (18,000 tons) of material were excavated from the 600-23 site and transported to ERDF for disposal. In addition, approximately 60 drums of tar and asphalt-like material were removed and sent to an offsite facility for treatment and disposal. Material excavated from the site included soil, concrete, equipment (1706-KE laboratory material), drums, and debris (batteries, elemental lead debris, chromium contaminated debris, vitrified glass). Other than a small amount of liquid present in some of the drums and in a piece of process equipment, there was no liquid waste encountered during the excavation. Clean overlying and co-mingled soil that was segregated during the excavation process was stockpiled at the site for use as backfill. This stockpiled soil is referred to as overburden throughout the rest of this CVP. Approximately 91.7 cubic meters (120 cubic yards) of concrete debris excavated during remediation, with individual</td>

</tbody>
</table>
The remaining soils at the 600-23 site have been sampled, analyzed, and modeled. The results of this effort indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River. Based on agreement between EPA and DOE on concrete sampling analyses results, remaining site concrete debris will be used to partially backfill the site excavation.

---

**Code:** 600-107  
**Classification:** Accepted  
**Names:** 600-107; Gable Mountain Plutonium Storage Vault Cribs; 213-J & K Cribs; 213-J&K Cribs  
**Reclassification:** Interim No Action (2/9/2004)  
**Type:** Crib  
**Status:** Inactive  
**Start Date:** 1/1/1944  
**End Date:** 1/1/1950  
**Description:** The site has been evaluated and determined to require No Action. The sites consisted of two small cribs (gravel filled culverts) located on the southwest corner of 213-J and the southeast corner of 213-K Storage Vaults.  
**Location:** The site was located north of Route 11A, at the base of Gable Mountain.  
**Related Sites/Structures:** The cribs were co-located with the 213-J&K Vaults.  
**Process Description:** The cribs were gravel-filled concrete culverts. Each had a black iron distributor pipe, 5.1-centimeter (2-inch) diameter, running its length approximately 1.2 meters (4 feet) below ground level. Each was covered by a 5.1-centimeter (2-inch) thick concrete slab.  
**Waste Type:** Animal Waste  
**Waste Description:** Very little water solution ever entered this unit. The distributor piping was removed and inspected. Rust scale taken from the interior of the pipes was found to be free of radioactivity background levels. The unit was removed from radiation zone status on November 11, 1974.  
**Closure Info:** A backhoe was used in November 1974 to excavate down to the crib structures to allow for radiological surveys and sampling of the soil and inlet piping. No contamination was found above background limits. The backhoe essentially destroyed the crib structures. The excavated material was returned to the hole and backfilled. The cribs were removed from radiation zone status. The words Contaminated Material had been inscribed on the concrete cover slabs. The words were removed with a jack hammer.  

Waste Site Evaluation, 600X-CA-V0025, Rev 3, (BHI 2004) demonstrated that the cleanup verification results from samples of underlying soil support the no action reclassification of the site. Residual material at the site achieves the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL-96-17) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (EPA 1999).  

In May 2003, confirmatory samples were collected from the two cribs by digging a test pit was dug at each crib. Smear samples were collected from the inlet piping of each crib. Subsurface
soil samples were collected from each crib. The sample results verify material at the site does not exceed the Remedial Action Goals (RAG).

**Code:** 600-108  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (7/19/2011)  

**Names:** 600-108; 213-J & K Magazine Waste Storage Cavern; 213-J&K Storage Facility (SF); 213-K Vault; 218-E-16  
**Start Date:** 1/1/1944  
**End Date:**  

**Type:** Storage  
**Status:** Inactive  

**Description:** Sitecode 600-108, refers to the 213-K Vault. The 213-J Vault is described in sitecode 600-257. Both vaults have been remediated and Interim Closed Out.

The 213 facility was constructed into the south side of the base of Gable Mountain. The vaults are two parallel reinforced concrete, earth covered storage facilities. The south end of each vault forms a continuous reinforced concrete wing-shaped retaining wall with an attached reinforced concrete loading platform. Distance between the two vaults is 13.6 meters (44.5 feet). Each vault contains three rooms: magazine, vestibule, and instrument room. There are two outside, steel-hinged doors opening onto the loading platform. An inner steel vault door separates the vestibule from the magazine. The 213-J Vault is the western vault. The 213-K Vault is the eastern vault.

**Location:** The unit is located north of Route 11A, east of Gable Mountain Pond.

**Related Sites/Structures:** The site is associated with two cribs (sitecode 600-107) and the 213-J Vault, sitecode 600-257.

**Process Description:** The vaults were originally built to store containers of processed plutonium product and waste boxes. Later, the vaults were used to store explosives and ammunition, and for seismic testing.

The 213-K vault was used to store equipment in drums that had been contaminated with radioactive sodium. A radiological survey done in October 1981 states the drums had maximum dose rates of 5 millirad per hour. The same radiological surveys reported no smearable contamination in the vault. A radiation survey on July 17, 1990, showed no contamination on the drums. Sodium-22 has a half-life of 2.6 years; sodium-24 has a half-life of 15 hours.

**Waste Type:** Steam Condensate  
**Waste Description:** The vaults were originally constructed for storage of Hanford plutonium product in containers. They were used only briefly, (1944-1947), for that purpose. They were subsequently used to store explosives, ammunition and drums of equipment contaminated with radioactive sodium. Dose rates up to 5 millirad/hour were measured inside 213-K, on the drums containing sodium contaminated equipment (10/21/1981). No smearable radioactivity was detected on any of the surfaces inside the vaults. All contaminated materials have been removed from the 213-K Vault. It is now empty. Both the 213-K and 213-J vaults have been released from radiation zone status. This site was listed as a candidate for sampling in the 100 Area Remaining Sites ROD. Based on a site walkdown conducted in 2003, it was determined that this site required remedial action. Material containing asbestos and other potentially hazardous material was observed.

**Closure Info:** The vaults were used for storage of processed plutonium from 1944 to 1947, and were surrounded by a barbed wire fence and guard tower, both of which are no longer present. Processed plutonium product and waste were sent to the vaults in boxes. The 213-K Vault had also been used to store drums containing equipment that had been contaminated with radioactive sodium. All contaminated materials have been removed from the 213-K Vault, and
it was empty prior to the initiation of remedial activities. The 213-J Vault was used in more recent years to store uncontaminated soil samples for use in fallout studies. These soil samples were removed from the vault in March 2002 in the process of emptying the vault. A waste site walkdown was performed on January 9, 2001, to verify that nothing was stored inside the 213-K Vault. The vault was empty and no radiological postings were found. An additional site walkdown was performed on May 1, 2003, at which time the fan room between the two vaults was assessed. Transite and other potential asbestos containing materials were used in construction of the fan room and in the construction of a fire-safe door in the interior of the vaults. The wood of the fan room building roof was found to be rotting and caving in. A 189-L (50-gal) condensate collection tank was found inside the fan room that may have been connected to the outside condensate piping seen on geophysical surveys of the area. No radiological readings were found in the floor drain or elsewhere in the fan room building.

The 600-108 and 600-257 waste sites were remediated together and documented in the RSVP-2011-051. The vaults were split into two sitecodes in June 1999 to accommodate multiple contractor responsibilities.

Remedial action at the sites began on November 8, 2010, and was completed on January 20, 2011. A small oil spill near the vault entrance was assessed. Concrete and other debris were stockpiled prior to removal from the 600-108 excavation for shipment and disposal to the Environmental Restoration Disposal Facility. The overburden soils that surrounded the vaults were stockpiled adjacent to the waste site and will be used to re-contour Gable Mountain to its pre-Hanford conditions. The foundation of the vaults was removed entirely, to a depth of approximately 1 to 2 meters (3 to 6 ft) at the base.

On December 9, 2010, an oil reservoir was found in the fan room at the 600-108 waste site, and a small amount of oil was released to the ground just south of the vault entrance. Most of this oil spilled onto a concrete slab that was subsequently removed; however, a small amount may have leaked under the wall into the area where the vaults were located. In-process samples were collected from this oil spill. The spilled oil was staged on Griflon to the south of the excavated area.

---

**Code:** 600-109  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (2/1/2011)  
**Names:** 600-109; Hanford Trailer Camp Landfill; HTCL  
**Type:** Sanitary Landfill  
**Start Date:** 1/1/1943  
**End Date:** 1/1/1945  
**Status:** Inactive  
**Description:** The waste site has been remediated and Interim Closed Out. Surface markings suggest that materials have been covered by bulldozing with excavation spoil. Visible debris, including glass, metal and concrete, was widely scattered within the gravel pit. A large pile of river rock was located in the central part of the excavation.  
**Location:** The site was located west of the old Hanford High School, north of Roosevelt Avenue, inside Gravel Pit 15.  
**Related Sites/Structures:** The site is associated with Gravel Pit 15.  
**Waste Type:** Steam Condensate  
**Waste Description:** The unit was used for typical domestic wastes that were used during construction of the Hanford Site facilities. Debris includes metal, glass, fabric and rubber. Nondomestic metal scrap, rebar and concrete is also present.
Closure Info: During a site walkdown in May 2004, minimal surface debris was found at the site. However, several relatively large anomalous zones were identified that have the character of buried debris or garbage. The majority of the debris appears to be buried within a 120 by 200 meter (394 by 656 feet) area, all within the Gravel Pit 15 boundary. Pre-Hanford orchards were located in this area.

Following an archaeological investigation and waste characterization sampling in September 2009, the site was remediated from January to March 2010. Based on the site walkdown, geophysical survey, and observations during an archaeological investigation, confirmatory sampling was determined to be unnecessary, and the waste site was recommended for Remove, Treat, and Dispose (RTD). The excavation was approximately 4.6 meters (15 ft) deep in most areas with several places that were slightly deeper. Approximately 9,108 bank cubic meters (BCM) (11,913 bank cubic yards [BCY]) of material was removed from the excavation. Potential asbestos-containing material was secluded from the rest of the excavation, and was directly loaded into ERDF cans.

Code: 600-110  Classification: Accepted
Type: Sanitary Landfill  Start Date:
Status: Inactive  End Date: 1/1/1943

Description: The site has been evaluated and determined to require No Action. It consisted of an unlined excavated area that had been backfilled.

Location: The unit was located south of the Hanford Construction Camp between Route 2S and the Hanford Swimming Pond in the horseshoe bend of the irrigation canal.

Process Description: Research indicated that the landfill was possibly used as a canal that carried water for irrigation. Additional research noted that it operated as an unlined excavation used to dispose of typical industrial and domestic wastes from 1850 to 1943 from the original Hanford townsite. Following the site's operational use, it was backfilled with clean fill for the construction of the Hanford Construction Camp. Stenner et al. (1988) reported that the waste site was not intended to receive radioactive waste. Research also suggested that this waste site was active after 1944 and continued to receive industrial and domestic waste. Early photographs indicated no Hanford Works related ground-disturbing activities prior to March 1944, other than construction for the nearby Hanford Irrigation Canal.

Waste Type: Steam Condensate

Waste Description: The site was used to dispose of normal industrial and domestic wastes common for the period.

Closure Info: In February 2004, a site walkdown documented the presence of domestic debris that included milk bottles, canning jars, colored glass and metal cans scattered on the surface of the site. A geophysical survey was done and identified subsurface debris. Three test pits were dug. No hazardous debris or stained soil was found, so no samples were collected.

The site reclassification to No Action decision was supported based on reviews of the site history, field observations, geophysical surveys, and the confirmatory field investigation results conducted for the Remaining Sites Verification Package (RSVP). No hazardous debris or stained soil was found at the surface of the site or in the subsurface soil during excavation of anomalous areas.
The waste site has been Interim Closed Out. The site consisted of the P-11 Critical Mass Laboratory which included two facilities (120 Experimental Building and 123 Control Building), a crib, two septic system associated tile field and pipelines, and underground piping and remaining soil contamination. The facilities, crib, and underground piping were decontaminated and demolished in 1974. The facility cleanup plan was unclear whether the concrete foundation of the 120 Building was removed. The foundation of the uncontaminated 123 Building does remain below grade. This site also included two septic tanks.

The 120 Building contained two test rooms, a change room with shower, lavatory, service sink and hot water tank. The flooring was a 30.5 cm (12 in) concrete slab perforated by floor drains. The floor drain material went via piping into a below grade catch basin. From the catch basin, the outlet pipeline went to the waste disposal crib.

The waste disposal crib was constructed of concrete slabs interlaced together to form an 2.4 m by 2.4 m by 1.5 m (8 ft by 8 ft by 5 ft) crib. At one time, a fence surrounded the crib.

The septic system was located due east of the 123 Building. There were two septic tanks, an old and a new (identified on drawing H-7-698). The old septic tank, located approximately 14.7 meters (48.2 ft) from the 123 Building was filled with dirt and abandoned in place. Drawing H-7-698 Note 3 identifies that the original tank had been damaged. The piping from the 123 Building to the new septic tank was replaced with new 10 cm (4 in) vitrified pipe. The new septic tank was located approximately 0.5 meter (1.6 ft) east of the abandoned septic tank. The tile field begins approximately 36.7 meters (120.4 ft) further east and had twelve laterals, six per side.

The crib and septic systems were located at the P-11 Critical Mass Laboratory, approximately 4.8 kilometers (3 miles) south-southeast of 100 F Area and 0.5 kilometers (1/3 mile) west of Route 2N.

On November 16, 1951, a critical excursion (an uncontrolled criticality) resulted in extensive plutonium contamination to the interior of the 120 Building. During the final stages of decontamination work to reactivate the facility, December 4, 1951, a fire broke out in the southwest part of the building apparently from spontaneous ignition of decontamination materials. The fire gutted the storage room and chemistry laboratory, burned through the ceiling, melted the aluminum filter ducts, and set fire to the exhaust filters. Contamination was extensive in this area and throughout the attic after the vent system was breached. Because connecting doors were open, contamination also spread to other parts of the building, particularly to the process rooms. The spread of contamination was augmented by fire control measures, resulting in radioactive particulates being washed to the outside of the building along the foundation and door thresholds. The contamination was fixed using sealants and concrete grout. The 120 Building was sealed off and abandoned in consideration of the high risk and cost to decontaminate and restore the facility for continued criticality studies.

The site is associated with the P-11 Critical Mass Laboratory (120 Building Criticality Laboratory) and UPR-600-16.

The P-11 Project was developed as an experimental facility to support proper design of new chemical separation facilities and was a prerequisite to increased batch size in the 200 Area.
process. Prior to 1952, the P-11 Facility was used as a laboratory for plutonium criticality studies. The facility consisted of two buildings, the 123 Building (a converted residence) and the 120 Building. The 123 Building, which served as the control house, had been razed (prior to 1974). No plutonium contamination was involved at this component of the site. The 120 Building, which was a single story sheet metal building (oriented north-south) contained the critical assembly room, a small chemistry laboratory, storage and tank room, and a change room. Drain lines from the building and process equipment were routed to an underground waste crib for retention of any disposed radioactive nuclides in the soil. The site was specifically sited isolated from the normal process areas because of the nature and hazards of the work. The 123 Experimental Building was located 48.8 m (160 ft) directly south of the 120 control building. The experimental building was so located relative to the control building that neither the generally prevailing breeze nor the force winds would carry any air-borne contamination towards the control building.

Waste Type: Stormwater Runoff

Waste Description: Contaminants of Potential Concern (COPCs) included isotopic plutonium, americium-241, gamma-emitting radionuclides, polychlorinated biphenyls (PCBs), inductively coupled plasma (ICP) metals, mercury, and semivolatile organic compounds (SVOCs). Although asbestos was a COPC, it was only to be sampled if suspect asbestos material was observed during sampling activities. The site received low-level plutonium waste from the 120 Building (Critical Assembly Room, Chemistry Laboratory, Storage and Tank Room, and Change Room). The 120 Building and the crib were demolished in 1974. The waste removed from the site during decontamination and demolition activities consisted of seven transuranic waste boxes, fiberglassed plywood and steel, that were buried in trench 8 of 218-W-4B (Burial Ground). All non-transuranic waste was buried in mixed fission product trenches 12 and 14 in 218-W-4A. The seventeen drums of transuranic waste were buried in trench 7 of 218-W-4B. The details are 268 - 208 liter (55 gallon) drums, mixed fission products, weighing 50,770 kilograms (111,695 pounds); 17 - 208 liter (55 gallon) drums, transuranic waste, weighing 3,809 kilograms (8,380 pounds); 5 - fiberglass reinforced plywood boxes, weighing 2,600 kilograms (5,200 pounds); 73 - plywood boxes, weighing 124,682 kilograms (274,300 pounds); 2 - steel boxes, weighing 5,009 kilograms (11,020 pounds); 6 truck loads, 8,364 kilograms (18,400 pounds). A total of 10,909 kilograms (24,600 pounds) were buried as transuranic waste and 183,816 kilograms (404,395 pounds) were buried as mixed fission products. Nontransuranic waste was based on a waste burial limit of 10 nanocuries per gram. This limit was determined by radiation monitoring personnel. These low level wastes were designated as mixed fission products and thus, did not require containment for 20 year retrievability.

Closure Info: Confirmatory sampling from test pits and trenches was performed from April 29 2004 through May 10, 2004. To track results of confirmatory sampling, the P-11 lab complex waste site was stratified into the following seven areas for evaluation and sample collection. Area 1 was the Former 120 Experimental Building location, Area 2 was the Former P-11 Crib location, Area 3 was the Former 123 Control Building location, Area 4 was the Geophysical anomaly, Area 5 was the Septic Drain Field, Area 6 was the Septic Tank and Area 7 was the Surface Depression. Results of confirmatory sampling at Areas 1, 2, 3 and radiological surveys at UPR-600-16 determined no action was required. Confirmatory samples from Areas 5 and 6 found elevated levels of PCB's, arsenic cadmium and lead.

Some minimal radioactivity was detected, but the RESRAD modeling determined the dose rate for all pathways was less than 15 millirem per year.

Remedial action of the septic system tank and drain field (Areas 5 and 6) located at 600-111 was performed between February 25, 2008 and March 25, 2008. The site was excavated to approximately 4.6 meters (15 ft) below grade (at the deepest portion), resulting in a combined volume of approximately 2,755 cubic meters (3,603 cu. yd) of material removed and disposed at the Environmental Restoration Disposal Facility. Verification soil samples for the septic...
system remediation were collected on April 21, 2008.

All test pits/trenches were excavated and sampled in late April 2004 through early May 2004 as specified in the sampling work instruction. During excavation, field monitoring for VOCs was performed and no constituents were detected. In addition, FIDLER radiological surveys were performed during the excavations. No radiological contamination above twice the background level was found.

### Classification:
- **Code:** 600-146
- **Classification:** Accepted
- **Reclassification:** Interim Closed Out (7/21/2010)

### Description:
The site has been dismantled and Interim Closed Out. It was a steel frame structure constructed of "I" beam and "L" beams. The interior of the structure contained stainless steel piping running throughout. Metal grating was located on three levels of the structure. The structure appeared to be laying in a horizontal position. Debris observed near the structure included stainless steel pipe, metal rings, metal boxes, empty cans and wood. Two earth berms were located east of the metal structure. To the east of the berms was a small concrete pad approximately 1.5-1.8 square meters (5-6 sq. feet). A pile of lumber was located near the metal structures. Some of the lumber had shingles attached. There was also a small area of discolored soil containing metal fragments and charred wood.

### Location:
The site is located on the north side of Gable Mountain and just south of the dirt road that runs east west along the north side of Gable Mountain. The site is best accessed by turning east just north of milepost 2 on Route 4 North. Continue east on the paved road until the road begins to turn up the mountain. At this point, continue straight ahead on the dirt road which continues east along the mountain. The site is located approximately 1.9 miles from Route 4 North. The site falls along a section of the dirt road that is bounded by signs reading "Hazardous Area, Keep Out - Authorized Personnel Only".

### Waste Type:
- **Sanitary Sewage Waste**

### Waste Description:
The waste is a steel structure, stainless steel piping, metal parts, metal fragments, and the lid from a military type ammunition can (no label).

### Closure Info:
In January 2002, the structure was searched for abandoned explosive material. No explosive material was found.

A radiological survey was conducted in September 2009 to support characterization of the waste site, and no radiological activity above background was indicated. In April and May 2010, the sheared steel, wood were removed and the underlying soil was bladed to flatten the area. The wood debris was sent to ERDF. The steel structure was recycled.

### Code:
- 600-149

### Classification:
- Accepted
- Reclassification: Interim Closed Out (11/15/2011)

### Description:
The site consisted of two subsites. Subsite 1 was the Range complex which included a Range...
House Building, Well Pump House, and four firing ranges. Subsite 2 consisted of the soil berm located behind the pistol/rifle range area. Both subsites have been investigated and Interim Closed Out, so the parent site is also considered Interim Closed Out.

Location: The site is located north of the east end of Gable Mountain. It is west of Route 2 North and the Hanford Airport.

Related Sites/ Structures: The Small Arms Range is associated with 600-349.

Process Description: The complex operated from the mid-1940's through the 1950's as a practice range for handguns, rifles, shotguns, machine guns, hand grenades, smoke bombs, and other small arms and incendiary devices. Complete information on all types of ordnance used is not readily available. The site was known as the "Machine Gun Range" and contained a club house, a pistol range, a machine gun range and a Tommy gun range. The club house was a wood frame structure, with gypsum board siding that had lighting, water, and heat. The pistol range had a gravel and sand, oiled, rolled surface and contained targets and stands. The machine gun and Tommy gun ranges had the same surface as the pistol range, and had moving targets.

Waste Type: Sanitary Sewage
Waste Description: The site contains miscellaneous trash scattered about the site.

Waste Type: Sanitary Sewage
Waste Description: The site contains transite piping remnants.

Waste Type: Sanitary Sewage
Waste Description: Lead bullets and spent cartridges are found throughout the area. Grenade canisters have also been found in the area.

This Site has the Following SubSites:
Code: 600-149:1
Names: 600-149:1; Rifle and Pistol Range; Small Arms Range

Code: 600-149:2
Names: 600-149:2; Berm Behind the Pistol/Rifle Range

Type: Military Compound
Status: Inactive
Description: The Small Arms Range complex consisted of a Range House Building, Well Pump House, and four firing ranges. The entire complex was 381 meters (1,250 feet) by 555 meters (1,820 feet) and encompassed approximately 52 acres. It was surrounded on three sides by a barbed wire fence. Gable Mountain formed a natural access barrier on the fourth side. There were four specialized firing ranges: an Army pistol range, a Federal Bureau of Investigation "killer course" range (also known as the "special range"), a submachine gun range, and "walk and draw" pistol range. The first two ranges were covered with a 5.1 centimeter (2-inch) thick bituminous road mix, and the latter two ranges were equipped with manually operated, moving targets. The Range House Building was located on the opposite side of the access road from the
firing ranges. It contained a conference room, equipment storage room, office, rest room, and three brick chimneys for stove heating purposes. The small Well Pumphouse pit was constructed of reinforced concrete and contained a hatch in the roof for the maintenance of pumping equipment.

The waste site shape was modified on 2/2/2011 so that the western boundary followed the irrigation canal. This canal served as a natural boundary for activities associated with the small arms range and was more appropriate than the arbitrary rectangle that was drawn previously. The tract of land that was cut out of 600-149:1 has been reassigned to 600-349.

Location: The area is approximately 19 miles north of Richland, at the foot of the northeastern slope of Gable Mountain.

Related Sites/Structures: The Small Arms Range is associated with 600-349.

Process Description: The complex operated from the mid 1940's through the 1950's to serve as a practice firing range for hand guns, rifles, machine guns, hand grenades and smoke bombs.

Closure Info: The objective of the 600-149 Munitions or Explosives of Concern (MEC) investigation and clearance project was to perform a surface sweep, subsurface characterization to determine the nature and extent of metallic anomalies, and subsurface clearance of MEC and Material Suspected of Potentially Presenting and Explosive Hazard (MPPEH) hazards within limitations defined for the project (> mV reading). A preliminary survey of the area was conducted in March 2006 using visual inspection methods aided by a magnetometer. Phase II was performed in the spring of 2008 using electromagnetic devices for subsurface investigations. Many anomalies were 18 inches below the surface. This activity cleared 7.2 acres of property. Phase III, conducted in October and November 2010, included a surface sweep that cleared 47 acres. Culturally sensitive debris was staged separately.

A Digital Geographic Mapping (DGM) survey of a 100-ft by 100-ft grid was conducted on November 3, 2010. After analyzing the results and initial dig of selected anomalies in the grid, a threshold value of 5 mV was determined to be the appropriate threshold criteria for selecting anomaly dig targets. The second phase of the investigation conducted DGM surveys of each grid between November 4 and December 17, 2010. DGM was conducted for the purpose of locating geophysical anomalies in the subsurface that could potentially be MEC. Sixty one grids were identified as high density (HD), containing large numbers of anomalies.

Dig sheets were provided to the intrusive investigation teams for identification and/or removal. The sifting stage of anomaly investigation and clearance in HD grids commenced on January 17, 2011 and was completed on March 22, 2011. An area near the northeast corner of the Site was thought to be a munitions burial pit, based on unsubstantiated historical information. The dig team sifted soil from an area approximately 20 ft by 10 ft to an average depth of approximately 24 inches.

**Description:** The subsite has been evaluated and Interim Closed Out. It consisted of the soil berm behind the pistol/rifle range.

**Location:** The berm is located north of the east end of Gable Mountain, west of Route 2, and northwest of the former Hanford town site.

**Closure Info:** Remedial action at the waste site was performed in September 2008. As part of the remedial action, a portion of the surrounding area was evaluated for unexploded ordnance (UXO) by digital geophysical mapping (DGM) using an electromagnetic detection instrument with a geographical mapping system to obtain positioning data over an area of approximately 2.9 hectares (7.2 acres). This area included the boundary of the current remediation excavation, as well as the area to the northeast that was needed to support the site remediation.

Due to concerns that UXO may be present, the soil berm was visually inspected aided with subsurface metal detection prior to the onset of remedial action. Three UXO items were discovered at a depth of approximately 18 cm (0.5 ft) during this inspection. The items included a rifle grenade, a fuse from a smoke grenade, and a riot shell (smoke round). Approximately 1.0 meter (3 ft) of soil was removed from the face of the berm and 0.6 meter (2 ft) of soil from the base/toe of the berm. The resulting 826 bank cubic meters (1,080 bank cubic yards) of soil was disposed at the Environmental Restoration Disposal Facility (ERDF).

The berm soil removal was completed to the extent allowed by the Cultural Resource review. Excavation on the southwest side of the berm was limited so that the PRID canal would not be disturbed. Bullets remain in this portion of the berm. It was agreed that this portion of the berm would be excluded from the 600-149:2 waste site.

Due to concerns that additional UXO may be present in the soil berm, direct load-out of soil for shipment to the ERDF was not performed. The material removed from the berm was staged for inspection of additional UXO and then sent to ERDF.

**The SubSite is Part Of:**

**Code:** 600-149

**Names:** 600-149; 600-54; 661 Complex; Rifle and Pistol Range; Small Arms Range

---

**Code:** 600-178  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (7/19/2011)

**Type:** Depression/Pit (nonspecific)  
**Status:** Inactive  
**Start Date:**  
**End Date:**

**Description:** The site has been remediated and Interim Closed Out. It was a toilet pit opening within a 4.3 by 4.9-meter (14 by 16-foot) concrete pad that remained from the demolished guard house. The opening in the concrete was connected to a sanitary sewage pit located beneath the pad. A lid to the septic pit is next to the concrete pad. No evidence of a sewage distribution system (septic tank or tile field) was apparent. No septic tank was found during remediation.

**Location:** The site is located north of Route 11A and 150 meters (490 feet) south of the 213-J and 213-K Vaults parking lot.

**Process Description:** This unit received human sewage from a guard house.

**Waste Type:** Chemicals
Waste Description: The waste was human sewage.

Closure Info: Remediation occurred at the 600-178 waste site on November 4 through 16, 2010. The concrete toilet system was removed entirely, along with a protruding pipe and sludgy material underlying the pipe. The concrete structure had dimensions of approximately 6 by 6 by 1.2 meters (20 by 20 by 4 ft). The excavated concrete, pipe, and associated soils were disposed at the Environmental Restoration Disposal Facility.

Due to the small size of the excavation, which included the waste staging pile area measuring 160 square meters (1,700 sq. ft.) and overburden footprint 100 square meters (1,075 sq. ft.), composite samples were collected, consisting of 25 aliquots of soil distributed across the surface of the sampling area. Two composite samples were collected over the footprint of the excavated area, one was collected at the waste staging pile area footprint, and one was collected over the overburden.

Code: 600-186 Classification: Accepted
Names: 600-186; Hanford Construction Camp Septic Tanks and Sewage Treatment Plants Reclassification: Interim No Action (9/14/2011)
Type: Trench Start Date: 1/1/1944
Status: Inactive End Date: 
Description: This site has been evaluated and determined to require No Action. The site includes all the septic tanks and sewage treatment plants at the Hanford Construction Camp. Five components of this site have been identified in the field and mapped.

Three former sewage treatment plant settling basins were identified from visual depressions or trenches. The northernmost site was the largest and deepest, beginning at a group of trees and extending to the river, cutting into the river bank. Small pieces of concrete, concrete pipe, vitrified clay pipe and wood were observed around the trench. The bottom of the trench has fine soil that did not appear to be sludge derived from sewage. The second trench, just south of the first trench was shallower and not as obvious. Small pieces of concrete were observed surrounding the trench. A layer of sludge like material was observed on the east side of the trench. The southernmost trench was obscured by tumbleweeds. The outline of a foundation was found on the north side of the most southern trench. One septic tank was found between this trench and the turn off to the Honey Dump site. A large area west of the sewage treatment plants was searched for septic tanks, but none were found.

Location: The sewage treatment plants were located on the river side of "A" Avenue between Fourth and Sixth Streets East and at Tenth Street East. Two of the treatment plants are located near the east end of 5th Street East. The southernmost treatment plant is located near the intersection of Tenth Street East and "A" Avenue, approximately 216 meters (709 feet) north of Well #A8744.

Related Sites/Structures: The site was related to the Hanford Construction Camp and the need for sanitary facilities. Septic tanks were scattered throughout the Camp Area at required locations for the retention of sewage. The septic tanks were related to waste treatment facilities where sewage was collected, treated and disposed.

Process Description: The Hanford Construction Camp was supported by a system of underground sanitary waste treatment facilities sufficient to support the 50,000 employees who lived there. These facilities consisted of 80 septic tanks and 3 waste treatment plants, in addition to an unspecified number of septic tanks and drain fields that predate the construction camp but were used for camp purposes. DuPont (1945) describes three sewage treatment plants for the camp. Each included a system of septic tanks and a waste treatment facility, connected by 10.2 to 76.2-centimeter (4 to
30-inch) vitrified clay or concrete pipe. Septic tanks were "standard design, three pass baffle, wooden box type" varying in size from 1.2 by 4.9 by 1.8 meters up to 7.3 by 18.3 by 3.05 meters (4 by 16 by 6 feet up to 24 by 60 by 10 feet). Although these dimensions are confusing, it is clear that some tanks were quite large and that a significant potential for surface collapse may exist at these sites. The septic tanks were scattered throughout the Camp Area at required locations (DuPont 1945). At the beginning of Hanford Camp, wooden grease traps were provided to separate the grease from the main sewage going to the settling basins. Serious trouble resulted when the grease traps were inadequate both in size and design. Further steps to control the grease build-up at the settling basins had to be taken. Garbage from the mess hall kitchens was also a problem, so a device to collect both grease and garbage was required.

Waste Type: Chemicals
Waste Description: All sewage carried by the three sewage disposal systems was chlorinated.

Closure Info: The results of the confirmatory sampling determined the waste site could be reclassified to No Action.

Code: 600-202
Names: 600-202; Hanford Townsite Four Burn and Burial Pits
Type: Burn Pit
Status: Inactive
Description: The site has been remediated and Interim Closed Out. It included multiple burn and burial pits, located close together and arranged to form a single rectangle. The waste contains miscellaneous municipal trash. Bulldozer marks suggest that debris was covered. There was extensive signs of burning over the site.
Location: The site is located southeast of the Hanford Construction Camp, near the river bank. It is 550 meters (1805 feet) southeast of the intersection of Avenue A and 9th Street, in the Hanford Construction Camp. It was southeast of the southernmost sewage treatment plant (sitecode 600-186).
Process Description: The area was used as a municipal dump by the Hanford Cap construction crews.
Waste Type: Chemicals
Waste Description: The waste is miscellaneous trash and debris and includes such items as fire-cracked rock, glass, china, jars, bottles, metal, kitchen materials, broken toilet bowl, and other materials. Bulldozer marks suggest that debris has been covered. The pits vary in depth, apparently because of varying levels of backfill. There is the potential that paints and solvents were burned in the pits. The site needs further evaluation.
Closure Info: Test pits and trenches were dug in 2005 and 2009 to collect Confirmatory samples. Asphalt shingles, sheet rock, tar paper, glass, batteries, nails, wood and stained soil were observed. Remediation occurred from March through May 2010. One large and one small area were excavated and a material staging area was created. White material was found that was later determined to be mussel shells. Cultural resources personnel were permanently staged at the waste site for the remainder of the excavation to oversee the handling of shells. Several batteries were found during excavation. The batteries were drummed and a sample was collected on March 31, 2010 from random aliquots of soil beneath one of the batteries. A 132-L
(35-gal) drum filled with dirt was removed and staged for disposal at the Environmental Restoration Disposal Facility (ERDF). On April 14, 2010, a 0.18-L (6-oz) bottle with a small amount of white liquid inside was found. The contents of the bottle were characterized for disposal. At the completion of all remedial activities, the depth of both excavations was approximately 4.8 meters (15.7 ft).

| Code: 600-204 | Classification: Accepted |
| Names: 600-204; Hanford Townsite Burn and Burial Trench | Reclassification: Interim Closed Out (9/16/2003) |
| Type: Burn Pit | Start Date: |
| Status: Inactive | End Date: |
| Description: The site has been remediated and Interim Closed Out. The site was a long, narrow trench that was used as a burn pit. The trench was oriented north to south. |
| Location: The site was located approximately 500 meters (1,641 feet) southwest of the intersection of Route 1 and Route 2 North and approximately 200 meters (656 feet) west of the United States Government Railroad. |
| Process Description: The area was used for dumping and burning trash. |
| Waste Type: Chemicals |
| Waste Description: The trash was miscellaneous debris, including metal and glass fragments, nails, fire-scarred rock, cans, and bottles. The waste has been placed in a discernible unit. |
| Closure Info: In April 2003, a field walkdown was conducted to finalize contaminants of potential concern, identify sample locations, and identify sample types for development of a sampling design. A remedial action activity was implemented to remove contaminated soil and debris from the site for disposal at the Environmental Restoration Disposal Facility. The material was removed to a depth of 25 centimeters (10 inches). |

| Code: 600-205 | Classification: Accepted |
| Type: Dumping Area | Start Date: |
| Status: Inactive | End Date: |
| Description: The site has been remediated and Interim Closed Out. It was a large area that was used for pre-Hanford dumping of domestic refuse and also Camp Hanford dumping. Historical photographs show several nearby buildings that appear to be vehicle maintenance facilities. Surface debris was evident and GPR scans identified subsurface anomalies. |
| Location: The site is located southeast of the intersection of Route 2 North and Route 11A. The area is relatively flat and appears to have been mechanically leveled with scattered domestic and building material. |
| Related Sites/Structures: The site is related to 600-110 Hanford Townsite Landfill 1. |
| Waste Type: Chemicals |
Waste Description: The waste is domestic debris, including heavy concentrations of tin cans, bottles, auto parts, and other domestic refuse. Bulldozing marks are evident, and it appears that landfill debris has been covered over and that additional concentrations may exist below grade.

Closure Info: Confirmatory sampling was done in January 2005. A test trench dug to a depth of 3.7 meters (12 feet) into Area 1 found no debris. One soil sample was collected. A test trench dug to a depth of 1.5 meters (5 feet) into Area 2 found no debris. One soil sample was collected. A test trench dug to a depth of 0.9 meters (3 feet) into Area 3 found no debris. One soil sample was collected. A test trench dug to a depth of 1.5 meters (5 feet) into Area 4 found no debris. No soil sample was collected. A test trench dug to a depth of 1.5 meters (5 feet) into Area 5 found no debris. One soil sample was collected. A test trench dug to a depth of 1.5 meters (5 feet) into Area 6 found no debris. One soil sample was collected. A test trench dug to a depth of 1.5 meters (5 feet) into Area 7 found no debris. One soil sample was collected.

Remediation occurred at Area 2 from February 24 to March 2, 2010. The excavated area was approximately 115 square meters (1,240 sq. ft.). The waste was staged to the southwest of the excavation, and had an area of approximately 80 square meters (860 sq. ft.). On March 15, 2010, one in-process sample, J19V17, was collected from the bottom of the waste site and the sidewalls of the excavation.

The battery and surrounding soil found in Area 1 was drummed on May 17, 2010. Per regulatory agreement, no sample was collected from this location.

The final depth of the excavation was approximately 4 meters (13 ft) deep and the staging pile area was 1 meter (3 ft) deep, resulting in 512 bank cubic meters (BCM) [670 bank cubic yards (BCY)] of soil that was loaded out to the Environmental Restoration Disposal Facility.

Code: 600-208
Names: 600-208; Hanford Construction Camp Boiler House Ponds
Type: Pond
Status: Inactive
Description: The waste site has been evaluated and determined to require No Action. 600-208 represents a series of liquid disposal ponds or trenches associated with the Hanford Construction Camp steam generating plants. The ponds were estimated to be roughly 6 meters (20 feet) by 20 meters (60 feet) and 1.5 meters (5 feet) deep.

Location: The sites were found within or close to the Hanford Construction Camp. The locations of thirteen of the eighteen ponds have been identified using photos of the camp. The ponds are located as follows: (1) between 1st and 2nd Street and east of Avenue A; (2) between 2nd Street and 3rd Street and east of Avenue A; (3) between 3rd Street and 4th Street and east of Avenue A; (4) between 4th Street and 5th Street and east of Avenue A; (5) at 6th Street and east of Avenue A; (6) between 7th Street and 8th Street and east of Avenue A; (7) east of 9th Street and northeast of the intersection of 9th Street and Avenue B; (8) approximately 250 meters (820 feet) northeast of the intersection of 7th Street and Avenue E; (9) between 5th Street and 6th Street and north of Avenue C; (10) between E Avenue and D Avenue and north of 4th Street; (11) between 3rd Street and 4th Street and south of Avenue C; (12) between 2nd Street and 3rd Street and south of Avenue C, close to the intersection of 3rd Street and Avenue C; (13) approximately 250 meters (820 feet) south of the intersection of Route 2 North and Doolittle Avenue on the east side of Route 2 North.

Process Description: Eighteen boiler houses were used at the Hanford Construction Camp to generate steam. Each boiler house was described as "100 boiler horse power, hand fired, horizontal return tubular
boilers, (arranged) either singly or in batteries". Each site had from one to eight boilers. Each had a wood-stave soft water storage tank and an open-boxed pit for the sluicing and removal of ashes by means of clamshell crane. Some had liquid waste disposal ponds. The ponds were designed to receive wastewater and chemicals used for the boiler houses (steam or power plants) at the Hanford Townsite Construction Camp. The steam produced was primarily for heating purposes. The ponds or trenches, referred to as Liquid Seep Ponds, were believed to have existed at each fixed steam plant (boiler house) and to have received waste common to the boilers.

**Waste Type:** Chemical Release

**Waste Description:** The waste was waste water and chemicals. The chemical released most frequently to the ponds would have been "water softener brine". There are no obvious signs of contamination.

**Closure Info:** Geophysical surveys were done in January and February 2004. Site walkdowns were done in May and June 2004.

The No Action decision is based on historical and field observations. No hazardous chemicals were used in the steam generation process.

---

**Code:** 600-239  
**Classification:** Accepted  
**Names:** 600-239; 615 Hot Mix Plant Debris; Debris in Pit 16; Hanford Aggregate Pit Debris  
**Reclassification:** Interim No Action (5/31/2001)  
**Type:** Dumping Area  
**Status:** Inactive  
**Start Date:**  
**End Date:**  
**Description:** The site has been evaluated and determined to require No Action. The non-contaminated debris was removed to ERDF in April 2012. It included several large wooden beams, wooden pallets, large diameter steel pipe, steel plates, large mesh steel screens and rubber tires. All wastes observed were lying in neat piles on the ground surface within Pit #16. None of the debris appeared to be partially buried. One stacked pile of metal posts had some radiation warning signs still attached. There was a spot of old paint, about one square foot, in the pit.

**Location:** The site is located approximately 200 meters (656.2 feet) west of Route 2 North and approximately 1.3 kilometers (0.8 miles) north of Route 11A. The approach to the site is marked with signs on the west side of Route 2 North just south of milepost 1.

**Related Sites/Structures:** Site 600-240 is similar debris in adjacent Pit 17. 600-20 is the Hot Mix Plant and is the source of much of the debris in both the 600-230 and 600-240 sites.

**Process Description:** This gravel pit was related to the adjacent Hot Mix Plant (600-20, reclassified as Rejected). However, some of the stored materials in the Pit may have come from other projects.

**Waste Type:** Chemicals  
**Waste Description:** The waste is wood, metal and rubber.

**Closure Info:** The debris was considered Miscellaneous Restoration debris. Debris removal was completed in April, 2012. A total of seven ERDF containers (44.12 US tons) were removed and disposed of to ERDF.

---

**Code:** 600-280  
**Classification:** Accepted  
**Names:** 600-280; Hardened Tar Site  
**Reclassification:** Interim Closed Out (4/26/2011)  
**Code:** 614

---

*Hanford Site Waste Management Units Report*  
February 2015
### Dumping Area

**Type:** Dumping Area  
**Status:** Inactive  
**Description:** The site has been remediated and Interim Closed Out. It was a 10 meter (33 foot) by 6 meter (19 foot) area where tar was dumped.

**Location:** The site is located south of the intersection of Route 1 and Route 2N. It is east of 600-204 and approximately 22 meters west of the north-south dirt access road, that is west of the railroad tracks.

**Waste Type:** Soil  
**Waste Description:** The site has patches of hardened tar.

**Closure Info:** On January 13, 2010, two waste characterization samples were collected. The first sample, J19DY7, was collected from the hardened tar/asphalt material. The second sample, J19D16 and its duplicate, J19D17, were collected from a mixture of the soil and charred material. These samples were analyzed for inductively coupled plasma (ICP) metals, mercury, pesticides, herbicides, polychlorinated biphenyls (PCBs), volatile organic compounds (VOCs), total petroleum hydrocarbons (TPH), and semivolatile organic compounds (SVOCs). The waste characterization sample results show that only lead and TPH exceed cleanup levels.

Remediation was started and completed on February 23, 2010. The depth of the main excavation is less than 0.3 meter (1 ft) and is approximately 28 meters (92 ft) in diameter. All waste material was directly loaded into cans for disposal at the Environmental Restoration Disposal Facility (ERDF).

On March 15, 2010, one composite in-process soil sample was collected from the excavated area. Several aliquots of soil were collected from across the surface of the excavated area and combined into one sample for analysis. The in-process sample was analyzed for ICP metals, mercury, TPH, pesticides, herbicides, PCBs, VOCs, and SVOCs.

Two smaller areas of tar were sampled (EX-1 and EX-2). These areas were determined to be more closely associated with the 600-320 (battery debris) waste site and will be address with that closure documentation.

### Burned Area and Oil Stained Soil

**Type:** Burn Pit  
**Status:** Inactive  
**Names:** 600-313; Burned Area and Oil Stained Soil  
**Classification:** Accepted

**Reclassification:** Interim Closed Out (10/17/2012)  
**Start Date:** Interim Closed Out (10/17/2012)  
**End Date:**

**Description:** The waste site has been remediated and Interim Closed Out. The site consisted of potentially contaminated soil that is either an oil stain or burned area.

**Location:** The site was located approximately 533.26 meters (0.33 miles) north and 288.81 meters (0.2 miles) west of the intersection of F Avenue and Route 2. The center point coordinates for the site are E580355.81, N145430.68.

**Waste Type:** Process Effluent
Contaminants of potential concern include TPH, PAH, PCBs and ICP metals.

Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-305 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.
The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

Description: The subsite has been remediated and Interim Closed Out. The subsite was a probable telecommunications junction or splice box that has hardened black liquid (possibly tar) on the outside surface. The suspect telephone communication components measure 40.6 cm by 22.9 cm (16 by 9 in) in diameter.

Location: The site was located approximately 25 meters (82 ft) west of F Avenue and 53 meters (174 ft) north of Route 2 North.

Closure Info: Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.
Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

Reclassification: Interim Closed Out (10/17/2012)

Type: Unplanned Release

Status: Inactive

Start Date: End Date:

Description: The subsite has been remediated and Interim Closed Out. It was a probable telecommunications junction or splice box that had hardened black liquid (possibly tar) on the outside surface. The suspect telephone communication components measure 40.6 cm by 22.9 cm (16 by 9 in) in diameter.

Location: The site was located approximately 868 meters (0.5 miles) west of Route 2 North and 4.7 kilometers (2.9 miles) north of Route 11A.

Closure Info: Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.
The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

Description:
- The site has been evaluated and determined to require No Action. It consists of soil associated with a black granular material visible on the surface. There is very little vegetation in the affected area. Confirmatory sampling done in 2010 determined the material was coal ash.

Location:
The site is located approximately 487.02 meters (0.3 miles) north and 31.21 meters (102 feet) east of the intersection of F Avenue and Route 2.

Closure Info:
- During a site visit in March 2010, it was determined that the black granular material did not appear to be petroleum based, as it was previously suggested. Rather, the black granular material appeared to resemble graphite. However, during confirmatory sampling in November 2010, the material was determined to be coal ash. Based on sampling data, Hanford coal ash is not regulated as a dangerous waste.

Based on confirmatory sampling at the 600-315 waste site, remedial action was determined to be unnecessary, and the confirmatory sampling data has been used to document this waste site for reclassification as a No Action site.

Description:
The waste site has been remediated and Interim Closed Out. The site was described as scattered surface debris consisting of wet cell battery plates, burned material, and a white granular substance. It was located in the bottom of a borrow pit.

Location:
The site was located approximately 342.15 meters (0.2 miles) south and 459.72 meters (0.3 miles) west of the intersection of F Avenue and Route 2. The coordinates for the site are E580184.90/N144555.27.
Waste Type: Chemicals

Waste Description: Lead and sulfuric acid from the batteries may be present.

Closure Info: Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.
The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

site consisted of a 3 meter (10 feet) diameter area of wet cell battery debris. It appeared to have been a car battery.

**Location:** The site was located approximately 78 meters (256 ft) south of Route 2 North and 181 meters (594 feet) southeast of the intersection of F Avenue and Route 2 North. Area 2 was located at E580765.7/N144702.4.

**Closure Info:** Site visits and geophysical surveys were done in June and November 2011. The results determined that remediation was required. Remediation activities began in July 2011 and continued through February 2013.

The waste site boundaries were re-defined during the remediation process. The excavation extent removed all the debris associated with the battery waste sites.

No anomalous material or stained soil was discovered during remediation activities of either the 600-316 or 600-318 waste sites. All material was direct loaded for disposal to the Environmental Restoration and Disposal Facility (ERDF).

**The SubSite is Part Of:**

Description: The subsites have been remediated and Interim Closed Out. Therefore the parent site is also considered Interim Closed Out. The three subsites were reclassified on a single form. The waste site was comprised of three areas of surface debris consisting of ferrous metal, stained soil and dried paint. Many items are believed to have supported Army Tent Camp 230. One location consisted of a 0.5 by 0.5 meter (2 by 2 feet) wooden lined, below grade structure that is 0.5 meters (2 feet) deep. It contained empty paint and paint thinner cans. One empty can of military paint thinner had a date of 1956.

Location: The coordinates for the three debris sites are:

Area 1 was at E580195.5/N144963.8.
Area 2 was at E581558.7/N142840.4.
Area 3 was at E585655.5/N139710.0.

Waste Type: Chemicals

Waste Description: Sulfur based cutting oils in the metal turnings and lead in the paint may be present.

Closure Info: Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.
The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

This subsite has been remediated and Interim Closed Out. It was a 7 meter (23 ft) diameter, circular area containing concentrated ferrous metal turnings, broken glass and orange stained soil.

The site was located south of Route 1 and west of Route 2 North, at coordinates E580196.8 N144963.2.
Closure Info: Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.
A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

The SubSite is Part Of:
The site consisted of nine areas with petroleum based material released to the ground surface. They were identified during a 2007 site walkdown. The nine areas were initially given individual subsite numbers. All nine areas were evaluated, remediated and Interim Closed Out in a single verification package and on a single reclassification form.

Area 1 consisted of a suspected oil dump area that is approximately 3 by 4 meters (10 by 13 feet). The soil was crusted with no vegetation growing in the affected area.

Area 2 consisted of an oil dump area that is approximately 8 by 5 meters (26 by 16 feet). There were two oil filters on the ground. The soil was crusted with no vegetation growing in the affected area.

Area 3 consisted of a suspected oil dump area that is approximately 3 meters (10 feet) in diameter. The soil is crusted with no vegetation growing in the affected area.

Area 4 consisted of a suspected oil dump area that is approximately 2 meters (6 feet) in diameter. The soil is crusted with no vegetation growing in the affected area.

Area 5 consisted of a suspected oil dump area that is approximately 2 meters (6 feet) in diameter. The soil is crusted with no vegetation growing in the affected area.

Area 6 consists of a suspected oil dump area that is approximately 0.5 meters (2 feet) in diameter. The soil is crusted with no vegetation growing in the affected area.

Area 7 consisted of a 3 meter (10 feet) diameter area with no vegetation growing and a crusty surface.

Area 8 consisted of a suspected oil dump area that is approximately 2 meters (6 feet) in diameter. The soil was crusted with no vegetation growing in the affected area.

Area 9 consisted of an area of surface tar. This area was discovered while remediating waste site 600-280. Samples (J1C007 and J1C008) were collected during the 600-280 sampling activity. The sample results had elevated concentrations of lead, so the area was added to waste site 600-320.

The nine area were found in an area extending from the old Hanford Camp to near the intersection of Route 2N and Route 1. The coordinates for the nine soil stained areas are:

Area 1 E580231.4/N144524.1
Area 2 E581892.6/N142045.3
Area 3 E583067.60/N140269.38
Area 4 E583131.98/N140209.13
Area 5 E583217.14/N140082.43
Area 6 E583472.12/N140270.74
Area 7 E585666.2/N140052.5
Area 8 E587461.7/N137843.3
Area 9 E580200.7/ N144927.4

**Process Description:** Materials found at these locations suggest that petroleum liquid was dumped from an oil accumulation container or was released from large equipment during lubricant change-out.

**Waste Type:** Chemicals

**Waste Description:** The waste is potentially contaminated soil. These sites may contain ICP metals, PAHs, TPH and possible PCB contamination within the release areas.

**Waste Type:** Chemicals

**Waste Description:** These areas may contain ICP metals, PAHs, TPH and possible PCB contamination.

**Closure Info:** Characterization samples were collected at areas 2, 7, 8 and 9 in March 2011. Geophysical surveys were conducted between March and November of 2011. The size and shape of the areas were redefined following the geophysical surveys.

Remediation of the nine 600-320 subsites occurred between June 27, 2011, and March 21, 2013, resulting in a total of approximately 1,354 bank cubic meters (1,771 bank cubic yards) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility. The excavation depths ranged from 0.3 to 1.2 meters (1 to 4 feet). No overburden soil was stockpiled to be used as backfill at any of the subsites.

Solar Site Waste Management Units Report
February 2015
Description: The nine areas were evaluated, remediated and Interim Closed Out in a single verification package and on a single reclassification form. The subsite was a suspected oil dump area that is approximately 3 by 4 meters (10 by 13 ft). The soil was crusted with no vegetation growing in the affected area.

Location: The site was located west of Route 2 North and south of Route 1 at E580231.4/N144522.9.

Closure Info: Characterization samples were collected at areas 2, 7, 8 and 9 in March 2011. Geophysical surveys were conducted between March and November of 2011. The size and shape of the areas were redefined following the geophysical surveys.

Remediation of the nine 600-320 subsites occurred between June 27, 2011, and March 21, 2013, resulting in a total of approximately 1,354 bank cubic meters (1,771 bank cubic yards) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility. The excavation depths ranged from 0.3 to 1.2 meters (1 to 4 feet). No overburden soil was stockpiled to be used as backfill at any of the subsites.

The SubSite is Part Of:
Code: 600-320
Names: 600-320; Oil Stains

Code: 600-320:2
Names: 600-320:2; Oil Stains Area 2
Type: Unplanned Release
Status: Inactive
Description: The nine areas were evaluated, remediated and Interim Closed Out in a single verification package and on a single reclassification form. The subsite consisted of an oil dump area that is approximately 8 by 5 meters (26 by 16 ft). There were two oil filters on the ground. The soil was crusted with no vegetation growing in the affected area.

Location: The site was located west of Route 2 North and north of Route 11A E581895.4/N142044.5.

Closure Info: Characterization samples were collected at areas 2, 7, 8 and 9 in March 2011. Geophysical surveys were conducted between March and November of 2011. The size and shape of the areas were redefined following the geophysical surveys.

Remediation of the nine 600-320 subsites occurred between June 27, 2011, and March 21, 2013, resulting in a total of approximately 1,354 bank cubic meters (1,771 bank cubic yards) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility. The excavation depths ranged from 0.3 to 1.2 meters (1 to 4 feet). No overburden soil was stockpiled to be used as backfill at any of the subsites.

Description: The waste site has been remediated and Interim Closed Out. It was four surface soil areas with scattered metal, fire brick, suspect friable asbestos and pipe lagging. The four areas became subsites, but the waste site and the subsites were closed in a single document, on a single reclassification form.

Location 1 consisted of an area approximately 10 meters by 7 meters (23 by 33 feet) area of suspect friable asbestos insulation, metal, fire brick and pipe lagging.

Location 2 consisted of an area approximately 1.5 meters in (5 feet) in diameter of suspect friable asbestos insulation.

Location 3 consisted of an area approximately 1.4 meters in (5 feet) in diameter of suspect friable asbestos insulation.

Location 4 consisted of an area approximately 0.4 by 2 meters in (1.5 by 6 feet) of suspect friable asbestos insulation.

Location: Three of the areas are located in the former Hanford Construction Camp and one area is located along Route 2 North, 5.6 km (3.5 mi) north of the former Hanford Construction Camp.

Location 1 was at E580439.1/N144153.2.
Location 2 was at E586098.525/N138015.83.
Location 3 was at E586169.24/N138189.21.
Location 4 was at E586859.096/N138757.09.

Waste Type: Chemicals
The areas consist of suspect asbestos containing material (ACM) insulation.

In October 2010, confirmatory samples were taken at the 600-303 waste site. The project team conducted site visits at various times from June 2011 to January 2013. The objective of the visits was to perform geophysical surveys and determine the extent (if any) of buried debris associated with the waste sites.

Remediation of the 600-303 waste site occurred on February 11, 2012, and February 12, 2012. The soil within this waste site was excavated to a depth of approximately 1.8 meters (6 ft) below ground surface (bgs) and resulted in the removal of 35 bank cubic meters (BCM) (46 bank cubic yards [BCY]) of soil and debris, which were disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation of the 600-321 waste site subsites occurred between June 28, 2011, and March 19, 2013. The soil within the subsites was excavated to a depth of approximately 1.2 meters (4 ft) bgs and resulted in the removal of 235 BCM (307 BCY) of soil and debris, which were disposed at ERDF.

The waste site dimensions were revised during the remedial investigation. The final extent of the excavations at these waste sites removed all subsurface staining and debris present.

This Site has the Following SubSites:

- **600-321:1**; Suspect ACM Sites Area 1
- **600-321:2**; Suspect ACM Sites Area 2
- **600-321:3**; Suspect ACM Sites Area 3

Type: Unplanned Release
Status: Inactive

Description: The waste site has been evaluated and determined to require No Action. It is an 8 inch (20 centimeter) diameter carbon steel pipe with a diamond hatched cover plate and the soil beneath the pipe. The pipe and cover are flush with the ground surface. The pipe drains to the south under a rail spur.

Location: This site is located approximately 350 meters (1150 feet) south west of WIDS site 600-240 (Debris in Gravel Pit 17). The coordinates for the pipe are E583129.93/N140262.979.

Related Sites/Structures: This pipe is located adjacent to a rail system that was constructed between 1943 through 1945. The rail spur possibly transported construction materials from nearby gravel pits.

Closure Info: Based on observations during the site visit and review of the history of the 600-322 waste site, confirmatory sampling was performed in November 2011.

Type: Unplanned Release
Status: Inactive

Description: The site has been evaluated and determined to require No Action. It is described as a bermed area with coal cinders and a ditch running east and west within the area.

Location: This site is located approximately 300 meters (985 feet) west of Route 2 North and 400 meters (1,300 feet) east of WIDS site 600-240 (gravel pit 17). The center point coordinates for the berm are E584073.7/ N140263.2.
Closure Info: Characterization sampling was collected from four test pits in November 2010. Based on the results of the characterization samples, no remediation was required at this site.

Code: 600-324  
Classification: Accepted  
Reclassification: Interim Closed Out (10/17/2012)

Names: 600-324; Burnt Debris Area  
Type: Burn Pit  
Start Date:

Status: Inactive  
End Date:

Description: The waste site has been remediated and Interim Closed Out. The site consisted of the a concrete pad with miscellaneous pipe and auto parts debris with burnt wood, metal debris and the underlying soil.

Location: This site was located approximately 1.5 kilometers (0.9 miles) north of Route 11 and 100 meters (330 feet) west of Route 2 North, 100 meters (330 feet) east of WIDS site 600-239 (gravel pit 16). The coordinates for the site are E584291.4/N140285.7.

Related Sites/Structures: This site may be associated with the Hanford Aggregate Pit 16 and 615 Hot Mix Plant.

Process Description: Based on the proximity to Gravel Pit 16 (WIDS 600-239), materials may have been used in support of the Hot Mix Plant and aggregate Pit 16 operations.

Closure Info: Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.
The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

DOE/RL-88-30
Rev. 24

Names: 600-325.1; Burned Roofing Materials Area 1

Reclassification: Interim Closed Out (8/2/2012)

Type: Burn Pit

Start Date: 

Status: Inactive

End Date: 

Description: The subsite has been remediated and Interim Closed Out. It consisted of a 5 meters (16 ft) diameter area of burned roofing material.

Location: The site is located west of 5th Street and north of Eisenhower Avenue in the Hanford Construction Camp at coordinates E585338.6 N139794.1.

Closure Info: Geophysical surveys were conducted to detect subsurface anomalies. Remediation of the 600-306 waste site occurred on April 3 and 4, 2012, and resulted in approximately 73.5 bank cubic meters (96.1 bank cubic yards) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF). Remediation of the 600-307 waste site occurred on April 3, 2012, and resulted in approximately 87.6 bank cubic meters (114.6 bank cubic yards) of soil and debris being removed and disposed at the ERDF. The 600-325.1 and 600-325.2 waste subsites were remediated between July 5 and 13, 2011, and resulted in approximately 176.0 bank cubic meters (230.2 bank cubic yards) of soil and debris being removed and disposed at the ERDF. No overburden soil was stockpiled to be used as backfill.

The SubSite is Part Of:

Hanford Site Waste Management Units Report
February 2015

651
**Names:** 600-326; Odorous Black Material  
**Reclassification:** None  
**Type:** Unplanned Release  
**Start Date:**  
**Status:** Inactive  
**End Date:**  

**Description:** The waste site is two areas of the underlying soil and material that appear to be brittle. There is also some angular items, black in color that have a hydrogen sulfide odor. Field visits were performed by the Orphan Site Evaluation team in May and July 2007. The site was separated into two subsites. 600-326:1, Black Material Area 1 and 600-326:2, Black Material Area 2.

**Location:** The subsites are located along the Columbia River in the Hanford Construction Camp.

**Waste Type:** Process Effluent  
**Waste Description:** The waste consists of the black material. There is also brown staining of the soil around and within these piles of material.

The contaminants of potential concern are unknown. The material may be Foamglas Insulation (Registered Trademark of Pittsburgh Corning Corporation). The material is also called cellular glass. This material contains hydrogen sulfide, carbon monoxide, carbon dioxide, glass dust, crystalline silica. (See MSDS for Foamglas Insulation.)

**This Site has the Following SubSites:**

**Name:** 600-326:1; Black Material Area 1  
**Code:** 600-326:1  
**Classification:** Accepted  
**Reclassification:** None  
**Start Date:**  
**End Date:**  

**Description:** The subsite consists of a 2 by 4 meter (6 by 13 ft) area of charcoal gray material suspected to be insulating material. It has a sulfur smell.

**Location:** The subsite is approximately 76 meters SW of the former 145 Bldg (CMX) facility in the Hanford townsite.

**The SubSite is Part Of:**

**Name:** 600-326; Odorous Black Material  
**Code:** 600-326  
**Classification:** Accepted  
**Reclassification:** None  
**Start Date:**  
**End Date:**  

**Description:** The subsite consists of a 6 meter (20 ft) diameter area of unknown black porous material. There is no vegetation growing in the affected area.

**Location:** The subsite is approximately 220 meters (720 ft) northwest of site 600-186 Hanford
Construction Camp Septic Tanks.

**The SubSite is Part Of:**

*Hanford Site Waste Management Units Report*  
February 2015
**Closure Info:** Remediation of the 600-328 waste site was conducted between January 30, 2013, and February 4, 2013, resulting in approximately 121 bank cubic meters (BCM) (158 bank cubic yards [BCY]) of soil and battery debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF). During excavation and remediation, the three areas of the 600-328 waste site were merged creating one excavation. The final excavation depth for the 600-328 waste site is approximately 0.9 meters (3 ft) below ground surface. Excavated materials were directly loaded out for disposal to ERDF. No soil staging pile or overburden areas were created.

<td></td>
<td></td>
<td></td>
<td></td>
<td>Process Description: The site was an unplanned release. An old wooden barrel that pre-dated Manhattan Engineering District (MED) operations deteriorated and collapsed, spilling the contents (about 45 kilograms) [100 lbs] of powdery lime sulfur onto the ground. The site was abandoned when the DeWitt Buckholdt Ranch was taken over by the U.S. Army Corps of Engineers in 1943. This site is located at a pre-Hanford Operations homestead, the Herriford (Buckoldt Ranch) home site.</td>
</tr>
</tbody>
</table>

**Code:** 600-332  
**Classification:** Accepted
Names: 600-332; Gable Mountain Firing Range Septic System
Type: Sanitary Sewer
Status: Inactive
Start Date: 
End Date: 
Reclassification: None

Description: The site consists of the underlying soil, septic tank, associated piping and drain field for a septic system. The Orphan Site's evaluation of historical features identified the septic system that supported the small arms firing range at Gable Mountain. A field investigation was conducted on 2/19/2008 to locate a potential site for the septic system. Based upon the Photo # D-4882-NEG (See photo #1.) and the field investigation, the above Washington State Plane coordinates listed for the site are of a potential location of the Range Building (not the coordinates for the septic system) shown in the photo. A fence like object seen in the photo on the northwest side of the building could be the septic tank location.

Location: The site is located in 600-149 (Small Arms Range), which did not previously identify this feature. 600-149 is located north of the east end of Gable Mountain. It is west of Route 2 North and the former Hanford Airport.

Related Sites/Structures: The site was related to the Range House which has been demolished (year unknown).

Process Description: The septic system supported the Range House building at the firing range, and this building was located on the opposite side of the access road from the firing ranges (HAN-10970 Volume IV). This was a septic tank, associated piping and drain field that supported the Range House building at the firing range. Hanford patrols were trained in the use of small arms (HAN-10970 Volume IV).

Waste Type: Chemicals
Waste Description: The waste includes the septic tank, associated piping, and drain field underlying soil. There is no reference to a drain field, however it is assumed that one exists. Contaminants of potential concern include heavy metals.

Code: 600-333
Classification: Accepted

Names: 600-333; Underground Concrete Structure
Type: Process Unit/Plant
Status: Inactive
Start Date: 
End Date: 
Reclassification: Rejected (3/16/2011)

Description: The waste site consists of a below grade concrete structure with three vertical 0.5 by 0.5 meters (1.6 by 1.6 feet) shafts that are 2.4 meters (8 feet) deep and are open to the surface. The orphan sites evaluation team originally believed that the concrete structure was a septic tank that was associated with the former 101 Building graphic machining facility operations. Further investigation determined it was not a septic tank.

Location: The 600-333, Underground Concrete Structure waste site was located in the 100-IU-6 Operable Unit, near the site of the former 101 Building. The coordinates for the site are E584750.19, N140382.7.

Related Sites/Structures: The structure is associated with the demolished 101 Graphite Machining Facility.

Process Description: On November 2, 2010, the site was evaluated and it was determined that the 600-333 concrete structure is not a septic tank. The concrete structure was observed to be very large in dimension. It extends deeper than 3.7 meters (12 feet) below ground surface, and is 9.8 meters

Hanford Site Waste Management Units Report
February 2015
(32 feet) long and 4.9 meters (16 feet) wide. A very large pipeline enters the east end of the concrete structure. There were no liquids, staining, or hazardous debris observed within the underground concrete structure. Due to the depth, size, and the nature of this concrete structure, no samples were collected from this waste site. The structure is suspected to be an underground facility rather than a septic tank.

---

**Code:** 600-334  
**Classification:** Accepted  
**Names:** 600-334; CMX Building  
**Reclassification:** None  
**Type:** Process Unit/Plant  
**Status:** Inactive  
**Start Date:**  
**End Date:**  

**Description:** This site consists of four areas divided into two subsites: 1. CMX Building and Surface Anomalies, 2. Burn area near CMX Building, both located in the vicinity of the former CMX Building.

Subsite 1 had been evaluated and requires No Action.

**Location:** The site is located next to the bank of the Columbia River approximately 275 m (902 ft) upstream of the Hanford town site former ferry landing at the end of Division Street (C-127).

**Process Description:** The CMX Building was constructed between June and September 1943. The original purpose of the facility was to perform experiments to determine the corrosion rate of reactor tubes and jackets under simulated operating conditions (IN-6263 Volume 1). The test equipment included six 3.05 m (10 ft) long aluminum tubes built according to the design specifications for the production piles. In early 1944, two of these tubes were replaced with full-length 12.2 m (40 ft) pile tubes. Auxiliary facilities consisted of a water laboratory, a completely equipped dark-room for photographic work, softening equipment for water used in steam generation, and office and locker-room space (HAN-73214-14). Although the initial purpose of CMX was to investigate corrosion of aluminum and evaluate equipment design, it was found, after a short period of operation, that iron and aluminum compounds were depositing on process equipment. The deposits were sufficiently heavy to cause a marked reduction in flow rate and would certainly cause high slug surface temperatures under plant conditions. Therefore, the program was expanded to include a fundamental study of film formation and its removal. In addition, it was found necessary to include in the program the development of several analytical procedures to ensure the precision required for several determinations (HW-7-4444). Columbia River water was supplied to the CMX Building by two 1,136 LPM (300 GPM) self-priming pumps mounted in a moveable shelter at the river's edge on the downstream side of the facility (HAN-73214-14). Alum or an alkali was added prior to being passed through closed settling tanks and sand filters. The water was further treated by passing through one of three treatment systems: a secondary filtered water treatment system, a deaerated water treatment system, or a demineralized water treatment system. These systems fed high-head pumps which produced 350 psi water to the process tubes. The treated water was also heated to the temperatures expected in pile operation. Between September 1, 1943 and October 30, 1944 the optimum concentrations of critical anti-corrosion (sodium dichromate) and anti-scaling (sodium silicate) chemicals were tested and perfected. Other chemicals used in the process were sulfuric acid, which was used extensively in the building for pH adjustments, ferric sulfate which was used during the development of coagulants, oxalic acid which was used as a film removal agent, and hydrogen peroxide which was used during testing for film removal. Much of the piping was either rubber-lined or stainless steel. Five railroad locomotives were connected in parallel to a single header just northwest of the 145 Building to furnish 1,500 boiler hp and process/heating steam. Air for the instruments and lab was supplied by a steam-driven compressor. Electric power and light was obtained from the Hanford Construction Site system (DUH-11843, HW-7-4444). In June 1944, a flocculator (with agitator) and a 95,635 L (25,000 gal) clearwell were
added to CMX to study the removal of iron and aluminum from river water. Building 145 was shut down October 30, 1944, when final CMX runs were concluded. The facilities remained in standby condition until January 1945 when satisfactory pile operations in 100-B and 100-D Areas had indicated that no major film or corrosion problems were to be anticipated. The equipment was subsequently dismantled and declared excess by Construction (HAN-73214-14). Similar experimental work continued through the use of flow laboratories that were installed adjacent to the production piles.

**Waste Type:** Animal Waste

**Waste Description:** The waste is potentially contaminated soil and abandoned in-ground piping. The contaminants of potential concern include sodium dichromate, ferric sulfate, lead (from sulfuric acid), mercury (from the sulfuric acid), sulfuric acid and petroleum products.

**This Site has the Following SubSites:**

<table>
<thead>

**This Site has the Following SubSites:**

<table>
<thead>
<tr>
<th>Code</th>
<th>Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>600-334:2</td>
<td>600-334:2; Burn area near CMX Building</td>
</tr>
</tbody>
</table>

**Description:** The 600-334:1 subsite has been evaluated and determined to require No Action. It consisted of three areas. Area 1 is a raised footprint where the 145 Building Complex was once located. Area 2 is located on the northwest, upstream side of Area 1, and is a 5- by 5-meter (16- by 16-ft) depression that is approximately 1.5 meters (5 ft) deep. Area 3 is on the north, riverbank side of Area 1, and consists of three open-ended outfall pipes that protrude horizontally from what appears to have been the middle of the CMX Building. Two of these are vitrified clay pipe, and the southernmost is stainless steel.

**Location:** This site is located next to the bank of the Columbia River approximately 275 m (902 ft) upstream of the Hanford town site former ferry landing at the end of Division Street (C-127).

**Process Description:** Refer to the parent waste site (600-334) for a process description of the 145 building complex. The site was identified during the Orphan Site Evaluation field walkdowns for the 100-IU-2 and 100-IU-6 areas on May 10, 2007 (EL-1616, OSR-2008-0001). The two vitreous pipes were sewers; one was the sanitary sewer for the 145 building and the other was the process sewer used to return the treated water back to the Columbia River (M-2899). The purpose of the cast iron pipe is unknown.

It was originally thought that the pipes may have carried contaminants from experimental procedures to the river.

Geophysics investigation GI# 0585886 was conducted at this site January 2008 using ground penetrating radar (GPR) and a high sensitivity metal detector (EM-61). The results are as follows: The footprint of the 145 building is relatively clear in the geophysical data. All three of the exposed pipes were traced from the riverbank to the eastern edge of the building, suggesting that they are indeed associated with the building. Two additional linears were also identified that extend from the river bank to the building footprint.

**Closure Info:** Confirmatory sampling of the 600-334:1 subsite was initiated and performed in October 2010.
Based on the confirmatory sample results, no remediation was performed at this site.

Samples were collected from one Test Pit, two Test Trenches and from an outfall pipe.

**The SubSite is Part Of:**

**Type:** Process Unit/Plant

**Status:** Inactive

**Description:** Subsite 2 consists of a 4.6 meter (15.1 ft) diameter burn area of unknown origin found off the northwest corner of the former CMX Building complex.

**Location:** This site is located next to the bank of the Columbia River approximately 275 m (902 ft) upstream of the Hanford town site former ferry landing at the end of Division Street (C-127).

**Process Description:** The parent site was identified during the Orphan Site Evaluation field walkdowns for the 100-IU-2 and 100-IU-6 areas on May 10, 2007 (EL-1616, OSR-2008-0001). The nearest facility to the site is the CMX Building (Building 145). Refer to the parent waste site (600-334) for a process description of Building 145.

</tbody>
</table>

**Type:** Dumping Area

**Status:** Inactive

**Description:** The site has been remediated and Interim Closed Out. The site originally consisted of a trench dug from east to west, located on the west side of a depression and used by the J.A. Jones Company. The area was used for the disposal of miscellaneous debris and paint products.

**Location:** The JA Jones 1 site is located north of the 300 Area, east of the point where the railroad tracks cross Route 4 South, in the 100-IU-6 Operable Unit of the Hanford Site in southeastern Washington State.

**Release Description:** In 1980, 77 cubic meters (100 cubic yards) of contaminated soil excavated from the 305-B Berm were placed in this pit (see UPR-600-11). When the contamination was identified, the soil was removed from this pit and taken to the 200 Area for proper disposal.

**Related Sites/ Structures:** This site is associated with UPR-600-11 which was an area within the JA Jones Pit #1 where contaminated material was mistakenly disposed. The contaminated material was removed in 1980 and the area released from radiological control. JA Jones 1 is also associated WIDS waste site is 600-1, a trench located adjacent to and east of the JA Jones #1 Pit. It was used by the 300 Area Westinghouse facilities as a disposal site for tumbleweeds that collected from the 300 Area fences.
Process Description: This site was used by the JA Jones company for the disposal of miscellaneous debris, construction waste and paint products. An interview with an employee revealed that in 1977, seven to ten pick up truck loads of overstocked paint and solvents were disposed of in this pit. The containers were opened and the contents emptied onto the ground in the pit. The empty containers were then thrown into the pit.

Waste Type: Water

Waste Description: The site may contain some low level uranium contaminated materials. However, this information can not be confirmed because of the uncertainty the location where the material was dumped.

Waste Type: Water

Waste Description: In 1977, seven to ten pick up truck loads of over stocked paint and solvents were disposed of into a pit located north of the 300 Area. A site visit with the employee who dumped the paint indicates it was placed in the trench known as JA Jones Pit 1. He indicated that latex, epoxy and enamel paints, as well as paint thinners were discarded. He opened the containers (one and 5 gallon cans) and emptied the contents into the pit. He then threw the empty containers into the pit.

Waste Type: Water

Waste Description: This site contains miscellaneous nonradioactive solid wastes from various construction sites. It contains wood scraps, concrete, miscellaneous construction wastes and paint products.

Closure Info: Remedial activities began in January 2001 and continued through March 2001. Approximately 12,700 metric tons (14,000 tons) of material was disposed of at the ERDF facility. Material excavated from the site included soil, concrete, construction-type debris, crushed paint cans, dried paint debris, sandblast material, and flame-retardant-like material. The excavation was approximately 2694 square meters with a maximum depth of 3.4 meters (12 feet). The site was backfilled and recontoured using clean soil and some concrete debris that had been excavated from the site. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

Radiological surveys and Industrial Hygienist monitoring was performed throughout the excavation process. With the exception of the suspect flame retardant, no radioactive material above background levels was identified for the excavated material, anomalous waste, or residual soil. Field instruments used for IH monitoring did not detect any organic vapors in the excavated material, anomalous waste, or residual soil. Visual observation of the excavated material did not identify any areas of discolored soil or concrete.

Code: UPR-600-11
Classification: Accepted

Names: UPR-600-11; Contaminated Soil Dumped at JA Jones Pit #1
Reclassification: Closed Out (1/27/1999)

Type: Unplanned Release
Start Date: 5/29/1980
End Date: 5/29/1980

Status: Inactive

Description: The site was declared Closed Out on Waste Site Reclassification form 98-215, signed in 1999. It was an area within the JA Jones Pit #1 where contaminated material was mistakenly disposed. The contaminated material was removed in 1980 and the area released from radiological control. There is no visual evidence of this occurrence. A Remedial Action was done at this site in 2001.

Location: The release occurred in the JA Jones Pit #1, which is located about 1.2 kilometers (2 miles) north of 300 Area.
On May 29, 1980, during a routine radiological survey, low-level beta-gamma contamination (approximately 600 counts per minute) was detected in a small amount of discarded blacktop rubble laying on the south end of the 305-B Berm. Some of the contaminated blacktop had mixed with the disturbed earthwork. JA Jones subcontractor workers had excavated 76.5 cubic meters (100 cubic yards) of soil from the 305-B Berm, which was thought to be uncontaminated, and taken it to the JA Jones Pit #1 before the contamination was detected. The JA Jones Pit #1 was designated as a non-radioactive landfill. Work was stopped immediately and the appropriate personnel were notified.

The site was declared Closed Out on Waste Site Reclassification form 98-215, signed in 1999.

Following the discovery of the contaminated material in May 1980, the two affected areas (the 305-B Berm and the JA Jones dump site) were roped off, surveyed and posted as radiation zones. The subcontractor personnel and equipment were carefully surveyed and found to be free of contamination. The subcontractor personnel were given whole body and lung counts. All were found to be below detection levels. The contaminated soil dumped into the JA Jones pit was removed and taken to the 200 Area for disposal in 1980. Further soil excavation at the 305-B Berm was closely surveyed by a radiation monitor. The event resulted in 77 cubic meters (100 cubic yards) of contaminated soil needing proper disposal.

The unplanned release was also evaluated in the Cleanup Verification Package for the JA Jones 1 site (CVP-2001-00019).

Remedial Action at the JA Jones 1 site began on January 8, 2001. The lowest elevation of the bottom of the excavation was approximately 112.6 meters (369.4 ft) upon completion. The excavation was approximately 2,694 square meters (29,000 sq. ft.) in area with a maximum depth of approximately 3.4 meters (11.2 ft). The excavation was completed on March 6, 2001. Approximately 12,700 metric tons (14,000 tons) of material from the site were disposed of at ERDF.

Material excavated from the site included soil, concrete, construction-type debris, crushed paint cans, dried paint debris, sandblast material, and flame-retardant-like material. No liquid wastes were encountered during excavation. Clean overlying and co-mingled soil that was segregated during the excavation process was stockpiled at the site for potential use as backfill. Based on agreement between the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy Unit Managers, large pieces of concrete debris will be used to partially backfill the site excavation. Approximately 38 cubic meters (50 yd) of concrete debris, with individual pieces as large as 1.2 meters by 2.4 meters by 0.6 meters (4 ft by 8 ft by 2 ft), were used to partially backfill the site excavation. Samples collected from the concrete indicate that the concrete is an inert demolition-type debris.
**Type:** Unplanned Release  
**Start Date:** 1/1/1951  
**End Date:**  

**Description:** The waste site has been Interim Closed Out. The fire and resulting contamination spread unplanned release occurred on December 4, 1951, when plutonium contamination was spread by a fire that ignited inside the 120 Experimental Building. The area was a flat, featureless field that has been sown with rye grass. The P-11 Laboratory structure had been removed but its location is marked with a permanent concrete benchmark.

**Location:** The 120 Building was located approximately 4.8 kilometers (3 miles) southeast of 100-F Area, approximately 0.48 kilometers (0.3 mile) west of Route 2 North.

**Release Description:** The P-11 Facility was a laboratory for plutonium criticality studies. In November 1951, a criticality excursion resulted in extensive plutonium contamination inside the laboratory building (120 Building). Activities in the laboratory were suspended to conduct decontamination work. On December 4, 1951 decontamination was in the final stages when a spontaneous ignition of decontamination materials caused a fire that gutted the entire building. Plutonium contamination was spread by the fire and also washed into the soil by the waster used to extinguish the fire. The area was stabilized with clean soil and gravel to prevent wind from spreading the contamination further. The 120 Building and its crib were removed in 1974 and the area was released from radiological posting.

**Related Sites/Structures:** The site was associated with the 120 Building and the P-11 Crib (site code 600-111).

**Waste Type:** Storage Tank

**Waste Description:** An estimated amount of 1 to 4 grams (0.035 to 0.14 ounces) of plutonium was deposited over an area approximately 1,660 square meters (18,000 square feet) from a structure fire in 1951.

**Closure Info:** Confirmatory sampling from test pits and trenches was performed from April 29 2004 through May 10, 2004. To track results of confirmatory sampling, the P-11 lab complex waste site was stratified into the following seven areas for evaluation and sample collection. Area 1 was the Former 120 Experimental Building location, Area 2 was the Former P-11 Crib location, Area 3 was the Former 123 Control Building location, Area 4 was the Geophysical anomaly, Area 5 was the Septic Drain Field, Area 6 was the Septic Tank and Area 7 was the Surface Depression. Results of confirmatory sampling at Areas 1, 2, 3 and radiological surveys at UPR-600-16 determined no action was required. Confirmatory samples from Areas 5 and 6 found elevated levels of PCB's, arsenic cadmium and lead.

Some minimal radioactivity was detected, but the RESRAD modeling determined the dose rare for all pathways was less than 15 millirem per year.

Remedial action of the septic system tank and drain field (Areas 5 and 6) located at 600-111 was performed between February 25, 2008 and March 25, 2008. The site was excavated to approximately 4.6 meters (15 ft) below grade (at the deepest portion), resulting in a combined volume of approximately 2,755 cubic meters (3,603 cu. yd) of material removed and disposed at the Environmental Restoration Disposal Facility. Verification soil samples for the septic system remediation were collected on April 21, 2008.

All test pits/trenches were excavated and sampled in late April 2004 through early May 2004 as specified in the sampling work instruction. During excavation, field monitoring for VOCs was performed and no constituents were detected. In addition, FIDLER radiological surveys were performed during the excavations. No radiological contamination above twice the background level was found.

**Description:** The site appears as a dry, shallow ditch which extends from the 116-K-3 (1904-K Outfall Structure) and the 116-K-1 Crib. A second ditch extends from the culvert to the Columbia River. The culvert conveyed process effluent leakage from the area surrounding the 107-KE Basins under the road and to the ditch. The two ditches intersect below the bank located just north of the basins. The ditch at the bottom of the bank is approximately 300 meters (980 feet) long and 2 meters (6.6 feet) wide and the ditch leading from the culvert to the river is approximately 270 meters (890 feet) long and the width is generally 2 meters (6.6 feet) wide but widens significantly in the middle section. The southern portion of the ditch is located in an area posted as a "Soil Contamination Area." The ditch is barricaded from the river by a three strand barbed wire fence and is posted with "Keep Out" signs.

**Location:** The site is located north of 100-K Area, north of the 107-KE Retention Basins. It is between the Columbia River and security road inside the 100 KE Flood Plain (sitecode 100-K-64). It is inside the boundaries of the 100-K-64 radiologically posted area.

**Related Sites/Structures:** The drainage ditch received process effluent from the 107-KE Retention Basins. It is associated with 100-K-64 flood plain.

**Waste Type:** Chemicals

**Waste Description:** The soil in and around the ditch is contaminated with radionuclides as a result of conveying reactor process effluent to the river.

</tbody>
</table>

**Description:** The waste site has been remediated and Interim Closed Out. It was a large portion on the flood plain, along the shore of the Columbia River, north of 100-K West Reactor Area. It was posted as a radiological contamination area. Most of it was posted as an Underground Radioactive Material Area, but there were two sections that were Soil Contamination Areas. The waste site also included four culverts that discharged directly into the flood plain.

**Location:** The waste site is located along the Columbia River shoreline, north of the 107-KW Basins. Significant quantities of the leakage accumulated on the floodplain over time and created preferential pathways through the natural topography of the site. The effluent concentrated in natural depressions, creating areas with potentially increased levels of contamination. Historical photographs taken during the operating period of the 107-KW Retention Basins show increased vegetation within the 100-K-63 Waste Site due to the periods of significant effluent leakage.
from the basins, which overflowed from the open drainage ditches and spread over the floodplain area.

**Release Description:** The 107-KW Basins developed leaks over time. Leaks were estimated to be as great as 18,900 to 75,700 liters/minute (5,000 to 20,000 gallons/minute). A metal culvert to an open ditch diverted the water to the river shoreline.

**Related Sites/Structures:** The 116-KW-3 (107-KW Basins) are related to this site.

**Process Description:** During reactor operations the 107-KW Retention Basins received cooling water effluent from the 105-KW Reactor to allow for radioactive decay and thermal cooling prior to release to the Columbia River. The 107-KW Retention Basins and their effluent lines developed leaks during their operating life. Most of the leakage was diverted to metal culverts, conveying the effluent to an open drainage ditch through the floodplain, which discharged to the Columbia River.

**Closure Info:** Remediation of the 100-K-63 Waste Site began in July 2010 and was completed by November 2010. The remediation was conducted with a maximum excavation depth of 4.05 meters (13.3 ft). Radiological surveys of the waste site and in-process samples were used to guide the excavation. All of the areas with elevated radiological readings were remediated. No staining or other visible identifiers which would indicate a need for further remediation were observed. Concurrent with excavation of the waste site, thirty-one discrete and composite surface in-process samples were collected within the excavation area. To evaluate the un-excavated portion of the waste site, pothole sampling was performed at 18 locations from multiple depths per pothole. The potholing resulted in an additional forty-six samples, with sample depths ranging from surface to 2.67 meters (14 ft) below ground surface. The sample locations in the unexcavated portion of the waste site were focused in low-lying depressions, channels, and soil erosion locations caused by effluent discharges, which had the greatest potential for contaminant accumulation. Four culverts that discharged directly into the flood plain were also removed.

During active excavation of the waste site on September 23, 2010, there was an inadvertent discovery of cultural material. Work at the 100-K-63 Waste Site was suspended for a cultural resources impact assessment. The maximum excavation depth of 4.6 meters (15 ft) below grade surface was agreed to with cultural resource experts in consult with the Tribes.

All contaminated soils and structures (approximately 85,431 tons) removed as part of the remediation were disposed of at the Environmental Restoration Disposal Facility (ERDF). A fiber mulch was applied to prevent further erosion of the excavated waste site area after sampling. Interim backfill was completed in October of 2011. Interim revegetation was completed in February of 2012.

**Code:** 100-K-64  
**Classification:** Accepted  
**Reclassification:** None

Waste Description: A surface radiological survey was performed at the 100-K-78 waste site on February 25, 2010. A sodium-iodide probe was used to collect information on potential contamination. Although the survey record notes direct beta/gamma readings up to 3.5 times background, no removable contamination above radiological control limits was present at the site.

Confirmatory sampling was performed at 100-K-78 on April 19 and November 5, 2010. During the first sampling event, two samples plus one duplicate were collected of surface soil. One sample was collected at a location previously identified as having the highest radiological readings at the site. The second sample and duplicate were collected from material composited from five locations within the waste site. Field instruments did not detect elevated radiological or organic vapor readings in the sample material.

During the second sampling event, a test pit was excavated near the center of the site. Soil samples were taken in approximate 0.8-meters (2.5-feet) intervals from the surface to 3 meters (10 feet) below ground surface (bgs). Excavated material from 2.1 meters (7 feet) bgs exhibited slightly elevated radiological readings. Background was noted as ~400 counts per minute (cpm); the material was reading ~550 cpm. This material was collected for the 1.5- to 2.3-meters (5.0- to 7.5-feet) bgs sample. No other elevated radiological or organic vapor readings were detected.

No debris, anomalous material, or stained soil was observed during sampling activities.

<tr>
<td>Type: Radioactive Process Sewer</td>
<td>Start Date:</td>
</tr>
<tr>
<td>Status: Inactive</td>
<td>End Date:</td>
</tr>
</tbody>
</table>
Description: 100-K-80 is a 213 centimeters (84 inches) diameter, carbon steel river effluent pipelines that extends from the face of 116-K-3 outfall structure to the Columbia River. The 100-K-96 pipeline runs parallel to 100-K-80. The pipelines are approximately 122 centimeters (48 inches) apart. In January 2012, the river effluent pipeline designations were split. The portion of the 100-K-80 pipeline that extends into the river was given a new WIDS sitecode (100-K-113).

Location: The 100-K-80 river pipeline is located on the Columbia River shore, adjacent to the 100K Area. It is west of the adjacent 100-K-96 pipeline.

Related Sites/Structures: The pipeline site is associated with the 116-K-3 Outfall Structure, the 100-K-83 Spillway, the 100-K-47 process sewer, 100-K-56 process effluent lines, 100-K-55 process effluent lines, the 100-K-60 process sewer, the 116-KW-3 Retention Basins, the 100-K-96 river pipeline, and the 100-K-113 river pipeline.

Process Description: 105-KW reactor cooling water was collected and temporarily stored in the 107-KW Retention Basins. The cooling water was discharged to the river, bypassing (underneath) the 116-K-3 (1908-K) outfall structure, through the 100-K-80 river pipeline. Process sewer waste, from both 100-KE and 100-KW facilities, entered the outfall structure and dropped into the 100-KE river pipeline (see 100-K-96) through large-diameter, vertical standpipes welded onto the pipelines.

Retention basins lines (100-K-55 and 100-K-56) did not discharge through the outfall structure, but passed under it. They are a continuous line that become the river effluent pipelines downstream of the outfall structure. The pipelines discharge into a recessed, sloped riprap river bed structure, measuring 9 meters (30 feet) wide by 12 meters (40 feet) long and 1 meter (3 feet) thick. The total drop from the face of the outfall structure to the discharge end of the pipelines is 18 meters (60 feet).

In 1955, the river effluent pipelines began to float and break. Both lines were damaged. To remedy the problem, a 2 to 3 meter (6 to 10 feet) thick riprap jetty was placed over the lines from the shoreline to a point approximately 320 meters (1050 feet) from the face of the outfall structure.

Waste Type: Process Effluent
Waste Description: The waste includes the pipeline and the contaminated scale contained within it. The effluent included both reactor cooling water and process sewer waste. The Contaminants of Potential Concern are based on the 116-K-3 outfall, and include Co-60, Cs-137, Eu-152, Eu-154, Pu-239/240, and Sr-90.

Code: 100-K-81
Names: 100-K-81; Contamination Area West of 116-K-3
Type: Unplanned Release
Status: Inactive
Classification: Accepted
Reclassification: None
Start Date: 
End Date: 
Description: The site consists of a large cylindrical piece of equipment surrounded by a rope and posted as Soil Contamination Area.

Location: The posted Soil Contamination area is adjacent to 116-K-3 Outfall Structure, approximately 6.1 meters (20 feet) west of the Outfall Structure fence. It is inside the boundaries of the 100-K-64 (Flood Plain) radiologically posted area.

Related Sites/Structures: The site is associated with the 100-K-64 flood plain, 116-K-3 Outfall, 100-K-83 spillway, the 116-KE-4 and 116-KE-3 retention basins, the 100-K-55 and 100-K-56 process effluent lines, the 100-K-47 process sewer, and the 100-K-80 and 100-K-113 river effluent pipelines.
Process Description: The large cylindrical piece of equipment could be lowered into the top of the outfall structure. It was used to plug the outfall structure and prevent water from going through the structure.

Waste Type: Oil

Waste Description: The Contaminants of Potential Concern include Co-60, Cs-137, Eu-152, Eu-154, Pu-239/240, and Sr-90.

Code: 100-K-83
Names: 100-K-83; 116-K-3; 1904-K Flume; 1904-K Outfall Structure; 1904-K Spillway
Type: Outfall
Status: Inactive
Description: The 100-K-83 spillway (also referred to as a flume) was a combination of a three-sided, reinforced concrete trough beginning at the 116-K-3 Outfall, followed by an open earthen trench extending from the end of the concrete trough to the Columbia River shore.

Location: The concrete portion of the spillway exits the east side of the 116-K-3 Outfall, takes an immediate 45-degree turn in the downstream direction. An earthen trench continues in the same direction from that point to the river shoreline.

Related Sites/Structures: The site is associated with 100-K-64 flood plain, 100-K-80, 100-K-96 (100-K River Effluent Pipelines) and 116-K-3 (1904-K) Outfall structure.

Process Description: The spillway was an alternate discharge point for the 116-K-3 Outfall structure. It was planned to be used only if the River Effluent Pipelines (sitecodes 100-K-80 and 100-K-96) were blocked, damaged, or undergoing maintenance. There is no corroborated physical or historical evidence that the spillway was ever used.

Waste Type: Process Effluent
Waste Description: If ever put into service, the COPCs for the 100-K-83 spillway would be the same as for the 116-K-3 outfall, including Cobalt-60, Cesium-137, Europium-152/154, Plutonium 239/240, and Strontium-90. There is no corroborated physical or historical evidence that the spillway was ever used.

Code: 100-K-86
Names: 100-K-86; Four Areas of Stained Soil in 100-K Area; 100-K Stain Areas
Type: Unplanned Release
Status: Inactive
Description: The site has been remediated and Interim Closed Out. It consisted of four areas with stained soil in and some surface debris.

Location: The coordinates locations for the areas are:

Area 1 - N568381.27 E146009.94
Area 2 - N568923.50 E145541.86
Area 3 - N568443.18 E145437.89
Area 4 - N568848.48 E145301.50

Hanford Site Waste Management Units Report
February 2015
Waste Type: Demolition and Inert Waste

Waste Description: The waste is potentially contaminated soil. There was no information describing the release of the observed materials.

Closure Info: Waste sites 100-K-84, 100-K-86, 100-K-87, 100-K-91, 100-K-92, 100-K-95 were evaluated and reclassified as a group in the same RSVP document.

Remediation of the waste sites began in November 2012 and was concluded in June 2013. Due to elevated residual concentrations of contaminants after the initial remediation(s), additional remediation was required for the 100-K-84, 100-K-87, and 100-K-95 waste sites. All materials removed from the excavations were disposed at the Environmental Restoration Disposal Facility (ERDF) via direct load out. No staging pile areas were associated with the waste sites.

The excavation at the 100-K-84 waste site began on November 5, 2012, and concluded on March 14, 2013. Approximately 2,695 bank cubic meters (BCM) (3,525 bank cubic yards [BCY]) of soil and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.91 meters (3 ft) bgs.

The excavation at the 100-K-86 waste site began on November 13, 2012, and concluded on January 22, 2013. Approximately 342 BCM (447 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 1.5 meters (5 ft) bgs.

The excavation at the 100-K-87 waste site began on February 26, 2013, and concluded on April 3, 2013. Approximately 72 BCM (94 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.91 meters (3 ft) bgs.

The excavation at the 100-K-91 waste site was conducted on November 28, 2012. Approximately 0.2 BCM (0.26 BCY) of suspect asbestos, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 1.2 meters (4 ft) bgs.

The excavation at the 100-K-92 waste site began on November 13, 2012, and concluded on December 13, 2012. Approximately 32 BCM (42 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.6 meters (2 ft) bgs.

The excavation at the 100-K-95 waste site began on January 8, 2013, and concluded on June 24, 2013. Approximately, 4,272 BCM (5,588 BCY) of soil and rock were removed and disposed at ERDF. The maximum depth of the excavation at the 100-K-95 waste site was approximately 1.5 meters (5 ft) bgs.
located approximately 15 meters (50 ft) outside the boundary of the 600-29 waste site (100-K Construction Lay-down Area). The Washington State Plane coordinates for the site are E568610.61 N145586.62.

**Related Sites/Structures:** 600-29 Construction Lay-Down Area

**Waste Type:** Asbestos (non-friable)

**Waste Description:** The waste is soil with potential friable asbestos. The contaminant of potential concern is asbestos.

**Closure Info:** Waste sites 100-K-84, 100-K-86, 100-K-87, 100-K-91, 100-K-92, 100-K-95 were evaluated and reclassified as a group in the same RSVP document.

Remediation of the waste sites began in November 2012 and was concluded in June 2013. Due to elevated residual concentrations of contaminants after the initial remediation(s), additional remediation was required for the 100-K-84, 100-K-87, and 100-K-95 waste sites. All materials removed from the excavations were disposed at the Environmental Restoration Disposal Facility (ERDF) via direct load out. No staging pile areas were associated with the waste sites.

The excavation at the 100-K-84 waste site began on November 5, 2012, and concluded on March 14, 2013. Approximately 2,695 bank cubic meters (BCM) (3,525 bank cubic yards [BCY]) of soil and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.91 meters (3 ft) bgs.

The excavation at the 100-K-86 waste site began on November 13, 2012, and concluded on January 22, 2013. Approximately 342 BCM (447 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 1.5 meters (5 ft) bgs.

The excavation at the 100-K-87 waste site began on February 26, 2013, and concluded on April 3, 2013. Approximately 72 BCM (94 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.91 meters (3 ft) bgs.

The excavation at the 100-K-91 waste site was conducted on November 28, 2012. Approximately 0.2 BCM (0.26 BCY) of suspect asbestos, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 1.2 meters (4 ft) bgs.

The excavation at the 100-K-92 waste site began on November 13, 2012, and concluded on December 13, 2012. Approximately 32 BCM (42 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.6 meters (2 ft) bgs.

The excavation at the 100-K-95 waste site began on January 8, 2013, and concluded on June 24, 2013. Approximately, 4,272 BCM (5,588 BCY) of soil and rock were removed and disposed at ERDF. The maximum depth of the excavation at the 100-K-95 waste site was approximately 1.5 meters (5 ft) bgs.

<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>In November 2010 a focused sampling approach was used to evaluate the white granular material at 100-K-90 and determine if there is any soil contamination due to its presence (WCH 2010b). One shallow soil sample (0 to 0.15 meters [0 to 6 in.] below ground surface) and one duplicate soil sample were collected from the waste site. No radiological activity or volatile organic compounds (VOCs) were detected during confirmatory sampling. Furthermore, no stained soil or anomalous material was observed during sampling. Analysis was performed to evaluate if contamination associated with the white granular material was present. Confirmatory sampling at the 100-K-90 waste site indicated that environmental contamination above cleanup levels was not present, and remedial action was not necessary. The confirmatory sampling data has been used for a No Action determination.</td>

Hanford Site Waste Management Units Report
February 2015
Status: Inactive  
End Date:  

Description: The site has been remediated and Interim Closed Out. It consisted of one intact, partially buried, vehicle battery and the underlying soil. The surrounding vegetation appears to be unaffected by its presence.

Location: The site is located off of an unpaved secondary road west of the 100 K operable unit. Traveling west on Route 1 from the intersection with K Avenue proceed 2.3 km (1.4 m) to the unpaved road on the right. Turn right and travel approximately 355 meters (1165 ft). The site is located approximately 33 meters (110 ft) east of the road in an open area. The Washington State Plane coordinates are E567290.29 N145486.16.

Process Description: The origin of this battery, whether from the pre-Hanford or Hanford eras, is unknown. It appears to have been random littering.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: The contaminants of potential concern may contain lead and possibly sulfuric acid in the soil. The waste is the battery and potentially contaminated soil.

Closure Info: Waste sites 100-K-84, 100-K-86, 100-K-87, 100-K-91, 100-K-92, 100-K-95 were evaluated and reclassified as a group in the same RSVP document.

Remediation of the waste sites began in November 2012 and was concluded in June 2013. Due to elevated residual concentrations of contaminants after the initial remediation(s), additional remediation was required for the 100-K-84, 100-K-87, and 100-K-95 waste sites. All materials removed from the excavations were disposed at the Environmental Restoration Disposal Facility (ERDF) via direct load out. No staging pile areas were associated with the waste sites.

The excavation at the 100-K-84 waste site began on November 5, 2012, and concluded on March 14, 2013. Approximately 2,695 bank cubic meters (BCM) (3,525 bank cubic yards [BCY]) of soil and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.91 meters (3 ft) bgs.

The excavation at the 100-K-86 waste site began on November 13, 2012, and concluded on January 22, 2013. Approximately 342 BCM (447 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 1.5 meters (5 ft) bgs.

The excavation at the 100-K-87 waste site began on February 26, 2013, and concluded on April 3, 2013. Approximately 72 BCM (94 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.91 meters (3 ft) bgs.

The excavation at the 100-K-91 waste site was conducted on November 28, 2012. Approximately 0.2 BCM (0.26 BCY) of suspect asbestos, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 1.2 meters (4 ft) bgs.

The excavation at the 100-K-92 waste site began on November 13, 2012, and concluded on December 13, 2012. Approximately 32 BCM (42 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.6 meters (2 ft) bgs.

The excavation at the 100-K-95 waste site began on January 8, 2013, and concluded on June 24, 2013. Approximately, 4,272 BCM (5,588 BCY) of soil and rock were removed and disposed at ERDF. The maximum depth of the excavation at the 100-K-95 waste site was
The site has been remediated and Interim Closed Out. It consisted of two areas containing reddish crusted soil and the underlying soil. Area 1 was reddish crusted soil indicating that a liquid may have been dumped to the ground. There is little or no vegetation growing in the stained area. Area 2 was reddish stained soil, metal debris and the remnants of a crushed drum. There is little or no vegetation growing in the affected area.

Location:
The Washington State Plane coordinates are:

Area 1 - E568334.35 N145456.30
Area 2 - E568355.99 N145418.29

These areas were outside the 100-K perimeter fence.

Related Sites/Structures:
100-K-84

Process Description:
It is suspected that this material is similar to that of 100-K-84 which was described as: crushed iron ore, a component of the concrete used in reactor and other facility construction because it provided additional shielding. The material is highly magnetic.

Waste Type: Process Effluent
Waste Description: The waste is the spilled/abandoned red material.

Closure Info: Waste sites 100-K-84, 100-K-86, 100-K-87, 100-K-91, 100-K-92, 100-K-95 were evaluated and reclassified as a group in the same RSVP document.

Remediation of the waste sites began in November 2012 and was concluded in June 2013. Due to elevated residual concentrations of contaminants after the initial remediation(s), additional remediation was required for the 100-K-84, 100-K-87, and 100-K-95 waste sites. All materials removed from the excavations were disposed at the Environmental Restoration Disposal Facility (ERDF) via direct load out. No staging pile areas were associated with the waste sites.

The excavation at the 100-K-84 waste site began on November 5, 2012, and concluded on March 14, 2013. Approximately 2,695 bank cubic meters (BCM) (3,525 bank cubic yards [BCY]) of soil and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.91 meters (3 ft) bgs.

The excavation at the 100-K-86 waste site began on November 13, 2012, and concluded on January 22, 2013. Approximately 342 BCM (447 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 1.5 meters (5 ft) bgs.

The excavation at the 100-K-87 waste site began on February 26, 2013, and concluded on April 3, 2013. Approximately 72 BCM (94 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.91 meters (3 ft) bgs.
The excavation at the 100-K-91 waste site was conducted on November 28, 2012. Approximately 0.2 BCM (0.26 BCY) of suspect asbestos, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 1.2 meters (4 ft) bgs.

The excavation at the 100-K-92 waste site began on November 13, 2012, and concluded on December 13, 2012. Approximately 32 BCM (42 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.6 meters (2 ft) bgs.

The excavation at the 100-K-95 waste site began on January 8, 2013, and concluded on June 24, 2013. Approximately, 4,272 BCM (5,588 BCY) of soil and rock were removed and disposed at ERDF. The maximum depth of the excavation at the 100-K-95 waste site was approximately 1.5 meters (5 ft) bgs.

**Names:** 100-K-93; 100-K Drum Remnant  
**Type:** Unplanned Release
**Status:** Inactive

**Description:** The site has been evaluated and reclassified to Consolidated with the 100-K-111 waste site. It consisted of a 208 liter (55 gal) drum remnant with approximately .03 cubic meters (1 cu. ft) of solidified gray/black tar like substance and the underlying soil. The drum tar-like material and underlying soil were removed in November 2012. The 0.5 bank cubic meters of material was disposed at ERDF. Cleanup verification samples were collected in February 2103. The sample results contained elevated levels of total chromium and hexavalent chromium. The chromium contamination was determined not to be associated with the drum remnant. Therefore, the residual contaminated soil is being consolidated with the 100-K-111 waste site (see WSRF 2013-063).

**Location:** The site is located approximately 162 meters (530 ft) north of the 116-K-1 crib and 610 meters (2000 ft) northeast of the 181 KE river pump house. The site is approximately 90 meters (300 ft) from the Columbia River. The site is located at Washington State Plane coordinates E569226.34/N147476.24. It is located within the boundaries of waste site 100-K-111.

**Related Sites/Structures:** 100-K-111

**Waste Type:** Equipment
**Waste Description:** The waste is the abandoned drum, tar like substance, and any contaminated soil.

**This Site Was Consolidated With:**

**Names:** 100-K-94; 1702-KE and 1702-KW Guard House Dry Wells
**Type:** French Drain

Hanford Site Waste Management Units Report  
February 2015
There are two identical dry wells, one at the 1702-KE guard house and one at the 1702-KW guard house. Each 76 centimeter (30 inch) dry well received drinking water through a 7.6 centimeter (3 inch) cast iron pipe that exited guard houses.

The dry well associated with 1702-KE is approximately north of the facility, centered at Washington State Plane coordinates E 569083.43, N 146600.77. The dry well associated with 1702-KW is approximately north of the facility, centered at Washington State Plane coordinates E 568808.6, N 146453.6.

Excess drinking water effluent flowed from the drinking fountain in each guard house through underground piping to the dry well.

No evidence of hazardous or dangerous waste being discharged to these sites was discovered. The waste was excess (unconsumed) water coming from the drinking fountains at both guard houses.

This waste site has been remediated and Interim Closed Out. It consisted of a large area, approximately 150 meters (500 ft) in diameter, of scattered tar and the underlying contaminated soil. A field walkdown of the site was conducted on July 07, 2008.

The site was located in the 100K Area at coordinates E569072.38 N145469.5. It was about 60 meters (200 feet) south of the 600-29 Construction Lay-down Area. The nearest maintained road is 270 meters (900 ft) away.

These tar dumps, located south of the 600-29 Construction Lay-down Area, probably occurred as a way of disposing of excess oil and tar during 100-K Area Construction.

The waste is construction debris. The contaminants of potential concern consist of PAHs and PCBs.

Remediation of the waste sites began in November 2012 and was concluded in June 2013. Due to elevated residual concentrations of contaminants after the initial remediation(s), additional remediation was required for the 100-K-84, 100-K-87, and 100-K-95 waste sites. All materials removed from the excavations were disposed at the Environmental Restoration Disposal Facility (ERDF) via direct load out. No staging pile areas were associated with the waste sites.

The excavation at the 100-K-84 waste site began on November 5, 2012, and concluded on March 14, 2013. Approximately 2,695 bank cubic meters (BCM) (3,525 bank cubic yards [BCY]) of soil and rock were removed and disposed at ERDF. The maximum depth of the
The excavation was approximately 0.91 meters (3 ft) bgs.

The excavation at the 100-K-86 waste site began on November 13, 2012, and concluded on January 22, 2013. Approximately 342 BCM (447 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 1.5 meters (5 ft) bgs.

The excavation at the 100-K-87 waste site began on February 26, 2013, and concluded on April 3, 2013. Approximately 72 BCM (94 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.91 meters (3 ft) bgs.

The excavation at the 100-K-91 waste site was conducted on November 28, 2012. Approximately 0.2 BCM (0.26 BCY) of suspect asbestos, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 1.2 meters (4 ft) bgs.

The excavation at the 100-K-92 waste site began on November 13, 2012, and concluded on December 13, 2012. Approximately 32 BCM (42 BCY) of debris, soil, and rock were removed and disposed at ERDF. The maximum depth of the excavation was approximately 0.6 meters (2 ft) bgs.

The excavation at the 100-K-95 waste site began on January 8, 2013, and concluded on June 24, 2013. Approximately, 4,272 BCM (5,588 BCY) of soil and rock were removed and disposed at ERDF. The maximum depth of the excavation at the 100-K-95 waste site was approximately 1.5 meters (5 ft) bgs.

### Code: 100-K-99

**Classification:** Accepted  
**Reclassification:** None  
**Type:** Unplanned Release  
**Start Date:**  
**End Date:**  
**Status:** Inactive  
**Description:** On August 25, 2009, while constructing the 100K Container Transfer Area north of 105-KE, the equipment operator unearthed radioactive contaminated material while excavating. The radioactive material was Griffon material. This material was typically used to wrap contaminated items. The 107-KE Retention Basins had been located in this area, but were removed in 1995 (see sitecode 116-KE-4).

**Location:** The site is located north of the 105-KE Reactor building, inside the 100-K fence.

**Related Sites/Structures:** The waste site is associated with 116-KE-4.

**Waste Type:** Misc. Trash and Debris  
**Waste Description:** Radioactively contaminated soil, Griffon material and a concrete block was found while excavating an area adjacent to the remediated 116-KE-4 basins. 24,000 dpm per 100 centimeters (squared) beta/gamma was found on the Griffon material. 6,000 dpm per 100 centimeters (squared) beta/gamma was found on the soil around the concrete block.

---

### Code: 100-K-100

**Classification:** Accepted
Names: 100-K-100; 116-KW-3 Remaining Contaminated Soil and Items; Radioactive Material Area Remaining After 107-KW Basin Removal
Reclassification: None

Type: Unplanned Release
Status: Inactive
Start Date: 
End Date: 
Description: The waste site is the discovery of potential contaminated soil and material adjacent to the remediation area. The 107-KW Retention Basins had been located in this area, but were removed in 1995 (see sitecode 116-KW-3).

Location: The site is located north of the 105-KW Reactor building, inside the 100-K Area fence.

Code: 116-K-1
Classification: Accepted
Names: 116-K-1; 116-K-1 Trench; 100-K Crib; 100-K Emergency Pond; 100-K Pond; 107-K Pond; 107-K(E) Sump

Type: Crib
Status: Inactive
Start Date: 1/1/1955
End Date: 1/1/1956

Description: The site has been remediated and Interim Closed Out.

Location: The site was northeast of 116-KE-4 (107-KE Retention Basins).

Related Sites/Structures: The crib was related to the 107-KE/KW Retention Basins (116-KE-4, 116-KW-3). The crib received cooling water from the reactor via 100-K-55 and 100-K-56 cooling water effluent pipelines.

Process Description: The unit was a structure within a structure, the dimensions were 61 meters (200 feet) by 61 meters (200 feet) at the bottom and 122 meters (400 feet) by 122 meters (400 feet) at the top of diked sides. The inner structure rested within a sand-filled excavation that was 3 meters (10 feet) wide at the sides, 3 meters (10 feet) deep (parallel to the excavation) with 0.3-meter (1-foot) of underlying gravel. Both the inner and outer structures had a side slope ratio of 4:1. The 41-centimeter (16-inch) sewer entered 8 meters (27 feet) below the top of grade. A 107-centimeter (42-inch) drain line entered north of the 41-centimeter (16-inch) line, and 6 meters (20 feet) below the top of the structure. The natural ground elevation was 406 feet (124 meters) above mean sea level (MSL). An earthen dike with a slope ratio of 4:1 surrounded the unit from 2.1 meters (7 feet) below grade (bottom of outer structure) to 8 meters (26 feet) above the natural ground surface (top of structure). A 0.6-meter (2-foot) layer of riprap surrounded the earthen dike from natural grade to 3.4 meters (11 feet) above grade.

Waste Type: Misc. Trash and Debris
Waste Description: The site received reactor coolant water from the 107-K Retention Basins during reactor outages due to fuel ruptures. The site received 107-K Basin cleanout slurry from February 1955 to May 1956.

Closure Info: Remedial action at the 116-K-1 site began in September 2003. Excavation of the site involved removing the overburden materials, crib structure, and underlying contaminated soil. Contaminated materials were disposed of at ERDF. The area to the northeast is likely the area where the washout of the crib occurred.

Portions of the 100-K-55 and 100-K-56 pipelines, located within the remedial excavation footprint of the 116-K-1 Crib, were removed during remediation of the 116-K-1 site. Excavations of these pipelines were terminated at the notched portion of the 116-K-1 Crib.
excavation along the southwest wall of the excavation. Final remediation of these pipelines will be included in a future CVP reports.

At the conclusion of excavation activities, the elevation of the bottom of the excavation was at approximately El. 124.1 meters (407 ft). The excavation was approximately 15,700 square meters (168,900 sq. ft.) in area, with a depth of approximately 11 meters (36 ft) as measured from the uphill or southern surface grade. Approximately 101,396 metric tons (111,536 tons) of material from the site were disposed of at ERDF.

<tr>
<td>Related Sites/ Structures:</td>
<td>The site was associated with 116-KE-4 and 116-KW-3 Retention Basins via the 100-K-55 and 100-K-56 pipelines. It is also associated with 100-K-111, Effluent Seepage Area from 116-K-2.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The trench was fed by a 40.6 centimeter (16 inch) pipe that was part of the retention basin drain system. The trench was originally 1250 meters (4100 feet) long, 17.2 meters (56.5 feet) wide at the top, 1.2 meters (4 feet) wide at the bottom, and 5.3 meters (17.5 feet) deep. The side slope ratio was 1.5:1. The spoil piles on both sides of the trench originally had a top width of approximately 3.7 meters (12 feet). The site received all contaminated effluent from floor drains in the 105-K and 105-KW Reactors, 105-K and 105-KW Reactors metal storage basin overflow. Until 105-K and 105-KW shut down around February 1, 1970, an undetermined amount of Retention Basin effluent leaked through 107-centimeter (42-inch) butterfly valves in the tank bottoms. Other periodic flows included low volume, neutralized, dummy decontamination waste, process-cooling water during charge/discharge; occasional special disposals; and occasional tanks of process cooling water that was collected after a fuel cladding failure. In 1972, a minor construction tractor and hydride tanks removed from 100-K Area facilities were buried in the trench. In 1978, the radioactive inventory at the site was calculated at 2,100 curies.</td>

waste, process-cooling water during charge/discharge; occasional special disposals; and occasional tanks of process cooling water that was collected after a fuel cladding failure. In 1972, a minor construction tractor and hydride tanks removed from 100-K Area facilities were buried in the trench. In 1978, the radioactive inventory at the site was calculated at 2,100 curies.

**Closure Info:** Remedial action activities were conducted from February 17, 2004, to October 27, 2005. Remediation involved excavation and staging of clean overburden material and removal of contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs. A previously disposed construction tractor, a small amount of concrete and steel debris were also excavated at the western end of the former trench. The maximum depth of excavation was 7.6 meters (25 feet).

Approximately 55,540 square meters (597,830 square feet) of plan area was excavated, including excavation within the deep zone (greater than 4.6 meters [15 feet] below ground surface) up to 7.6 meters (25 feet) below ground surface. Approximately 410,000 metric tons (451,900 U.S. tons) of contaminated material from the site was removed and disposed at the ERDF.

The trench received liquid effluent waste via the retention basin drain system (100-K-55 and 100-K-56 pipelines). The liquid consisted of reactor cooling water effluent, overflow from the 105-KW and 105-KE Reactor Building fuel storage basins, contaminated liquid from the 105-KW and 105-KE Reactor Building floor drains, dummy decontamination waste, process cooling water following fuel cladding failures, and some special disposal. Up to 76,000 Liters per minute (20,000 gallons per minute) of leakage through the 100-K retention basin butterfly valves was also discharged to the trench. The 100-K Area was deactivated in 1971 and 1972, at which time the 116-K-2 trench was backfilled with the soil from the original excavation. A small construction tractor and all (empty) 100-K Area hydride tanks were also disposed in the trench during deactivation.

Waste Type: Asbestos (friable)

Waste Description: The unit received reactor coolant water from the 107-K Retention Basins. The radionuclide content is unknown. The structure also received general area wastes through the concrete box sewer. The concrete box sewer wastes went into the single chamber of the structure and then drained into the two pipelines into the river. The Contaminants of Potential Concern include Co-60, Cs-137, Eu-152, Eu-154, Pu-239/240, and Sr-90.

Code: 116-KE-4  Classification: Accepted

Type: Retention Basin  Start Date: 1/1/1955

Status: Inactive  End Date: 1/1/1971

Description: The site has been remediated and Interim Closed Out. The site consisted of three open top, carbon-steel circular tanks with steel bottoms.

Location: The site was located northeast of 118-KE-1 (105-KE Reactor Building).

Release Description: The basins and their 1.5-meter (5-foot) diameter effluent line developed leaks during the site's operating life. The leakage rate from the butterfly valves (which went to an adjacent trench) could have been as high as 18,930 to 37,850 liters/minute (5,000 to 10,000 gallons/minute). Most of the basin leakage was diverted to an open canal and disposed to the river.

Related Sites/Structures: The associated sites include 100-K-64 (100 KE Contaminated Flood Plain), 100-K-57 (107-KE Drainage Ditch), 100-K-41, 150-KE and 105-KE and 100-K-99 (Contaminated Material).

Process Description: The circular basins were 6.1 meters (20 feet) apart. The basins received 105-KE reactor effluent via a 183-centimeter (72-inch) pipe. Additional effluent from the 150-KE Building was received via 61-centimeter (24-inch), 46-centimeter (18-inch), 10-centimeter (4-inch) and 7.6-centimeter (3-inch) steel pipes. Basin effluent was discharged to the outfall structure via a 152-centimeter (60-inch) pipe. Discharges to the 116-K-1 and 116-K-2 Trenches could be made through 91-centimeter (36-inch) pipes that combined flows in a 106-centimeter (42-inch) pipe.

Waste Type: Equipment

Waste Description: This site received cooling water effluent from the 105-KE Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Eighty percent of the total radionuclide inventory was contained within the soil adjacent to the basin.

Closure Info: The steel walls of the tanks were removed and the site was interim stabilized in 1995. Decommissioning activities included removal of large steel access plates. The bottoms of the tanks were left in place and 45.7 to 61 centimeters (18 to 24 inches) of uncontaminated backfill was placed over them.

Remedial action activities at the 116-KE-4 site began on October 2, 2003. No clean overburden material was associated with this site. The excavation of the site involved removing piping, debris, and contaminated soil. Contaminated materials were disposed of at ERDF. Remedial action excavation was completed on March 15, 2005. At the conclusion of excavation activities, the average surface elevation of the bottom of the excavation was approximately 132.6 meters (435 ft). The excavation covered an area of approximately 16,730 square meters (180,000 sq. ft.) with a maximum depth of approximately 4.3 meters (14.1 ft). Approximately 167,634.1 metric tons (184,785 U.S. tons) of material from the site were removed and disposed of at ERDF.

**Description:** The site has been remediated and Interim Closed-Out. The unit consisted of three open-top, circular carbon steel tanks with steel bottoms. The tanks were 61 meters (20 feet) apart. Decommissioning activities included removal of large steel access plates.

**Location:** The site was located north of 118-KW-1 (105-KW Reactor Building).

**Release Description:** The basins and their effluent lines developed leaks during their operating life. The leak rate from the butterfly valves (that went to an adjacent trench) could have been as high as 18,930 to 37,850 liters/minute (5,000 to 10,000 gallons/minute). Most of the basin leakage was diverted to an open canal and discharged to the Columbia River.

**Related Sites/Structures:** The structures associated with the basins were 100-K-63 (100 K West Contaminated Flood Plain), 118-KW-1 (105-KW Reactor Building), 116-KW-4 (150-KW Heat Recovery Station) and 100-K-100 (Contaminated soil).

**Process Description:** The basins received 105-KW Reactor effluent via a 183-centimeter (72-inch) pipe. Additional effluent from the 150-KW Building was received via 61-centimeter (24-inch), 45.72-centimeter (18-inch), 10-centimeter (4-inch) and 7.6-centimeter (3-inch) steel pipes. Basin effluent was discharged to the outfall structure via a 152.4-centimeter (60-inch) pipe. Discharges to the 116-K-1 and 116-K-2 Trenches could be made through 91.4-centimeter (36-inch) pipes that combined flows in a 106-centimeter (42-inch) pipe.

**Waste Type:** Sanitary Sewage

**Waste Description:** This site received cooling water effluent from the 105-KW Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Eighty percent of the total radionuclide inventory is contained within the soil adjacent to the basin.

**Closure Info:** The steel walls of the tanks were removed in 1995. The bottoms of the tanks were left in place with 45.7 to 61 centimeters (18 to 24 inches) of uncontaminated backfill placed over them.

The remedial action at 116-KW-3 began on December 11, 2002 and continued through October 20, 2003. At the completion of remedial action, the excavation was approximately 17,240 square meters (185,570 square feet) in area with an maximum depth of approximately 6.1 meters (20 feet). Approximately 169,893 metric tons (167,209 tons) of material, including soil, debris, and piping were removed from the 116-KW-3 site and disposed of at the Environmental Restoration Disposal Facility (ERDF).

The pipelines beneath the retention basin floor will be addressed during the closeout of the effluent pipelines (100-K-55).
### 100-KR-2

**Code:** 100-K-1  
**Classification:** Accepted  
**Names:** 100-K-1; 100-K-45; 119-KW Exhaust Air Sample Building French Drain; 119-KW French Drain  
**Reclassification:** None  
**Type:** French Drain  
**Status:** Inactive  
**Start Date:**  
**End Date:**  
**Description:** The site is a 0.46 meter (1.5 foot) diameter concrete french drain that extends approximately 15 centimeters (6 inches) above the surrounding grade. It had a blue metal cover that is posted with "Confined Space" and "Surface Contamination" warning signs. A site visit in April 2000 found the area had been covered with cobble and surrounded with posts and chain. A sign reading "116-KW-1 Storage Basin French Drain is still marking the area.

**Location:** The site is located to the east of the 105-KW Reactor Building, north of the 116-KW Stack, and south of the 119-KW Exhaust Air Sample Building.

**Waste Type:** Water

**Waste Description:** The unit received heat exchanger cooling water from sample equipment in the 119-KW Building, wastewater from a swamp-type cooler and effluent from a floor drain also located in the 119-KW Building.

---

**Code:** 100-K-3  
**Classification:** Accepted  
**Names:** 100-K-3; 1706-KE Fish Pond Heat Exchanger Pit. Pump Pit and Associated Piping; Water Studies Semi-Works  
**Reclassification:** Interim Closed Out (10/23/2012)  
**Type:** Valve Pit  
**Start Date:** 1/1/1956  
**End Date:** 1/1/1965  
**Status:** Inactive  
**Description:** The waste site has been remediated and Interim Closed Out. It included the Heat Exchanger Pit, the Pump Pit and the pipelines that were specific to the 1706-KE Water Studies Semi-Works.

The Heat Exchanger Pit was a concrete pad on the surface. The structure was entirely below grade. A 1.2 by 3.0-meter (4 by 10-foot) access hatch was located at the south end. Adjacent to the access hatch was a square inlet ventilation pipe. A 61 centimeters (24 inches) in diameter exhaust vent pipe was visible on the north end. On the west side of the pad, a 7.6-centimeter (3-inch) pipe extended approximately 0.3 meters (1 foot) above the surface of the pad. It was surrounded by a 4.9 by 7.3-meter (16 by 24-foot) yellow wooden fence and a light duty post and chain barricade posted with "Surface Contamination" signs.

The Pump Pit was a concrete pad on the surface. The structure was entirely below grade. The Pump Pit above-grade concrete pad had been painted and marked as a "Confined Space".

Two 3 inch diameter pipelines connected the Heat Exchanger and Pump Pit to the 100-K-56 (36 inch and 72 inch diameter) pipelines. A 2.54-centimeter (1-inch) pipeline exited the 105-KE Reactor, near the two main effluent lines, and extended to the Heat Exchanger Pit. This pipeline is labeled PIEX (Pile Effluent from Experimental Tubes) on drawing H-1-24974KE.

The Heat Exchanger egress pipelines provided raw water that "cooled" process effluent to the fish troughs in the 1706-KE Wet Fish Studies Laboratory (Sitecode: 100-K-52). The pipelines
ran from the Heat Exchanger Pit to the northwest corner of the 1706-KE Building. They included a 7.6-centimeter (3-inch) raw water pipeline, a 2.54-centimeter (1-inch) PIE pipeline, and a 5.1-centimeter (2-inch) PIEX pipeline. A 3.8-centimeter (1.5-inch) PIE pipeline and a 5.1-centimeter (2-inch) pipeline that connected the Heat Exchanger Pit and to the Valve Pit at the front of the Fish Pond (Site: 100-K-4). Portions of these pipelines were removed during the demolition of the 1706-KE, KER and KEL buildings in 2010 (see DOE/RL-2012-40). The pipeline removal was completed during the 100-K-3 structure remediation (see DOE/RL-2012-46).

Location: The 1706-KE Heat Exchanger Pit was located west of the northwest corner of the 105-KE Reactor Building. The Pump Pit is located to the east of the Heat Exchanger Pit.

Related Sites/Structures: The site is related to 100-K-52, 1706-KE Wet Fish Studies Laboratory, 100-K-4, 1706-KE Wet Fish Studies Ponds and Valve Pit and pipeline 100-K-56.

Waste Type: Sanitary Sewage

Waste Description:

Closure Info: For the purposes of implementing and documenting remedial activities, the 100-K Area was divided into several informal remediation areas. The waste sites of this remedial activity were informally designated as being located within the Area AG Zone 1 remediation area, adjacent to the northwest corner of the reactor. (Note: One waste site located within Area AG Zone 1, the 116-KE-3 (105-KE Fuel Storage Basin Sub-Basin Drainage Disposal System Crib), was not remediated. Due to the extent of the deep zone contamination attributed to the 116-KE-3 waste site, it was placed in an "excluded region" within Area AG Zone 1. Waste site 116-KE-3 will be addressed at a later date.)

The remediated waste sites located in Area AG Zone 1 include 100-K-68, 100-K-69, 100-K-70, 100-K-71 and 100-K-3. A portion of the 100-K-3 pipeline was remediated with the area AG Zone 2 (see DOE/RL-2012-40). (Note: Portions of 100-K-47 and 100-K-56 pipelines were removed and considered part of the Area AG Zone 1 remediation activities. Approximately 452 feet of the 100-K-56, 36-inch pipeline was removed from Area AG Zone 1 and 3. Approximately 338 feet of the 100-K-56, 72-inch pipeline was removed from Area AG Zone 1 and 3. Approximately 344 feet of the 100-K-47, 12-inch pipeline exiting the 100-K-71 collection box was removed from Area AG Zone 1 and 3. Approximately 344 feet of the 100-K-47, 16-inch pipeline (exiting the 100-K-71 collection box) was removed from Area AG Zone 1 and 3. The remaining portions of the 100-K-47 and 100-K-56 pipelines will be addressed in future remediation activities.)

Remediation of the waste sites within Area AG Zone 1 began in September 2009 and was finished in May 2012. In-process samples were collected and radiological surveys were conducted to guide the remediation. Contaminated structures, pipelines, and associated soil and debris attributed to these waste sites have been removed and disposed at the ERDF. During this remedial activity, Stockpile #3 was created from excavated soil from the overburden and layback from Area AG Zone 1 waste sites. Radiological surveys were conducted on the material prior to placing it in the stockpile. Stockpile #3 was located northwest of Area AG.

The 105-KE fuel storage basin (100-K-42 waste site) borders the Area AG Zone 1. UPR-100-K-1 (105-KE Fuel Storage Basin Leak) is an unplanned release from the discharge chute of the fuel storage basin. It leaked highly radioactive water underneath the basin into the ground for an unknown period of time. Boreholes were drilled to evaluate the subsurface soil conditions. The results indicated significant residual radioactivity underneath the footprint of the fuel storage basin. The residual radioactivity distorted the radiological surveys conducted within the adjacent Area AG Zone 1.
The remediation of the 100-K-3 waste site began in January 2010 and was completed in May 2012. The remediation of this waste site included excavation of the heat exchanger, the pump pit, associated piping and contaminated soil. A total of 709 ERDF containers (11,513 metric tons [12,691 short tons]) was disposed at the ERDF from the Area AG 100-K-3 waste site (Zones 1 and 2 combined). Along with remediation of the waste sites in Area AG Zone 1, a 20.3 cm (8 in.) diameter Process Sewer Outside (PSO) drain line was also excavated. This pipeline exited the 100-K-3 heat exchanger pit and tied into the 100-K-47 concrete process sewer. This portion of pipeline was removed with a composite in-process sample taken along the length of the excavation in August 2011. The in-process sample results did not exceed the RAGs. The region within Area AG Zone 1 where this pipeline was removed was included in the Shallow Zone decision unit. In addition, the 100-K-3, 2.54 cm (1 in.) diameter PIEX pipeline (connecting the 100-K-3 heat exchanger to the 105-KE reactor) was documented in the shallow zone decision unit. This pipeline was originally buried 1.2 meters (4 ft) deep. When removed, the footprint was wholly contained within the layback region of the 100-K-56 waste site.

The 100-K-68 waste site structure (caisson with catch tank) was removed during waste site remediation. The remediation of the 100-K-68 waste site began in April 2010 and was completed in May 2012. The remediation of the waste site excavated the corrugated steel caisson, catch tank and pumping equipment. However, deep residual contamination associated with the 116-KE-3 waste site remains underneath the footprint of the 100-K-68 waste site.

The remediation of the 100-K-69 waste site began in April 2010 and was completed in May 2012. The remediation of the waste site excavated the concrete sump and associated contaminated soil.

The remediation of the contaminated soil beneath the 100-K-70 waste site began in April 2010 and was completed in May 2012. The tank associated with the 100-K-70 waste site had been previously removed, prior to the fuel storage basin demolition in 2008.

A total of 599 ERDF containers (11,920 metric tons [13,139 short tons]) was disposed at the ERDF from the combined 100-K-68, 100-K-69, and 100-K-70 waste sites.

The remediation of the 100-K-71 waste site began in March 2010 and was completed in May 2012. The remediation of the waste site included excavation of the collection box and associated contaminated soil. A total of 285 ERDF containers (5,858 metric tons [6,457 short tons]) was disposed at the ERDF from the 100-K-71 waste site. In-process samples collected at the collection box were analyzed for carbon-14 and tritium. The results indicated no residual contamination of these COCs.

The remediation of portions of the 100-K-47 pipeline began in November 2009 and was completed in September 2011. The partial remediation of the pipeline waste site included excavation of the underground process sewer pipelines and associated contaminated soil. In-process samples were collected within the remediated portion of the 100-K-71 waste site (collection box) footprint, because the 10.2 cm (4 in.) diameter cement asbestos pipeline from the 117-KE Filter Building (100-K-62 waste site) terminated at the collection box. Samples were analyzed for carbon-14 and tritium. The results indicated no residual contamination of these contaminants of concern (COCs). Therefore, carbon-14 and tritium were eliminated from the list of COCs for this waste site. A total of 1,240 ERDF containers (20,802 metric tons [22,930 short tons]) was disposed at the ERDF from the Area AG 100-K-47 waste site (Zones 1 and 3 combined).

The remediation of portions of the 100-K-56 Subsite 2 pipeline began in September 2009 and was completed in June 2011. The remediation excavated the part of the process effluent...
underground pipelines and associated contaminated soil. A total of 800 ERDF containers (13,071 metric tons [14,408 short tons]) was disposed at the ERDF from the Area AG 100-K-56 waste site (in Zones 1 and 3 combined).

A total of 63,292 metric tons of material was disposed at the ERDF during the AG Zone 1 remediation activity. (33,873 metric tons was related to the 100-K-47 and 100-K-56 partial pipeline excavations.)

No evidence of spills or leaks from Area AG Zone 1 waste sites was found after remediation. Post remediation, a Global Positioning Environmental Radiological Survey (GPERS) and radiological surveys using hand-held instrumentation were conducted. The GPERS is rendered ineffective in regions close to the 105-KE Reactor fuel storage basin (100-K-42 waste site) and the unplanned release site (UPR-100-K-1) due to the sensitive detection capabilities of the sodium iodide instrumentation and the elevated radiation background levels associated with the fuel storage basin subsurface soil.

Follow-up radiological surveys using hand-held instruments were conducted in the region around the 100-K-68, 100-K-69, 100-K-70, and 100-K-71 waste sites, immediately north of the fuel storage basin. The survey indicated elevated radiological contamination where piping from the 105-KE Reactor fuel storage basin traveled to the 105-KE Collection Box (100-K-71 waste site). One of the pipelines entering the south side of the collection box was equipped with a direct buried flanged gate valve, located at a depth of approximately 8.5 meters (27 ft 11 in.). A focused verification sample of this location was collected to determine contamination levels present in the soil. This follow-up survey also indicated elevated radiological contamination in the area around the 100-K-68 waste site. Verification sampling beneath the 100-K-68 waste site was not conducted because the residual soil contamination is attributed to the 116-KE-3 waste site. NOTE: 116-KE-3 is located within Area AG Zone 1 but was not part of the remediation work scope.

<td>Description:</td>
<td>This waste site has been demolished and Interim Closed Out. The site was two, 9.1 meter (30 foot) diameter circular ponds separated by a 2.7 by 9.1 meter (9 by 30 foot) rectangular pond and valve pit. The ponds contained drains which presumably discharged to the process sewer.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The ponds were located approximately 50 meters (164 feet) west of the northwest corner of the 105-KE Reactor Building.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Related Sites/ Structures:</td>
<td>The site was related to the 1706-KE Wet Fish Studies Laboratory (Site: 100-K-52) and the 1706-KE Heat Exchanger Pit (Site: 100-K-3). Process piping connected the ponds to the Heat Exchanger Pit (100-K-3).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>Waste Site 100-K-4, 1706-KE Wet Fish Studies Ponds and Valve Pit, supported the 1706-KE Wet Fish Studies Laboratory (Waste Site 100-K-52) and the 1706-KE Heat Exchanger Pit (Waste Site 100-K-3). Waste Site 100-K-52 was a small laboratory consisting of long troughs used to conduct wet fish studies using a mixture of raw water and heated effluent water from the 105-KE Reactor, which normally flowed to the Heat Exchanger Pit (100-K-3). Originally the laboratory was constructed to function as a backup laboratory in the event of shutdown of the 105-F Reactor and its associated aquatic biology laboratory. The 100-K-4 ponds were constructed in 1956 and operated intermittently through 1965, receiving mixed water effluents</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
from the Laboratory (100-K-52).

**Waste Type:** Misc. Trash and Debris

**Waste Description:** A mixture of raw water and heated effluent water passed though the troughs.

**Closure Info:** The selected remedy for waste site 100-K-4 was Remove, Treat and Dispose. This was achieved through removal and disposal of the 1706-KE Wet Fish Studies Ponds and Valve Pit and remediation of underlying contaminated soil.

The waste site excavation was initiated in January of 2010 and completed in February of 2010. Radiological surveys done during the remediation indicated minor residual radioactivity in the drains. The concrete ponds and associated piping were removed and disposed. The waste site was excavated to a maximum depth of approximately 5.37 meters (17.6 feet) in the deep zone of the excavation. A total of 2,989.26 tons of soil and debris were disposed of at the ERDF. No cracking was noted in the concrete and the piping appeared to be intact. The 100-K-4 Waste Site remediation coincided with the ongoing remediation of the 100-K-3, 100-K-47, and 100-K-56 Waste Sites.

---

**Names:**

**Type:** French Drain

**Status:** Inactive

**Description:** The site is a french drain consisting of a 0.9 meter (3 foot) diameter vitrified clay pipe which protrudes approximately 0.3 meter (1 foot) above grade and has a heavy wooden cover.

**Location:** The site is located just east of the 1705-KE Water Treatment Facility.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The site received waste effluent from floor drains, overflows, and drainage from the 1705-KE Experimental Water Treatment Basin and facilities.

---

**Names:**

**Type:** Process Unit/Plant

**Status:** Inactive

**Description:** The waste site has been remediated and Interim Closed Out. The vacuum pit contained a cyclone separator in a vertically oriented 3-meter (10-foot) diameter culvert which extends from grade level to 9.2 meters (30 feet) below grade.

**Location:** The site is located on the east side of the 105-KE Reactor Building and just south of the reactor stack.

**Related Sites/Structures:** The site is associated with the Turco Pit in the 105-KE Reactor Building.

**Process Description:** The cyclone separator was used to separate solids from the vacuum air stream. The cyclone separator was used to separate solids from the vacuum air stream associated with the reactor.
building decontamination solution pit, which was inside the basement of the 105-KE Reactor and contained a large stainless steel tank. The tank was used to mix decontamination solutions within the reactor facility. Site employees report that the vacuum system portion of the cyclone separator was used during maintenance on the reactor core or for the movement of the Ball 3X Safety System balls, which were collected in drums. Vacuum hoses exited and entered the reactor pit via a small concrete trench with a steel lid located at grade and running due east under the concrete sidewalk and into and out of the vacuum pit in a closed loop system, during normal operation.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The 100-K-6 Waste Site received radiologically-contaminated exhaust air from the decontamination solution pit. The contaminants were cobalt-60, cesium-137, carbon-14, and tritium, as well as strontium-90, europium-152, europium-154, and europium-155. The soil beneath the steam turbine is reported to have been contaminated with radioactive materials and was covered with about 0.3 meters (1 foot) of gravel. The dose rate at the pit opening on January 20, 1994 was slightly less than 2 millirad/hour, suggesting a higher dose rate at the pit bottom.

**Closure Info:** Remediation and sampling began in January of 2009 and was completed in April of 2012. The large excavation area, known as 100-K Area AH, encompassed waste sites 100-K-6, 100-K-46, 100-K-62 and 132-KE-1. The excavation area also included Stockpile #4, which contained overburden and layback soil from the excavation of the 116-KE-1 Condensate Crib. Information supporting the use of Stockpile #4, located within the AH excavation, as backfill was also included in the DOE/RL-2012-38 Remaining Sites Verification Package report.

Remediation of the identified Area AH waste sites was accomplished by demolishing the structures and excavating contaminated soil. All waste (soil and debris) associated with these waste sites was disposed at the Environmental Restoration and Disposal Facility (ERDF). The demolition activities were conducted using standard demolition techniques, including explosives for demolition of 132-KE-1 (116-KE Reactor Exhaust Stack). Approximately 1,809 ERDF containers (37,700 tons) of waste from these waste sites were sent to the ERDF for disposal.

Remediation of the 100-K-6 vacuum pit began in August 2011 and was completed in September 2011. An excavator was used to remove the vacuum pit and excavate the surrounding soil. The original waste site description estimated the depth of the cyclone separator as 9.14 meters (30 ft). However, during remediation the actual excavation depth was measured as 5.8 meters (19 ft).

The remediation of the 100-K-46 french drain was associated with the removal of the 119-KE building, which began in January 2009 and was completed in February 2009. The drywell was less than 1.5 meters (5 ft) deep.

The remediation activities at the 100-K-62 filter building began in August 2010 and were completed in May 2011. An excavator was used to remove the vacuum pit and excavate the surrounding soil. The maximum depth from grade within the waste site footprint was approximately 10.6 meters (34.8 ft).

The remediation activities at waste site 132-KE-1 exhaust stack began in July 2010 and were completed in September 2011. Removal of the above-grade portion of the stack was conducted using explosives placed near the base of the stack. The explosion caused the debris to fall in a designated area. The material was then loaded and disposed at ERDF. The entire below grade portion of the stack base was then removed. The maximum depth from grade within the waste site footprint was approximately 6.1 meters (20 ft).
In October of 2010, excavation of the overburden and layback soil for the 116-KE-1 Crib began and Stockpile #4 was created. Samples were collected in the 116-KE-1 waste site footprint and sent for analytical leach testing of the soils to determine carbon-14 leachability from the 100-K soil. During remediation of the co-located waste sites inside the AH excavation area, the 116-KE-1 crib was partially backfilled with soil from Stockpile #4 as a contamination control measure.

Note: Area-wide carbon-14 contamination exists in the deep zone above the criteria for protectiveness. This contamination is associated with the 105-KE Reactor ventilation filtration system and the deep contamination from the condensate that collected in the previously excavated 116-KE-1 Condensate Crib. Additional remediation of the deep vadose zone cannot be completed in proximity to the 105-KE Reactor without impacting structural stability. Available information about the nature and extent of the carbon-14 contamination has been documented in the 116-KE-1 Condensate Crib waste site description. Due to the depth of the contamination, the carbon-14 remediation will coincide with the final decision on 105-KE reactor removal.

| Code: 100-K-13 | Classification: Accepted |
| Names: 100-K-13; French Drain West of the 166-KW Oil Storage Tank Facility | Reclassification: None |
| Type: French Drain | Start Date: |
| Status: Inactive | End Date: |

Description: The site is a french drain that is a 1.5 meter (5-foot) diameter vertical concrete pipe filled with gravel. Prior to the construction of the Cold Vacuum storage Facility, the drain had been almost flush with the ground surface. Facility construction required the area to be graded. The construction project has scraped the ground down about 1.8 meters (6 feet) leaving the french drain about 2.3 meters (7.5 feet) above ground level. The french drain is now covered by a corrugated metal caisson to protect the french drain structure. Prior to current construction activities, the drain extended above grade about 0.46 meters (1.5 feet) and was surrounded by a yellow wooden barricade. The french drain has no markings of any kind. No other documentation or drawings could be found that identify the site or its purpose. Prior to current construction, no facilities were close to the site.

Location: The site was located on a small rise that is west of the southwest corner of the 166-KW Oil Storage Tank Facility and 10.4 meters (34 feet) west of the small access road that runs along side of the 166-KW. The Cold Vacuum Storage Facility was recently built in this area and graded the area to accommodate construction.

| Code: 100-K-14 | Classification: Accepted |
| Names: 100-K-14; 183-KE Acid Neutralization Pit and Overflow French Drain | Reclassification: None |
| Type: French Drain | Start Date: |
| Status: Inactive | End Date: |

Description: The pit is 4.6 meters (15 feet) deep with a bottom dimension of 1.5 meters (5 feet) in diameter. Eight to thirteen centimeter (3 to 5 inch) aggregate was placed to a depth of 2.1 meters (7 feet). A 0.76 meter (2.5 foot) diameter, 2.4 meter (8 foot) long vitrified clay pipe (VCP) was placed vertically in the center of the pit and 1.2 meters (4 feet) of aggregate were placed around the pipe exterior. Approximately 1.5 meters (5 feet) of limestone chips were added to the pipe interior. A 5.1-centimeter (2 inch) schedule 80 polyvinyl chloride (PVC) pipe enters through
the side 1 meter (3.3 feet) below grade. The pipe is an overflow and drain line for the 183-KE Day Use Acid Tank. The pit was then backfilled to grade. The VCP is exposed a few inches above grade and is covered with a 0.64 centimeter (0.25 inch) steel plate with four 2.54 centimeter (1 inch) vent holes. Four steel yellow corner posts surround the above grade VCP.

**Location:**
The site is located near the 183-KE Alum Storage Tanks, 11 meters (36 feet) southeast of the railroad track, and directly south of the 183-KE Head House.

**Related Sites/Structures:**
The site received overflow and drainage from the 183-KE Day Use Acid Tank.

**Waste Type:**
Process Effluent

**Waste Description:**
The site received sulfuric acid overflow and drainage from the 183-KE Day Use Acid Tank.

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The waste site has been remediated and Interim Closed Out. The site was originally an above-ground, cylindrical, vertical steel storage tank on a concrete base. The above-ground tank was 7.8 meters (25.5 feet) in diameter with a 287,660 liter (76,000 gallon) capacity. Some time in the past (date unknown) the tank was removed. Then the waste site was a 9.1-meter (30-foot) diameter grade-level concrete tank base and the soil surrounding the base.

The site was related to the 183-KW Head House that controlled and monitored water quality. The site was also related to the 100-K-18 Neutralization Pit. Overflow and transfer waste from this tank was routed to the nearby caustic neutralization pit.

Caustic soda (sodium hydroxide) was injected into the filtered water as a pH correction. It was proportioned and metered in a single step operation. Caustic soda was injected into a softened water stream in the 183-KE Head House. The softened water was used as a dilutant and as a vehicle to transport the caustic to the injection point at the clearwells. Since caustic soda was injected at only two points, the proportioning was regulated by the half plant effluent rate. Sodium hydroxide was also used to regenerate the ion exchange columns in the water softener system and for maintaining a neutral pH of the reactor cooling water. It was most likely the neutralizing agent for excess or spilled sulfuric acid that was used in the 183-K facilities.

Spills may have occurred near the tank and the piping system may have developed leaks. This is likely to have resulted in sodium hydroxide leaking to the soil beneath and around the tank. No known sampling has been performed at this site.

The unit was used to store sodium hydroxide. Spills may have occurred near the unit. The piping system may have developed leaks. This is likely to have resulted in sodium hydroxide in the soil beneath and around the unit.

Remediation of the Area AA, Zone 2 waste sites (100-K-18, 100-K-19, 100-K-79:1, 100-K-79:2, 100-K-97, 120-KW-5 and 120-KW-7) began in May 2010. Throughout the remedial activity, because of the contaminants found in the process equipment and surface soils, in-process samples were collected and analyzed for metals, including chromium VI and anions (e.g., sulfate due to the sulfuric acid), at multiple locations and depths. | Description   | The site has been remediated and Interim Closed Out. Before remediation the site surface was
gravel/cobble and purple garnet. It was irregularly shaped and covered an area of 46 meters (50
yards) x 27 meters (30 yards). |
| Location      | Located 40-feet SW of the 183-KE Chlorine Storage Vault and just west of the 183-KE Alum
Storage Tanks (126-KE-1 and 126-KE-2). |
| Process       | In the early 1980s, steel components from the 183-KE settling basins were sandblasted at this
site prior to being sold as scrap. The site consisted of surface gravel/cobble and red/purple
garnet. |
| Waste Type    | Chemicals |
| Waste Description | At this site in the early 1980's, steel components from the 183-KE settling basins were
sandblasted prior to being sold as scrap. Sampling in 1989 indicated the material present to be
nonregulated for EP Toxicity. |
| Closure Info  | A phased sampling approach was implemented at the site based on site photographs, historical
use information, suspected waste materials, and statistical information. Confirmatory sampling
was conducted during April 2003. The analytical laboratory results for total chromium, lead,
hexavalent chromium, and Aroclor-1254 exceeded action levels, indicating that site remediation
(remove, treat, and dispose) was required. A cleanup action was implemented during December
2003, removing the sandblast media and approximately 5.1 centimeters (2 inches) of underlying
soil from the site. A total of 187 metric tons (206 tons) of sandblast media and underlying soil were removed and
disposed of it at the Environmental Restoration Disposal Facility. The maximum detected
results from underlying soil samples collected at locations suspected of having the greatest
potential for contamination were shown to meet the cleanup objectives for direct exposure,
groundwater protection, and river protection. |

</table>
Description: The site has been remediated and Interim Closed Out. The site consisted of two, above ground, U-shaped concrete bases and above ground piping. A cylindrical tank had laid horizontally on the two concrete U-shaped bases. The tank measured 3 meters (10 feet) in diameter, 10 meters (33 feet) long and had a 77,140-liter (20,380-gallon) capacity. It is unknown when the tank was removed.

Location: The site was located in the 100-K Area. It was 8.2 meters (27 feet) northeast of 120-KE-4.

Related Sites/Structures: The site was associated with 100-K-31 and the 183-KE Water Treatment Plant.

Process Description: The 183-KE Sulfuric Acid Storage Tank was associated with 183-KE Water Treatment Plant. West of this tank were two smaller sulfuric acid tanks (120-KE-4 and 120-KE-5) which were used for the same purpose. East of the tank was another tank the same size, that was used for the same purpose.

Waste Type: Equipment

Waste Description: The tank bases held a tank that was used to store sulfuric acid.

Closure Info: Results from the historical research and confirmatory sampling that had been conducted during April 2003 were used to make decisions for reclassifying the site. The soil achieved compliance with the remedial objectives, but the concrete and felt material exceeded the remedial action levels. In January 2004, a remedial action activity was implemented to remove the stained concrete bases and felt to a depth of 1 meter (3 ft.). The material from the site was disposed at the Environmental Restoration Disposal Facility. Since the soil already met the RAOs, no further verification sampling was required.

Results from confirmatory sampling that had been conducted in April 2003 were used to make
decisions for reclassifying the site. The confirmatory samples exceeded the action levels for, barium, cadmium, lead, mercury and hexavalent chromium. A cleanup action was implemented during December 2003, removing the concrete bases and about 0.61 meters (2 feet) of contaminated soil and disposing them at the Environmental Restoration Disposal Facility.

The sampling results supported a reclassification of the waste site to interim closed out.

*Hanford Site Waste Management Units Report*

February 2015
Status: Inactive

Description: The site has been remediated and Interim Closed Out. The unit consisted of two above-ground U-shaped concrete bases and above-ground piping. Yellow stains and tar-like material was in the surrounding gravel.

Location: The unit was located 8.2 meters (27 feet) northeast (60 degrees) of 120-KW-4.

Related Sites/Structures: The Sulfuric Acid Storage Tank was associated with 183-KW Water Treatment Plant. West of this tank were two smaller sulfuric acid tanks (120-KW-3 and 120-KW-4) which were used for the same purpose. East of the tank location described by this entry was another tank (100-K-32) the same size that was used for the same purpose.

Process Description: The U-shaped bases were 3.7 meters (12 feet) wide, 1.2 meters (4 feet) long, 1.8 meters (6 feet) high, and 10 meters (33 feet) apart. A cylindrical tank laying horizontally on the two concrete U-shaped bases was observed in a March 1962 photograph. The tank was 3 meters (10 feet) in diameter, 10 meters (33 feet) long and had a 77,140-liter (20,380-gallon) capacity. The tank was used to store sulfuric acid and was removed at an unknown date.

Waste Type: Soil

Waste Description: The unit consisted of two above-ground U-shaped concrete bases and above-ground piping. The U-shaped bases were 3.7 meters (12 feet) wide, 1.2 meters (4 feet) long, 1.8 meters (6 feet) high, and 10 meters (33 feet) apart. A cylindrical tank laying horizontally on the two concrete U-shaped bases was observed in a March 1962 photograph. The tank was used to store sulfuric acid and was removed at an unknown date.

Closure Info: A remedial action was implemented in December 2003. The concrete bases, including the felt pads, were removed and about 30 cubic meters (990 cubic feet) of contaminated soil was disposed of at the Environmental Restoration Disposal Facility.

A test pit was dug in the center of the excavation to a depth of 4 meters (13 feet) to collect soil data on mercury for RESidual RADioactivity (ANL 2002) modeling and characterize the potential depth of metals contamination beneath the other 100-K Area sulfuric acid tanks (100-K-30, 100-K-31, and 100-K-32).

Following remediation, verification sampling was conducted during December 2003 and January 2004. The post-remediation verification sampling contaminants of concern (COCs) for the 100-K-33 waste site were identified based on the results of the confirmatory sampling effort. The results indicated that the remedial action achieved compliance with the remedial action objectives for the site. The results of the verification sampling were used to support decisions to reclassify the site in accordance with the waste site reclassification guideline TPA-MP-14 (DOE-RL 1998) process.

Code: 100-K-34

Classification: Accepted

Names: 100-K-34; 183-KW Acid Neutralization Pit

Reclassification: Interim Closed Out (7/10/2012)

Type: Sump

Start Date: Interim Closed Out (7/10/2012)

Status: Inactive

End Date: Interim Closed Out (7/10/2012)

Description: The waste site has been remediated and Interim Closed Out. The acid pit consisted of 2.5 by 1.9-meter (8.3 by 6.3-foot) brick-lined concrete boxes. The boxes were 1.5 meters (5 feet) deep and backfilled with crushed limestone. Drain pipes entered about 0.6 meters (2 feet) below grade and emptied into a 0.9-meter (3-foot) diameter vitrified clay pipe (VCP) placed vertically in
limestone chips. The VCP was filled with limestone chips. The VCP was intentionally broken at the top to allow acid solutions to overflow into the interior of the pit.

**Location:** The unit is located in the 100KW Area, adjacent and 0.6 meters (2 feet) west of 183-KW and 3.7 meters (12 feet) east of the 183-KW Chlorine Vault.

**Related Sites/Structures:** The site received transfer and overflow waste from nearby sulfuric acid tanks associated with the 183-KW Water Treatment Plant. The site drained to the process sewer back into the 183.1-KW Headhouse, and into a floor drain to the process sewer line that ran through the 183.7-KW Tunnel.

**Waste Type:** Chemicals

**Waste Description:** The site was used to neutralize and dispose of overflow and transfer waste from nearby sulfuric acid tanks.

**Closure Info:** Remediation of the Area AA Zone 1 Waste Sites began in April 2010 and ended in January 2012. The waste site structures and soils have been excavated as part of the remedial activities for the 100-K Area. The excavation area was designated as 100-K Area AA, Zone 1 (Area AA, Zone 1). It encompassed the individual waste sites 100-K-34, 100-K-102 and 1607-K3. Stockpile #11 contains layback soil from remediation of Area AA, Zone 1. These waste sites are adjacent to the 100-K-59 pipelines. Since visible sediment was observed in the severed pipelines, a sample was collected in February 2011 from the open end of the pipe west of the 183.1KW Headhouse. A section of the 100-K-59 pipeline was removed.

Excavation of the waste sites continued to a final remediation maximum depth of 9.82 meters (32.2 ft), which was located within the footprint of 100-K-102. To support the deeper excavation for Area AA, Zone 1, layback soil was accumulated and managed as Stockpile #11. The excavation decision unit was approximately 7,331 square meters (78,910 fl2) for 100-K Area AA, Zone 1. The original footprint prior to additional process sewer pipe removal was divided into evenly spaced areas for statistical sampling outside the waste sites to address any potential for contamination spread.

### Code: 100-K-35  
**Classification:** Accepted

### Names: 100-K-35; 183-KE Acid Neutralization Pit  
**Reclassification:** None

### Type: Sump  
**Start Date:**

### Status: Inactive  
**End Date:**

**Description:** The site is a below grade, 2.5 meter by 1.9 meter (8.33 feet by 6.33 feet) brick-lined concrete box, approximately 1.5 meters (5 feet) deep and backfilled with crushed limestone. Drain pipes entered the pit approximately 0.6 meters (2 feet) below grade and emptied into a vertical 0.9 meter (3 foot) diameter vitrified clay pipe. The vitrified clay pipe is also filled with limestone chips and appears to be broken at the top. The site is covered by a wooden lid labeled "Confined Space" and is surrounded by post and chain.

**Location:** The site is located between the 183-KE Head House and the 183-KE chlorine vault.

**Related Sites/Structures:** The site received transfer and overflow waste from nearby sulfuric acid tanks associated with the 183-KE Water Treatment Plant. The site drained to the process sewer.

**Waste Type:** Soil

**Waste Description:** The site was used to neutralize and dispose of overflow and transfer waste from nearby sulfuric acid tanks.
The waste site has been remediated and Interim Closed Out. It was a dry well (french drain) that was added to the 1706-KE Building as part of the Chemical Storage Facility. The drain was located at grade level and centered between the 1706-KE Caustic Tank and the 1706-KE Sulfuric Acid Tank. The french drain was constructed from an 0.46 meter (18 inch) vitrified clay pipe that is 1.2 meters (4 feet) long and extended 7.6 centimeters (3 inches) above grade. The site was filled to grade with crushed limestone. Overflow and drain pipes [two 5.1 centimeter (2 inch) pipelines from each chemical storage tank] extended to just above the surface of the limestone fill.

The site was located in the southeast corner and adjacent to the 1706-KE Building. The site was between the 100-K-37, 1706-KE Sulfuric Acid Tank and 100-K-38, 1706-KE Caustic Soda Tank.

The dry well was located near an underground tunnel to the 105-KE Reactor Building. At a point within the tunnel very near the drain, a white crystalline material was seen in the cracks of the tunnel ceiling. This may be sodium hydroxide from the 100-K-38, 1706-KE Caustic Soda Tank. A former site employee reports that small spills did occur during filling operations of the storage tanks on several occasions.

The site is related to the 1706-KE Building, 100-K-37, 1706-KE Sulfuric Acid Tank, and 100-K-38, 1706-KE Caustic Soda Tank.

The chemical storage facility at 1706-KE was installed in 1963 to provide bulk quantities of 93 percent by weight sulfuric acid and 50 percent by weight sodium hydroxide. The chemicals were used to regenerate the ion columns in the 1706-KE demineralizer plant. The demineralizer plant supplied demineralized water to two experimental single pass process tube in the 105-KE reactor core. The demineralizer plant was a duplex unit with two sets of ion columns. It operated with one set in service and the other either being regenerated or in a ready-standby condition. Typically three regenerations were performed each day during this period. Shipping manifests indicate that approximately 7,948.5 liters (2100 gallons) of sulfuric acid and 10,976.5 liters (2900 gallons) of sodium hydroxide were delivered to 1706-KE at 4-6 week intervals. In 1971, the 100-K production reactors were shut down and the demineralizer plant was deactivated. It was reactivated some years later to provide demineralized water to the 100-K area fuel storage basins. The quantity of demineralized water produced during this period of operation was a small fraction of that produced during reactor operation. Thus, the number of regenerations was steadily reduced from an initial amount of approximately 12 times per year to 3 times per year when the demineralizer plant was finally taken out of service.

A white crystalline material that may be sodium hydroxide can be seen in cracks of the tunnel. This may indicate that large quantities of sodium hydroxide and/or water have been disposed to this drain.

The D4 (deactivation, decommissioning, decontamination and demolition) organization removed the above ground parts of the 1706-KE, 1706-KEL, and 1706-KER buildings, plus three feet of the below ground structures. The 1706-KE, 1706-KER, 1706-KEL building demolition to grade was completed in October 2010. Directly after completing D4 work, the area was transitioned to the soil remediation organization. The 100-K-36 french drain, and portions of the 100-K-3 pipeline and a portion of the 100-K-79 Subsite 7 pipeline were

Hanford Site Waste Management Units Report
February 2015
removed, as designed along with the 1706-KE, 1706-KEL, and 1706-KER buildings.

For the purposes of implementing and documenting remedial activities, the 100-K Area was divided into several informal remediation areas. The waste sites of this remedial activity were informally designated as being located within the Area AG Zone 2 remediation area, adjacent to the southwest corner of the reactor. Remediation of the Area AG, Zone 2 waste sites and removal of the below grade 1706-KE, 1706-KEL, and 1706-KER buildings began in June 2010. Remediated soil and debris disposed were of at the ERDF. Remediation of the waste sites coincided with the removal of the below ground portions of the 1706-KE, 1706-KEL, and 1706-KER buildings. Below-grade demolition 1706-KE and 1706-KER and waste site remediation completed in September 2011. The final maximum remediation depth of excavation for the area was 11.15 meters (36.58 ft) below ground surface.

Pipelines connected to the 1706-KE, 1706-KEL and 1706-KER buildings (excluding 100-K-3 associated pipelines) were gravity flow systems which drained away from the buildings to either the 100-K-47 Process Effluent Line, the 116-KE-2 Crib, the 1607-K4 or the 1607-K5 Sanitary Sewer System waste sites. Remediation of these pipelines was beyond the scope of the remedial action and this RSVP. However, during building removal, portions of these pipelines were removed to the edge of the excavation footprint. Although the ends of the pipelines were not capped due to the higher elevations at the pipeline openings, any residual liquids would flow away from the excavation footprint, rather than into it. Remediation of these pipelines will be completed at a later date during remediation of their respective waste sites. The GPS locations where the lines were severed at the sloped edge of the excavation footprint were documented.

The 100-K-36 dry well remediation area was approximately 0.17 square meters (1.83 sq. ft.). Due to the size of the sample area, only one discrete sample was collected. Following removal of all components of the 100-K-36 french drain waste site, stained soil was found adjacent to the waste site. In-process sampling indicated that copper, chromium and zinc were present in exceedance of the Remedial Action Goals. The stained soil area associated with 100-K-36 was approximately 54.0 square meters (581.3 square feet). Four sample increments were collected from randomly selected nodes within the stained soil sample area and combined into a single composite sample. The stained soil was removed to a depth of approximately 8 meters (26.2 ft) below grade.

The 100-K-79 confirmatory samples collected in August 2011 exceeded the RAGs for metals and the site was assigned a RTD remedy. Two samples were collected for the 100-K-79 Subsite 7 (partial) pipeline remediation area. One was a composite per the sample design. The other was a composite sample collected with the "sample as you go" strategy. The 100-K-79 Subsite 7 pipeline sample area was approximately 65.9 square meters (709.3 sq. ft.). It consisted of one sample area. Four sample increments were collected from randomly selected nodes within the sample area and combined into a single composite sample. The second composite sample was collected from the area extending from the end of the pipeline in AG Zone 2 to where it entered the pipe valve box south of the 105-KE Reactor.

The partial 100-K-3 pipeline remediation area was approximately 196.4 square meters (2,114.0 sq. ft). It consisted of three sample areas. Four sample increments were collected from randomly selected nodes within each sample area and combined into a single composite sample.

A portion of the sewer line discharging from the 1706-KER building was removed (40.8 sq. meters [439.2 sq. feet]) incidental to the building removal. To evaluate this area, four sample increments were collected from randomly selected nodes within the sample area and combined into a single composite sample.

In August 2012, the sample results were received and excavation backfill activity began.
The waste site has been remediaged and Interim Closed Out. It consisted of an above ground, vertical, stainless steel storage tank. The tank rested on a redwood timber deck above a 1.4 meter (4.45 foot) service space (at grade) that is protected by guard posts. A 5.1 centimeter (2 inch) fill line for tank truck usage was also located in the same area. Two 5.1 centimeter (2 inch) drain lines, one for vent and overflow and the other for valve leakage, entered a French drain (Site: 100-K-36) that was located (in the service area) between the caustic soda tank (100-K-38) and the sulfuric acid tank. The tank had a liquid level gauge, a 5.1 centimeter (2 inch) fill line, and a vent and overflow line. The top of the tank could be accessed via a ladder and platform at the top elevation of the tank. The tank was constructed with a bottom sloping towards the drain. When installed, the tank was shimmed to level it.

The site was located southeast of the reactor and adjacent to the 1706-KE Building. 1706-KE Building, 0-Foot Level from the Part B Application shows the location of the tank.

Site employees report that during operational history, the tank was rinsed down on a few occasions and the material went to the general soil area.

The site is related to the 1706-KE Building, 100-K-38, 1706-KE Caustic Soda Tank, and 100-K-36, 1706-KE Chemical Storage Facility Dry Well.

The chemical storage facility at 1706-KE was installed in 1963 to provide bulk quantities of 93 percent by weight sulfuric acid and 50 percent by weight sodium hydroxide. The chemicals were used to regenerate the ion columns in the 1706-KE demineralizer plant. The demineralizer plant supplied demineralized water to two experimental single pass process tube in the 105-KE reactor core. The demineralizer plant was a duplex unit with two sets of ion columns. It operated with one set in service and the other either being regenerated or in a ready-standby condition. Typically three regenerations were performed each day during this period. Shipping manifests indicate that approximately 7,948.5 liters (2100 gallons) of sulfuric acid and 10,976.5 liters (2900 gallons) of sodium hydroxide were delivered to 1706-KE at 4-6 week intervals.

in 1971, the 100-K production reactors were shut down and the demineralizer plant was deactivated. It was reactivated some years later to provide demineralized water to the 100-K area fuel storage basins. The quantity of demineralized water produced during this period of operation was a small fraction of that produced during reactor operation. Thus, the number of regenerations was steadily reduced from an initial amount of approximately 12 times per year to 3 times per year when the demineralizer plant was finally taken out of service.

A heel of sulfuric acid remains on the bottom of the tank, and an unknown quantity of sulfuric acid remains in the transfer lines inside the 1706KE facility.

The 100-K-37 and 100-K-38 waste sites were removed using standard industrial equipment for structural demolition. The removed tanks and related debris were disposed at the Environmental Restoration Disposal Facility on November 19, 2009 and November 23, 2009. Verification sampling was not required to demonstrate protectiveness for waste sites 100-K-37 and 100-K-38. The CERCLA removal action for the 1706-KE Building will address the underlying foundation.
**Code:** 100-K-38  
**Classification:** Accepted  
**Names:** 100-K-38; 1706-KE Caustic Soda Tank  
**Reclassification:** Interim Closed Out (8/4/2010)  
**Type:** Unplanned Release  
**Start Date:** 1/1/1963  
**End Date:** 1/1/1986  
**Status:** Inactive  

**Description:** The waste site has been remediated and Interim Closed Out. The site consisted of contaminated soil from spills related to a caustic soda storage tank. The tank was an above ground, vertical, stainless steel storage tank. The tank rested on a redwood timber deck above a 1.4 meter (4.45 foot) service space (at grade) that is protected by guard posts. A 5.1 centimeter (2 inch) fill line for tank truck usage was also located in the same area. Two 5.1 centimeter (2 inch) drain lines, one for vent and overflow and the other for valve leakage, entered a french drain (Site: 100-K-36) that is located (in the service area) between the caustic soda tank and the sulfuric acid tank (Site: 100-K-37). The tank was insulated, had a liquid level gauge, a 5.1 centimeter (2 inch) fill line, a vent and overflow line, thermostat, and heating element. The top of the tank could be accessed via a ladder and platform at the top elevation of the tank. The tank was constructed with a bottom sloping towards the drain. When installed, the tank was shimmed to level it.

**Location:** The site is located in the southeast corner and adjacent to the 1706-KE Building. Figure B-4 1706-KE Building, 0-Foot Level from the Part B Application shows the location of the tank.

**Release Description:** Site employees report that during the operational history, spills occurred. The tank exterior was rinsed down after these spills and the material was released to the soil.

**Related Sites/Structures:** The site is related to the 1706-KE Building, 100-K-37, 1706-KE Sulfuric Acid Tank, and 100-K-36, 1706-KE Chemical Storage Facility Dry Well.

**Process Description:** The chemical storage facility at 1706-KE was installed in 1963 to provide bulk quantities of 93 percent by weight sulfuric acid and 50 percent by weight sodium hydroxide. The chemicals were used to regenerate the ion columns in the 1706-KE demineralizer plant. The demineralizer plant supplied demineralized water to two experimental single pass process tube in the 105-KE reactor core. The demineralizer plant was a duplex unit with two sets of ion columns. It operated with one set in service and the other either being regenerated or in a ready-standby condition. Typically three regenerations were performed each day during this period. Shipping manifests indicate that approximately 7,948.5 liters (2100 gallons) of sulfuric acid and 10,976.5 liters (2900 gallons) of sodium hydroxide were delivered to 1706-KE at 4-6 week intervals. In 1971, the 100-K production reactors were shut down and the demineralizer plant was deactivated. It was reactivated some years later to provide demineralized water to the 100-K area fuel storage basins. The quantity of demineralized water produced during this period of operation was a small fraction of that produced during reactor operation. Thus, the number of regenerations was steadily reduced from an initial amount of approximately 12 times per year to 3 times per year when the demineralizer plant was finally taken out of service.

**Waste Type:** Process Effluent  
**Waste Description:** Site employees have reported that spills occurred at the site. The tank exterior was rinsed down after the spills and into the soil column. A white material that may be sodium hydroxide powder can be seen in the cracks of the lower level ceiling beneath the location of the tank base.

**Closure Info:** The 100-K-37 and 100-K-38 waste sites were removed using standard industrial equipment for structural demolition. The removed tanks and related debris were disposed at the Environmental Restoration Disposal Facility on November 19, 2009 and November 23, 2009. Verification sampling was not required to demonstrate protectiveness for waste sites 100-K-37 and 100-K-38. The CERCLA removal action for the 1706-KE Building will address the underlying foundation.

<td>Description:</td>
<td>The waste site is the fuel storage basin for the 105-KE Reactor. The fuel storage basin was demolished in 2009. It was located at the rear of the reactor. All that remains is a portion of the discharge chute that is off of the building. Determination that asbestos containing material (ACM) was left in place and abated during demolition is based on a Quality Assurance review of project documentation and interviews with activity personnel. The concrete basin area served as a collection, storage, and transfer facility for the irradiated fuel elements discharged from the reactor. Irradiated reactor fuel elements were stored at the bottom of large water filled storage basins pending their shipment to the chemical separations facilities in the 200 Areas. The water in the basins served both as coolant and as shielding. The basin consists of a discharge chute and fuel element pickup area, a storage area, a transfer area, and a wash pad area. After reactor operations were terminated in 1975, a number of irradiated uranium fuel elements were found in both fuel storage basins when sludge was removed. Dorian and Richards (1978) reports that the 105-KW storage basin was cleaned, modified and being used for the storage of irradiated fuels from N Reactor. At the time of the report the 105-KE basin had been cleaned and was in the process of being modified for the same purpose. In 1974 and 1975, both basins were modified to a recirculating cooling system by the utilization of heat exchangers once used to transfer heat from the reactor cooling water elimination system to facility heating (Project H-501). The 105-KE basin has been used to store irradiated fuel in open containers. Consequently, the 105-KE basin is considered more radioactively contaminated than the 105-KW basin.</td>
<td>Location:</td>
<td>The storage basin extended from the north wall of the 105-KE Reactor Building to the open area behind the reactor, with its longitudinal axis running parallel to the north wall of the building. Its east-west location was roughly in the center of the building.</td>
</tr>
<tr>
<td>Release Description:</td>
<td>The 105-KE Fuel Storage Basin was constructed with a secondary seepage barrier in the form of an asphalt membrane under the basin floor. The 5.1 centimeters (2 inches) thick membrane was installed under the entire storage basin except for the pickup chute area and was designed to collect leakage in perforated pipes that lie on top of the membrane. These pipes drain to a sump. During testing that was conducted in 1974, a 16 day basin drawdown established a 15.1 liters per minute (4 gallons per minute) seepage rate from the basin system. At least 90 percent of this seepage was thought to be collected by the membrane system and sump. Two automatic pumps were installed in the sump to return any seepage back to the basin. 10 percent of the seepage was assumed to discharge to the soil beneath the basin. In mid-February 1977, an unusually high seep rate 51.1 liters (13.5 gallons per minute) was identified. The increased seepage was determined to have been caused by reduced basin water temperature, which caused concrete contraction to expand existing minor cracks in the basin. Detailed analysis showed that no radioactivity was being released in liquid effluents from K Area and no water was being collected in the membrane drainage sump. Therefore, all of the seepage was assumed to be going to ground either through or past the membrane. A number of steps were taken to control and reduce the basin leakage, including maintaining higher basin temperatures, identification and repair of seep areas, use of ion exchange system to reduce cesium, and improving monitoring. In spite of the repairs, drawdown testing in 1979 showed that the basin was still...</td>

</table>
Process Description:
The transfer area contained two sets of standard gauge railway tracks which extend into the building at ground level through the west wall. Adjacent to each track was a loading pit, which lead from the main basin. Irradiated metal slugs dropped from the rear or discharge face of the reactor through a discharge gate to the bottom of the bay between reactor and basin. A heavy rubber mattress was installed to cushion the fall of the slugs. The slugs were picked up by long handled tongs manipulated from the floor grating, and placed into buckets. The loaded buckets were suspended on the monorail conveyor system, and conveyed across and around the storage basin to the loading pits. This transfer was timed in short moves over a lengthy period so that the slugs are stored for some time in the storage basin, for the purpose of dissipating radioactivity. When the slugs reached the transfer area they were placed, still underwater, into large specially constructed containers called "casks". The loaded casks were hoisted from the bottom of the pits and placed on the cask cars, which were switched in on the adjacent tracks. The cars approximate were designed and built for the cask freightage. The viewing and weasel pits at the other end of the storage basin contained equipment for manipulating and examining selected slugs while under water. The function of the entire basin installation was to provide handling of radioactive metal under a shielding layer of water.

During the reactor refueling process, the fuel storage basins were used to receive the discharged fuel rods. New fuel elements were pushed into the process tube by a charging machine which caused the irradiated fuel elements in the tube to be displaced. The discharged irradiated fuel elements dropped into a water filled discharge chute and slid down into the metal pickup area at the end of the storage basin. The water in the chute area provided shielding as the elements accumulated and were sorted into buckets using long, hand-operated tongs. The buckets were then transferred by an overhead monorail system to the storage aisles where they were held for a time to allow the decay of short-lived radionuclides. Following the storage period, the buckets of fuel elements were moved by the overhead monorail system to the transfer area. At the transfer area, the irradiated fuel was loaded into a cask, then raised by a crane and placed in special railroad cars for shipment to the chemical reprocessing facilities in the 200 Area.

Occasionally, fuel elements would rupture or become damaged during handling and storage, causing contamination to the basin shielding water. Experience at other Hanford reactors suggests that the occurrence and inspections of the fuel element ruptures almost certainly occurred at both 100-KE and 100-KW basins throughout their operating histories.

Although the basins originally served the K Reactors, N Reactor fuel was accumulated from 1979 through 1987. Storage at K Basins was intended to be only as needed to sustain operation of N Reactor while the Plutonium and Uranium Recovery through Extraction Facility (PUREX) was placed in standby for refurbishment and restart. Although PUREX processed much of the N Reactor fuel as planned, the decision by the Department of Energy in December 1993 to deactivate the PUREX facility left approximately 2,100 metric tons (2,310 tons) of N Reactor spent nuclear fuel in the K Basins with no provision for near term removal and processing.

Waste Type: Process Effluent
Waste Description: The spent nuclear fuel in the KE basin was in the form of irradiated uranium elements clad in aluminum or zirconium alloy and immersed in water. The fuel elements in the K East Basin were stored in open canisters. By-product material which includes corroded cladding, fuel particles, and insoluble plutonium and uranium metal had settled on the basin floor. Concrete debris resulting from erosion of the basin walls, transient soil and other types of dregs had also accumulated in the basins. This concurrent accumulation of various materials in the basins was commonly referred to by the Spent Nuclear Fuel (SNF) Project as the 100-K Basins sludge. The 100-K East Basin contained approximately 50 cubic meters of sludge.

Code: 100-K-43
Names: 100-K-43; 105-KW Fuel Storage Basin; Irradiated Fissile Material Storage; K West Basin; KW Basin
Type: Storage
Status: Active

Description: The site is the fuel storage basin for the 105-KW Reactor. The fuel storage basin is located at the rear of the reactor. The concrete basin area served as a collection, storage, and transfer facility for the irradiated fuel elements discharged from the reactor. Irradiated reactor fuel elements were stored at the bottom of large water filled storage basins pending their shipment to the chemical separations facilities in the 200 Areas. The water in the basins served both as coolant and as shielding. The basin consists of a discharge chute and fuel element pickup area, a storage area, a transfer area, and a wash pad area. The basin area is floored throughout at ground level with steel grating which is suspended from the steelwork of the roof above by means of vertical pipe columns. A grid of 32 monorails evenly spaced crosses the basin, overhead, from north to south, connects at the ends with a monorail which completely encircles the area. Bars suspended from trolleys which roll on these rails extend down through slots in the floor grating to a point near the bottom of the basin, where they support and carry buckets used for conveying the processed metal. Transverse rails extend from the outer rail loop into the transfer area at the west end of the basin, and the viewing and weasel pits at the east end. Crossovers are installed for switching the trolleys from track to track. The transfer area contains two sets of standard gauge railway tracks which extend into the building at ground level through the west wall. Adjacent to each track is a loading pit, which leads off from the main basin. As the system functions, irradiated metal slugs drop from the rear or discharge face of the reactor through a discharge gate of special design to the bottom of the bay between reactor and basin. A heavy rubber mattress is installed here to cushion the fall. The slugs are picked up by long handled tongs manipulated from the floor grating, and placed into buckets. The loaded buckets are suspended on the monorail conveyor system, by which they are conveyed across and around the storage basin to the loading pits. This transfer is timed in short moves over a lengthy period so that in effect the slugs are stored for some time in the storage basin, for the purpose of dissipating radioactivity. When the slugs reach the transfer area they are placed, still underwater, into large specially constructed containers called "casks". The loaded casks are hoisted from the bottom of the pits and placed on the cask cars, which are switched in on the adjacent tracks. The cars approximate standard railway equipment in size, and are designed and built for the cask freightage. The viewing and weasel pits at the other end of the storage basin contain equipment for manipulating and examining selected slugs while underwater. The function of the entire basin installation is to provide for handling radioactive metal under a shielding layer of water. A number of irradiated uranium fuel elements were found in both fuel storage basins when sludge was removed in 1975 after reactor operations were terminated. Dorian and Richards (1978) reports that the 105-KW storage basin was cleaned, modified and being used for the storage of irradiated fuels from N Reactor. At the time of the report the 105-KE basin had been cleaned and was in the process of being modified for the same purpose. In 1974 and 1975, both basins were modified to a recirculating cooling...
system by the utilization of heat exchangers once used to transfer heat from the reactor cooling water elimination system to facility heating (Project H-501). The 105-KW basin has been used to store fuels in sealed storage containers. Consequently, the 105-KW basin is far less radioactively contaminated than the 105-KE basin.

**Location:** The storage basin extends from the north wall of the 105-KW Reactor Building to the open area behind the reactor, with its longitudinal axis running parallel to the north wall of the building. Its east-west location is roughly in the center of the building.

**Related Sites/Structures:** The site is related to the 105-KW Reactor Building and an Unplanned Release - sitecode 100-K-82.

**Process Description:** During the reactor refueling process, the fuel storage basins were used to receive the discharged fuel rods. New fuel elements were pushed into the process tube by a charging machine which caused the irradiated fuel elements in the tube to be displaced. The discharged irradiated fuel elements dropped into a water filled discharge chute and slid down into the metal pickup area at the end of the storage basin. The water in the chute area provided shielding as the elements accumulated and were sorted into buckets using long, hand-operated tongs. The buckets were then transferred by an overhead monorail system to the storage aisles where they were held for a time to allow the decay of short-lived radionuclides. Following the storage period, the buckets of fuel elements were moved by the overhead monorail system to the transfer area. At the transfer area, the irradiated fuel was loaded into a cask, then raised by a crane and placed in special railroad cars for shipment to the chemical reprocessing facilities in the 200 Area. Occasionally, fuel elements would rupture or become damaged during handling and storage, causing contamination to the basin shielding water. Experience at other Hanford reactors suggests that the occurrence and inspections of the fuel element ruptures almost certainly occurred at both 100-KE and 100-KW basins throughout their operating histories. Although the basins originally served the K Reactors, N Reactor fuel was accumulated from 1979 through 1987. Storage at K Basins was intended to be only as needed to sustain operation of N Reactor while the Plutonium and Uranium Recovery through Extraction Facility (PUREX) was placed in standby for refurbishment and restart. Although PUREX processed much of the N Reactor fuel as planned, the decision by the Department of Energy in December 1993 to deactivate the PUREX facility left approximately 2,100 metric tons (2310 tons) of N Reactor spent nuclear fuel in the K Basins with no provision for near term removal and processing.

**Waste Type:** Process Effluent

**Waste Description:** The spent nuclear fuel in the KW basin was in the form of irradiated uranium elements clad in aluminum or zirconium alloy and immersed in water. The fuel elements in the K West Basin were stored in closed canisters. By-product material which included corroded cladding, fuel particles, and insoluble plutonium and uranium metal gas settled on the basin floor. Concrete debris resulting from erosion of the basin walls, transient soil and other types of dregs had also accumulated in the basins. This concurrent accumulation of various materials in the basins was commonly referred to by the Spent Nuclear Fuel (SNF) Project as the K Basins sludge. The K West Basin contained relatively little sludge as compared with the K East Basin which had approximately 50 cubic meters (38.2 cubic yards) of sludge.

</table>
crushed rock and there was no visible evidence of the drywell on the ground surface.

**Location:**
The drywell was located 8.7 meters (28.5 meters) from the east side of the 105-KE Reactor Building and 8 feet (2.4 meters) south of the 119-KE Sample Building.

**Related Sites/Structures:**
The drywell is associated with the 119-KE Sample Building.

**Process Description:**
The 119-KE Sample Building was situated over the intake and exhaust ducts to the 117-KE Filter Building and was used to sample effluent gases and particulates. Floor drainage from the 119-KE Exhaust Air Sample Building was directed to the drywell by a 5 centimeter (2 in) pipe buried at least 0.9 m (3 ft) below grade. In addition, a 1.9 centimeter (0.75 in) pipe from the building evaporative cooler also connected into the 5 centimeter (2 in) floor drain pipe near the southern edge of the building and discharged into the 100-K-46 Waste Site.

**Waste Type:**
Process Effluent

**Waste Description:**
The drywell received effluent from the building's evaporative cooler. It is likely that the floor drain also received sample waste and janitorial waste since the building had no other drains or connections to the process sewer system. The drywell was potentially contaminated with cobalt-60, cesium-137, carbon-14, and tritium, as well as strontium-90, europium-152, europium-154, and europium-155 from the exhaust air system and heavy metals from the floor drain.

**Closure Info:**
Remediation and sampling began in January of 2009 and was completed in April of 2012. The large excavation area, known as 100-K Area AH, encompassed waste sites 100-K-6, 100-K-46, 100-K-62 and 132-KE-1. The excavation area also included Stockpile #4, which contained overburden and layback soil from the excavation of the 116-KE-1 Condensate Crib. Information supporting the use of Stockpile #4, located within the AH excavation, as backfill was also included in the DOE/RL-2012-38 Remaining Sites Verification Package report.

Remediation of the identified Area AH waste sites was accomplished by demolishing the structures and excavating contaminated soil. All waste (soil and debris) associated with these waste sites was disposed at the Environmental Restoration and Disposal Facility (ERDF). The demolition activities were conducted using standard demolition techniques, including explosives for demolition of 132-KE-1 (116-KE Reactor Exhaust Stack). Approximately 1,809 ERDF containers (37,700 tons) of waste from these waste sites were sent to the ERDF for disposal.

Remediation of the 100-K-6 vacuum pit began in August 2011 and was completed in September 2011. An excavator was used to remove the vacuum pit and excavate the surrounding soil. The original waste site description estimated the depth of the cyclone separator as 9.14 meters (30 ft). However, during remediation the actual excavation depth was measured as 5.8 meters (19 ft).

The remediation of the 100-K-46 french drain was associated with the removal of the 119-KE building, which began in January 2009 and was completed in February 2009. The drywell was less than 1.5 meters (5 ft) deep.

The remediation activities at the 100-K-62 filter building began in August 2010 and were completed in May 2011. An excavator was used to remove the vacuum pit and excavate the surrounding soil. The maximum depth from grade within the waste site footprint was approximately 10.6 meters (34.8 ft).

The remediation activities at waste site 132-KE-1 exhaust stack began in July 2010 and were completed in September 2011. Removal of the above-grade portion of the stack was conducted using explosives placed near the base of the stack. The explosion caused the debris to fall in a designated area. The material was then loaded and disposed at ERDF. The entire below grade
portion of the stack base was then removed. The maximum depth from grade within the waste site footprint was approximately 6.1 meters (20 ft).

In October of 2010, excavation of the overburden and layback soil for the 116-KE-1 Crib began and Stockpile #4 was created. Samples were collected in the 116-KE-1 waste site footprint and sent for analytical leach testing of the soils to determine carbon-14 leachability from the 100-K soil. During remediation of the co-located waste sites inside the AH excavation area, the 116-KE-1 crib was partially backfilled with soil from Stockpile #4 as a contamination control measure.

Note: Area-wide carbon-14 contamination exists in the deep zone above the criteria for protectiveness. This contamination is associated with the 105-KE Reactor ventilation filtration system and the deep contamination from the condensate that collected in the previously excavated 116-KE-1 Condensate Crib. Additional remediation of the deep vadose zone cannot be completed in proximity to the 105-KE Reactor without impacting structural stability. Available information about the nature and extent of the carbon-14 contamination has been documented in the 116-KE-1 Condensate Crib waste site description. Due to the depth of the contamination, the carbon-14 remediation will coincide with the final decision on 105-KE reactor removal.

<td>Description: This site includes the underground process sewer pipelines that begin at the 105-KE Reactor, 105-KW Reactor, 165-KE, 190-KE, 1706-KE, and terminate either at the 116-K-3 Outfall or join the 100-K-56 Pipeline south of the outfall. Manholes indicate the location of some sections of the process sewer. The main portion of the sewer that extends from the point of intersection of the 30.5 and 40.6 centimeter (12 and 16 inch) pipelines coming from 105-KW Reactor and 165-KE building with Manhole #5. This section is a 1.68 meters by 1.68 meters (66 inches by 66 inches) concrete sewer. All other process sewer pipelines are constructed of carbon steel. The pipelines near 100-K-71 include a 6 inch clean drain line, a 10 inch contaminated drain line, a 10 inch potentially contaminated drain line, a 6 inch rod cooling water line, a 6 inch drain line to the pluto crib, a 12 inch basin drain line, an 8 inch basin overflow line, a 6 inch vent line and a 4 inch vitrified clay decontamination drain line to the filter. In 2002, approximately 600 feet of pipe, adjacent to 100-K-39, was removed. Portions of the 100-K-47 pipeline, located in remediation area AG Zone 1, were removed in 2011. Location: This pipeline system includes process sewer lines from both the 105-KE and 105-KW reactor areas. The process sewer piping originates on the south (pre-reactor) and north (post-reactor) sides of the 105-KE and 105-KW Buildings. Portions run in an east-west direction to a point just west of the KE facilities and east of the KW facilities. The pipelines then run in a northerly direction to a point just south of the 116-K-3 Outfall where they intersect into a single discharge line to the Outfall structure. Related Sites/Structures: These pipelines are associated with 165-KE, 190-KE, 105-KW, 105-KE, and 1706-KE. Pipeline 100-K-60 is the corresponding pipeline from 165-KW and joins 100-K-47 midway between the two reactors.</td>
<td></td>

### Description:

The waste site is areas that show evidence of past fuel oil spills, especially around the railroad tracks. The spills have been absorbed into the soil and have formed an asphalt like substance. Some areas may have been covered with clean soil.

**Location:** The site is located in 100-K Area just north of the 166-KE Oil Storage Tank at the rail car holding point and just west of the 166-KE Oil Storage Tank.

**Release Description:** The site appears to be oil spillage from rail car off loading procedures. The oil appears to have been absorbed by sand and has formed a hard asphalt-like covering on the surface. It appears that the oil substance has exceeded the capacity of the sand absorbent and has formed a few tar-like patches of liquid oil that appear to be Bunker C type oil. There are some oil stains on the concrete tank top as well.

**Related Sites/Structures:** The site is related to the 166-KE Fuel Oil Storage Bunker.

**Waste Type:** Chemical Release

**Waste Description:** The waste is oil solidified into a hard asphalt-like substance.

### Start Date:
Rev. 24

The waste site is areas that show evidence of past fuel oil spills, especially around the railroad tracks. The spills have been absorbed into the soil and have formed an asphalt like substance. The area between the 166-KW and the road south of 166-KW was discovered to be contaminated with oil during excavation of a trench for the Cold Vacuum Drying Facility. An oil contaminated layer of soil about 7.6 to 10.2 centimeters (3 to 4 inches) thick was discovered a few inches below the surface.

The site is located in 100K Area and adjacent to the 166-KW Oil Storage Tank, extending to the road off the north and west sides of 166-KW Oil Storage Tank. The site also extends to the northwest to a depression located 50 to 60 meters (140 to 170 feet) west of the 105-KW Reactor. Due to the discovery of subsurface oil contamination the full extent of the contamination is unknown.

The site appears to have been created from spills of fuel oil that occurred during off loading operations. The largest portion of the contamination appears to have been absorbed by sand and formed a hard asphalt-like substance. This substance begins at the railcar offloading area and extends down gradient from the tank to an area west of the 105-KW Reactor Facility.

The site is related to the 166-KW Fuel Oil Storage Bunker.

The waste is oil solidified into a hard asphalt-like substance.

The site is an underground, sanitary sewage holding tank that services 1725-K and 1726-K. The site is marked by eight red concrete posts. The tank is constructed of concrete and has three manholes on top and one hinged hatchcover. A 20.3 centimeter (8 inch) sanitary sewer pipeline runs in a north-south direction 9.1 meters (30 feet) east of the 1725-K (MO-293) and the 1726-K (MO-442) buildings into the south side of the holding tank. The tank is divided into two chambers. The normal operating volume is 11,355 liters (3000 gallons) and the total reserve volume is 17,032 liters (4500 gallons).

The site is located approximately 35 meters (115 feet) south southeast of the southeast corner of the 183-KE Settling Basins and 9.1 meters (30 feet) east of 1725-K.

The holding tank collects septage from 1725-K and 1726-K mobile offices. Periodically, the septage is pumped out and taken to the 124-N-10 Sewage Lagoon for disposal.

The waste is Misc. Trash and Debris.
This waste site has been remediated and Interim Closed Out. It included two underground pipelines that transported glycol solutions from the 116-KE-5 (150 KE Heat Recovery Station) to their entrance to the 165-KE Powerhouse (Power Control Building) facilities. The pipelines consist of two 0.46-meter (1.5-foot) steel supply and return pipelines. It does not include the above-grade pipelines at the 116-KE-4 Station, the 100-K-7 Storage Tanks and piping, or the pipelines housed within these facilities. The waste site consisted of two pipelines; one 0.46-meter (1.5-ft) diameter steel supply and one 0.46-m (1.5-ft) diameter steel return pipeline. The two pipelines ran parallel to each other and were buried approximately 1.5 meters (5 ft) below grade surface.

The pipelines were located east of the 105-KE Reactor building. They originated at the 116-KE-5 (150-KE Heat Recovery Station) and terminated at the 165-KE Building north wall. The pipelines ran in a north-south direction.

The site was associated with 116-KE-5 (150-KE Heat Recovery Station) and 165-KE (Power Control Building).

This system was used to distribute heat taken, via a heat exchanger (116-KE-5, 150-KE Heat Recovery Station) to area buildings for space heating and process needs. The facilities, makeup and storage tanks where the pipelines terminated are not included. The heat recovery station was used to transfer heat from the 105-KE Reactor cooling water effluent. The pipelines contained an ethylene glycol and water solution that was maintained at a slightly positive pressure to preclude leakage of reactor effluent water into the system.

The waste is pipelines that contained an ethylene glycol/water solution that was maintained at a slightly positive pressure to preclude leakage of reactor effluent water into the system via the 150-KE Heat Exchanger.

The remediation of the 100-K-53 Waste Site began in May 2010 and was completed in July 2011. Remediation of the pipelines had to be completed in stages due to interference from other buildings and waste sites, which required removal first to provide access to the remaining 100-K-53 pipelines. The ethylene glycol was drained from the pipelines inside the 165-KE Powerhouse and solidified for disposal at ERDF. Excavation and removal of the pipelines then began on the north end. The pipelines were again checked for any ethylene glycol holdup at the first valve box on that north end and then the piping and valves were removed. As remediation progressed to the south, the pipelines were removed along with other structures and waste sites, which resulted in a deeper excavation (approximately 5.8 to 6.1 meters [19 to 20 ft]) on the east side of the 105-KE Reactor. During remediation, a new substation was built near the south end of the pipelines, resulting in a power line interference. The portion of the pipeline required to remain place was filled with grout. This interference deviated from the original design drawing for the remediation of the 100-K-53 Waste Site. The remediation of the waste site was completed by removal of the two ethylene glycol pipelines, except for the grouted portion left in place due to the power line interference. The grouted pipelines will remain in place and require no further remediation. The pipeline remediation ended outside the north end of the 165-KE Powerhouse. No holdup of ethylene glycol was found during removal of the pipelines. The pipelines and soils (a total of 22,240 tons) that were excavated were disposed of at the ERDF. No stockpiling of soils was completed during the remediation of 100-K-53.
The deep zone underneath the footprint of 100-K-53 is contaminated with carbon-14 from the reactor ventilation filtration system. The contamination is not associated with 100-K-53, but is associated with the nearby 116-KE-1 Condensate Crib waste site. This residual contamination will be remediated at a future date, and the 100-K-53 waste site and adjacent area will have institutional controls in place until it is remediated.

<td>This site consists of two subsites. Subsite 1 has been remediated and Interim Closed Out. It included the underground process effluent pipelines located on the north side of 105 KW Reactor and pipelines located outside of the security fence that terminated at the 116-K-3 Outfall, the 116-K-1 Crib, the 116-K-2 Trench, and the 116-KW-3 Retention Basins. Remedial action activities at the 100-K reactor effluent pipelines began on December 9, 2002 by Washington Closure Hanford (WCH). Remediation of the pipelines involved excavation and staging of overburden material and removal of contaminated piping, debris and soil at the 100-K-55:1, 100-K-56:1, 116-KW-4 and 116-KE-5 waste sites. Contaminated materials were disposed at the ERDF. Remedial action excavation was completed on April 15, 2005.</td>
</tr>
</tbody>
</table>
Subsite 2 consists of the remaining portion of the underground effluent pipeline inside the Reactor security fence and some segments near the 116-K-1 Crib, the 116-KW-3 Retention Basin and the 116-K-2 Trench.

In the interest of preserving the reactor security fence and some active underground utility features, some segments of pipe were not removed in 2002-2005.

**Location:** The pipelines ran in a north-south direction, north of the 105-KW Reactor Building and east-west on the outside of the reactor fence.

**Related Sites/Structures:** The site was related to the 105-KW Reactor, the 116-K-3 Outfall, 100-K-83 Spillway, the 100-K-80 River Pipelines, the 116-K-1 Crib, the 116-K-2 Trench, and the 116-KW-3 Retention Basins.

**Process Description:** The effluent system transported the reactor process effluent water by means of gravity flow to the river. There, the effluent water was discharged underwater to be diluted both thermally and radioactively by the flow of the river. The effluent system piping was located underground to provide shielding from the radioactive water. Before the water was discharged into the river, it was held for a period of time in retention basins, located approximately midway between the reactor building and the river, to allow decay of short-lived radioisotopes. In addition, the basins served to hold up flow of effluent with high radioactive isotope concentrations resulting from a ruptured fuel element. This effluent could be isolated and diverted by gravity to an open pond area, from which the effluent filtered through the ground before discharging to the river. Between the 105-KW Reactor Building downcomer outlet and the diversion valve box at the inlet of the 107-KW Retention Basins, the effluent pipeline was a single, 1.83-meter (72-inch), carbon steel pipeline measuring 190 meters (625 feet) in length. At the diversion valve box the flow could be diverted to any or all of the three retention basins by three, motor-operated, 1.83-meter (72-inch) butterfly valves. A 1.83-meter (72-inch) bypass pipeline was provided around the diversion valve station. This bypass pipeline tied into the inlet piping of one of the retention basins. During normal operation of the effluent system, flow was restricted in this bypass pipeline by an inverted ‘U’ bend which extended 9.1 meters (30 feet) higher than the elevation of the diversion valve station. If all the valves inadvertently closed, the effluent water flowed over the inverted ‘U’ bend and into the basin. The inlet 1.83-meter (72-inch) effluent piping ran to the side of a basin and discharged into an inlet chute, which in turn discharged to the bottom of the basin. The basin discharged to the river through a sump at the center of the basin. The basin discharge piping extended from the sump beneath the basins in reinforced concrete tunnels at the sides of the basins. The basin discharge piping was 1.7-meter (66-inch) carbon steel piping. The combined length of the discharge pipes from all three basins measured 478 meters (1,568 feet). The basin discharge piping combined into a common effluent pipeline. This pipeline discharged into the outfall structure (116-K-3). The common effluent from the 105-KW Reactor was a 1.83-meter (72-inch) pipeline. The effluent pipe system was Dresser coupling connected. Concrete anchors were provided at each turn in the pipeline. The motor operated valves in the effluent system were controlled from the 105-KW Building Control Room. Miscellaneous piping included pipes to the 116-K-1 Crib, 116-K-2 Trench, and process sewer and piping to and from the 150-KW Heat Recovery Building. Discharges to 116-K-1 and 116-K-2 were made via 910-millimeter (36-inch) pipes that combined to flow into a 1,070-millimeter (42-inch) steel main pipe. Discharges to the process sewer were made through 250-millimeter (10-inch) steel pipes that combined into a 360-millimeter (14-inch) steel main pipe. Effluent from the 150-KW Building consisted of a 610-millimeter (24-inch), 460-millimeter (18-inch), 100-millimeter (4-inch) and 76-millimeter (3-inch) steel effluent piping system. Effluent from the 105-KW and 150-KW Buildings could bypass the retention basins through a 910-millimeter (36-inch) or a 300-millimeter (12-inch) steel pipe. Pipe depth varied from 1.3 meters (4 feet) to 9.7 meters (32 feet). The deepest pipes ran under an elevated contour that coincided with the retention basin exclusion fence.

**Waste Type:** Soil
Waste Description: The waste was contaminated steel piping, concrete, and soil. Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, diatomaceous earth (a scouring agent), and sodium dichromate. Water pH was maintained at about 7.5, and free chlorine residual was about 0.2 milligrams per liter. Radionuclide content at the retention basin during sampling by Richards for UNI-946, included the following: cesium-134, plutonium 239/240, cesium-137, strontium-90, hydrogen-3, nickel-63, europium-152, europium-154, europium-155, and cobalt-60.

This Site has the Following SubSites:

- **Code:** 100-K-55:1
  - **Names:** Process Pipelines Outside of Reactor Fence to Outfall

- **Code:** 100-K-55:2
  - **Names:** Effluent Pipelines Inside 105KW Reactor Security Fence

**Subsite 1** was remediated and Interim Closed Out. Remedial action activities involved excavation and staging of overburden material and removal of contaminated piping, debris, and soil. The project began on December 9, 2002. Contaminated materials were disposed at the ERDF. Subsite 1 included the underground process effluent pipelines located on the north side of 105 KW Reactor, from the outside of the security fence to the active utilities 116-K-1 Crib, 116-K-2 Trench and 116-KE-4 Retention Basin, and the Process Water Pipeline between Reactors. The Process Pipelines were located outside of 105-KW Reactor Security Fence and extended to 116-K-3 Outfall.

**Waste Type:** Batteries

**Waste Description:** The waste is contaminated piping, debris, and soil.

**Closure Info:** Remedial action activities at the 100-K reactor effluent pipelines began on December 9, 2002 by Washington Closure Hanford (WCH). Remediation of the pipelines involved excavation and staging of overburden material and removal of contaminated piping, debris and soil at the 100-K-55:1, 100-K-56:1, 116-KW-4 and 116-KE-5 waste sites. Contaminated materials were disposed at the ERDF. Remedial action excavation was completed on April 15, 2005. The previously documented waste site boundaries for the 116-KW-4 and 116-KE-5 sites were much larger than the actual footprint of the heat recovery facilities. The soil area beneath each of the former heat recovery stations was excavated in its entirety with the removal of the co-located pipelines. Approximately 55,960 square meters (602,350 sq ft) of plan area was excavated, including excavation within the deep zone (greater than 4.6 meters [15 ft] below ground surface) up to 8.8 meters (29 ft) below ground surface where necessary to complete remediation. Approximately 86,551 metric tons (95,406 U.S. tons) of material from the sites was removed and disposed at the ERDF. The active 100-K-47 concrete culvert was not removed during remediation of the adjacent section of the 100-K-55 pipeline. Several 100-K-56 pipe segments, located west of 116-KE-4, were not included in the remediation scope.
The contaminated materials from these sites have been excavated and disposed at the ERDF. The remaining soils at the sites have been sampled, analyzed, and modeled, and the results do not preclude any future uses (as bounded by the rural-residential scenario), allow unrestricted use of shallow zone soils, and pose no threat to groundwater or the Columbia River. The 100-K-55:1, 100-K-56:1, 116-KW-4, and 116-KE-5 sites were verified to be remediated in accordance with the ROD and may be backfilled.

**Description:** The waste site is the gravity flow effluent pipelines that serviced the 105-KE Reactor. They terminated at the 116-K-1 Crib, the 116-K-2 Trench, and the 116-KE-4 retention basins. The effluent lines were primarily carbon steel pipes ranging in size from 3 inches to 72 inches in diameter. This site has been divided into three subsites.

Subsite 1 has been remediated and Interim Closed Out. Subsite 1 included the underground process effluent pipelines north of the 105 KE Reactor from the outside of the security fence. The pipelines terminated at the 116-K-1 Crib, the 116-K-2 Trench, and the 116-KE-4 Retention Basins. A portion of 100-K-56:1 was removed with the excavation of the 116-K-1 crib in 2003. The remainder of 100-K-56:1 was remediated and Interim Closed Out in 2005.
Subsite 2 consists of 36 inch and 72 inch diameter process effluent underground pipelines located inside the original 100-K Area security fence (note: the fence has now been removed). These pipelines exited the west side of 105-KE reactor. The 72 inch line extended beyond the former security fence, and was addressed with Subsite 1. The 36 inch line tied into the 100-K-47 concrete sewer. The 100-K-56:2 pipeline that was located in remediation area AG Zone 1 and Zone 3 (northwest of 105KE) was removed in 2011.

Subsite 3 consists of process sewer pipeline segments located near the 116-K-3 Outfall Structure and the 116-K-4 Retention Basins. These pipe segments are adjacent to the remediated 100-K-56:1 excavation area. They were not considered part of the remediation scope in 2003 and were left in place.

In the interest of preserving the reactor security fence and some active underground utility features, some segments of pipe were not removed in 2002-2005.

**Location:** The pipelines mostly run in a north-south direction, northeast of the 105-KE Reactor Building.

**Related Sites/Structures:** The waste site is related to the 105-KE Reactor, 100-K-79, the 116-K-3 Outfall, the 100-K-83 Spillway, the 100-K-80 River Pipelines, the 116-K-1 Crib, the 116-K-2 Trench, the 150-KE, and the 116-KE-4 Retention Basins.

**Process Description:** The effluent system transported the reactor process effluent water by means of gravity flow to the river. There, the effluent water was discharged underwater to be diluted both thermally and radioactively by the flow of the river. The effluent system piping was located underground to provide shielding from the radioactive water. Before the water was discharged into the river, it was held for a period of time in retention basins, located approximately midway between the reactor building and the river, to allow decay of short-lived radioisotopes. In addition, the basins served to hold up flow of effluent with high radioactive isotope concentrations resulting from a ruptured fuel element. This effluent could be isolated and diverted by gravity to an open pond area, from which the effluent filtered through the ground before discharging to the river. Between the 105-KE Reactor Building downcomer outlet and the diversion valve box at the inlet of the 107-K Retention Basins, the effluent pipeline was a single, 1.83-meter (72-inch), carbon steel pipeline measuring 277 meters (908 feet) in length. At the diversion valve box the flow could be diverted to any or all of the three retention basins by three, motor-operated, 1.83-meter (72-inch), butterfly valves. A 1.83-meter (72-inch) bypass pipeline was provided around the diversion valve station. This bypass pipeline tied into the inlet piping of one of the retention basins. During normal operation of the effluent system, flow was restricted in this bypass pipeline by an inverted ‘U’ bend which extended 9.1 meters (30 feet) higher than the elevation of the diversion valve station. However, if all the valves closed, the effluent water flowed over the inverted ‘U’ bend and into the basin. The inlet 1.83-meter (72-inch) effluent piping ran to the side of a basin and discharged into an inlet chute, which in turn discharged to the bottom of the basin. The basin discharged to the river through a sump at the center of the basin. The basin discharge piping extended from the sump beneath the basins in reinforced concrete tunnels at the sides of the basins. The basin discharge piping was 1.7-meter (66-inch) carbon steel piping. The basin discharge piping combined into a common effluent pipeline. This pipeline discharged into the outfall structure. The common effluent from the 105-KE Reactor was a 1.7-meter (66-inch) pipeline. The combined length of the discharge pipes from the three basins was 752 meters (2,469 feet). The effluent pipe system was Dresser coupling connected. Concrete anchors were provided at each turn in the pipeline. The motor operated valves in the effluent system were controlled from the 105-KE Building Control Room. Miscellaneous piping included pipes to the 116-K-1 Crib, 116-K-2 Trench, and process sewer and piping to and from the 150-KE Heat Recovery Building. Discharges to 116-K-1 and 116-K-2 were made via 910-millimeter (36-inch) pipes that combined to flow into a 1,070-millimeter (42-inch) steel main pipe. Discharges to the process sewer were made through 250-millimeter (10-inch) steel pipes that combined into a 360-millimeter (14-inch) steel main pipe. Effluent from the 150-KE Building consisted of a 610-millimeter (24-inch), 460-millimeter (18-inch), 100-millimeter (4-
inch) and 76-millimeter (3-inch) steel effluent piping system. Effluent from the 105-KE and 150-KE Buildings could bypass the retention basins through a 910-millimeter (36-inch) or a 300-millimeter (12-inch) steel pipe. Pipe depth varied from 1.3 meters (4 feet) to 9.7 meters (32 feet). The deepest pipe ran under an elevated contour that coincided with the retention basin exclusion fence.

Waste Type: Construction Debris

Waste Description: The waste was contaminated steel piping, concrete, and soil. Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, diatomaceous earth (a scouring agent), and sodium dichromate. Water pH was maintained at about 7.5, and free chlorine residual was about 0.2 milligrams per liter. Radionuclide content at the retention basin during sampling by Richards for UNI-946, included the following: cesium-134, plutonium 239/240, cesium-137, strontium-90, hydrogen-3, nickel-63, europium-152, europium-154, europium-155, and cobalt-60.

Type: Radioactive Process Sewer

Status: Inactive

Description: 100-K-56 subsite 1 has been remediated and Interim Closed Out. The 100-K-56 pipelines consisted of the gravity-flow process effluent pipelines that formerly serviced the 105-KE Reactor, terminating at the 116-K-1 Crib, the 116-K-2 Trench, and the 116-KE-4 retention basins. Subsite 1 is the portion of pipeline from the 105-KE reactor building to the 116-K-1 Crib, the 116-K-2 Trench, and the 116-KE-4 retention basins. A portion of the pipeline was removed during the remediation of the 116-K-1 crib.

Location: The pipelines ran from outside the 105-KE Reactor security fence to the 116-K-1 Crib, the 116-K-2 Trench, and the 116-KE-4 retention basins.

Related Sites/Structures: The remediated pipelines are associated with the 100-K-56:3 pipe segments that were left in place.

Waste Type: Oil

Waste Description: The waste is contaminated steel piping, concrete, and soil.

Closure Info: Remedial action activities at the 100-K reactor effluent pipelines began on December 9, 2002 by Washington Closure Hanford (WCH). Remediation of the pipelines involved excavation and
staging of overburden material and removal of contaminated piping, debris and soil at the 100-K-55:1, 100-K-56:1, 116-KW-4 and 116-KE-5 waste sites. Contaminated materials were disposed at the ERDF. Remedial action excavation was completed on April 15, 2005. The previously documented waste site boundaries for the 116-KW-4 and 116-KE-5 sites were much larger than the actual footprint of the heat recovery facilities. The soil area beneath each of the former heat recovery stations was excavated in its entirety with the removal of the co-located pipelines. Approximately 55,960 square meters (602,350 sq ft) of plan area was excavated, including excavation within the deep zone (greater than 4.6 meters [15 ft] below ground surface) up to 8.8 meters (29 ft) below ground surface where necessary to complete remediation. Approximately 86,551 metric tons (95,406 U.S. tons) of material from the sites was removed and disposed at the ERDF. The active 100-K-47 concrete culvert was not removed during remediation of the adjacent section of the 100-K-55 pipeline. Several 100-K-56 pipe segments, located west of 116-KE-4, were not included in the remediation scope.

The contaminated materials from these sites have been excavated and disposed at the ERDF. The remaining soils at the sites have been sampled, analyzed, and modeled, and the results do not preclude any future uses (as bounded by the rural-residential scenario), allow unrestricted use of shallow zone soils, and pose no threat to groundwater or the Columbia River. The 100-K-55:1, 100-K-56:1, 116-KW-4, and 116-KE-5 sites were verified to be remediated in accordance with the ROD and may be backfilled.

<td>Description:</td>
<td>100-K-56 Subsite 2 consists of the 1.8 meter (72 in.) diameter pipeline and a 91 cm (36 in.) diameter underground effluent pipeline located inside the 105-KE Reactor security fence (although this fence has since been removed). Both the 91 cm (36 in.) and 1.8 meter (72 in.) diameter process effluent underground pipelines exited the west side of the 105-KE Reactor. The 91 cm (36 in.) diameter pipeline connected with the 100-K-3 heat exchanger pit and pump pit and traveled north and turned northwest to tie into the 1.68 meter by 1.68 meter (66 in.) 100-K-47 concrete sewer. Short lengths of 5.1 cm (2 in.) and 15.2 cm (6 in.) diameter pipelines connected the 91 cm (36 in.) diameter process effluent line to the 100-K-3 pump pit. The 1.8 meter (72 in.) diameter pipeline exited the reactor and continued north for approximately 90 meters (295 ft.), where it passed under the security fence and became 100-K-56 Subsite 1. A portion of the 100-K-56:2 pipeline, located in remediation area AG Zone 1 (northwest of 105KE), was removed during 2009 through 2011. The 0.9 m (36 in.) pipeline, located in remediation area AG Zone 3 was also removed in 2011. Sample Area #15 of this excavation site exceeded remediation goals for Eu-152 and received a cover of backfill material. The 1.8 meter (72 in.) diameter pipeline connected to the 100-K-3 heat exchanger pit via a 7.6 cm (3 inch) diameter pipeline. The pipelines connecting the 0.9 meter (36 in.) and 1.8 meter (72 in.) pipelines to 100-K-3 were removed during this activity.</td>

Type: Radioactive Process Sewer
Status: Inactive

**Description:** Subsite 3 consists of process sewer pipeline segments located near the 116-K-3 Outfall Structure and the 116-K-4 Retention Basins. These pipe segments are adjacent to the remediated 100-K-56:1 excavation area. They were not considered part of the remediation scope in 2005 and were left in place.

The pipe segments either terminated at the 116-K-3 outfall, or tied into the 100-K-47 and 100-K-55 pipelines near the 1908-KE building.

**Location:** The pipe segments are located north of the 100-KE reactor operation area.

**The SubSite is Part Of:**
Code: 100-K-56
Names: 100-K-56; 100-KE Reactor Cooling Water Effluent Underground Pipelines; 100-KR-1 Pipelines

Type: Process Sewer
Status: Inactive

**Description:** This site includes the underground process sewer pipeline that begins at 165-KW and runs up to the point of intersection with the 30.5 and 40.6-centimeter (12 and 16-inch) pipelines coming from 105-KW Reactor. The portion of the sewer that extends from the 165-KW Building to the point of intersection with the 30.5 and 40.6-centimeter (12 and 16-inch) pipelines coming from 105-KW Reactor is a 1.68 by 1.68-meter (66 by 66-inch) concrete sewer.

This site does not include those underground process sewer pipelines that begin at the 105-KE Reactor, the 105-KW Reactor, the 165-KE, the 190-KE, or the 1706-KE, and terminate at the 116-K-3 Outfall. These components are included in 100-K-47. The site has been split because of the different programmatic responsibilities associated with the two sites.

The site does not include the facilities where the pipelines terminate, or pipelines that are housed within building structures, which are addressed separately. This site does not include the radioactive process sewer pipelines, water supply pipelines, glycol heat pipelines, or other reactor effluent underground pipelines addressed by other sites.

**Location:** The process sewer originates on the north side of 165-KW and runs east and then northeast to a
point where it meets the process sewer pipelines coming from 105-KW. At that point the site is described in 100-K-47.

Related Sites/Structures:
The site is related to the 165-KW Building.

Waste Type: Demolition and Inert Waste

Waste Description:
Discharges included overflows from chemical makeup facilities that included chemical additives to reactor cooling water, e.g., aluminum sulfate (alum), with excess hydrated calcium oxide, sulfuric acid, and chlorine. Water pH was maintained at about 7.5, and free chlorine residual was about 0.3 milligrams per liter. Other discharges to the system included: filter backflush waste water; coagulated sediments from the water treatment settling basins; demineralizer regeneration wastes, which included neutralized sulphuric acid and sodium hydroxide; brine wastes from water softeners; and pump cooling waste water.

Code: 100-K-61
Classification: Accepted

Names: 100-K-61; 117-KW Filter Building
Reclassification: None

Type: Process Unit/Plant
Start Date: 1/1/1960
End Date: 1/1/1970

Description:
The ventilation exhaust filter building houses blowers and particulate filters used to treat the ventilation exhausted from the 105-KW Reactor Building. Included in this site are the 117-KW Building, the intake ventilation duct from the 105-KW Reactor Building, and the exhaust ventilation ducts to the 116-KW Reactor Exhaust Stack. A large portion of the building is below ground. The building and duct work are all made of reinforced concrete, 0.3 to 0.6 meters (1 to 2 feet) thick. The building is 12.2 meters (40 feet) high with 2.4 meters (8 feet) above grade. A soil berm is built up around the building from grade level to the top of the structure. The hatch on the top of the above ground portion of the filter structure is posted as Contamination Area and Danger-Restricted Area, Multiple Hazards.

The building is divided into two large filter cells with a smaller operating area between them. The filter cells each can hold six filter frames (two wide and three deep). The filter frames were designed to hold thirty-six filters that were 0.6 meters (2 feet) square by 0.3 meters (1 foot) thick. There are spaces between the frames to allow access for filter maintenance. The operating area between the two cells is divided into two levels. The upper level, called the access gallery has ten doors that lead from it. Four doors open into each of the filter cells and the two other doors provide access to the intake and exhaust ducts. The operating gallery is located below the access gallery. A sump is located at each end of the operating gallery to collect incidental drainage from above. A large open area extends the full length of the structure above the access gallery and the filter cells. It ranges in height between 2.5 and 2.4 meters (8.1 and 7.8 feet) due to the structure's sloping roof. The space provides access to the cement cover blocks that are positioned over each of the filter frames.

Location: The 117-KW Filter Building is located east of the 105-KW Reactor Building, northeast of the 116-KW Reactor Exhaust Stack.

Related Sites/Structures:
The site is associated with the 105-KW Reactor (118-KW-1), the 116-KW Reactor Exhaust Stack (132-KW-1), the 119-KW Sample Building, and the 1904-K Process Sewer (100-K-47).

Process Description:
The 117-KW Building was constructed as part of the reactor confinement project. Prior to its use, unfiltered ventilation was exhausted directly from the reactor to the atmosphere. The confinement project diverted the exhaust just before the stack and routed it to the filter building where it passed through a series of filters. The filtered exhaust was then routed back to the...
ventilation exhaust stack where it was discharged to the atmosphere. Sealwells within the filter building provided the ability to direct the exhaust into one or both of the filter cells.

**Waste Type:** Abandoned Chemicals  
**Waste Description:** When the 116-KW Reactor Exhaust Stack was shortened, the debris was placed inside the stack. Some debris is probably within the exhaust duct connecting the filter building to the stack.

**Waste Type:** Abandoned Chemicals  
**Waste Description:** The building contains radiologically contaminated equipment and surfaces that remain from when it was in use.

---

**Code:** 100-K-62  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (8/29/2012)  
**Type:** Process Unit/Plant  
**Names:** 100-K-62; 117-KE Filter Building  
**Start Date:** 1/1/1960  
**End Date:** 1/1/1971  
**Location:** The 117-KE Filter Building was located east of the 105-KE Reactor Building, northeast of the 116-KW Reactor Exhaust Stack.

**Process Description:** The 117-KE Building was constructed as part of the reactor confinement project. Prior to its use, unfiltered ventilation was exhausted directly from the reactor to the atmosphere. The confinement project diverted the exhaust just before the stack and routed it to the filter building where it passed through a series of filters. The filtered exhaust was then routed back to the ventilation exhaust stack where it was discharged to the atmosphere. Sealwells within the filter building provided the ability to direct the exhaust into one or both of the filter cells.

**Related Sites/Structures:** The site is associated with the 105-KE Reactor (118-KE-1), the 116-KW Reactor Exhaust Stack (132-KE-1), the 119-KE Sample Building, and the 1904-K Process Sewer (100-K-47).

**Closure Info:** Remediation and sampling began in January of 2009 and was completed in April of 2012. The large excavation area, known as 100-K Area AH, encompassed waste sites 100-K-6, 100-K-46, 100-K-62 and 132-KE-1. The excavation area also included Stockpile #4, which contained overburden and layback soil from the excavation of the 116-KE-1 Condensate Crib. Information supporting the use of Stockpile #4, located within the AH excavation, as backfill was also included in the DOE/RL-2012-38 Remaining Sites Verification Package report.

---

Hanford Site Waste Management Units Report  
February 2015
Remediation of the identified Area AH waste sites was accomplished by demolishing the structures and excavating contaminated soil. All waste (soil and debris) associated with these waste sites was disposed at the Environmental Restoration and Disposal Facility (ERDF). The demolition activities were conducted using standard demolition techniques, including explosives for demolition of 132-KE-1 (116-KE Reactor Exhaust Stack). Approximately 1,809 ERDF containers (37,700 tons) of waste from these waste sites were sent to the ERDF for disposal.

Remediation of the 100-K-6 vacuum pit began in August 2011 and was completed in September 2011. An excavator was used to remove the vacuum pit and excavate the surrounding soil. The original waste site description estimated the depth of the cyclone separator as 9.14 meters (30 ft). However, during remediation the actual excavation depth was measured as 5.8 meters (19 ft).

The remediation of the 100-K-46 french drain was associated with the removal of the 119-KE building, which began in January 2009 and was completed in February 2009. The drywell was less than 1.5 meters (5 ft) deep.

The remediation activities at the 100-K-62 filter building began in August 2010 and were completed in May 2011. An excavator was used to remove the vacuum pit and excavate the surrounding soil. The maximum depth from grade within the waste site footprint was approximately 10.6 meters (34.8 ft).

The remediation activities at waste site 132-KE-1 exhaust stack began in July 2010 and were completed in September 2011. Removal of the above-grade portion of the stack was conducted using explosives placed near the base of the stack. The explosion caused the debris to fall in a designated area. The material was then loaded and disposed at ERDF. The entire below grade portion of the stack base was then removed. The maximum depth from grade within the waste site footprint was approximately 6.1 meters (20 ft).

In October of 2010, excavation of the overburden and layback soil for the 116-KE-1 Crib began and Stockpile #4 was created. Samples were collected in the 116-KE-1 waste site footprint and sent for analytical leach testing of the soils to determine carbon-14 leachability from the 100-K soil. During remediation of the co-located waste sites inside the AH excavation area, the 116-KE-1 crib was partially backfilled with soil from Stockpile #4 as a contamination control measure.

Note: Area-wide carbon-14 contamination exists in the deep zone above the criteria for protectiveness. This contamination is associated with the 105-KE Reactor ventilation filtration system and the deep contamination from the condensate that collected in the previously excavated 116-KE-1 Condensate Crib. Additional remediation of the deep vadose zone cannot be completed in proximity to the 105-KE Reactor without impacting structural stability. Available information about the nature and extent of the carbon-14 contamination has been documented in the 116-KE-1 Condensate Crib waste site description. Due to the depth of the contamination, the carbon-14 remediation will coincide with the final decision on 105-KE reactor removal.

**Code:** 100-K-66  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 100-K-66; 165-KW Power Control Building  
**Type:** Control Structure  
**Status:** Inactive  
**Start Date:**  
**End Date:**  
**Description:** The building is painted a pink color and has three large stacks on the west end of the building.
This site is a bomb resistant shelter without windows. All ventilation is supplied by fans. The building is posted Danger - Restricted Area - Asbestos (internal building asbestos).

**Location:**
The 165-KW Building is located between the 183-KW Water Treatment Plant and the 105-KW Reactor Building. The 190-KW Main Pumphouse directly adjoins the south side of the 165-KW Power Control Building.

**Process Description:**
The purpose of the 165-KW Power Control Building was to provide housing for the powerhouse, control room, valve pit, and electrical switchgear of the water supply system.

The control room and valve pit are located directly over the pipe tunnel that extends from the 183 Building to the 105 Building. This section is 15 meters (50 feet) wide, and the two rooms are separated by a 46-centimeter (18-inch) concrete wall. The valve pit contains most of the motor-operated valves included in the cooling water, service water, and raw water systems. Steel grating serves as a floor at the operating level above the pit.

The electrical switchgear room houses all switchgear for the electrical system. Outside and adjoining the building is the 230 kilovolt Switchyard. Directly beneath the 165 Switchgear Room is the electrical cable room, occupied by two battery rooms, control panels for battery power, and 4,160 volt switchgear and building service transformers.

The control room is the nerve center of the entire water and power plant, more so than the comparable 190 Control Rooms in any of the older reactor areas. The importance of this center to the continuity of operation of the area has been recognized by its placement within the bomb-resistant shelter that also encloses the boiler and turbine room, the electrical switchgear, and the valve pit. Virtually all important pieces of equipment pertaining to maintaining water flow are started, stopped, or positioned directly from the control board in this room.

Steam is supplied by three complete package boilers. The steam is used to generate emergency power by three steam-driven turbo-generator sets, which provide 4.16 kilowatts of power to buses supplying selected low-lift pump motors in the 190-KW Building for reactor cooling and miscellaneous critical electrical components in the system. The power may also be used to operate river pumps to supply raw water to the 183-KW Water Treatment Plant.

In addition to the electrically-operated pumping system, a separate steam turbine driven pump is provided in the 190 Building to supply emergency flow to the reactor in the event both primary Bonneville Power Administration (BPA) and turbo-generator electrical power fails.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The building contains asbestos and has been cleaned twice (in 1993) for PCBs.

**Names:** 100-K-67; 165-KE Power Control Building

**Type:** Control Structure

**Status:** Active

**Description:** The building is painted a pink color and has three large stacks on the west end of the building. This site is a bomb resistant shelter without windows. All ventilation is supplied by fans. The building is posted Danger - Restricted Area - Asbestos (internal building asbestos).

**Location:** The 165-KE building is located between the 183-KE Water Treatment Plant and the 105-KE Reactor Building. The 190-KE Main Pumphouse directly adjoins the south side of the 165-KE
Power Control Building.

Process Description:
The purpose of the 165-KE Power Control Building was to provide housing for the power house, control room, valve pit, and electrical switchgear of the water supply system. It is constructed as a bomb resistant shelter, without windows and all ventilation is supplied by fans.

The control room and valve pit are located directly over the pipe tunnel that extends from the 183 Building to the 105 Building. This section is 50 feet wide, and the two rooms are separated by an 18-inch concrete wall. The valve pit contains most of the motor-operated valves included in the cooling water, service water, and raw water systems. Steel grating serves as a floor at the operating level above the pit.

The electrical switchgear room houses all switchgear for the electrical system. Outside and adjoining the building is the 230 kilovolt Switchyard. Directly beneath the 165 Switchgear Room is the electrical cable room, occupied by two battery rooms, control panels for battery power, and 4160 volt switchgear and building service transformers.

The control room is the nerve center of the entire water and power plant, more so than the comparable 190 Control Rooms in any of the older reactor areas. The importance of this center to the continuity of operation of the area has been recognized by its being placed within the bomb-resistant shelter that also encloses the boiler and turbine room, the electrical switchgear, and the valve pit. Virtually all important pieces of equipment pertaining to maintaining water flow are started, stopped, or positioned directly from the control board in this room.

Steam is supplied by three complete package boilers. the steam is used to generate emergency power by three steam-driven turbo-generator sets, which provide 4.16 kilowatt power to buses supplying selected low-lift pump motors in the 190-KE Building for reactor cooling and miscellaneous critical electrical components in the system. The power may also be used to operate river pumps to supply raw water to the 183-KE Water Treatment Plant.

In addition to the electrically-operated pumping system, a separate steam turbine driven pump is provided in the 190 Building to supply emergency flow to the reactor in the event both primary (BPA) and turbo-generator electrical power fails.

---

**Code:** 100-K-68

**Names:** 100-K-68; 105-KE Pump Gallery and Catch Tank; D Sump

**Type:** Catch Tank

**Status:** Inactive

**Description:** The waste site has been remediated and Interim Closed Out. The structure was constructed of an 2.44 meter (8 foot) diameter corrugated steel caisson. A vinyl lined concrete catch tank was located at the bottom of the caisson. The pump gallery, containing two sump pumps and a ladder for access was above the tank. The total depth of the caisson is 10.87 meters (35.67 feet) and extended from just above grade level.

**Location:** The site was located approximately 22 meters (61.8 feet) north of the northwest corner of the 105-KE Reactor Building and is located just south of 116-KE-3 (105KE Storage Basin French Drain).

**Related Sites/Structures:** The catch tank receives basin overflow from an 20.3 centimeter (8 inch) galvanized storage basin overflow header and diverts tank overflow to site 116-KE-3 (Sub basin drainage disposal system).
Waste Type: Misc. Trash and Debris

Waste Description: Waste water from 105-KE Spent Fuel Storage Basin sub-basin drainage header.

Closure Info: For the purposes of implementing and documenting remedial activities, the 100-K Area was divided into several informal remediation areas. The waste sites of this remedial activity were informally designated as being located within the Area AG Zone 1 remediation area, adjacent to the northwest corner of the reactor. (Note: One waste site located within Area AG Zone 1, the 116-KE-3 (105-KE Fuel Storage Basin Sub-Basin Drainage Disposal System Crib), was not remediated. Due to the extend of the deep zone contamination attributed to the 116-KE-3 waste site, it was placed in an “excluded region” within Area AG Zone 1. Waste site 116-KE-3 will be addressed at a later date.)

The remediated waste sites located in Area AG Zone 1 include 100-K-68, 100-K-69, 100-K-70, 100-K-71 and 100-K-3. A portion of the 100-K-3 pipeline was remediated with the area AG Zone 2 (see DOE/RL-2012-40). (Note: Portions of 100-K-47 and 100-K-56 pipelines were removed and considered part of the Area AG Zone 1 remediation activities. Approximately 452 feet of the 100-K-56, 36-inch pipeline was removed from Area AG Zone 1 and 3. Approximately 338 feet of the 100-K-56, 72-inch pipeline was removed from Area AG Zone 1 and 3. Approximately 344 feet of the 100-K-47, 16-inch pipeline (exiting the 100-K-71 collection box) was removed from Area AG Zone 1 and 3. The remaining portions of the 100-K-47 and 100-K-56 pipelines will be addressed in future remediation activities.)

Remediation of the waste sites within Area AG Zone 1 began in September 2009 and was finished in May 2012. In-process samples were collected and radiological surveys were conducted to guide the remediation. Contaminated structures, pipelines, and associated soil and debris attributed to these waste sites have been removed and disposed at the ERDF. During this remedial activity, Stockpile #3 was created from excavated soil from the overburden and layback from Area AG Zone 1 waste sites. Radiological surveys were conducted on the material prior to placing it in the stockpile. Stockpile #3 was located northwest of Area AG.

The 105-KE fuel storage basin (100-K-42 waste site) borders the Area AG Zone 1. UPR-100-K-1 (105-KE Fuel Storage Basin Leak) is an unplanned release from the discharge chute of the fuel storage basin. It leaked highly radioactive water underneath the basin into the ground for an unknown period of time. Boreholes were drilled to evaluate the subsurface soil conditions. The results indicated significant residual radioactivity underneath the footprint of the fuel storage basin. The residual radioactivity distorted the radiological surveys conducted within the adjacent Area AG Zone 1.

The remediation of the 100-K-3 waste site began in January 2010 and was completed in May 2012. The remediation of this waste site included excavation of the heat exchanger, the pump pit, associated piping and contaminated soil. A total of 709 ERDF containers (11,513 metric tons [12,691 short tons]) was disposed at the ERDF from the Area AG 100-K-3 waste site (Zones 1 and 2 combined). Along with remediation of the waste sites in Area AG Zone 1, a 20.3 cm (8 in.) diameter Process Sewer Outside (PSO) drain line was also excavated. This pipeline exited the 100-K-3 heat exchanger pit and tied into the 100-K-47 concrete process sewer. This portion of pipeline was removed with a composite in-process sample taken along the length of the excavation in August 2011. The in-process sample results did not exceed the RAGs. The region within Area AG Zone 1 where this pipeline was removed was included in the Shallow Zone decision unit. In addition, the 100-K-3, 2.54 cm (1 in.) diameter PIEX pipeline (connecting the 100-K-3 heat exchanger to the 105-KE reactor) was documented in the shallow zone decision unit. This pipeline was originally buried 1.2 meters (4 ft) deep. When removed, the footprint was wholly contained within the layback region of the 100-K-56 waste
The 100-K-68 waste site structure (caisson with catch tank) was removed during waste site remediation. The remediation of the 100-K-68 waste site began in April 2010 and was completed in May 2012. The remediation of the waste site excavated the corrugated steel caisson, catch tank and pumping equipment. However, deep residual contamination associated with the 116-KE-3 waste site remains underneath the footprint of the 100-K-68 waste site.

The remediation of the 100-K-69 waste site began in April 2010 and was completed in May 2012. The remediation of the waste site excavated the concrete sump and associated contaminated soil.

The remediation of the contaminated soil beneath the 100-K-70 waste site began in April 2010 and was completed in May 2012. The tank associated with the 100-K-70 waste site had been previously removed, prior to the fuel storage basin demolition in 2008.

A total of 599 ERDF containers (11,920 metric tons [13,139 short tons]) was disposed at the ERDF from the combined 100-K-68, 100-K-69, and 100-K-70 waste sites.

The remediation of the 100-K-71 waste site began in March 2010 and was completed in May 2012. The remediation of the waste site included excavation of the collection box and associated contaminated soil. A total of 285 ERDF containers (5,858 metric tons [6,457 short tons]) was disposed at the ERDF from the 100-K-71 waste site. In-process samples collected at the collection box were analyzed for carbon-14 and tritium. The results indicated no residual contamination of these COCs.

The remediation of portions of the 100-K-47 pipeline began in November 2009 and was completed in September 2011. The partial remediation of the pipeline waste site included excavation of the underground process sewer pipelines and associated contaminated soil. In-process samples were collected within the remediated portion of the 100-K-71 waste site (collection box) footprint, because the 10.2 cm (4 in.) diameter cement asbestos pipeline from the 117-KE Filter Building (100-K-62 waste site) terminated at the collection box. Samples were analyzed for carbon-14 and tritium. The results indicated no residual contamination of these contaminants of concern (COCs). Therefore, carbon-14 and tritium were eliminated from the list of COCs for this waste site. A total of 1,240 ERDF containers (20,802 metric tons [22,930 short tons]) was disposed at the ERDF from the Area AG 100-K-47 waste site (Zones 1 and 3 combined).

The remediation of portions of the 100-K-56 Subsite 2 pipeline began in September 2009 and was completed in June 2011. The remediation excavated the part of the process effluent underground pipelines and associated contaminated soil. A total of 800 ERDF containers (13,071 metric tons [14,408 short tons]) was disposed at the ERDF from the Area AG 100-K-56 waste site (in Zones 1 and 3 combined).

A total of 63,292 metric tons of material was disposed at the ERDF during the AG Zone 1 remediation activity. (33,873 metric tons was related to the 100-K-47 and 100-K-56 partial pipeline excavations.)

No evidence of spills or leaks from Area AG Zone 1 waste sites was found after remediation. Post remediation, a Global Positioning Environmental Radiological Survey (GPERS) and radiological surveys using hand-held instrumentation were conducted. The GPERS is rendered ineffective in regions close to the 105-KE Reactor fuel storage basin (100-K-42 waste site) and the unplanned release site (UPR-100-K-1) due to the sensitive detection capabilities of the sodium iodide instrumentation and the elevated radiation background levels associated with the fuel storage basin subsurface soil.
Follow-up radiological surveys using hand-held instruments were conducted in the region around the 100-K-68, 100-K-69, 100-K-70, and 100-K-71 waste sites, immediately north of the fuel storage basin. The survey indicated elevated radiological contamination where piping from the 105-KE Reactor fuel storage basin traveled to the 105-KE Collection Box (100-K-71 waste site). One of the pipelines entering the south side of the collection box was equipped with a direct buried flanged gate valve, located at a depth of approximately 8.5 meters (27 ft 11 in.). A focused verification sample of this location was collected to determine contamination levels present in the soil. This follow-up survey also indicated elevated radiological contamination in the area around the 100-K-68 waste site. Verification sampling beneath the 100-K-68 waste site was not conducted because the residual soil contamination is attributed to the 116-KE-3 waste site. NOTE: 116-KE-3 is located within Area AG Zone 1 but was not part of the remediation work scope.

---

**Code:** 100-K-69  
**Classification:** Accepted  

**Names:** 100-K-69; 105-KE Sump C  
**Reclassification:** Interim Closed Out (10/23/2012)  

**Type:** Sump  
**Start Date:**  
**End Date:**  

**Status:** Inactive  

**Description:** The waste site has been remediated and Interim Closed Out. The 100-K-69 waste site was a rectangular concrete structure, measuring approximately 2.3 meters (7.5 ft) by 1.4 meters (4.6 ft) by 3.7 meters (12 ft) deep. It received water from 105-KE fuel storage basin floor drains. Two electric powered sump pumps returned the drain water to the basin.

**Location:** The sump was located just off the north side of the 105-KE Reactor Building and is near the northwest corner of the building.

**Waste Type:** Misc. Trash and Debris

**Waste Description:**

**Closure Info:** For the purposes of implementing and documenting remedial activities, the 100-K Area was divided into several informal remediation areas. The waste sites of this remedial activity were informally designated as being located within the Area AG Zone 1 remediation area, adjacent to the northwest corner of the reactor. (Note: One waste site located within Area AG Zone 1, the 116-KE-3 (105-KE Fuel Storage Basin Sub-Basin Drainage Disposal System Crib), was not remediated. Due to the extend of the deep zone contamination attributed to the 116-KE-3 waste site, it was placed in an "excluded region" within Area AG Zone 1. Waste site 116-KE-3 will be addressed at a later date.)

The remediated waste sites located in Area AG Zone 1 include 100-K-68, 100-K-69, 100-K-70, 100-K-71 and 100-K-3. A portion of the 100-K-3 pipeline was remediated with the area AG Zone 2 (see DOE/RL-2012-40). (Note: Portions of 100-K-47 and 100-K-56 pipelines were removed and considered part of the Area AG Zone 1 remediation activities. Approximately 452 feet of the 100-K-56, 36-inch pipeline was removed from Area AG Zone 1 and 3. Approximately 338 feet of the 100-K-56, 72-inch pipeline was removed from Area AG Zone 1 and 3. Approximately 344 feet of the 100-K-47, 12-inch pipeline exiting the 100-K-71 collection box was removed from Area AG Zone 1 and 3. Approximately 344 feet of the 100-K-47, 16-inch pipeline (exiting the 100-K-71 collection box) was removed from Area AG Zone 1 and 3. The remaining portions of the 100-K-47 and 100-K-56 pipelines will be addressed in future remediation activities.)

Remediation of the waste sites within Area AG Zone 1 began in September 2009 and was
finished in May 2012. In-process samples were collected and radiological surveys were conducted to guide the remediation. Contaminated structures, pipelines, and associated soil and debris attributed to these waste sites have been removed and disposed at the ERDF. During this remedial activity, Stockpile #3 was created from excavated soil from the overburden and layback from Area AG Zone 1 waste sites. Radiological surveys were conducted on the material prior to placing it in the stockpile. Stockpile #3 was located northwest of Area AG.

The 105-KE fuel storage basin (100-K-42 waste site) borders the Area AG Zone 1. UPR-100-K-1 (105-KE Fuel Storage Basin Leak) is an unplanned release from the discharge chute of the fuel storage basin. It leaked highly radioactive water underneath the basin into the ground for an unknown period of time. Boreholes were drilled to evaluate the subsurface soil conditions. The results indicated significant residual radioactivity underneath the footprint of the fuel storage basin. The residual radioactivity distorted the radiological surveys conducted within the adjacent Area AG Zone 1.

The remediation of the 100-K-3 waste site began in January 2010 and was completed in May 2012. The remediation of this waste site included excavation of the heat exchanger, the pump pit, associated piping and contaminated soil. A total of 709 ERDF containers (11,513 metric tons [12,691 short tons]) was disposed at the ERDF from the Area AG 100-K-3 waste site (Zones 1 and 2 combined). Along with remediation of the waste sites in Area AG Zone 1, a 20.3 cm (8 in.) diameter Process Sewer Outside (PSO) drain line was also excavated. This pipeline exited the 100-K-3 heat exchanger pit and tied into the 100-K-47 concrete process sewer. This portion of pipeline was removed with a composite in-process sample taken along the length of the excavation in August 2011. The in-process sample results did not exceed the RAGs. The region within Area AG Zone 1 where this pipeline was removed was included in the Shallow Zone decision unit. In addition, the 100-K-3, 2.54 cm (1 in.) diameter PIEX pipeline (connecting the 100-K-3 heat exchanger to the 105-KE reactor) was documented in the shallow zone decision unit. This pipeline was originally buried 1.2 meters (4 ft) deep. When removed, the footprint was wholly contained within the layback region of the 100-K-56 waste site.

The 100-K-68 waste site structure (caisson with catch tank) was removed during waste site remediation. The remediation of the 100-K-68 waste site began in April 2010 and was completed in May 2012. The remediation of the waste site excavated the corrugated steel caisson, catch tank and pumping equipment. However, deep residual contamination associated with the 116-KE-3 waste site remains underneath the footprint of the 100-K-68 waste site.

The remediation of the 100-K-69 waste site began in April 2010 and was completed in May 2012. The remediation of the waste site excavated the concrete sump and associated contaminated soil.

The remediation of the contaminated soil beneath the 100-K-70 waste site began in April 2010 and was completed in May 2012. The tank associated with the 100-K-70 waste site had been previously removed, prior to the fuel storage basin demolition in 2008.

A total of 599 ERDF containers (11,920 metric tons [13,139 short tons]) was disposed at the ERDF from the combined 100-K-68, 100-K-69, and 100-K-70 waste sites.

The remediation of the 100-K-71 waste site began in March 2010 and was completed in May 2012. The remediation of the waste site included excavation of the collection box and associated contaminated soil. A total of 285 ERDF containers (5,858 metric tons [6,457 short tons]) was disposed at the ERDF from the 100-K-71 waste site. In-process samples collected at the collection box were analyzed for carbon-14 and tritium. The results indicated no residual contamination of these COCs.
The remediation of portions of the 100-K-47 pipeline began in November 2009 and was completed in September 2011. The partial remediation of the pipeline waste site included excavation of the underground process sewer pipelines and associated contaminated soil. In-process samples were collected within the remediated portion of the 100-K-71 waste site (collection box) footprint, because the 10.2 cm (4 in.) diameter cement asbestos pipeline from the 117-KE Filter Building (100-K-62 waste site) terminated at the collection box. Samples were analyzed for carbon-14 and tritium. The results indicated no residual contamination of these contaminants of concern (COCs). Therefore, carbon-14 and tritium were eliminated from the list of COCs for this waste site. A total of 1,240 ERDF containers (20,802 metric tons [22,930 short tons]) was disposed at the ERDF from the Area AG 100-K-47 waste site (Zones 1 and 3 combined).

The remediation of portions of the 100-K-56 Subsite 2 pipeline began in September 2009 and was completed in June 2011. The remediation excavated the part of the process effluent underground pipelines and associated contaminated soil. A total of 800 ERDF containers (13,071 metric tons [14,408 short tons]) was disposed at the ERDF from the Area AG 100-K-56 waste site (in Zones 1 and 3 combined).

A total of 63,292 metric tons of material was disposed at the ERDF during the AG Zone 1 remediation activity. (33,873 metric tons was related to the 100-K-47 and 100-K-56 partial pipeline excavations.)

No evidence of spills or leaks from Area AG Zone 1 waste sites was found after remediation. Post remediation, a Global Positioning Environmental Radiological Survey (GPERS) and radiological surveys using hand-held instrumentation were conducted. The GPERS is rendered ineffective in regions close to the 105-KE Reactor fuel storage basin (100-K-42 waste site) and the unplanned release site (UPR-100-K-1) due to the sensitive detection capabilities of the sodium iodide instrumentation and the elevated radiation background levels associated with the fuel storage basin subsurface soil.

Follow-up radiological surveys using hand-held instruments were conducted in the region around the 100-K-68, 100-K-69, 100-K-70, and 100-K-71 waste sites, immediately north of the fuel storage basin. The survey indicated elevated radiological contamination where piping from the 105-KE Reactor fuel storage basin traveled to the 105-KE Collection Box (100-K-71 waste site). One of the pipelines entering the south side of the collection box was equipped with a direct buried flanged gate valve, located at a depth of approximately 8.5 meters (27 ft 11 in.). A focused verification sample of this location was collected to determine contamination levels present in the soil. This follow-up survey also indicated elevated radiological contamination in the area around the 100-K-68 waste site. Verification sampling beneath the 100-K-68 waste site was not conducted because the residual soil contamination is attributed to the 116-KE-3 waste site. NOTE: 116-KE-3 is located within Area AG Zone 1 but was not part of the remediation work scope.

<tr>
<td>Description:</td>
<td>The waste site has been remediated and Interim Closed Out. It was a modified steel storage tank for the 105-KE Spent Fuel Storage Basin radioactive drains. The tank was buried under a 1.8 meter (6 foot) deep earth berm. An absolute filter was located on the east end of the tank and a tank level gauge was located on the west end of the tank. A 0.9 meter (3 ft) diameter access port</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
was located at the approximate center of the tank and extended just above grade level. The tank associated with the 100-K-70 waste site was removed prior to the fuel storage basin demolition in 2008.

**Location:** The site was located approximately 8 meters (22.5 feet) north of the 105-KE Building.

**Related Sites/Structures:** A pipeline designated as 100-K-47 connected 100-K-70 to the 105-KE waste storage tank. This section of 100-K-47 pipeline was within the remediation area AG Zone 1 and was removed.

**Waste Type:** Equipment

**Waste Description:**

**Closure Info:** For the purposes of implementing and documenting remedial activities, the 100-K Area was divided into several informal remediation areas. The waste sites of this remedial activity were informally designated as being located within the Area AG Zone 1 remediation area, adjacent to the northwest corner of the reactor. (Note: One waste site located within Area AG Zone 1, the 116-KE-3 (105-KE Fuel Storage Basin Sub-Basin Drainage Disposal System Crib), was not remediated. Due to the extent of the deep zone contamination attributed to the 116-KE-3 waste site, it was placed in an "excluded region" within Area AG Zone 1. Waste site 116-KE-3 will be addressed at a later date.)

The remediated waste sites located in Area AG Zone 1 include 100-K-68, 100-K-69, 100-K-70, 100-K-71 and 100-K-3. A portion of the 100-K-3 pipeline was remediated with the area AG Zone 2 (see DOE/RL-2012-40). (Note: Portions of 100-K-47 and 100-K-56 pipelines were removed and considered part of the Area AG Zone 1 remediation activities. Approximately 452 feet of the 100-K-56, 36-inch pipeline was removed from Area AG Zone 1 and 3. Approximately 338 feet of the 100-K-56, 72-inch pipeline was removed from Area AG Zone 1 and 3. Approximately 344 feet of the 100-K-47, 12-inch pipeline exiting the 100-K-71 collection box was removed from Area AG Zone 1 and 3. Approximately 344 feet of the 100-K-47, 16-inch pipeline (exiting the 100-K-71 collection box) was removed from Area AG Zone 1 and 3. The remaining portions of the 100-K-47 and 100-K-56 pipelines will be addressed in future remediation activities.)

Remediation of the waste sites within Area AG Zone 1 began in September 2009 and was finished in May 2012. In-process samples were collected and radiological surveys were conducted to guide the remediation. Contaminated structures, pipelines, and associated soil and debris attributed to these waste sites have been removed and disposed at the ERDF. During this remedial activity, Stockpile #3 was created from excavated soil from the overburden and layback from Area AG Zone 1 waste sites. Radiological surveys were conducted on the material prior to placing it in the stockpile. Stockpile #3 was located northwest of Area AG.

The 105-KE fuel storage basin (100-K-42 waste site) borders the Area AG Zone 1. UPR-100-K-1 (105-KE Fuel Storage Basin Leak) is an unplanned release from the discharge chute of the fuel storage basin. It leaked highly radioactive water underneath the basin into the ground for an unknown period of time. Boreholes were drilled to evaluate the subsurface soil conditions. The results indicated significant residual radioactivity underneath the footprint of the fuel storage basin. The residual radioactivity distorted the radiological surveys conducted within the adjacent Area AG Zone 1.

The remediation of the 100-K-3 waste site began in January 2010 and was completed in May 2012. The remediation of this waste site included excavation of the heat exchanger, the pump pit, associated piping and contaminated soil. A total of 709 ERDF containers (11,513 metric tons [12,691 short tons]) was disposed at the ERDF from the Area AG 100-K-3 waste site (Zones 1 and 2 combined). Along with remediation of the waste sites in Area AG Zone 1, a

20.3 cm (8 in.) diameter Process Sewer Outside (PSO) drain line was also excavated. This pipeline exited the 100-K-3 heat exchanger pit and tied into the 100-K-47 concrete process sewer. This portion of pipeline was removed with a composite in-process sample taken along the length of the excavation in August 2011. The in-process sample results did not exceed the RAGs. The region within Area AG Zone 1 where this pipeline was removed was included in the Shallow Zone decision unit. In addition, the 100-K-3, 2.54 cm (1 in.) diameter PIEX pipeline (connecting the 100-K-3 heat exchanger to the 105-KE reactor) was documented in the shallow zone decision unit. This pipeline was originally buried 1.2 meters (4 ft) deep. When removed, the footprint was wholly contained within the layback region of the 100-K-56 waste site.

The 100-K-68 waste site structure (caisson with catch tank) was removed during waste site remediation. The remediation of the 100-K-68 waste site began in April 2010 and was completed in May 2012. The remediation of the waste site excavated the corrugated steel caisson, catch tank and pumping equipment. However, deep residual contamination associated with the 116-KE-3 waste site remains underneath the footprint of the 100-K-68 waste site.

The remediation of the 100-K-69 waste site began in April 2010 and was completed in May 2012. The remediation of the waste site excavated the concrete sump and associated contaminated soil.

The remediation of the contaminated soil beneath the 100-K-70 waste site began in April 2010 and was completed in May 2012. The tank associated with the 100-K-70 waste site had been previously removed, prior to the fuel storage basin demolition in 2008.

A total of 599 ERDF containers (11,920 metric tons [13,139 short tons]) was disposed at the ERDF from the combined 100-K-68, 100-K-69, and 100-K-70 waste sites.

The remediation of the 100-K-71 waste site began in March 2010 and was completed in May 2012. The remediation of the waste site included excavation of the collection box and associated contaminated soil. A total of 285 ERDF containers (5,858 metric tons [6,457 short tons]) was disposed at the ERDF from the 100-K-71 waste site. In-process samples collected at the collection box were analyzed for carbon-14 and tritium. The results indicated no residual contamination of these COCs.

The remediation of portions of the 100-K-47 pipeline began in November 2009 and was completed in September 2011. The partial remediation of the pipeline waste site included excavation of the underground process sewer pipelines and associated contaminated soil. In-process samples were collected within the remediated portion of the 100-K-71 waste site (collection box) footprint, because the 10.2 cm (4 in.) diameter cement asbestos pipeline from the 117-KE Filter Building (100-K-62 waste site) terminated at the collection box. Samples were analyzed for carbon-14 and tritium. The results indicated no residual contamination of these contaminants of concern (COCs). Therefore, carbon-14 and tritium were eliminated from the list of COCs for this waste site. A total of 1,240 ERDF containers (20,802 metric tons [22,930 short tons]) was disposed at the ERDF from the Area AG 100-K-47 waste site (Zones 1 and 3 combined).

The remediation of portions of the 100-K-56 Subsite 2 pipeline began in September 2009 and was completed in June 2011. The remediation excavated the part of the process effluent underground pipelines and associated contaminated soil. A total of 800 ERDF containers (13,071 metric tons [14,408 short tons]) was disposed at the ERDF from the Area AG 100-K-56 waste site (in Zones 1 and 3 combined).

A total of 63,292 metric tons of material was disposed at the ERDF during the AG Zone 1 remediation activity. (33,873 metric tons was related to the 100-K-47 and 100-K-56 partial
pipeline excavations.)

No evidence of spills or leaks from Area AG Zone 1 waste sites was found after remediation. Post remediation, a Global Positioning Environmental Radiological Survey (GPERS) and radiological surveys using hand-held instrumentation were conducted. The GPERS is rendered ineffective in regions close to the 105-KE Reactor fuel storage basin (100-K-42 waste site) and the unplanned release site (UPR-100-K-1) due to the sensitive detection capabilities of the sodium iodide instrumentation and the elevated radiation background levels associated with the fuel storage basin subsurface soil.

Follow-up radiological surveys using hand-held instruments were conducted in the region around the 100-K-68, 100-K-69, 100-K-70, and 100-K-71 waste sites, immediately north of the fuel storage basin. The survey indicated elevated radiological contamination where piping from the 105-KE Reactor fuel storage basin traveled to the 105-KE Collection Box (100-K-71 waste site). One of the pipelines entering the south side of the collection box was equipped with a direct buried flanged gate valve, located at a depth of approximately 8.5 meters (27 ft 11 in.). A focused verification sample of this location was collected to determine contamination levels present in the soil. This follow-up survey also indicated elevated radiological contamination in the area around the 100-K-68 waste site. Verification sampling beneath the 100-K-68 waste site was not conducted because the residual soil contamination is attributed to the 116-KE-3 waste site. NOTE: 116-KE-3 is located within Area AG Zone 1 but was not part of the remediation work scope.

---

**Code:** 100-K-71  
**Classification:** Accepted  
**Names:** 100-K-71; 105-KE Collection Box  
**Reclassification:** Interim Closed Out (10/23/2012)  
**Type:** Diversion Box  
**Start Date:** 1/1/1953  
**Status:** Inactive  
**End Date:**  
**Description:** The waste site has been remediated and Interim Closed Out. The 105-KE Collection Box collected effluent from nine underground process sewer lines that originated in the 105-KE Reactor Building and also from the 117-KE filter building (100-K-62). The effluent exited the Collection Box via 12 inch and 16 inch cast iron process sewer pipelines. The Process Sewer pipelines that entered and exited the 100-K-71 Collection Box are part of sitecode 100-K-47.  
**Location:** The site was located underground approximately, 12 meters north of the 105-KE Reactor Building.  
**Related Sites/Structures:** Two pipelines designated as 100-K-47 exited the north side of the 100-K-71, 105-KE collection box. The portions of the 100-K-47 pipelines that connected to the collection box were within the remediation area AG Zone 1 and were removed.  
**Waste Type:** Stormwater Runoff  
**Waste Description:** The collection box received waste water from the contaminated drain, potentially contaminated drain, clean drain, drain to pluto crib, basin drain line, ink system drain, rod cooling water drain, floor drains, the decon drain to filter and basin overflow drain.  
**Closure Info:** For the purposes of implementing and documenting remedial activities, the 100-K Area was divided into several informal remediation areas. The waste sites of this remedial activity were informally designated as being located within the Area AG Zone 1 remediation area, adjacent to the northwest corner of the reactor. (Note: One waste site located within Area AG Zone 1, the 116-KE-3 (105-KE Fuel Storage Basin Sub-Basin Drainage Disposal System Crib), was not remediated. Due to the extent of the deep zone contamination attributed to the 116-KE-3 waste site, it was placed in an "excluded region" within Area AG Zone 1. Waste site 116-KE-3 will be
addressed at a later date.)

The remediated waste sites located in Area AG Zone 1 include 100-K-68, 100-K-69, 100-K-70, 100-K-71 and 100-K-3. A portion of the 100-K-3 pipeline was remediated with the area AG Zone 2 (see DOE/RL-2012-40). (Note: Portions of 100-K-47 and 100-K-56 pipelines were removed and considered part of the Area AG Zone 1 remediation activities. Approximately 452 feet of the 100-K-56, 36-inch pipeline was removed from Area AG Zone 1 and 3. Approximately 338 feet of the 100-K-56, 72-inch pipeline was removed from Area AG Zone 1 and 3. Approximately 344 feet of the 100-K-47, 12-inch pipeline exiting the 100-K-71 collection box was removed from Area AG Zone 1 and 3. The remaining portions of the 100-K-47 and 100-K-56 pipelines will be addressed in future remediation activities.)

Remediation of the waste sites within Area AG Zone 1 began in September 2009 and was finished in May 2012. In-process samples were collected and radiological surveys were conducted to guide the remediation. Contaminated structures, pipelines, and associated soil and debris attributed to these waste sites have been removed and disposed at the ERDF. During this remedial activity, Stockpile #3 was created from excavated soil from the overburden and layback from Area AG Zone 1 waste sites. Radiological surveys were conducted on the material prior to placing it in the stockpile. Stockpile #3 was located northwest of Area AG.

The 100-K-3 waste site began in January 2010 and was completed in May 2012. The remediation of this waste site included excavation of the heat exchanger, the pump pit, associated piping and contaminated soil. A total of 709 ERDF containers (11,513 metric tons [12,691 short tons]) was disposed at the ERDF from the Area AG 100-K-3 waste site (Zones 1 and 2 combined). Along with remediation of the waste sites in Area AG Zone 1, a 20.3 cm (8 in.) diameter Process Sewer Outside (PSO) drain line was also excavated. This pipeline exited the 100-K-3 heat exchanger pit and tied into the 100-K-47 concrete process sewer. This portion of pipeline was removed with a composite in-process sample taken along the length of the excavation in August 2011. The in-process sample results did not exceed the RAGs. The region within Area AG Zone 1 where this pipeline was removed was included in the Shallow Zone decision unit. In addition, the 100-K-3, 2.54 cm (1 in.) diameter PIEX pipeline (connecting the 100-K-3 heat exchanger to the 105-KE reactor) was documented in the shallow zone decision unit. This pipeline was originally buried 1.2 meters (4 ft) deep. When removed, the footprint was wholly contained within the layback region of the 100-K-56 waste site.

The remediation of the 100-K-68 waste site structure (caisson with catch tank) was removed during waste site remediation. The remediation of the 100-K-68 waste site began in April 2010 and was completed in May 2012. The remediation of the waste site excavated the corrugated steel caisson, catch tank and pumping equipment. However, deep residual contamination associated with the 116-KE-3 waste site remains underneath the footprint of the 100-K-68 waste site.

The remediation of the 100-K-69 waste site began in April 2010 and was completed in May 2012. The remediation of the waste site excavated the concrete sump and associated contaminated soil.
The remediation of the contaminated soil beneath the 100-K-70 waste site began in April 2010 and was completed in May 2012. The tank associated with the 100-K-70 waste site had been previously removed, prior to the fuel storage basin demolition in 2008.

A total of 599 ERDF containers (11,920 metric tons [13,139 short tons]) was disposed at the ERDF from the combined 100-K-68, 100-K-69, and 100-K-70 waste sites.

The remediation of the 100-K-71 waste site began in March 2010 and was completed in May 2012. The remediation of the waste site included excavation of the collection box and associated contaminated soil. A total of 285 ERDF containers (5,858 metric tons [6,457 short tons]) was disposed at the ERDF from the 100-K-71 waste site. In-process samples collected at the collection box were analyzed for carbon-14 and tritium. The results indicated no residual contamination of these COCs.

The remediation of portions of the 100-K-47 pipeline began in November 2009 and was completed in September 2011. The partial remediation of the pipeline waste site included excavation of the underground process sewer pipelines and associated contaminated soil. In-process samples were collected within the remediated portion of the 100-K-71 waste site (collection box) footprint, because the 10.2 cm (4 in.) diameter cement asbestos pipeline from the 117-KE Filter Building (100-K-62 waste site) terminated at the collection box. Samples were analyzed for carbon-14 and tritium. The results indicated no residual contamination of these contaminants of concern (COCs). Therefore, carbon-14 and tritium were eliminated from the list of COCs for this waste site. A total of 1,240 ERDF containers (20,802 metric tons [22,930 short tons]) was disposed at the ERDF from the Area AG 100-K-47 waste site (Zones 1 and 3 combined).

The remediation of portions of the 100-K-56 Subsite 2 pipeline began in September 2009 and was completed in June 2011. The remediation excavated the part of the process effluent underground pipelines and associated contaminated soil. A total of 800 ERDF containers (13,071 metric tons [14,408 short tons]) was disposed at the ERDF from the Area AG 100-K-56 waste site (in Zones 1 and 3 combined).

A total of 63,292 metric tons of material was disposed at the ERDF during the AG Zone 1 remediation activity. (33,873 metric tons was related to the 100-K-47 and 100-K-56 partial pipeline excavations.)

No evidence of spills or leaks from Area AG Zone 1 waste sites was found after remediation. Post remediation, a Global Positioning Environmental Radiological Survey (GPERS) and radiological surveys using hand-held instrumentation were conducted. The GPERS is rendered ineffective in regions close to the 105-KE Reactor fuel storage basin (100-K-42 waste site) and the unplanned release site (UPR-100-K-1) due to the sensitive detection capabilities of the sodium iodide instrumentation and the elevated radiation background levels associated with the fuel storage basin subsurface soil.

Follow-up radiological surveys using hand-held instruments were conducted in the region around the 100-K-68, 100-K-69, 100-K-70, and 100-K-71 waste sites, immediately north of the fuel storage basin. The survey indicated elevated radiological contamination where piping from the 105-KE Reactor fuel storage basin traveled to the 105-KE Collection Box (100-K-71 waste site). One of the pipelines entering the south side of the collection box was equipped with a direct buried flanged gate valve, located at a depth of approximately 8.5 meters (27 ft 11 in.). A focused verification sample of this location was collected to determine contamination levels present in the soil. This follow-up survey also indicated elevated radiological contamination in the area around the 100-K-68 waste site. Verification sampling beneath the 100-K-68 waste site was not conducted because the residual soil contamination is attributed to the 116-KE-3 waste
site. NOTE: 116-KE-3 is located within Area AG Zone 1 but was not part of the remediation work scope.

<td>Description</td>
<td>The waste site has been remediated. The site was railroad ties discovered at the bottom of an open excavation. The excavation measured approximately 2.9 meters by 3.1 meters by 2.1 meters deep (9.5 feet by 10 feet by 6.9 feet deep). The sidewalls were braced with lumber. The open excavation had been backfilled, and the railroad ties at the bottom of the excavation were left in place. The sidewall braces were probably removed prior to backfilling. In June 2011, the</td>
<td></td>
</tr>
</tbody>
</table>
The area was re-excavated. The railroad ties and original backfill soil was removed. The second excavation was backfilled in July 2011.

**Location:** The site is located approximately 7 meters (23 feet) east southeast of the 1706KE building.

**Related Sites/Structures:** The reason for the railroad ties is not known, consequently associated structures are also unknown.

**Process Description:** The sides of the excavation were braced with lumber to prevent cave in and the top was covered with a tarp to keep precipitation out. Ultrasonic testing was used to find any pipe leaks that might have been causing the subsidences, but no leaks were identified.

**Waste Type:** Chemicals

**Waste Description:** Buried railroad ties.

**Closure Info:** The exact location of the buried railroad ties was not known. Several areas near the 1706-KE Building were excavated while searching for the waste site location. When the correct location was identified, the railroad ties and original backfilled soil were removed. Approximately 4,651 tons of railroad ties and soil were disposed of in the ERDF landfill. No visual evidence of spills or leaks was found during or after remediation in the excavation. No in-process sampling was conducted for this waste site. The excavation was backfilled in July 2011.

**Code:** 100-K-79  **Classification:** Accepted

**Names:** 100-K-79; Sodium Dichromate and Sulfuric Acid Product Pipelines at 100-KE and 100-KW  **Reclassification:** None

**Type:** Product Piping  **Start Date:**

**Status:** Inactive  **End Date:**

**Description:** This waste site includes the pipelines that carried pure chemical and treated cooling water at both the 105KE and 105KW reactors. The piping in this waste site has been split into eight subsites.

Subsite 1 - The sodium dichromate product pipelines at KW, that ran from the railroad offloading areas to the dichromate storage tanks and then to the adjacent 183.1KW Headhouse, became subsite 1. This subsite has been remediated and is Interim Closed Out.

Subsite 2 - The sulfuric acid product pipelines at KW, that ran from the sulfuric acid storage tanks to the 183.1KW Headhouse, and then adjacent railroad offloading areas, became subsite 2. This subsite has been remediated and is Interim Closed Out.

Subsite 3 - The sodium dichromate lines at 183.1KE became subsite 3.

Subsite 4 - The sulfuric acid lines at 183.1KE became subsite 4.

Subsite 5 - The treated water pipelines, that ran north/south between the 105KW Reactor and 165KW Power Control Building, became subsite 5.

Subsite 6 - The treated water pipelines, that ran north/south between the 105KE Reactor and 165KE Power Control Building became subsite 6.

Subsite 7 - The 0.61-meter (24-inch) process water pipeline that connected the 105KE and 105KW reactor buildings is known as the original cross-tie line. The parallel, replacement 0.61-meter (24-inch) process water pipeline that connected to the 105KE and 105KW reactor buildings is known as the "New" cross-tie line. Both the original and new cross tie lines are considered Subsite 7.

Subsite 8 - The 1.21 meter (48 inch) Clearwell cross tie line became subsite 8.

**Location:** These pipelines are located south of 105KE and south of 105KW. They connect the 105 Reactor buildings to the 165 and 183.1 Buildings. There is also cross-tie pipeline between the
105KE and 105KW Reactors buildings that is orientated in a east/west direction.

**Release Description:** No releases to the environment have been recorded from the pipelines enclosed in the tunnels. However, the railroad offloading facilities and pipe valves may have leaked at various times.

**Related Sites/Structures:** These pipelines are related to the 120-KW-5 and 120-KE-6 dichromate tank foundations, the 120-KE-4, 120-KE-5, 120-KW-3, and 120-KW-4 sulfuric acid tank foundations, the 183.1 Headhouses and the 165 Power Control Buildings, and 105 Reactors.

**Process Description:** Concentrated sodium dichromate and sulfuric acid flowed through the product lines, which are encased inside concrete pipe tunnels. The pipelines between the 165 Buildings and the 105 Reactors carried treated water with more dilute sodium dichromate.

**Waste Type:** Ordnance

**Waste Description:** The waste is residual sodium dichromate (chromium 6) and mercury (from sulfuric acid) in the pipes and potential leaks from the offloading station.

**This Site has the Following SubSites:**

**Code:** 100-K-79:1
**Names:** 100-K-79:1; 100-KW Sodium Dichromate Product Pipelines from the Railroad Offloading areas to the Sodium Dichromate storage tanks and 183.1 KW Headhouse

**Code:** 100-K-79:8
**Names:** 100-K-79:8; 48 Inch Line between 183.4 KW and 183.4KE; Clearwell Cross Tie Line

**Classification:** Accepted

**Reclassification:** Interim Closed Out (6/27/2012)

**Start Date:**

**End Date:**
Description: The subsite has been remediated and Interim Closed Out. It was the sodium dichromate product pipelines that ran from the railroad offloading areas to the sodium dichromate storage tanks and to the adjacent 183.1 KW Headhouse.

Related Sites/Structures: These pipelines were related to the 120-KW-5 dichromate tank, the 120-KW-3 and 120-KW-4 sulfuric acid tanks, and the 183.1-KW Headhouse.

Process Description: Concentrated sodium dichromate (70% solution) and sulfuric acid flowed through 3/8-inch product lines, which were encased in concrete pipe tunnels. The sulfuric acid was known to have had mercury contamination. In July 1985, a sample of sulfuric acid sludge was collected for analysis; regulated levels of mercury were detected in the sludge with lesser amounts of barium, total chromium, lead, and selenium.

Closure Info: Remediation of the Area AA, Zone 2 waste sites (100-K-18, 100-K-19, 100-K-79:1, 100-K-79:2, 100-K-97, 120-KW-5 and 120-KW-7) began in May 2010. Throughout the remedial activity, because of the contaminants found in the process equipment and surface soils, in-process samples were collected and analyzed for metals, including chromium VI and anions (e.g., sulfate due to the sulfuric acid), at multiple locations and depths. In-process sampling occurred across all four zones in 100-K Area AA, although this report focuses on Zone 2 only. Throughout remediation, stained areas were targeted for in-process sampling; soils often were yellow-colored and high in lead, total chromium and mercury. Hexavalent chromium, which is the groundwater contaminant of greatest concern at 100-K, was detected on the soil surface down to 6 feet, at the beginning of remediation for Area AA Zone 2. Excavation continued to a final remediation depth of 10.96 meters (35.96 ft).

During a walkdown of Area AA by RL and EPA on September 20, 2011, it was determined that piping found within Zone 1 needed to be further investigated. The piping identified was determined to be a part of the process sewer line and was subsequently removed.

The excavation decision unit was approximately 3,228 square meters (34,745.9 sq. ft.). All contaminated soils and debris from the waste sites was disposed of in the Environmental Restoration Disposal Facility (ERDF).

</tbody>
</table>
The 100-K-79, Subsite 7 is known as the Cross Tie Line. It is composed of two, parallel treated water pipelines that connect the 105-KE Reactor and the 105-KW Reactor. One 24-inch pipeline is the Original Cross Tie line. The other 24-inch pipeline is known as the New Cross tie line. It replaced the Original pipeline. They ran east to west. It also includes a 36 inch high pressure discharge line segment, that connected to the 182-K Emergency Cooling Water Pump House.

Both pipelines are constructed from 24 inches in diameter carbon steel. They are connected to each reactor through valve pits located on the south end of each reactor building. The treated water into each pipeline is fed from a 36-inch carbon steel pipeline from the 182-K Emergency Water Reservoir Pump House, which used diesel-fueled pumps to supply treated water for the 100-K Coolant Backup System. The treated water flowed into the 182-K Pump House from the 183.4-KE and 183.4-KW Clearwells.

Each of the 24-inch pipelines is enclosed in 36-inch corrugated piping. The corrugated piping rests on concrete footings. The 36-inch pipeline is enclosed in a 48-inch corrugated pipe which also rests on concrete footings.

A portion of 100-K-79:7 was removed during the demolition of the 1706-KE, KER and KEL buildings in 2010 (see DOE/RL-2012-40). Verification samples collected in 2011 found contamination that exceeded Remedial Action Goals for metals. Additional excavation was required. Verification sampling was completed in July 2012 on the remediated portion of 100-K-79:7.

The parallel pipelines are located in the center of 100-K Area, just south or the reactor buildings.

The pipeline is part of the Reactor Cooling Water Backup System.
Code: 100-K-82  
Names: 100-K-82; 105-KW Fuel Storage Basin Leak  
Type: Unplanned Release  
Status: Inactive  
Description: The release is not marked or posted. It is part of the 105-KW reactor building structure.  
Location: The storage basin extends from the north wall of the 105-KW Reactor Building to the open area behind the reactor, with its longitudinal axis running parallel to the north wall of the building. Its east-west location is roughly in the center of the building. The leak occurred on the north side of the 105 KW basin.  
Related Sites/Structures: This unplanned release at the 105 KW basin (100-K-43) is analogous to the documented release that occurred at 105 KE basin (100-K-42), known as UPR-100-K-1.  
Process Description: In 1978, the 105-KW basin was approved to be used as supplemental storage for irradiated 100-N irradiated fuel storage.  
Waste Type: Ash  
Waste Description: Fuel storage basin effluent that included debris from fuel cladding failures. The release is analogous to the release at 105-KE basin. Cobalt-60, Strontium-90, Cesium-137 and small amounts of plutonium were noted in the soil beneath the 105-K East basin.

Code: 100-K-85  
Names: 100-K-85; 100-K Temporary Construction Pit  
Type: Trench  
Status: Inactive  
Description: The site is a large open pit estimated to be 30 m (98 ft) in diameter and appears to have supported construction operations. The site appears as a flat grassy area.  
Location: The site is located in the 100-KR-2 Operable Unit, approximately 284 m (932 ft) southeast of the 1720-K building. It was dug approximately 10 m (33 ft) south of the temporary construction area outside of Site 600-29.  
Waste Type: Vegetation  
Waste Description: The waste may be temporary construction debris.  
Closure Info: The 100-K-85, 100-K Temporary Construction Pit waste site, located in the 100-KR-2 Operable Unit, consisted of a large open pit that appears in a historical photograph of 100-K Area from 1953. The pit was expected to be 30 m (100 ft) in diameter, covering and area of approximately 700 m2 (7,600 ft2), and assumed to have supported construction operations. A site visit in December 2009 indicated no debris, staining, and no vegetation differences in comparison to the surrounding area. Based on the 1953 photograph, the 2009 site visit, knowledge of historical processes, and a 2008 geophysical survey of the 100-K-85 waste site, confirmatory sampling was performed in November 2010. The results indicated that the waste site achieved compliance with the remedial action objectives (RAOs) and remedial action goals (RAGs) for the 100-K-85 waste site; therefore, remediation was not necessary. A summary of the cleanup evaluation for the soil
analyses against the applicable RAGs is presented in Table ES-1. The results of the confirmatory sampling are used to make reclassification decisions for the 100-K-85 waste site in accordance with the TPA-MP-14 procedure in the Tri-Party Agreement Handbook Management Procedures (DOE-RL 2007).

### Code: 100-K-89

**Classification:** Accepted

<table>

<tr>
<td><strong>Description:</strong> The waste site has been remediated and Interim Closed Out. Prior to remediation this site consisted of burnt materials laying on the ground surface. The 100-K-89 waste site was completely remediated and removed when one of the 600-29 excavations was expanded beyond the original waste site boundary to encompass additional contamination found during remediation.</td>
<td></td>
</tr>
</tbody>
</table>

| **Location:** The site is 60 meters (197 ft) south of site 600-29. The Washington State Plane coordinates for the site are E 568597.54, N 145529.56. |

| **Related Sites/Structures:** The waste site is associated with 600-29. |

<table>
<thead>
<tr>
<th><strong>Waste Type:</strong> Soil</th>
</tr>
</thead>
</table>

| **Waste Description:** Contaminants of potential concern may include asbestos and petroleum products. The waste is burned debris (wood, metal and roofing material) and any potentially contaminated soil. |

| **Closure Info:** Remedial action at the 600-29 and 100-K-89 waste sites began on September 21, 2011, and continued through April 5, 2012. Most of the remedial excavations were the result of visible surface debris, stains, and materials. These areas were excavated from a minimum of 0.3 meter (1 ft) in depth to as much as 3 meters (10 ft) in depth, as needed, to remove contamination. Excavations for french drains ranged from 1.2 to 1.8 meters (4 to 6 ft) in depth. A septic vault in the eastern portion of 600-29 required excavation to 10 feet below ground surface. All materials removed from the excavations were stockpiled within the excavations and then directly loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). No stockpiles external to the excavations were created. The 100-K-89 waste site comprised a burned area with burnt material present on the surface (wood, metal, and roofing material) and the underlying soil. Contamination identified on the southwest edge of the 600-29 waste site led to an excavation that was expanded during remediation based on field observations. The expansion encompassed and completely removed the 100-K-89 waste site. |

| Contaminated materials removed from the 600-29 waste site consisted of red, black, and white stained soils or colored materials, concrete pads and rubble, a concrete sewer junction box, abandoned iron and vitrified clay piping, abandoned wiring, friable and nonfriable asbestos, metallic and wood debris, burnt wood, ash, tar, and other miscellaneous demolition debris. Materials removed from the 100-K-89 waste site consisted of burned debris (wood, metal, roofing material) and associated soils. |

| A total volume of 10,293 bank cubic meters (BCM) (6,157 BCM from the east side of 600-29 and 4,136 BCM from the west side of 600-29) was removed and disposed to ERDF during remediation. |

---

*Hanford Site Waste Management Units Report*

February 2015  740
Names: 100-K-97; 183-KW French Drain and Rail Spur
      Unplanned Release

Reclassification: Interim Closed Out (6/27/2012)

Type: French Drain
Status: Inactive

Description: The waste site has been remediated and Interim Closed Out. The site consisted of a French Drain that was used to collect drainage from the chromate system transfer hose after unloading the railcar. It also included an unplanned release along the railroad tracks on the Head House rail spur.

Location: The French Drain was located south of the 183 KW Head House, just south of the 100-K-19 (183-KW Caustic Soda Storage Tank Site), southwest of 100-K-18 (183-KW Caustic Neutralization Pit), and north of the railroad.

Process Description: The Head House rail spur was used for delivery of water treatment equipment and chemicals. Anecdotal information indicates that sodium dichromate and sulfuric acid spills were not uncommon during railcar unloading operations, which led to the assignment of the unplanned release along the rail spur. After railcar unloading operations were complete, the sodium dichromate transfer hose was placed into the open French Drain to collect excess product in a controlled manner.

Closure Info: Remediation of the Area AA, Zone 2 waste sites (100-K-18, 100-K-19, 100-K-79:1, 100-K-79:2, 100-K-97, 120-KW-5 and 120-KW-7) began in May 2010. Throughout the remedial activity, because of the contaminants found in the process equipment and surface soils, in-process samples were collected and analyzed for metals, including chromium VI and anions (e.g., sulfate due to the sulfuric acid), at multiple locations and depths. In-process sampling occurred across all four zones in 100-K Area AA, although this report focuses on Zone 2 only. Throughout remediation, stained areas were targeted for in-process sampling; soils often were yellow-colored and high in lead, total chromium and mercury. Hexavalent chromium, which is the groundwater contaminant of greatest concern at 100-K, was detected on the soil surface down to 6 feet, at the beginning of remediation for Area AA Zone 2. Excavation continued to a final remediation depth of 10.96 meters (35.96 ft).

During a walkdown of Area AA by RL and EPA on September 20, 2011, it was determined that piping found within Zone 1 needed to be further investigated. The piping identified was determined to be a part of the process sewer line and was subsequently removed.

The excavation decision unit was approximately 3,228 square meters (34,745.9 sq. ft.). All contaminated soils and debris from the waste sites was disposed of in the Environmental Restoration Disposal Facility (ERDF).

---

Names: 100-K-98; 183-KE French Drain and Rail Spur
      Unplanned Release

Reclassification: None

Type: French Drain
Status: Inactive

Description: The site consists of a French Drain that was used to collect the drainage from the transfer hose after unloading the railcar.

Location: The French Drain is located south of the 183 KE Head House, just south of the 100-K-25, 183-KE Caustic Neutralization Pit, southwest of 100-K-25, 183-KE Caustic Neutralization Pit, and north of the railroad.
The Head House rail spur was used for delivery of water treatment equipment and chemicals. Anecdotal information indicates that sodium dichromate and sulfuric acid spills were not uncommon during railcar unloading operations, which led to the assignment of the unplanned release along the rail spur. After railcar unloading operations were complete, the sodium dichromate transfer hose was placed into the open French Drain to collect excess product in a controlled manner.

### Code: 100-K-101
**Classification:** Accepted
**Names:** 100-K-101; French Drains and Mercury Stained Soils near the 183KE Sedimentation Basin
**Type:** French Drain
**Status:** Inactive
**Description:** The site consists of a French Drain surrounded by mercury stained soil adjacent to the KE Sedimentation Basin near the abutments. There is also a black hose assembly.
**Location:** The site is located in the KE area along the south face of the Sedimentation Basin.

### Code: 100-K-102
**Classification:** Accepted
**Names:** 100-K-102; French Drains and Mercury Stained Soils near the 183KW Sedimentation Basin
**Type:** French Drain
**Status:** Inactive
**Description:** The waste site has been remediated and Interim Closed Out. It consisted of two French drains surrounded by sulfuric acid stained soil adjacent to the 183.2-KW Flocculation and Sedimentation Basins near the abutments. It also had a partially exposed acid delivery piping (i.e., dosing pipes) system and associated man-holes.
**Location:** The site is located in the KW area between the Sedimentation Basin and the Headhouse.
**Process Description:** Sulfuric acid, along with sodium silicate and alum, was piped from the 183.1-KW Headhouse through the dosing pipes into the abutments to initiate flocculation of the raw river water as an initial step in the reactor cooling water treatment process. The sulfuric acid was contaminated with metals, including mercury with lesser amounts of barium, total chromium, lead and selenium. Disposal of excess acid into the French drains, as well as leakage and overspray from the dosing pipes, led to contamination of the surrounding soils.

**Closure Info:** Remediation of the Area AA Zone 1 Waste Sites began in April 2010 and ended in January 2012. The waste site structures and soils have been excavated as part of the remedial activities for the 100-K Area. The excavation area was designated as 100-K Area AA, Zone 1 (Area AA, Zone 1). It encompassed the individual waste sites 100-K-34, 100-K-102 and 1607-K3. Stockpile #11 contains layback soil from remediation of Area AA, Zone 1. These waste sites are adjacent to the 100-K-59 pipelines. Since visible sediment was observed in the severed pipelines, a sample was collected in February 2011 from the open end of the pipe west of the 183.1KW Headhouse. A section of the 100-K-59 pipeline was removed.

Excavation of the waste sites continued to a final remediation maximum depth of 9.82 meters (32.2 ft), which was located within the footprint of 100-K-102. To support the deeper excavation for Area AA, Zone 1, layback soil was accumulated and managed as Stockpile #11. The excavation decision unit was approximately 7,331 square meters (78,910 ft2) for 100-K...
Area AA, Zone 1. The original footprint prior to additional process sewer pipe removal was divided into evenly spaced areas for statistical sampling outside the waste sites to address any potential for contamination spread.

### 100-K-103 Settling Tank

**Classification:** Accepted  
**Reclassification:** None

**Names:** 100-K-103; 1704-K and 1717-K Septic Systems; Additional Components of 1607-K4

**Type:** Settling Tank

**Status:** Unknown

**Description:** This WIDS site addresses seven components of the 1717K Septic System (1607-K4) that were not included in the Closed Out documentation for the 1607-K4 waste site. 100-K-103 includes the Original Tile Field, the Replacement Septic Tank, one Leaching Trench and four distinct Replacement Tile Field, built in 1995.

**Location:** The additional septic system components surround the Closed Out 1607-K4 Septic Tank and Tile Field. All of the components are located north of the 1717K building, inside the 100-K Area.

**Related Sites/Structures:** 1607-K4 Septic Tank was abandoned in 1999.

**Process Description:** The leaching trench received waste from only the 1717-L Maintenance Building. The remaining components received waste from both 1717-K and the 1704-K office building.

### 100-K-104 French Drain

**Classification:** Accepted  
**Reclassification:** None

**Names:** 100-K-104; 166-KE French Drain

**Type:** French Drain

**Status:** Unknown

**Description:** A site visit in July 2008 could not visually identify the french drain. The drain was fed by approximately 30 meters (100 feet) of underground piping.

**Location:** The french drain is described on drawings to be approximately 30 meters (100 feet) west of the 166-KE building.

**Process Description:** The source of the effluent is a sump in the 166-KE Pump Room.

### 100-K-105 Depression/Pit (nonspecific)

**Classification:** Accepted  
**Reclassification:** None

**Names:** 100-K-105; Pit at Southeast Corner of 100K

**Type:** Depression/Pit (nonspecific)

**Status:** Inactive

**Start Date:** 1/1/1955

**End Date:**

**Description:** The pit cannot be visually identified at the present time. An open pit was clearly visible on historical photograph 3346-NEG, taken in April 1955. Later photographs do not show any evidence of the pit. It is presumed to have been backfilled prior to 1965.

**Location:** The open pit is located in the southwest corner of 100-K West Area, near the perimeter road.
Process Description: There are no facilities near the open pit. It is not known what the pit was used for.

<table>
<thead>
<tr>
<th>Code</th>
<th>Classification: Accepted</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type: Crib</td>
<td>Start Date:</td>
</tr>
<tr>
<td>Status: Inactive</td>
<td>End Date:</td>
</tr>
</tbody>
</table>

Description: The site has been remediated and Interim Closed Out. It was an underground, rock filled drainage crib next to the demolished 182-K Building.

Location: The centerline of the crib was approximately 6.1 meters (20 feet) west of the northwest corner of the 182-K building.

Process Description: The crib supported the 182-K midway pump station that contained three diesel powered pumps. Discharge to crib was via a 15 centimeter (6 inch) diameter crib drain, that exited the building in two locations. One exited on the north end of the building and entered the east end of crib. Upon entering the crib, the piping consists of a 6 inch diameter corrugated metal perforated pipe. The other source to the crib is through a floor drain that collected drainage from a fuel oil centrifuge and a refrigerated drinking fountain. Influent to the waste site would have been water or, potentially, an oily, nonradioactive liquid waste.

Closure Info: The crib, drain pipeline, and associated contaminated soil from the excavation site (including from beneath the 182-K Emergency Water Pump House) have been removed and disposed at the Environmental Restoration Disposal Facility (ERDF). Approximately 400 ERDF containers (7,324 tons [8,073 short tons]) of soil and debris were disposed at ERDF from the combined waste site and 182-K pump house excavation site.

Remediation of Waste Site 100-K-106 and removal of the drain pipeline coincided with the removal of the below grade portions of the 182-K Emergency Water Pump House, which began in March 2012 and was completed in June 2012. Because the sump of the pump house extended to approximately 10.8 meters (35.5 ft) below grade, the excavation removed the crib structure, the sump and the drain pipeline.

The soil excavated from the waste site appeared to be stained, indicating the possibility of one or more releases to the crib. Soil from the crib area was in-process sampled to characterize residual contamination. Sampling results exceeded land disposal restrictions for chromium and required some of the soil be segregated for treatment before disposal at the ERDF. Sample results also indicated elevated levels of copper, lead, vanadium, and zinc. An area of soil staining was also observed at the excavation floor just east of the waste site. A focused sample was collected from this location during verification sampling. Sample results were below Hanford Site background values or constituents were undetected.

Three stockpiles were created from the excavated soil of the joint 182-K Emergency Water Pump House and Waste Site 100-K-106 excavation site. Stockpile 1 was located northeast of the excavation site. Stockpile 2 was located to the south of the excavation site. Stockpile 3 was located northwest of the excavation site. Due to safety issues associated with the steep side-slopes of the excavation and protruding pipelines, a civil survey of the excavation site was not prepared. A civil survey of the stockpiles was completed post remediation. The combined stockpiles were approximately 5,378 square meters (57,889 sq. ft) and consisted of two sampling subunits with the eight sampling areas. Sampling areas of the stockpiles did not their side slopes because the stockpiles surrounded the edge of the excavation site. The side slopes of the stockpiles joined the steep side slopes of the excavation, making them unstable.
Therefore, for the safety of sampling personnel, stockpile side slopes were not included within the sampling areas.

The crib and pipeline sample area was approximately 9.29 square meters (100 sq. ft.) in size. Four sample increments were collected from randomly selected nodes within this sampling area and combined into a single composite sample for that area. Soil from six discrete locations in the vicinity of the waste site and drain pipeline were sampled.

The excavation was backfilled in August 2012.

NOTE: During excavation activities, evidence of a past fuel oil spill, along with some concrete, was encountered approximately 30 meters (98 ft) northeast of the pump house. This spill was not explored further, but was covered with a layer of protective soil. Remediation of this spill is planned for future work as a part of either the adjacent 100-KE Oil Contamination Area (sitecode 100-K-48) or the 166-KE Oil Storage Tank bunker waste site (sitecode 130-KE-2). It is not associated with the pump house, Waste Site 100-K-106, or drain pipeline. Also, after backfill for the excavation site was completed, potentially asbestos containing material was found in the footprint of the excavation site. Consequently, a discovery waste site (100-K-119) was assigned to the excavation site which is currently being evaluated for future action to address potential residual asbestos in the soil.

**Code:** 100-K-107  
**Classification:** Accepted

**Names:** 100-K-107; 1706-KER Abandoned Drain Field

**Type:** Drain/Tile Field

**Status:** Inactive

**Description:** A fenced area 31 meters (102 feet) northwest of the northwest corner of the 1706-KER building is assumed to be this abandoned drain field.

**Location:** The abandoned drain field is located north and west of 1706-KER.

**Process Description:** The 1706-KER facility provided experimental data on the effect of water qualities, water temperature and pressure, and physical and chemical properties of materials of construction upon reactor operation and control, upon reactor tubes and slugs, and upon associated equipment when operating closed in-pile recirculation systems at elevated temperatures and pressures. It was also known as a decontamination and hot shop. Effluent from the building toilets and floor drains exited the facility via a 10.2 centimeter (4 inch) drain line to this drain field.

**Code:** 100-K-108  
**Classification:** Accepted

**Names:** 100-K-108; 1706-KER Septic System; 1706-KER Septic Tank; Crib and Sewer Line

**Type:** Septic Tank

**Status:** Unknown

**Description:** The site consists of a septic tank, crib, and associated piping that received effluent from the hot maintenance shop in 1706-KER building.

**Location:** The septic tank, crib, and associated piping are located northwest of the 1706-KER Building.
| **Process Description:** | The 1706-KER facility provided experimental data on the effect of water qualities, water temperature and pressure, and physical and chemical properties of materials of construction upon reactor operation and control, upon reactor tubes and slugs, and upon associated equipment when operating closed in-pile recirculation systems at elevated temperatures and pressures. It was also known as a decontamination and hot shop. The septic tank has a 2271 liter (600 gallon) capacity tank, measuring 1.37 meters (54 inches) diameter by 1.78 meters (70 inches) depth. It is asphalt coated. The septic tank weighs 197 kilograms (435 pounds) and is constructed of 14 gauge steel. The crib is 1.8 meters (6 feet) wide by 2.1 meters (7 feet) tall. It was constructed of 15.2 by 15.2 centimeter (6x6 inch) treated (coal tar creosote) wooden timbers. The outside of the crib is covered with wire mesh. A 10.2 centimeter (4 inch) vent pipe exits the top of the crib. During operation of the building, the crib was surrounded by wood guard posts. The pipeline has a minimum soil cover of 0.8 meters (2.5 feet). |
| **Waste Type:** | Misc. Trash and Debris |
| **Waste Description:** | Contaminants of Potential Concern may include radionuclides (fission products), ICP metals, mercury, TPH and hexavalent chrome. |
| **Code:** | 100-K-109 |
| **Classification:** | Accepted |
| **Names:** | 100-K-109; Unplanned Chemical Release near 183.1KW Head House; Yellow Stained Soil adjacent to 183.1KW Head House |
| **Reclassification:** | Interim Closed Out (11/18/2011) |
| **Type:** | Unplanned Release |
| **Start Date:** | |
| **Status:** | Inactive |
| **End Date:** | |
| **Description:** | The waste site has been remediated and Interim Closed Out. It was an area of yellow stained soil, from an unplanned release that is adjacent to the railroad track, south-southwest of the demolished 183.1KW headhouse. |
| **Location:** | The visible stained soil was located near the southwest corner of the demolished 183.1KW Head House building near the railroad track. |
| **Related Sites/Structures:** | The area is associated with the 183.1KW Head House and the 100-K-15 and 100-K-16 Alum tanks. |
| **Process Description:** | The Head House rail spur was used for delivery of water treatment equipment and chemicals. Anecdotal information indicates that sodium dichromate and sulfuric acid spills were common during railcar unloading operations, which led to the unplanned releases along the rail spur. Historical drawings and photographs show this stained soil area is adjacent to a rail car unloading area. It is also adjacent to a 183.1KW head house and two alum storage tanks (previously removed). |
| **Closure Info:** | Excavation of 100-K-109 began in August, 2010 to remove stained soils, and excavation was completed in June, 2011, when the last stained soil was removed and disposed at the Environmental Restoration Disposal Facility (ERDF). The original area, based on the posted Underground Radioactive Material Area, was estimated to be 48.7 meters (160 ft) long by 21.3 meters (70 ft) wide that equaled an area of 981 square meters (10,559 sq. ft.). The actual remediated area more than double the original estimate. 1,861 square meters (20,031.6 sq. ft.) was excavated, due to removal of a significant amount of stained soils. The excavation was anticipated to end at a depth of 4.6 meters (15 ft). However, the excavation the yellow-colored contaminated soil continued to the final depth of the remediation was 7.84 meters (25.7 ft), due to the ongoing detection of mercury contamination at levels above the RAGs in the RDR/RAWP (DOE/RL-96-17). |
The 118-K-1 burial ground has been remediated and Interim Closed Out. The trenches ran northwest and southwest. It contained approximately fifty trenches and pits and eleven silos. The trenches and pit dimensions varied greatly. The silos ranged from 1.4 meter (4.5 feet) to 3 meters (10 feet) in diameter with depths from 7.6 meters (25 feet) to 9.8 meters (32 feet deep). The site had two parts, the main burial ground and the area known as the CGI-791 addition. Based on the results reported in CVP-2013-00002, the radiological postings were removed from the 118-K-1 burial ground in February 2014.

The burial ground is associated with sitecode 100-K-132, Deep Contamination Below Trenches N and O of the 118-K-1.

This burial ground received solid waste from both the 100-K and 100-N Areas. A low level waste incinerator was located near the southeast corner of the burial ground. The incinerator was constructed of a steel plate box, measuring 1.8 meters (6 feet) by 6.1 meters (20 feet). It had a 2.4 meter (8 foot) high stack. There are eleven silos. Six silos received reactor hardware, three silos contain incinerator ashes and two silos contain irradiated nickel plated boron balls from the emergency 3X system.

The site was located 244 meters (800 feet) northeast of 105-KE Reactor Building, outside the 100-K Area perimeter fence.

Remedial action at the 118-K-1 Burial Ground began on May 30, 2006. Trenches A and B were excavated to a depth of approximately 5.5 meters (18 ft) and 4.0 meters (13 ft) bgs, respectively, resulting in approximately 4,035 bank cubic meters (BCM) (5,278 bank cubic yards [BCY]) of material removed for disposal at ERDF. Excavation of Trench M began on July 10, 2006, to a depth of approximately 4.6 m (15 ft) bgs, resulting in approximately 1,170 BCM (1,530 BCY) of material removed for disposal at ERDF. The remediation was partially completed in July 2008 (phase 1 remediation) and then placed in a safe shutdown mode. Two sorting cells were established east of the burial ground and were used to process the soil from the burial ground prior to being loaded out for disposal at ERDF. Field observations during excavation and sorting of material from Trenches A, B, and M indicated that only construction debris was discovered and removed. No spent nuclear fuel (SNF) or other anomalous materials (containers, stained soils, or other waste forms) were discovered. Phase 1 verification sampling indicated that additional remediation was needed for Trench A and a portion of one of the sorting cells. Verification sampling of Trenches B and M indicated that remedial action objectives were met and a backfill concurrence was approved on June 16, 2009.

The stabilization of the remaining trenches, pits, and silos was deferred to the Phase 2 remediation, that resumed in October 2009 and was completed in March 2012. Approximately 127,768 BCM (167,114 BCY) of material was removed for disposal at ERDF or other approved
facilities. During the excavation, in-process field radiological surveys using hand-held instrumentation and in-process soil samples were collected. Field screening at the site included using systematic global positioning radiological data mapping surveys (Global Positioning Environmental Radiological Surveyor [GPERS]) in the excavation with instrumentation specific to the detection of radiation associated with gamma- and beta-emitting radionuclides. In-process samples were collected from Trenches C and F; Trenches D, E, P, G; Trench K; Trench N; and Trench O at locations of elevated radiological activity identified by GPERS. In-process sample results for Trenches O and K identified strontium-90 in excess of groundwater and river protection RAGs at the base of the excavation.

On October 27, 2011, test pits were excavated at the base of both Trenches K and O excavations to collect vertical profile samples to evaluate residual strontium-90 activity with depth. Samples were collected at 0.9 meter (3 ft) intervals and analyzed for strontium-90, tritium, nickel-63, carbon-14, and gamma-emitting radionuclides. The results of this sampling showed strontium-90 decreasing with depth to activities less than the RAGs. However, tritium was detected in the deep vadose zone at Trench O with concentrations increasing with depth and above soil lookup values for groundwater protection. Tritium was not detected above RAGs in the Trench K characterization test pit samples. However, tritium above groundwater and river protection RAGs was detected at a separate excavation surface location in the Trench K deep zone.

On March 29, 2012, a test pit was excavated to a depth of 4.6 meters (15 ft) at the base of the Trench N excavation to collect vertical profile samples at 0.9 meter (3 ft) intervals to evaluate residual tritium contamination. Tritium was detected in all the test pit samples at activities exceeding criteria for protection of groundwater. The maximum activity detected was 13,400 pCi/g. All Phase 2 remediation areas have been backfilled. A new waste site, 100-K-132, was created to address residual deep vadose contamination within the context of the future final ROD. The buried waste removed included non-reactor construction debris, reactor debris, lead shielding, reactor tubing, lead lined pigs, various glass and plastic containers, graphite canisters, drums, boron balls, incinerated radioactive material, zirconium jackets, dried paint, highly radioactive piping and spent nuclear fuel. High dose rate material was shipped in concrete containers. Twelve pieces of spent nuclear fuel were removed, characterized and shipped to the 100-K Fuel Storage Basins.

Trenches A and B were excavated to a depth of 6 meters (19.7 ft). Trenches C and F were excavated to a depth of 7.1 meters (23 ft). Trenches D, E, P and G were excavated to a depth of 8.4 meters (27.5 ft). Trench H was excavated to a depth of 3.2 meters (10.5 ft). Trench I was excavated to a depth of 10 meters (35.7 ft). Trenches J and L were excavated to a depth of 9.9 meters (32.5 ft). Trench K was excavated to a depth of 9.4 meters (30.8 ft). Trench N was excavated to a depth of 15.6 meters (51.3 ft). Trench O was excavated to a depth of 12.2 meters (40 ft). Trench M contained only construction debris. The Phase 1 excavations were sampled and backfilled.

Remediation of the internal contents of the Trench I silos was completed on May 17, 2011. A total of 1,040 clamshell buckets of waste material were removed to empty these silos. These silos were found to contain soil, spacers, perforated aluminum fuel spacers, fuel baskets, activated metal wire, miscellaneous metal debris, fiberglass, conduit, crushed 208 liter (55 gal) drums, paraffin, various crushed containers, discarded tools, pipe, and pieces of SNF.

All Phase 2 remediation areas have been backfilled.
Names: 128-K-1; 100-K Burning Pit
Reclassification: Interim Closed Out (8/24/2004)

Type: Burn Pit
Start Date: 1/1/1955

Status: Inactive
End Date: 1/1/1971

Description: The site has been remediated and Interim Closed Out. The site was a slight depression, about 0.91 meters (3.0 feet) below the surrounding grade, with pieces of concrete and metal debris visible at the surface.

Location: The site was located outside of the perimeter fence, southeast of the 100-K Burial Ground (118-K-1) and northeast of the 183-KE Settling Basins.

Process Description: This site was used for the disposal of nonradioactive combustible materials such as paint waste, office waste, and chemical solvents.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: The site was used for the disposal of nonradioactive, combustible materials, such as paint waste, office waste, and chemical solvents.

Closure Info: Remedial action at the site consisted of two phases of confirmatory sampling that was conducted at the site in April and May 2003. Phase I consisted of test trenches and a test pit to evaluate the potential presence of buried debris or contaminated soil. Phase II consisted of identification and removal of surface debris with waste characterization and soil sampling, as needed. During the Phase II sampling, one location (P16) was found to have semivolatile organic contamination that required remediation. With agreement from the U.S. Environmental Protection Agency, the area with elevated levels of contamination was excavated during December 2003.

Debris identified during the May 14, 2003, walkdown was removed and disposed of at the ERDF during Phase II confirmatory sampling. As previously stated, the Phase I confirmatory sampling results indicated that no remediation of the subsurface soil was required. However, based on the results of the Phase II confirmatory soil sampling, selective remediation of the 128-K-1 site at the P16 location was necessary due to the presence of benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[k]fluoranthene, bis(2-ethylhexyl)phthalate, carbazole, chrysene, dibenz[a,h]anthracene, and indeno(1,2,3-cd)pyrene, which exceeded the cleanup criteria. The remediation at the P16 location was performed during December 2003 by removing contaminated soil from an approximate 7 by 15 meters (23 by 49 ft) area to a depth of approximately 0.5 meter (1.6 ft) based on field observations of discolored soil. A total of 161 tons of contaminated soil from this location was disposed of at the ERDF.

After remediation, a verification sample of the underlying soil was collected to confirm that cleanup levels had been met. The results indicated that the waste removal action achieved compliance with the remedial action objectives for 128-K-1 site. The maximum detected residual contaminant levels from the soil samples were used to support site reclassification.

---

Names: 128-K-2; 100-K Construction Dump
Reclassification: Interim Closed Out (10/18/2012)

Type: Burn Pit
Start Date: 

Status: Inactive
End Date: 

Description: The waste site has been remediated and Interim Closed Out. The 128-K-2 waste site was a former construction dump and burn pit area. It had been marked with a single chain fence with "Danger - Asbestos" warning signs marks the area.
Location: The site was located approximately 0.3 kilometers (0.2 miles) southwest of the 100-K Area perimeter fence, along the old Hanford Irrigation Project Canal.

Process Description: The waste site was used as a construction dump pit and burn pit.

Waste Type: Process Effluent

Waste Description: A wide variety of trash is exposed on the ground surface. There is evidence of burning in many locations. Most of the material on the surface is scrap metal and glass. Office waste, paint, solvents, laboratory waste have also been found. The area is also covered with nonfriable and friable asbestos.

Closure Info: Remedial action at the 128-K-2 waste site began on December 13, 2011 and was completed on May 8, 2012. Excavated material consisted of miscellaneous construction disposal debris scattered throughout the excavation area. The materials removed from the 128-K-2 waste site consisted of friable and nonfriable asbestos, metallic and wood debris, burnt wood, ash, tar, yellow paint, broken and intact glassware, and concrete debris. Remediation of the 128-K-2 waste site extended from 0.3 meter (1 ft) to a maximum depth of 6.5 meters (21 ft) below ground surface (bgs). The excavation resulted in the removal of 13,465 bank cubic meters (BCM) (17,612 bank cubic yards [BCY]) of miscellaneous construction disposal debris including friable and non-friable asbestos, metallic and wood debris, burnt wood, ash, tar, yellow paint, broken and intact glassware, and concrete. All material removed from the site was disposed at the Environmental Restoration Disposal Facility (ERDF).

While excavating near the center of the 128-K-2 waste site, field personnel noticed fuel oil odor from the soil at coordinates N146174.9/E567968.3. Additional remediation was performed in the fuel oil-contaminated area with all soil directly loaded out for disposal at ERDF.

---

Code: 130-K-2
Names: 130-K-2, 1717-K Waste Oil Storage Tank
Type: Storage Tank
Status: Inactive
Start Date: 1/1/1955
End Date: 1/1/1972

Classification: Accepted
Reclassification: None

Description: The site was an underground waste oil storage tank oriented with the long axis of the tank in a north-south direction. The tank was excavated in July 1989. The tank was used for storing used motor oil. The tank was left with a residual heel when the facilities were deactivated in 1971. The concrete pad over the top of the tanks was removed in July 1989. This allowed Pacific Northwest Laboratories to return to the tank site and perform Ground Penetrating Radar (GPR) to aid in locating the tank without the interference caused by the rebar in the concrete. The soil around where the tanks had been located was sampled, the results analyzed, and the site backfilled to match the surrounding grade.

Location: The site was located approximately 0.3 meters (1 foot) north of the 1717-K Maintenance and Transportation Service Building and 6.1 meters (20 feet) from the northwest corner of this building.

Related Sites/Structures: The site was related to the 1717-K Maintenance and Transportation Service Building.

Waste Type: Process Effluent

Waste Description: The unit was used for storage of used motor oil.
**Code:** 1607-K1

**Description:** The waste site has been remediated and Interim Closed Out. The tank and drain field were enclosed within a wooden fence and marked with Septic Tank and Drain Field signs.

**Location:** The site is located west of 183-KW (Head House) and northwest of the 183-KW Chlorine Vault.

**Related Sites/Structures:** The site serviced the 183-KW Building.

**Process Description:**

The 1607-K3 Sanitary Sewer System supported the 183-KW Water Treatment Plant, operating from 1955 to 1970. The volume of waste received is unknown. The sewer system was not known to have received hazardous or radioactive wastes, as it was installed for sanitary use.

The sanitary sewer system is composed of a septic tank, leaching trench, and associated piping. The 1900-liter (500-gallon) septic tank is constructed of steel per Hanford Standard E-5-11. There is a maximum of 1.5 meters (5 feet) of fill on the cover slab. The inlet pipe is 26 meters (85 feet) long and is constructed of 15-centimeter (6-inch) vitrified clay pipe. The pipe from the tank to the leach trench is 6.1 meters (20 feet) long and is also constructed of 15-centimeter (6-inch) vitrified clay pipe. The leaching trench contains 33.5 meters (110 feet) of 15-centimeter (6-inch) vitrified clay pipe laid with open joints.

**Waste Type:** Process Effluent

**Waste Description:** This unit received sanitary sewage from 183-KW Water Treatment Plant. The flow rate is estimated to have been 1,230 liters (325 gallons) per day.

**Closure Info:** Remediation of the Area AA Zone 1 Waste Sites began in April 2010 and ended in January 2012. The waste site structures and soils have been excavated as part of the remedial activities for the 100-K Area. The excavation area was designated as 100-K Area AA, Zone 1 (Area AA, Zone 1). It encompassed the individual waste sites 100-K-34, 100-K-102 and 1607-K3. Stockpile #11 contains layback soil from remediation of Area AA, Zone 1. These waste sites are adjacent to the 100-K-59 pipelines. Since visible sediment was observed in the severed pipelines, a sample was collected in February 2011 from the open end of the pipe west of the 183.1KW Headhouse. A section of the 100-K-59 pipeline was removed.

Excavation of the waste sites continued to a final remediation maximum depth of 9.82 meters (32.2 ft), which was located within the footprint of 100-K-102. To support the deeper excavation for Area AA, Zone 1, layback soil was accumulated and managed as Stockpile #11. The excavation decision unit was approximately 7,331 square meters (78,910 ft²) for 100-K Area AA, Zone 1. The original footprint prior to additional process sewer pipe removal was divided into evenly spaced areas for statistical sampling outside the waste sites to address any potential for contamination spread.

**Code:** 1607-K5  
**Classification:** Accepted

**Names:** 1607-K5; 1607-K5 Sanitary Sewer System; 1607-K5 Septic Tank; 1607-K5 Septic Tank and Associated Drain Field; 124-KE-2

**Reclassification:** None

**Type:** Septic Tank

**Status:** Active
Description: The unit includes a tile field.

Location: This septic tank and drain field are east of the 105-KE Reactor and west of the 118-K-1 Burial Ground.

Related Sites/Structures: This site services the 1706-KER Flow Laboratory, 1706-K Water Treatment Laboratory, 165-KE Powerhouse, 105-KE Reactor Building, and 115-KE Gas Recirculation System.

Waste Type: Process Effluent

Waste Description: This unit receives sanitary sewage from 1706-KER Flow Laboratory, 1706-K Water Treatment Laboratory, 165-KE Powerhouse, 105-KE Reactor Building, and 115-KE Gas Recirculation System. The flow rate to this unit is estimated at 700 gal/d.

---

Description: The unit includes a tile field and the piping from the facilities to the tile field.

Location: This facility is east of the 105-KW Reactor.

Related Sites/Structures: This unit receives sanitary sewage from 105-KW Reactor Building, 115-KW Gas Recirculation Building, and 165-KW Powerhouse.

Waste Type: Demolition and Inert Waste

Waste Description: This unit receives sanitary sewage from 105-KW Reactor Building, 115-KW Gas Recirculation Building, and 165-KW Powerhouse.

---

Description: The crib and pipeline were remediated in 2004, but the status was not reclassified. The Cleanup Status Report for the 116-KE-1 and 116-KW-1 (BHI-01737), documented the status of remediation at the sites to assist in future decision making. The crib structure was removed along with contaminated soil. At the completion of the 2004 project, the excavation approximately 717 square meters (7713 sq. ft.) with a depth of approximately 9.1 meters (30 ft.). The site excavation was backfilled with clean soil to the average adjacent grade elevation at that time. Carbon-14 was detected in deep zone soil at concentrations ranging from 1,880 pCi/g to 7,600 pCi/g. To avoid impacting adjacent building foundations and because of the depth of residual Carbon-14 contamination, impacted soils that did not meet the objectives of the interim ROD Amendment (EPA -1997) remain in place. Disposition of this site will be determined at a later date.

Remediation and sampling of a large excavation area, known as 100-K Area AH, began in January of 2009 and was completed in April of 2012. It encompassed waste sites 100-K-6, 100-K-46, 100-K-62 and 132-KE-1 waste sites and also the site of the previously excavated 116-KE-
1 crib. Area-wide carbon-14 contamination exists in the deep zone above the criteria for protectiveness. This contamination is associated with the 105-KE Reactor ventilation filtration system and the deep contamination from the condensate that collected in the previously excavated 116-KE-1 Condensate Crib. Additional remediation of the deep vadose zone cannot be completed in proximity to the 105-KE Reactor without impacting structural stability. Due to the depth of the contamination, the carbon-14 remediation will coincide with the final decision on 105-KE reactor removal.

Location: The crib was located north of 115-KE and east of 118-KE-1 (105-KE Reactor Building).

Related Sites/Structures: The distribution system was composed of a 10.2-centimeter (4-inch) pipe that led into an 20.3-centimeter (8-inch) corrugated galvanized steel perforated pipe, 3.2 meters (10.5 feet) long, with two 2-meter (6.5-foot) sections branching off at 45 degrees. The site received effluent from the 105-KE Reactor Buildings.

Process Description: The crib was constructed to receive condensate from the 105-KE gas purification system. The base of the crib was 1.8 meters (6 feet) in diameter and was positioned 7.8 meters (25.5 feet) below the ground surface. The top of the crib measures 12.2 meters (40 feet) in diameter. The crib was filled with coarse gravel to 3 meters (10 feet) above the base. The remainder of the crib was backfilled with dirt to grade. The site included the feed pipeline coming from the 115-KE Building.

Waste Type: Process Effluent

Waste Description: The site received condensate and other waste from reactor gas purification systems. Beta/gamma concentrations within the crib, taken from two sample boreholes drilled in 1976, range from 4.5E+05 picocuries per gram to 8.6E+05 picocuries per gram. The radionuclide inventory curies decayed through April 1, 1986, includes tritium (56.5 curies), carbon-14 (110 curies), and small amounts of other elements.

Code: 116-KE-2
Names: 116-KE-2; 1706-KER Waste Crib and Pipeline
Type: Crib
Status: Inactive
Description: The waste site is a wooden crib structure and the associated piping.
Location: The crib is located west of the 1706-KER Building.
Waste Type: Equipment
Waste Description: The site received wastes from cleanup columns in the 1706-KER loop. Drilling in the mid-1970's next to the crib revealed concentrations of radionuclides in the soil. The total estimated concentration was 38 curies. The radionuclide inventory decayed through April 1, 1986, was estimated at approximately 14.6 curies, and is composed predominantly of cobalt-60 and strontium-90. Approximately 100,000 kilograms (220,500 pounds) of sodium hydroxide may have been disposed of into the crib as well as 100,000 kilograms (220,500 pounds) of sulfuric acid.

Code: 116-KE-3
Names: 116-KE-3; 105-KE Fuel Storage Basin Storage Basin French Drain; 105-KE Sub-Basin Drainage Disposal System Crib
Classification: Accepted
Reclassification: None
The waste site is part of the sub-basin drainage disposal system for the 105-KE Fuel Storage Basin (100-K-42). The site includes a feed pipe, crib structure, dry well, and test hole. Although 116-KE-3 was located inside the Area AG, Zone 1 boundary, it was in an "excluded region" and not considered part of the AG Zone 1 remediation scope. Remedial action from 2010 through 2012 at adjacent waste sites impacted waste site 116-KE-3. At this location, the excavation depth was approximately 12.5 meters (41 ft) from original grade at 116-KE-3 to 130 meters (426 ft) above mean sea level. Excavation to this depth resulted in the removal of the perforated crib pipelines. The gravel directly below the pipelines and the 8\(\text{in.}\) steel well casing to groundwater were not completely removed. Remedial activities did not remove all of the vadose zone contamination encountered at 116-KE-3. The expected depth of the excavation necessary to remediate the contaminated soil was not possible without threat to the integrity of the KE Reactor. To provide immediate protection to human health, the area was backfilled with clean soil.

It had been cobble covered and posted with "Underground Radioactive Material" warning signs. A mound of soil, installed in 1977 or 1978, covered some of the ancillary units related to this site. The test hole's 10.2-centimeter (4-inch) diameter steel casing originally extended above finish grade level but was no longer visible.

A 20.3-centimeter (8-inch) corrugated galvanized steel feed pipe 8.8 meters (29 feet) below grade comes from the fuel storage basin. The feed pipe enters the crib structure at elevation 133 meters (435.5 feet).

The crib structure is trapezoid shaped with the top at grade level (Elevation: 142 meters [464.5 feet]) and approximately 18.3 meters (60 feet) in width (excavation and backfill width) and the bottom (Elevation: 425.5 feet) 3.05 meters (10 feet) in width. The bottom 3.7 meters (12 feet) of the crib is filled with coarse gravel.

The distribution system (drain field) within the crib is a central feeder with side feeders ("fishbone") located 8.8 meters (29 feet) below grade. All feeder piping is composed of 20.3-centimeter (8-inch) corrugated and perforated galvanized steel pipe. The main feeder pipe within the drain field is 6.1 meters (20 feet) long. The side feeders coming from each side of the central feeder are 2.7 meters, 3.2 meters, 2.6 meters, and 1.5 meters (9.0 feet, 10.5 feet, 8.5 feet, and 5.0 feet) in length, 1.75 meters, 1.7 meters, and 1.3 meters (5.75 feet, 5.5 feet, 4.25 feet) apart, and set at an angle of 30 degrees (Drawing #H-1-23207 is labeled 30 degrees, however, it appears on the drawing to be closer to 60 degrees.) The drain field is 6.1 meters (20 feet) in diameter.

A dry well (injection well) was installed at the midpoint (Washington State Plane Coordinates: Easting 569130.985, Northing 146753.534) of the drain field main feeder pipe. The dry well is constructed of 20.3-centimeter (8-inch) schedule 40 steel well casing. The dry well casing runs from elevation 435.5 feet (8.8 meters/29 feet below grade) downward to a point 3.05 meters (10 feet) below the mean water table. The bottom 6.1 meters (20 feet) of the well casing is perforated.

The 10.2-centimeter (4-inch) steel test hole extended from the surface to the head end of the drain field. The test hole piping was the only part of site's structure that was above grade. The construction of the "D" catch tank modification would have covered the test hole.

The site is located north of the 105-KE Reactor Building (118-KE-1) about 23 meters (75 feet).
Process Description: The site operated from 1955 to 1971 as an overflow crib for sub-basin drainage from the 105-KE Fuel Storage Basin (100-K-42).

Waste Type: Equipment
Waste Description: The waste is contaminated structures and soil from the fuel storage basin sub-basin drainage system.

Related Sites/Structures: The site is associated with 100-K-42 fuel storage basin.

Code: 116-KE-5
Names: 116-KE-5; 150-KE Heat Recovery Station
Type: Process Unit/Plant
Status: Inactive
Description: The site has been remediated and Interim Closed Out. The facility was constructed on a concrete pad and consisted of heat exchangers and associated piping. The heat exchangers had been removed and are being used elsewhere. Exposed piping had wooden covers installed over the open ends. Remedial action activities at the 100-K reactor sites began on December 9, 2002 by Washington Closure Hanford (WCH). Remediation involved excavation and staging of overburden material and removal of contaminated piping, debris and soil at the 100-K-55:1, 100-K-56:1, 116-KW-4 and 116-KE-5 waste sites. Contaminated materials were disposed at the ERDF. Remedial action excavation was completed on April 15, 2005.

Location: The site was located north of 118-KE-1 (105-KE Reactor Building) and east of the reactor cooling effluent lines near 116-KE-4 (107-KE Retention Basins).

Release Description: There were no known releases from this heat exchange station. Only surface contamination is on the remaining pipes.

Process Description: The heat recovery station was used to transfer heat from the 105-KE Reactor cooling water effluent. The station used an ethylene glycol solution as the heat exchanger medium. The system was no longer intact.

Waste Type: Batteries
Waste Description: Trace amounts of radioactive contamination remain on piping.

Closure Info: Remedial action activities at the 100-K reactor effluent pipelines began on December 9, 2002 by Washington Closure Hanford (WCH). Remediation of the pipelines involved excavation and staging of overburden material and removal of contaminated piping, debris and soil at the 100-K-55:1, 100-K-56:1, 116-KW-4 and 116-KE-5 waste sites. Contaminated materials were disposed at the ERDF. Remedial action excavation was completed on April 15, 2005. The previously documented waste site boundaries for the 116-KW-4 and 116-KE-5 sites were much larger than the actual footprint of the heat recovery facilities. The soil area beneath each of the former heat recovery stations was excavated in its entirety with the removal of the co-located pipelines. Approximately 55,960 square meters (602,350 sq ft) of plan area was excavated, including excavation within the deep zone (greater than 4.6 meters [15 ft] below ground surface) up to 8.8 meters (29 ft) below ground surface where necessary to complete remediation. Approximately 86,551 metric tons (95,406 U.S. tons) of material from the sites was removed and disposed at the ERDF. The active 100-K-47 concrete culvert was not removed during remediation of the adjacent section of the 100-K-55 pipeline. Several 100-K-56 pipe segments, located west of 116-KE-4, were not included in the remediation scope.
The contaminated materials from these sites have been excavated and disposed at the ERDF. The remaining soils at the sites have been sampled, analyzed, and modeled, and the results do not preclude any future uses (as bounded by the rural-residential scenario), allow unrestricted use of shallow zone soils, and pose no threat to groundwater or the Columbia River. The 100-K-55:1, 100-K-56:1, 116-KW-4, and 116-KE-5 sites were verified to be remediated in accordance with the ROD and may be backfilled.

</table>

**Description:** The site has been remediated and Interim Closed Out. The site consisted of a 96 gallon condensate collection tank, which was part of the 1706-KE Waste Treatment System installed in 1984.

**Location:** The tank was located northwest of the 1706-KER building.

**Release Description:** On August 18, 1986, a 30 gallon epoxy vessel overheated. The event resulted in the forcible ejection of some of the resin material from the treatment unit. The epoxy overheating caused the emission of thick white vapors but no fire was observed. The ejected waste material was slightly radioactive. The material was cleaned up and packaged for low-level burial by operations personnel. No radioactivity was found outside the radiation zone. The area was cleaned to background radiation levels. (see Event Investigation Report D/T-86-01)

**Related Sites/Structures:** Other WTS sites were 116-KE-6B, 6C, 6D.

**Process Description:** In 1984, a new system of radioactive waste treatment was initiated that consisted of an evaporation and epoxy encapsulation unit. During the original operation, a small stream of waste water was fed into a drum of hot epoxy at a constant rate. The water flashed to steam and traveled to a condenser where it was cooled and collected in the condensate collection tank. The liquid was sampled to determine if the radionuclide content was below releasable limits. Solids were collected in the epoxy. When a sufficient volume of epoxy (containing solid waste) was accumulated, a catalyst was added to harden the epoxy in the drum. The drum of solid epoxy was sealed and transported to a radioactive burial ground. This process ended in August 1986 when an ion exchange column was attached the accumulation tank. This process circulated the radioactive waste water through the ion exchange column until the radionuclide content was below the releasable limit.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The unit was used to treat radioactive wastes generated from sample analysis and test activities conducted in the laboratories of the 1706-KE Building. The system stopped operating in 1987. All of the waste was removed in 1994.

**Closure Info:** The 1706-KE Waste Treatment System (WTS), was a Treatment, Storage and Disposal (TSD) unit located in the 1706-KER Building under the Resource Conservation and Recovery Act of 1976 (RCRA) and subject to RCRA corrective action requirements. As documented in the 100 Area Remaining Sites ROD, the RCRA corrective actions and CERCLA remedial actions were coordinated such that the result of the remedial action satisfied both sets of requirements. RCRA closure of the WTS was completed in 2009. The DOE/RL-2010-42 RSVP addresses the completion of the CERCLA remedial action.

The 116-KE-6A, 116-KE-6B, 116-KE-6C, and 116-KE-6D waste sites were removed using
standard industrial materials and equipment. Remedial action activities were accomplished from June 15 through July 9, 2009. The waste materials from sites 116-KE-6A, 116-KE-6B, and 116-KE-6C were loaded on shipping containers July 1, 2009, and shipped to the Environmental Restoration Disposal Facility (ERDF) on July 9, 2009. The 116-KE-6D site was disposed in October 1996 at the low-level burial grounds. The ion exchange column, 116-KE-6D, was removed from the WTS in 1994. The column was containerized for future disposal at the Low-Level Burial Grounds and disposed in October 1996. Remedial activities for the 116-KE-6A, 116-KE-6B, and 116-KE-6C waste sites were initiated in June 2009, under RCRA TSD closure plan (DOE/RL-2009-29) and the RDR/RAWP for the 100 Area (DOE/RL-96-17) requirements. A pre-existing hatchway located immediately above the WTS area was utilized to move the condensate collection tank (116-KE-6A), evaporator tank (116-KE-6B), and waste accumulation tank (116-KE-6C) directly into shipping containers for disposal. Because of the size of the waste accumulation tank in relation to the hatchway, reducing the size of the tanks was necessary in order to remove them from the building. Following removal of the tanks, the room in which the tanks were located was cleaned of debris and surveyed for radiological contamination.

After completion of the TSD closure activities, Ecology provided an approval letter for the RCRA TSD closure plan. Upon completion of remediation, a Professional Engineer’s Certification for the RCRA Closure of the 1706-KE WTS was issued. The engineer's certification and Ecology's acceptance letter were provided in Appendices A and B of the RSVP.

Verification sampling was not required under the scope of closure for the waste sites, since the floor and walls in the 1706-KER Building were not included as part of either the RCRA TSD closure certification or under this CERCLA remedial action.

The cost to remove the above-grade portion of the 1706-KER Facility, which included removal and disposal of the waste sites was approximately $1.60 million. The effort to remove the waste sites was estimated at 10 percent of the project cost, which yielded an estimated cost of $160,000 for remediation of the four waste sites.

Hanford Site Waste Management Units Report
February 2015

The 116-KE-6A, 116-KE-6B, 116-KE-6C, and 116-KE-6D waste sites were removed using standard industrial materials and equipment. Remedial action activities were accomplished from June 15 through July 9, 2009. The waste materials from sites 116-KE-6A, 116-KE-6B, and 116-KE-6C were loaded on shipping containers July 1, 2009, and shipped to the Environmental Restoration Disposal Facility (ERDF) on July 9, 2009. The 116-KE-6D site was disposed in October 1996 at the low-level burial grounds. The ion exchange column, 116-KE-6D, was
removed from the WTS in 1994. The column was containerized for future disposal at the Low-Level Burial Grounds and disposed in October 1996. Remedial activities for the 116-KE-6A, 116-KE-6B, and 116-KE-6C waste sites were initiated in June 2009, under RCRA TSD closure plan (DOE/RL-2009-29) and the RDR/RAWP for the 100 Area (DOE/RL-96-17) requirements. A pre-existing hatchway located immediately above the WTS area was utilized to move the condensate collection tank (116-KE-6A), evaporator tank (116-KE-6B), and waste accumulation tank (116-KE-6C) directly into shipping containers for disposal. Because of the size of the waste accumulation tank in relation to the hatchway, reducing the size of the tanks was necessary in order to remove them from the building. Following removal of the tanks, the room in which the tanks were located was cleaned of debris and surveyed for radiological contamination.

After completion of the TSD closure activities, Ecology provided an approval letter for the RCRA TSD closure plan. Upon completion of remediation, a Professional Engineer's Certification for the RCRA Closure of the 1706-KE WTS was issued. The engineer's certification and Ecology's acceptance letter were provided in Appendices A and B of the RSVP.

Verification sampling was not required under the scope of closure for the waste sites, since the floor and walls in the 1706-KER Building were not included as part of either the RCRA TSD closure certification or under this CERCLA remedial action.

The cost to remove the above-grade portion of the 1706-KER Facility, which included removal and disposal of the waste sites was approximately $1.60 million. The effort to remove the waste sites was estimated at 10 percent of the project cost, which yielded an estimated cost of $160,000 for remediation of the four waste sites.

| In 1984, a new system of radioactive waste treatment was initiated that consisted of an evaporation and epoxy encapsulation unit. During the original operation, a small stream of waste water was fed into a drum of hot epoxy at a constant rate. The water flashed to steam and traveled to a condenser where it was cooled and collected in the condensate collection tank. The liquid was sampled to determine if the radionuclide content was below releasable limits. Solids were collected in the epoxy. When a sufficient volume of epoxy (containing solid waste) was accumulated, a catalyst was added to harden the epoxy in the drum. The drum of
solid epoxy was sealed and transported to a radioactive burial ground. This process ended in August 1986 when an ion exchange column was attached the accumulation tank. This process circulated the radioactive waste water through the ion exchange column until the radionuclide content was below the releasable limit.

**Waste Type:** Ordnance

**Waste Description:** The unit was used to treat radioactive wastes generated from sample analysis and test activities conducted in the laboratories of the 1706-KE Building. The system stopped operating in 1987. All of the waste was removed in 1994.

**Closure Info:** The 1706-KE Waste Treatment System (WTS), was a Treatment, Storage and Disposal (TSD) unit located in the 1706-KER Building under the Resource Conservation and Recovery Act of 1976 (RCRA) and subject to RCRA corrective action requirements. As documented in the 100 Area Remaining Sites ROD, the RCRA corrective actions and CERCLA remedial actions were coordinated such that the result of the remedial action satisfied both sets of requirements. RCRA closure of the WTS was completed in 2009. The DOE/RL-2010-42 RSVP addresses the completion of the CERCLA remedial action.

The 116-KE-6A, 116-KE-6B, 116-KE-6C, and 116-KE-6D waste sites were removed using standard industrial materials and equipment. Remedial action activities were accomplished from June 15 through July 9, 2009. The waste materials from sites 116-KE-6A, 116-KE-6B, and 116-KE-6C were loaded on shipping containers July 1, 2009, and shipped to the Environmental Restoration Disposal Facility (ERDF) on July 9, 2009. The 116-KE-6D site was disposed in October 1996 at the low-level burial grounds. The ion exchange column, 116-KE-6D, was removed from the WTS in 1994. The column was containerized for future disposal at the Low-Level Burial Grounds and disposed in October 1996. Remedial activities for the 116-KE-6A, 116-KE-6B, and 116-KE-6C waste sites were initiated in June 2009, under RCRA TSD closure plan (DOE/RL-2009-29) and the RDR/RAWP for the 100 Area (DOE/RL-96-17) requirements. A pre-existing hatchway located immediately above the WTS area was utilized to move the condensate collection tank (116-KE-6A), evaporator tank (116-KE-6B), and waste accumulation tank (116-KE-6C) directly into shipping containers for disposal. Because of the size of the waste accumulation tank in relation to the hatchway, reducing the size of the tanks was necessary in order to remove them from the building. Following removal of the tanks, the room in which the tanks were located was cleaned of debris and surveyed for radiological contamination.

After completion of the TSD closure activities, Ecology provided an approval letter for the RCRA TSD closure plan. Upon completion of remediation, a Professional Engineer's Certification for the RCRA Closure of the 1706-KE WTS was issued. The engineer's certification and Ecology's acceptance letter were provided in Appendices A and B of the RSVP.

Verification sampling was not required under the scope of closure for the waste sites, since the floor and walls in the 1706-KER Building were not included as part of either the RCRA TSD closure certification or under this CERCLA remedial action.

The cost to remove the above-grade portion of the 1706-KER Facility, which included removal and disposal of the waste sites was approximately $1.60 million. The effort to remove the waste sites was estimated at 10 percent of the project cost, which yielded an estimated cost of $160,000 for remediation of the four waste sites.

**Code:** 118-KE-2  
**Names:** 118-KE-2; Rod Cave; 105-KE Horizontal Control Rod Storage Cave  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (6/14/2011)
Storage  
Start Date: 1/1/1955  
End Date: 1/1/1971

Description: The waste site has been remediated and Interim Closed Out. The site was constructed by pouring a concrete slab 18 meters (60 feet) long by 2.4 meters (8 feet) wide. Two sections of 61-centimeter (24-inch) pipe were cut in half lengthwise, laid open side down on the slab. Vertical concrete walls and steel doors were added to the ends of the pipe sections, with the walls forming a wing at each end. The pipe sections were then covered with 1.8 meters (6 feet) of clean fill material, forming a 12-meter (40-foot) long tunnel. The berm width after the fill material was added is approximately 8 meters (25 feet). The entire structure is above grade.

Location: The site is located northeast of the 105-KE Building.

Related Sites/Structures: 105-KE Reactor and the 100-K-9 and 100-K-10 french drains.

Process Description: The unit was used for temporary storage of radioactive rod tips associated with the 105-KE Reactor for radioactive decay pending subsequent disposal.

Waste Type: Demolition and Inert Waste

Waste Description: This site contains trace amounts of radionuclides. The radiation level at the entrance to the cave with the door open is 1 millirad/hour. The unit was used for temporary storage of radioactive rod tips for radioactive decay pending subsequent disposal.

Closure Info: The entire 118-KE-2 Waste Site structure, including the concrete slab, was removed in September 2009 to facilitate heavy equipment access to the 105-KE Building and associated Fuel Storage Basin to support ongoing remedial activities. The interim action consisted of successful removal and disposal of the entire 118-KE-2 Waste Site. Materials from the demolition of the structure and shipped to the ERDF for disposal.

Code: 120-KE-1

Names: 120-KE-1; 183-KE Acid Neutralization Pit; 183-KE Filter Waste Facility Dry Well; 183-KE Filter Water Facility; 100-K-26; 100-KE-1

Type: Sump

Start Date: 1/1/1955  
End Date: 1/1/1971

Description: The site was an underground concrete structure used to neutralize acid waste prior to disposal. The "pit" was a concrete box lined with acid proof bricks. The structure was divided into three sections by dividing brick weirs. Effluent released into the system was held up in a small chamber by the first weir. Effluent overflowed the first weir into a second small chamber and then overflowed the second weir into the third larger chamber. A 10.2-centimeter (4-inch) vitrified tile drain was located in the bottom of the third large chamber and is believed to discharge to the process sewer (see Site Comment). The top of the pit was level with the surface and had a 7.6-centimeter (3-inch) plank cover that was posted with "Confined Space" and "Caution, Acid" warning signs. In August 2000, the area around the acid tanks was stabilized with gravel. The french drain and sump were backfilled. They are no longer visible. They are not marked or posted.

Location: The site is located near the southeast corner of the 183-KE Head House, south of the 120-KE-5 Sulfuric Acid Tank and east of the 100-K-23 Sodium Silicate Tank Site.

Related Sites/Structures: The site was associated with the 183-KE Head House and the 183-KS Sulfuric Acid Tanks.
The method of acid neutralization is not known. When two other acid neutralization pits (100-K-34 and 100-K-35) that were associated with the elevated day use tanks at 183-KE and 183-KW were opened, crushed limestone was visible. Limestone may also be at the 120-KE-1 site beneath the discarded sludge.

Waste Type: Demolition and Inert Waste

The site received sulfuric acid for neutralization and acid sludge waste that was removed from the sulfuric acid storage tanks in the late 1960's and early 1970's.

Code: 120-KE-2

Names: 120-KE-2; 183 KE Filter Water Facility; 183-KE Filter Waste Facility French Drain; 100-KE-2

Type: French Drain

Status: Inactive

Description: The unit was an open-bottomed french drain with a depth of 0.9 meters (3 feet) and a diameter of 0.9 meters (3 feet). It is had been located inside four, yellow posts with chain. In August 2000, the drain was backfilled and the area around the acid tanks was stabilized with gravel. The french drain and sump were backfilled. They are no longer visible. They are not marked or posted.

Location: The site is located 37 meters (121.4 feet) east of the southeast corner of 183-1KE head house and adjacent to the 120-KE-4 Sulfuric Acid Tanks.

Process Description: Hanford drawing H-1-25264 describes this drain as being a 0.9-meter (3-foot) diameter, 1.8-meter (6-foot) long vitrified clay pipe placed vertically in an excavation that was about 4 meters (13 feet) across and 3.4 meters (11 feet) deep. The bottom 0.3 meters (1 foot) of the pipe was filled with course rock, as was the bottom 1.5 to 1.8 meters (5 to 6 feet) of the excavation.

Waste Type: Misc. Trash and Debris

The site received sulfuric acid sludge that was removed from sulfuric acid storage tanks.

Code: 120-KE-3

Names: 120-KE-3; 183-KE Filter Water Facility Trench; 100-KE-3

Type: Trench

Status: Inactive

Description: The unit was a trench lined with sand. The trench received a sludge-water slurry. The contaminated soil was removed by an offsite vendor.

Location: The site was located east of 183-1KE, head house, north of the 120-KE-4 and 120-KE-5 sulfuric acid tanks, on the north side of the railroad tracks.

Waste Type: Demolition and Inert Waste

The site received sulfuric acid sludge that was removed from sulfuric acid storage tanks.

Description: The site is a foundation where a sodium dichromate storage tank was placed. The tank has been removed and all that remains is the concrete pad, contaminated soil, and any remaining piping. The vertical steel storage tank was 6.1 meters (20 feet) high, 5.8 meters (19 feet) in diameter, and had a 159,000-liter (42,000-gallon) storage capacity.

Location: The site is located on the east side of the 183-KE Building. The center of the pad is 6.1 meters (20 feet) from the building's east wall.

Release Description: There are no documented releases. However, there is evidence of residual sodium dichromate in the soil that has accumulated from many years of unloading and handling.

Related Sites/Structures: The site is associated with the 183-KE Building.

Process Description: Sodium dichromate was added to the process water as a corrosion inhibitor. It was metered and proportioned by a single step operation in the head house, and diluted and injected into the process water in the process water pump house. The proportioning pumps took their suction directly from the storage tank. Near the process water pump house, the pumps discharged through a back pressure valve into a service water stream which diluted the dichromate on its way to injection into the process water. The injection point was located on the discharge of the low lift pump. Dichromate injection was determined by the process water flow. The chemical storage facilities at the 183-KE Building were sized to provide sufficient chemicals for two to three months continuous operation. Chemicals were delivered to the 183-KE Building by rail. With the exception of chlorine, all chemicals were transferred to their storage tanks by pumping or by pressurizing the tank cars with compressed air.

Waste Type: Construction Debris

Waste Description: Staining from sodium dichromate can be seen in the soil near the concrete pad.

Code: 120-KE-8
Names: 120-KE-8; 165-KE Brine Mixing Tank; 165-KE Brine Pit
Type: Sump
Status: Inactive
Start Date: 1/1/1955
End Date: 1/1/1971

Description: The unit is a below grade concrete structure the provided brine for the 165-KE Powerhouse. The roof of the structure is approximately 0.3 meters (1 foot) above ground level. The opening into the pit is covered by a wooden cover that is in poor condition. The bottom of the pit has subsided and appears to have leaked or drained to the soils beneath the structure. Just south of the brine pit is a valve pit located within a vertical section of 1.2 meter (4 foot) diameter corrugated galvanized pipe. This valve pit contains residue and apparently was part of the brine operation. The brine pit has inner dimensions of 4.3 meters (14 feet) long by 2.4 meters (8 feet) wide by 2.7 meters (9 feet) tall. The bottom of each pit is filled with a 1.27 centimeter (7 inch) layer of 1.3 to 2.6 centimeter (1/2 to 1 inch) gravel topped by a 17.8 centimeter (7 inch) layer of 0.3 to 0.6 centimeter (1/8 to 1/4 inch) gravel. The pit has a 1.2 meter (4 foot) by 1.1 meter (3.5 foot) opening for receiving salt.

Location: The site is located near the northwest corner of the 165-KE Powerhouse.

Related Sites/Structures: The site is associated with the 165-KE Powerhouse.
### Process Description:
The brine was probably used to regenerate the water softeners that treated water prior to steam generation within the 165-KE Powerhouse. Salt was off-loaded from rail cars and placed in the pit. Water was then circulated through the pit, and brine was pumped back to the 165-KE Powerhouse for further use.

### Waste Type:
Demolition and Inert Waste

### Waste Description:
The unit contains salt brine and residue. Based on sampling performed at the 120-KE-9 and 120-KW-7 brine pits, the brine and residue may be regulated as dangerous per WAC 173-303.

<tr>
<td>Description:</td>
<td>The site was an above ground vertical stainless steel storage tank mounted on a concrete base. The tank has been removed and disposed at ERDF. This tank is no longer in existence. The tank was part of a system called &quot;The Liquid Alum System&quot;, that supplied liquid alum for water</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
treatment. The liquid was supplied either by rail car or tank truck, as both connections are shown on the Liquid Alum System diagram in HW-24800-103. The piping and instrument identification diagram, H-1-16552, shows the pipelines, valves, and instrumentation related to the tank. During the winter, the liquid alum was pumped through heat exchangers for purpose of heating and agitating the chemicals. Use of this tank for the storage of alum was discontinued in the Fall of 1996.

Location: The site was the western-most of two alum storage tanks located approximately 15.2 meters (50 feet) from the southwest corner of the 183-KE Head House and 10.7 meters (35 feet) south of the 183-KE chlorine vault.

Related Sites/Structures: The tank was associated with the 183-KE Head House. The head house was the water quality center for the entire water treatment plant. It was the facilities for metering raw water, for chemical injection into raw, filtered, and process water, and for effluent and influent control throughout the filter plant.

Process Description: Alum was used as a coagulant in water treatment. During the season of water high turbidity activated silica was added as an aid in coagulation. Alum was fed from the storage tank and proportioned directly into the raw water line. The proportioning pump was paced by the flow of raw water in its 91 centimeters (36 inches) raw water pipeline and fed at 30 parts per million (ppm) at a maximum flow rate of 121,000 liters per minute (32,000 gallons per minute).

Waste Type: Demolition and Inert Waste

Waste Description: The unit was used for storage of liquid alum (aluminum sulfate). Material Safety Data Sheet (MSDS) #040407 lists aluminum sulfate as an EPA hazardous substance. The tank has not been cleaned out.

Code: 130-KE-1 Classification: Accepted

Names: 130-KE-1; 105-KE Emergency Diesel Fuel Tank; 105-KE Emergency Diesel Oil Storage Tank

Type: Storage Tank Start Date: 1/1/1955

Status: Inactive End Date: 1/1/1971

Description: The 130-KE-1 waste sites consisted of two 7,600-liter (2,000 gallon) capacity storage tanks, 130-KE-1A and 130-KE-1B. Once the storage tanks were removed from the site, the site was backfilled with native soil to grade and covered with gravel.

Location: The site is located on the east side of 105-KE, adjacent to the reactor exhaust stack.

Related Sites/Structures: 105-KE Reactor

Process Description: The 130-KE-1 Waste Site Tank System was used for storing diesel fuel from 1955 to 1971 to support use of the emergency fans housed in the basement of the 105-KE Reactor. The fans were in place as a backup ventilation system for the reactor.

Waste Type: Oil

Waste Description: The unit was used for storage of diesel fuel (product).

Closure Info: The 130-KE-1 Waste Site Tank System (including tanks 130-KE-1A and 130-KE-1B) was permanently closed by removal of the below-grade tanks and accessible piping on October 5, 1992. The remedial action for the 130-KE-1 Waste Site included removal and disposal of the tanks and sampling and analysis of the underlying soils for total petroleum hydrocarbons (TPH).
The 130-KE-1 Waste Site was removed using standard industrial equipment. The two tanks were empty upon removal. No visible staining was observed and no organic vapors were detected during monitoring of the excavation and 130-KE-1 Waste Site Tank System removal. Soils samples from the excavated area and the overburden were collected and analyzed in accordance with Ecology Publication 90-52. The 130-KE-1 Waste Site Tank System was received by Northwest EnviroField Services, Inc. on February 5, 1993, for disposal as scrap steel.

A complete site assessment was performed per WAC 173-360-390 immediately following the 130-KE-1 Waste Site Tank System removal. Samples were collected from the excavated area and the overburden. After the 130-KE-1 Waste Site Tank System was removed, the area was sampled and final data received, the site was backfilled to grade.

*Hanford Site Waste Management Units Report*

February 2015 769
discharged through a floor drain into the ground below the stack.

**Location:**
The unit is located on the northeast side of the 105-KE Reactor Building.

**Related Sites/Structures:**
Following completion of the confinement project in 1960, the air was diverted via underground reinforced concrete ducts to the 117-KE Filter Building. After flowing through the filters, the air went through below-grade concrete ducts and into the exhaust stack.

**Process Description:**
The 132-KE-1 Waste Site (aka 116-KE Reactor Exhaust Stack) was designed to discharge ventilation exhaust air into the atmosphere from the 105-KE Reactor Building to prevent the possible buildup of radioactivity near the reactor area. The 116-KE Reactor Exhaust Stack operated from 1955 to 1971. Prior to 1960, air from the 105-KE Reactor Building flowed through concrete ducts directly out of the stack, later the air was diverted via underground reinforced concrete ducts to the 117-KE Filter Building. After flowing through the filters, the air went through below-grade concrete ducts and into the 116-KE Reactor Exhaust Stack.

**Waste Type:** Oil

**Waste Description:** Discharged ventilated air from the 105-KE Building flowed through concrete ducts directly out of the stack. The Exhaust Stack received radiologically contaminated exhaust air. The contaminants were cobalt-60, cesium-137, carbon-14, europium-152, europium-154, and europium-155, strontium-90 and tritium.

**Closure Info:**
Remediation and sampling began in January of 2009 and was completed in April of 2012. The large excavation area, known as 100-K Area AH, encompassed waste sites 100-K-6, 100-K-46, 100-K-62 and 132-KE-1. The excavation area also included Stockpile #4, which contained overburden and layback soil from the excavation of the 116-KE-1 Condensate Crib. Information supporting the use of Stockpile #4, located within the AH excavation, as backfill was also included in the DOE/RL-2012-38 Remaining Sites Verification Package report.

Remediation of the identified Area AH waste sites was accomplished by demolishing the structures and excavating contaminated soil. All waste (soil and debris) associated with these waste sites was disposed at the Environmental Restoration and Disposal Facility (ERDF). The demolition activities were conducted using standard demolition techniques, including explosives for demolition of 132-KE-1 (116-KE Reactor Exhaust Stack). Approximately 1,809 ERDF containers (37,700 tons) of waste from these waste sites were sent to the ERDF for disposal.

Remediation of the 100-K-6 vacuum pit began in August 2011 and was completed in September 2011. An excavator was used to remove the vacuum pit and excavate the surrounding soil. The original waste site description estimated the depth of the cyclone separator as 9.14 meters (30 ft). However, during remediation the actual excavation depth was measured as 5.8 meters (19 ft).

The remediation of the 100-K-46 french drain was associated with the removal of the 119-KE building, which began in January 2009 and was completed in February 2009. The drywell was less than 1.5 meters (5 ft) deep.

The remediation activities at the 100-K-62 filter building began in August 2010 and were completed in May 2011. An excavator was used to remove the vacuum pit and excavate the surrounding soil. The maximum depth from grade within the waste site footprint was approximately 10.6 meters (34.8 ft).

The remediation activities at waste site 132-KE-1 exhaust stack began in July 2010 and were completed in September 2011. Removal of the above-grade portion of the stack was conducted using explosives placed near the base of the stack. The explosion caused the debris to fall in a designated area. The material was then loaded and disposed at ERDF. The entire below grade
portion of the stack base was then removed. The maximum depth from grade within the waste site footprint was approximately 6.1 meters (20 ft).

In October of 2010, excavation of the overburden and layback soil for the 116-KE-1 Crib began and Stockpile #4 was created. Samples were collected in the 116-KE-1 waste site footprint and sent for analytical leach testing of the soils to determine carbon-14 leachability from the 100-K soil. During remediation of the co-located waste sites inside the AH excavation area, the 116-KE-1 crib was partially backfilled with soil from Stockpile #4 as a contamination control measure.

Note: Area-wide carbon-14 contamination exists in the deep zone above the criteria for protectiveness. This contamination is associated with the 105-KE Reactor ventilation filtration system and the deep contamination from the condensate that collected in the previously excavated 116-KE-1 Condensate Crib. Additional remediation of the deep vadose zone cannot be completed in proximity to the 105-KE Reactor without impacting structural stability. Available information about the nature and extent of the carbon-14 contamination has been documented in the 116-KE-1 Condensate Crib waste site description. Due to the depth of the contamination, the carbon-14 remediation will coincide with the final decision on 105-KE reactor removal.

### 116-KW-1; 115-KW Condensate Crib

**Code:** 116-KW-1

**Name:** 116-KW-1; 115-KW Condensate Crib

**Type:** Crib

**Status:** Inactive

**Classification:** Accepted

**Recategorization:** None

**Start Date:** 1/1/1955

**End Date:** 1/1/1971

**Description:** The crib and pipeline were remediated in 2004, but the status was not reclassified. The Cleanup Status Report for the 116-KE-1 and 116-KW-1 (BHI-01737), documented the 2004 status of remediation at the sites to assist in future decision making. Site excavation, to the extent that could be safely conducted in the vicinity of adjacent buildings and to the capability of the onsite excavation equipment, is complete. Excavated waste disposal is complete, and the exposed surfaces of the excavation have been sampled and analyzed to assess remaining contaminant concentrations. The excavation has been backfilled. At the completion of the 2004 project, the excavation for the 116-KW-1 site was approximately 759 meters squared (8,162 square feet) in area. The bottom of the excavation for the site was approximately 9.1 meters (30 feet) below the surrounding grade. Approximately 2,519 bank cubic meters of material from the 116-KW-1 site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

**Location:** The crib was located north of 115-KW and east of 118-KW-1 (105-KW Reactor Building).

**Related Sites/Structures:** The distribution system was composed of a 10.2 centimeter (4 inch) pipe that led into an 20.3 centimeter (8 inch) corrugated galvanized steel perforated pipe that was 3.2 meters (10.5 feet) long, with two 2-meter (6.5 foot) sections branching off at 45 degrees. The site received effluent from the 105-KW Reactor Buildings.

**Process Description:** The crib was constructed to receive condensate from the 105-KW gas purification system. Before the 2004 remediation the bottom of the crib was 1.8 meters (6 feet) in diameter and was 7.8 meters (25.5 feet) below the ground surface. The top of the crib measures 12.2 meters (40 feet) in diameter. The bottom of the crib was filled with 3 meters (10 feet) of course gravel, then backfilled with dirt to grade. This site included the feed pipeline from the 115-KW Building.

**Waste Type:** Demolition and Inert Waste
Waste Description: The site received condensate and other wastewater from reactor gas purification systems. Drilling of the crib in the mid-1970's revealed high concentrations of tritium and carbon-14. The radionuclide inventory in curies decayed through April 1, 1986, includes tritium (81.9 curies), carbon-14 (110 curies), and small amounts of other elements.

Code: 116-KW-2
Classification: Accepted
Reclassification: None

Names:
- 116-KW-2
- 105-KW Basin Reverse Well
- 105-KW Fuel Storage Basin Sub-Basin Drainage Disposal System Crib
- 105-KW Storage Basin French Drain

Type: Injection/Reverse Well
Start Date: 1/1/1955
End Date: 1/1/1970
Status: Inactive

Description: The site is part of the sub-basin drainage disposal system for the 105-KW Fuel Storage Basin (100-K-43). The site includes the following components: a feed pipe, crib structure, dry well, and test hole. The area of the site is cobble covered and posted with "Underground Radioactive Material" warning signs. A mound of soil, installed in 1977 or 1978, is located nearby and covers some of the ancillary units related to this site. The test hole's 10.2-centimeter (4-inch) diameter steel casing that originally extended above finish grade level is no longer visible. A 20.3-centimeter (8-inch) corrugated galvanized steel feed pipe 8.8 meters (29 feet) below grade comes from the fuel storage basin. The feed pipe enters the crib structure at elevation 133 meters (435.5 feet). The crib structure, in plan view, is trapezoid shaped with the top at grade level (Elevation: 142 meters [464.5 feet]) and approximately 18.3 meters (60 feet) in width (excavation and backfill width) and the bottom (Elevation: 425.5 feet) 3.05 meters (10 feet) in width. The bottom 3.7 meters (12 feet) of the crib is filled with coarse gravel. The distribution system (drain field) within the crib is a central feeder with side feeders ("fishbone") located 8.8 meters (29 feet) below grade. All feeder piping is composed of 20.3-centimeter (8-inch) corrugated and perforated galvanized steel pipe. The main feeder pipe within the drain field is 6.1 meters (20 feet) long. The side feeders coming from each side of the central feeder are 2.7 meters, 3.2 meters, 2.6 meters, and 1.5 meters (9.0 feet, 10.5 feet, 8.5 feet, and 5.0 feet) in length, 1.75 meters, 1.7 meters, and 1.3 meters (5.75 feet, 5.5 feet, 4.25 feet) apart, and set at an angle of 30 degrees (Drawing #H-1-23207 is labeled 30 degrees, however, it appears on the drawing to be closer to 60 degrees.) The drain field is 6.1 meters (20 feet) in diameter. A dry well (injection well) was installed at the midpoint (Washington State Plane Coordinates: Easting 568589.544, Northing 146473.534) of the drain field main feeder pipe. The dry well is constructed of 20.3-centimeter (8-inch) schedule 40 steel well casing. The dry well casing runs from elevation 435.5 feet (8.8 meters [29 feet] below grade) downward to a point 3.05 meters (10 feet) below the mean water table. The bottom 6.1 meters (20 feet) of the well casing is perforated. The 10.2-centimeter (4-inch) steel test hole extended from the surface to the head end of the drain field. The test hole piping was the only part of site's structure that was above grade. The construction of the "D" catch tank modification would have covered the test hole.

Location: The site is located north of the 105-KW Reactor Building (118-KW-1) about 23 meters (75 feet).

Process Description: The site operated from 1955 to 1970 as an overflow crib for sub-basin drainage from the 105-KW Fuel Storage Basin (100-K-43).

Waste Type: Soil
Waste Description: The waste is contaminated structures and soil from the fuel storage basin sub-basin drainage system.
The site has been remediated and Interim Closed Out. The site consisted of heat exchangers, pumps, and associated piping on a concrete pad. Remedial action activities at the 100-K reactor sites began on December 9, 2002 by Washington Closure Hanford (WCH). Remediation involved excavation and staging of overburden material and removal of contaminated piping, debris and soil at the 100-K-55:1, 100-K-56:1, 116-KW-4 and 116-KE-5 waste sites. Contaminated materials were disposed at the ERDF. Remedial action excavation was completed on April 15, 2005.

The site was located south of 116-KW-3 (107-KW Retention Basins) and north of the 118-KW-1 (105-KW Reactor Building).

The site was used to transfer heat from the 105-KW Reactor cooling water effluent. The heat recovery stations used an ethylene glycol solution as the heat exchanger medium. The system is no longer intact.

Trace amounts of radioactive contamination remained on the piping. The heat exchange medium consisted of a 34% ethylene glycol-water solution.

Remedial action activities at the 100-K reactor effluent pipelines began on December 9, 2002 by Washington Closure Hanford (WCH). Remediation of the pipelines involved excavation and staging of overburden material and removal of contaminated piping, debris and soil at the 100-K-55:1, 100-K-56:1, 116-KW-4 and 116-KE-5 waste sites. Contaminated materials were disposed at the ERDF. Remedial action excavation was completed on April 15, 2005. The previously documented waste site boundaries for the 116-KW-4 and 116-KE-5 sites were much larger than the actual footprint of the heat recovery facilities. The soil area beneath each of the former heat recovery stations was excavated in its entirety with the removal of the co-located pipelines. Approximately 55,960 square meters (602,350 sq ft) of plan area was excavated, including excavation within the deep zone (greater than 4.6 meters [15 ft] below ground surface) up to 8.8 meters (29 ft) below ground surface where necessary to complete remediation. Approximately 86,551 metric tons (95,406 U.S. tons) of material from the sites was removed and disposed at the ERDF. The active 100-K-47 concrete culvert was not removed during remediation of the adjacent section of the 100-K-55 pipeline. Several 100-K-56 pipe segments, located west of 116-KE-4, were not included in the remediation scope.

The contaminated materials from these sites have been excavated and disposed at the ERDF. The remaining soils at the sites have been sampled, analyzed, and modeled, and the results do not preclude any future uses (as bounded by the rural-residential scenario), allow unrestricted use of shallow zone soils, and pose no threat to groundwater or the Columbia River. The 100-K-55:1, 100-K-56:1, 116-KW-4, and 116-KE-5 sites were verified to be remediated in accordance with the ROD and may be backfilled.
**Description:** The waste site has been remediated and Interim Closed Out. The cave was constructed by pouring a concrete slab 18.3 meters (60 feet) long by 2.4 meters (8 feet) wide. Two sections of 0.61-meter (24-inch) pipe were cut in half lengthwise and laid open side down, on the slab. Vertical concrete walls and steel doors were added to the ends of the pipe sections, with the walls forming a wing at each end. The pipe sections were then covered with 1.8 meters (6 feet) of clean fill material, forming a 12.2-meter (40-foot) long tunnel. The berm width after the fill material was added measured 7.6 meters (25 feet). The entire structure was above grade.

**Location:** The site was located northeast of the 105-KW Building.

**Related Sites/Structures:** 105-KW Reactor, 100-K-11 and 100-K-12.

**Process Description:** The unit was used for temporary storage of radioactive rod tips associated with the 105-KW Reactor for radioactive decay pending subsequent disposal.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The unit was used for temporary storage of irradiated and radioactively contaminated horizontal control rods containing unknown quantities of radionuclides. The tunnel contains four rod tips and other rod removal components. The radiation reading at the entrance to the cave with the door open is 50 millirad/hour.

**Closure Info:** The entire 118-KW-2 Waste Site structure, including the concrete slab and drain system, was removed in November 2010 to facilitate future heavy equipment access to the 105-KW Building and associated Fuel Storage Basin to support remedial activities. The interim action consisted of successful removal and disposal of the entire 118-KW-2 Waste Site including rod tips stored within the cave. Minor soil contamination detected after demolition. The soil was excavated and taken to ERDF.

---

**Code:** 120-KW-1

**Names:** 120-KW-1; 183-KW Acid Neutralization Pit; 183-KW Filter Water Facility Dry Well; 100-K-17; 100-KW-1

**Type:** Sump

**Status:** Inactive

**Start Date:** 1/1/1955

**End Date:** 1/1/1970

**Classification:** Accepted

**Reclassification:** Interim Closed Out (10/28/2011)

**Description:** The site was an underground concrete structure used to neutralize acid waste prior to disposal. The "pit" was a concrete box with approximate dimensions of 2.5 m (8.5 ft) x 2.0 m (6.3 ft) x 1.5 m (5 ft), and was lined on the sides with acid proof bricks. The structure is divided into three sections by dividing brick weirs. Effluent released into the system was held up in a small chamber by the first weir. Effluent overflowed the first weir into a second small chamber and then overflowed the second weir into the third larger chamber. A 10.2-centimeter (4-inch) vitrified tile drain was located in the bottom of the third chamber and is believed to discharge to the process sewer (see Site Comment). The top of the pit was level with the surface and had a 7.6-centimeter (3-inch) plank cover that is posted with "Confined Space" and "Caution, Acid" warning signs. In August 2000, the area around the acid tanks was stabilized with gravel. The french drain and sump were backfilled. They are no longer visible. They are not marked or posted.

**Location:** The site is located near the southeast corner of the 183.1-KW Headhouse, south of the 120-KW-3 Sulfuric Acid Tank and east of the 100-K-21 Sodium Silicate Tank Site.

**Related Sites/Structures:** The site was associated with the 183-KW Head House and the 183-KW Sulfuric Acid Tanks.
Process Description: The method of acid neutralization is not known. When two other acid neutralization pits (100-K-34 and 100-K-35) that were associated with the elevated day use tanks at 183-KE and 183-KW were opened, crushed limestone was visible. Limestone may also be at the 120-KW-1 site beneath the discarded sludge. From 1968 to 1971 commercial grade sulfuric acid was stored in the 183-KE/KW acid tanks. A heavy precipitate would accumulate in the bottom of the tanks. The tank sludge was periodically flushed from the tanks to adjacent drywells. When the K Reactors were shut down (1970-1971), the acid was removed from the tanks. Approximately 4950 kilograms (11,000 pounds) of sludge was washed out of the tanks into adjacent drainage trenches. The sludge was packaged into 55 gallon drums and sold to an off site vendor. Small amounts of sludge remained in the 183-KE/KW drywells. The drywell sludge was sampled in July 1985. The drywell at 183-KW exceeded the Washington State Department of Ecology Dangerous Waste Regulations limit for mercury. The dangerous waste limit for mercury was 0.2 parts per million. The sample collected in 1985 contained 0.387 parts per million of mercury.

Waste Type: Demolition and Inert Waste

Waste Description: The site received sulfuric acid for neutralization and acid sludge waste from the sulfuric acid storage tanks. The drywell sludge was sampled in 1985 and was analyzed for arsenic, barium, cadmium. Chromium, lead, mercury, silver and selenium. The sample taken from the 183-KW drywell contained elevated levels of mercury. The Washington State dangerous waste limit for mercury is 0.2 parts per million. The sample contained 0.387 parts per million of mercury. The other metals were below dangerous waste limitations.

Closure Info: Waste Sites 120-KW-1, 120-KW-2, 120-KW-3 and 120-KW-4 were remediated to remove the remaining structures and associated contaminated soil between May 2010 and June 2011. The original remediation activity for was anticipated to end once excavation to a depth of 4.6 m (15 ft) was achieved. Excavation to support remediation of the yellow-colored contaminated soil, however, continued due to the ongoing detection of mercury contamination levels above the RAGs in the RDR/RAWP (DOE/RL-96-17). The final depth of the remediation was 14.2 meters (46.6 ft), which was located within the footprint of 120-KW-2. To support the deeper excavation, layback soil was accumulated in stockpiles (#7 and #9).

Stockpile #7 was started on April 19, 2011. No field quality control samples were collected; however the samples were analyzed for metals, hexavalent chromium and anions.

Stockpile #9 was started on May 17, 2011. No field quality control samples were collected however the samples were analyzed for metals, hexavalent chromium and anions.

Remediation south of the sedimentation basin (183.2-KW) at 100-KW was conducted as an area-wide remediation (100-K Area AA) to examine the soil underneath several co-located waste sites. Based on proximity and process, the remediation area was divided into 4 zones. The four waste sites included in this report comprise Zone 3.

Code: 120-KW-2
Classification: Accepted

Names: 120-KW-2; 183-KW Filter Water Facility French Drain; 100-KW-2
Reclassification: Interim Closed Out (10/28/2011)

Type: French Drain
Start Date: 1/1/1955

Status: Inactive
End Date: 1/1/1970

Description: The waste site has been remediated and Interim Closed Out. This unit was an open-bottomed french drain with a depth of 0.9 meters (3 feet) and a diameter of 0.9 meters (3 feet). In August 2000, the area around the acid tanks was stabilized with gravel. The french drain and sump were backfilled. They are no longer visible. They are not marked or posted.
Location: The site is located 37 meters (121.4 feet) east of the southeast corner of 183.1-KW Headhouse.

Process Description: The drain was constructed in an excavation that was about 4.0 meters (13 feet) across and 3.4 meters (11 feet) deep. The bottom 1.5 to 1.8 meters (5 to 6 feet) of the excavation was filled with course rock. A 0.9-meter (3-foot) diameter, 1.8-meter (6-foot) long vitrified clay pipe was placed vertically over the rock fill and the excavation was backfilled to grade. The bottom 0.3 meters (1 foot) of the pipe was filled with course rock.

Waste Type: Demolition and Inert Waste

Waste Description: The site received sulfuric acid sludge that was removed from sulfuric acid storage tanks.

Closure Info: Waste Sites 120-KW-1, 120-KW-2, 120-KW-3 and 120-KW-4 were remediated to remove the remaining structures and associated contaminated soil between May 2010 and June 2011. The original remediation activity for was anticipated to end once excavation to a depth of 4.6 m (15 ft) was achieved. Excavation to support remediation of the yellow-colored contaminated soil, however, continued due to the ongoing detection of mercury contamination levels above the RAGs in the RDR/RAWP (DOE/RL-96-17). The final depth of the remediation was 14.2 meters (46.6 ft), which was located within the footprint of 120-KW-2. To support the deeper excavation, layback soil was accumulated in stockpiles (#7 and #9).

Stockpile #7 was started on April 19, 2011. No field quality control samples were collected; however the samples were analyzed for metals, hexavalent chromium and anions.

Stockpile #9 was started on May 17, 2011. No field quality control samples were collected however the samples were analyzed for metals, hexavalent chromium and anions.

Remediation south of the sedimentation basin (183.2-KW) at 100-KW was conducted as an area-wide remediation (100-K Area AA) to examine the soil underneath several co-located waste sites. Based on proximity and process, the remediation area was divided into 4 zones. The four waste sites included in this report comprise Zone 3.

Code: 120-KW-3 Classification: Accepted

Names: 120-KW-3; 183-KW1 Sulfuric Acid Storage Tank Reclassification: Interim Closed Out (10/28/2011)

Type: Storage Tank Start Date: 1/1/1955

Status: Inactive End Date: 1/1/1970

Description: The site is the westernmost of the two original sulfuric acid tanks at the 183.1-KW Headhouse. The tank is a horizontal, cylindrical-shaped, steel tank supported above ground on concrete saddles. The tank has a capacity of 38,267 liters (10,109 gallons).

Location: The tank is located near the southeast corner of the 183.1-KW Headhouse, east of the eastern Sodium Silicate Storage Tank Site (100-K-21) and west of the second original Sulfuric Acid Storage Tank (120-KW-4).

Release Description: The supply pipe from this unit to the point of use inside the 183.1-KW Building developed slow leaks that deposited an unknown amount of sulfuric acid in the ground between the tanks and the building. The soil in the general area of the leak was neutralized.

Related Sites/Structures:

Process Description: The sulfuric acid was used to activate sodium silicate. During seasons of high turbidity, activated silica solution was fed into the raw water to aid in coagulation.
Waste Type: Misc. Trash and Debris
Waste Description:

Closure Info: Waste Sites 120-KW-1, 120-KW-2, 120-KW-3 and 120-KW-4 were remediated to remove the remaining structures and associated contaminated soil between May 2010 and June 2011. <tr>
<td>Description: The waste site has been remediated and Interim Closed Out. The site was a foundation where a sodium dichromate storage tank was placed. The tank had been removed in 1971. All that remained was the concrete pad, the contaminated soil, and any remaining piping.</td>
<td></td>
</tr>
<tr>
<td>Location: The site was located on the east side of the 183-KW Building. The center of the pad was 6.1 meters (20 feet) from the building's east wall.</td>
<td></td>
</tr>
<tr>
<td>Release Description: There are no documented releases. However, there is evidence of residual sodium dichromate in the soil that has accumulated from many years of unloading and handling.</td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures: The site is associated with the 183-KW Building.</td>
<td></td>
</tr>
<tr>
<td>Process Description: Sodium dichromate was added to the process water as a corrosion inhibitor. It was metered and proportioned by a single step operation in the head house, and diluted and injected into the process water in the process water pump house. The proportioning pumps took their suction directly from the storage tank. Near the process water pump house, the pumps discharged through a back pressure valve into a service water stream which diluted the dichromate on its way to injection into the process water. The injection point was located on the discharge of the low lift pump. Dichromate injection was determined by the process water flow. The chemical storage facilities at the 183-KW Building were sized to provide sufficient chemicals for two to three months continuous operation. Chemicals were delivered to the 183-KE Building by rail. With the exception of chlorine, all chemicals were transferred to their storage tanks by pumping or by pressurizing the tank cars with compressed air.</td>

</tbody>
</table>
(e.g., sulfate due to the sulfuric acid), at multiple locations and depths. In-process sampling occurred across all four zones in 100-K Area AA, although this report focuses on Zone 2 only. Throughout remediation, stained areas were targeted for in-process sampling; soils often were yellow-colored and high in lead, total chromium and mercury. Hexavalent chromium, which is the groundwater contaminant of greatest concern at 100-K, was detected on the soil surface down to 6 feet, at the beginning of remediation for Area AA Zone 2. Excavation continued to a final remediation depth of 10.96 meters (35.96 ft).

During a walkdown of Area AA by RL and EPA on September 20, 2011, it was determined that piping found within Zone 1 needed to be further investigated. The piping identified was determined to be a part of the process sewer line and was subsequently removed.

The excavation decision unit was approximately 3,228 square meters (34,745.9 sq. ft.). All contaminated soils and debris from the waste sites was disposed of in the Environmental Restoration Disposal Facility (ERDF).

---

Code: 120-KW-6
Names: 120-KW-6; 165-KW Brine Mixing Tank; 165-KW Brine Pit
Type: Sump
Status: Inactive
Description: The unit is a below grade concrete structure that provided brine for the 165-KW Powerhouse. The roof of the structure was approximately 0.3 meters (1 foot) above ground level. The opening into the pit was covered by a wooden cover. Just south of the brine pit is a valve pit located within a vertical section of 1.2-meter (4-foot) diameter corrugated galvanized pipe. This valve pit contains residue and apparently was part of the brine operation. In August 1998, remaining liquid was removed and the open pit was backfilled to grade. The brine pit has inner dimensions of 4.3 meters (14 feet) long by 2.4 meters (8 feet) wide by 2.7 meters (9 feet) tall. The bottom of each pit is filled with a 13-centimeter (7-inch) layer of 1.3 to 2.6-centimeter (0.5 to 1-inch) gravel topped by a 18-centimeter (7-inch) layer of 0.3 to 0.6-centimeter (1/8 to 1/4-inch) gravel. The pit has a 1.2-meter (4-foot) by 1.1-meter (3.5-foot) opening for receiving salt.
Location: The site is located near the northwest corner of the 165-KW Powerhouse.
Related Sites/Structures: The site is associated with the 165-KW Powerhouse.
Process Description: The brine was probably used to regenerate the water softeners that treated water prior to steam generation within the 165-KW Powerhouse. Salt was off-loaded from rail cars and placed in the pit. Water was then circulated through the pit, and brine was pumped back to the 165-KW Powerhouse for further use.
Waste Type: Equipment
Waste Description: The unit contains salt brine and residue. Based on sampling performed at the 120-KE-9 and 120-KW-7 Brine Pits, the brine and residue may be regulated as dangerous waste per Washington Administrative Code (WAC) 173-303.

---

Code: 120-KW-7
Names: 120-KW-7; 183-KW Brine Pit; 183-KW Salt Dissolving Pits and Brine Pump Pit
Type: Sump
Status: Inactive
Description: The unit contains salt brine and residue. Based on sampling performed at the 120-KE-9 and 183-KW Brine Pits, the brine and residue may be regulated as dangerous waste per Washington Administrative Code (WAC) 173-303.
Type:  Sump  
Start Date:  1/1/1955

Status:  Inactive  
End Date:  1/1/1970

Description:  The waste site has been remediated and Interim Closed Out. Only four wooden covers and one metal cover were visible at the surface. The wooden covers were in poor condition. The unit contained saltcake and brine. In August 1998, remaining liquid was removed. The pit utilities were isolated, the ceiling slabs were demolished and the unit was backfilled to grade. The area was later excavated and Interim Closed Out.

Location:  The site was located approximately 37 meters (120 feet) east of the east end of the 183-KW Water Filter Plant and just north of the railroad spur that serviced the plant.

Related Sites/Structures:  The brine pit is associated with the 183-KW Water Filter Plant.

Process Description:  The salt brine was used to regenerate water softeners.

Waste Type:  Animal Waste

Waste Description:  The unit contains salt brine and residue. A minimal sampling was performed at the site. The brine samples were analyzed by Hanford Environmental Health Foundation (HEHF) on September 5, 1989. A sample from one of the dissolving pits was described as a light yellow water-miscible liquid with approximately 1% yellow/orange residue and a pH of 6. The sample contained 12.5% sodium ion, 19.8% chloride ion, and 33 milligrams/liter potassium. The measured concentrations of EP-Toxicity metals were 0.12 milligrams/liter arsenic, 1.3 milligrams/liter barium, 0.1 milligrams/liter cadmium, 0.78 milligrams/liter chromium, 0.58 milligrams/liter lead, 0.28 milligrams/liter selenium, and 0.66 milligrams/liter silver. All other analytes were below detection limits. A sample from the other dissolving pit was also described as a very light yellow water-miscible liquid with approximately 10% white and tan crystals and a pH of 6. The sample contained 7.9% sodium ion, 19.7% chloride ion, and 240 milligrams/liter potassium. The measured concentrations of EP-Toxicity metals were 0.14 milligrams/liter arsenic, 1.9 milligrams/liter barium, 0.57 milligrams/liter cadmium, 0.72 milligrams/liter lead, 0.31 milligrams/liter selenium, and 0.58 milligrams/liter silver. All other analytes were below detection limits. Only the liquid portions of the samples were analyzed. An informal review of results by the Sitewide Hazardous Waste Engineering Support Unit (SHWES) indicated that the brine and residue may be regulated as Dangerous Waste per Washington Administrative Code (WAC) 173-303.

Closure Info:  Remediation of the Area AA, Zone 2 waste sites (100-K-18, 100-K-19, 100-K-79:1, 100-K-79:2, 100-K-97, 120-KW-5 and 120-KW-7) began in May 2010. Throughout the remedial activity, because of the contaminants found in the process equipment and surface soils, in-process samples were collected and analyzed for metals, including chromium VI and anions (e.g., sulfate due to the sulfuric acid), at multiple locations and depths. In-process sampling occurred across all four zones in 100-K Area AA, although this report focuses on Zone 2 only. Throughout remediation, stained areas were targeted for in-process sampling; soils often were yellow-colored and high in lead, total chromium and mercury. Hexavalent chromium, which is the groundwater contaminant of greatest concern at 100-K, was detected on the soil surface down to 6 feet, at the beginning of remediation for Area AA Zone 2. Excavation continued to a final remediation depth of 10.96 meters (35.96 ft).

During a walkdown of Area AA by RL and EPA on September 20, 2011, it was determined that piping found within Zone 1 needed to be further investigated. The piping identified was determined to be a part of the process sewer line and was subsequently removed.

The excavation decision unit was approximately 3,228 square meters (34,745.9 sq. ft.). All contaminated soils and debris from the waste sites was disposed of in the Environmental
Restoration Disposal Facility (ERDF).

<tr>
<td>Description:</td>
<td>The site is the location of two underground diesel storage tanks that were removed in 1992. Although the location description states the diesel tanks were located between the 105-KW exhaust stack and the 119-KW building, a sign is posted at the northwest corner of the 115 KW building that reads &quot;130-KW-1 Diesel Tanks&quot; This is further east and south of the reactor stack. There is no visual evidence of the tanks in either location. The site has been backfilled with uncontaminated soil to grade and covered with gravel. There is a very large Underground Radioactive Material area that surrounds the reactor facility. This site is not separately posted or marked.</td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The site is located on the east side of the 105-KW Reactor Building. The underground diesel tanks were located between the reactor exhaust stack and the 119-KW Building.</td>
<td></td>
</tr>
<tr>
<td>Release Description:</td>
<td>During the excavation of the diesel tanks, the site was found to be radioactively contaminated with contamination levels up to 400 counts per minute in the soil and on the exterior of the tanks. Due to this contamination, the pit was backfilled with uncontaminated soil and posted appropriately. Attempts to decontaminate the tanks were unsuccessful. The tanks were wrapped with plastic and disposed of on the Hanford site. Since the tanks were located very close to the reactor building, the long term plan for is to decontaminate or remove the remaining contaminated soil when the reactor and surrounding site is remediated. The site was not released due to the radioactive contamination.</td>

<td>The tanks were used for storage of diesel fuel (product). Radioactive contamination was discovered on the exterior of both tanks when they were removed. The Organic Vapor Monitor readings were below the detection limit.</td>
<td></td>
</tr>
</tbody>
</table>
**Process Description:**
The tank was used for storage of fuel oil (product) for the 165-KW Boilers. Fuel was delivered to the bunkers from rail cars and filled through 15 centimeter (6 inch) diameter gravity lines. Two day tanks are located on the south side of each bunker. Each Day Tank had a 186,621 liter (49,300 gallon) capacity.

**Waste Type:** Equipment

**Waste Description:**
The tank was used for storage of oil (product) for the 165-KW Boilers.

---

**Code:** 132-KW-1  
**Classification:** Accepted

**Names:** 132-KW-1; 116-KW Reactor Exhaust Stack  
**Reclassification:** None

**Type:** Stack  
**Start Date:** 1/1/1955

**Status:** Inactive  
**End Date:** 1/1/1970

**Description:** The original height for this unit was 91.5 meters (300 feet). The current height is 53.4 meters (175 feet). The unit was decontaminated and shortened 38 meters (125 feet) between 1980 and 1981. All debris is contained in the below-ground portion of the site.

**Location:** The unit is located on the northeast side of the 105-KW Building.

**Related Sites/Structures:** Following completion of the confinement project in 1960, the air was diverted via underground reinforced concrete ducts to the 117-KW Filter Building. After flowing through the filters, the air went out the exhaust stack.

**Waste Type:** Equipment

**Waste Description:** Discharged ventilation air from the 105-KW Building flowed through concrete ducts directly out the exhaust stack.

---

**Code:** 600-29  
**Classification:** Accepted

**Names:** 600-29; 100-K Construction Lay-down Area; 100-K-41  
**Reclassification:** Interim Closed Out (8/15/2012)

**Type:** Dumping Area  
**Start Date:** 1/1/1952

**Status:** Inactive  
**End Date:** 1/1/1954

**Description:** The waste site has been remediated and Interim Closed Out. The 600-29 waste site was approximately 82 acres (333,287 sq. meters) that, prior to remediation, contained multiple french drains, areas of burned material, barren soil, stained soil, suspect asbestos, and a variety of demolition-related surface debirs. It was an abandoned dumping area containing several rectangular depressions and burn pits. Many areas of discolored soil included coal, rust colored soil and white residue patches. It also included a cement building foundation with two adjacent french drains. During the 2007 Orphan Site Evaluation (OSE) for the 100-K operable unit, the 600-29 waste site was walked down to collect further site characterization data. A total of forty discrete feature locations within the 600-29 site boundaries were collected using a hand-held GPS unit. Photographs and GPS coordinates were documented for each feature. Each feature was categorized as a 600-29 waste component or as a miscellaneous restoration or stewardship item.

South of a gravel road that transverses the site is the Strong Motion Accelerometer (SMA) also known as H1K. The SMA site consists of a four-panel solar array and two 30-gallon galvanized drums. The two 30-gallon drums are set in the ground such that the base of the drum is about 1
meter below the surface. One drum houses only the SMA. The other drum contains the batteries and is connected to the SMA drum with a conduit.

**Location:** The site is located outside of the southern perimeter fence at 100K.

**Related Sites/Structures:** This site is associated with 100-K-41 and 100-K-89.

**Process Description:**

This location was originally used as the construction camp and lay-down yard during construction of 105-KW. The lay-down area was in operation from approximately 1952 through 1954. The 105-KW was commissioned in January 1955. Discolored soil and suppressed vegetation are evident within the unit. Old roadways and rectangular depressions are still distinguishable today based on 1952 and 1953 aerial photographs. No facilities were on the site prior to the start of construction of the 100-K Reactors. Both new and pre-existing structures moved from other areas around the Hanford Site were used as temporary construction facilities. The structures included warehouses, small offices, huts, and fabrication shops. Areas on the southwest side of the 600-29, 100-K Construction Laydown Area were cleared and made suitable for bus and car parking.

**Waste Type:** Water

**Waste Description:** Unit wastes consist of miscellaneous metals, wood, cans, bottles, construction hardware and materials, what appears to be tar dumped on the ground, buckets and mops covered with what appears to be tar, a 18.725-liter (5-gallon) bucket of oily rags, broken pieces of a toilet bowl, what appears to be asbestos and transite, and wire rope.

**Closure Info:** Remedial action at the 600-29 and 100-K-89 waste sites began on September 21, 2011, and continued through April 5, 2012. Most of the remedial excavations were the result of visible surface debris, stains, and materials. These areas were excavated from a minimum of 0.3 meter (1 ft) in depth to as much as 3 meters (10 ft) in depth, as needed, to remove contamination. Excavations for french drains ranged from 1.2 to 1.8 meters (4 to 6 ft) in depth. A septic vault in the eastern portion of 600-29 required excavation to 10 feet below ground surface. All materials removed from the excavations were stockpiled within the excavations and then directly loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). No stockpiles external to the excavations were created. The 100-K-89 waste site comprised a burned area with burnt material present on the surface (wood, metal, and roofing material) and the underlying soil. Contamination identified on the southwest edge of the 600-29 waste site led to an excavation that was expanded during remediation based on field observations. The expansion encompassed and completely removed the 100-K-89 waste site.

Contaminated materials removed from the 600-29 waste site consisted of red, black, and white stained soils or colored materials, concrete pads and rubble, a concrete sewer junction box, abandoned iron and vitrified clay piping, abandoned wiring, friable and nonfriable asbestos, metallic and wood debris, burnt wood, ash, tar, and other miscellaneous demolition debris. Materials removed from the 100-K-89 waste site consisted of burned debris (wood, metal, roofing material) and associated soils.

A total volume of 10,293 bank cubic meters (BCM) (6,157 BCM from the east side of 600-29 and 4,136 BCM from the west side of 600-29) was removed and disposed to ERDF during remediation.

**Code:** UPR-100-K-1

**Classification:** Accepted

**Names:**

- UPR-100-K-1; 105-KE Fuel Storage Basin Leak;
- UN-100-K-1; UN-116-KE-2

**Recategorization:** None

**Type:** Unplanned Release

**Start Date:** 1/1/1974

*Hanford Site Waste Management Units Report*

February 2015
Status: Inactive  
End Date: 1/1/1979

**Description:** The site is not marked or posted on the surface.

**Location:** The leak occurred beneath the 105-KE Fuel Storage Basin.

**Release Description:** The 105-KE pickup chute area (of the 105-KE Fuel Storage Basin) had an estimated release to the ground of more than 1700 liters/hour (450 gallons/hour) for an unknown period of time. Leak rates ranging from 2.6 to 9.5 gallons per minute were documented between 1974 and 1978.

**Related Sites/Structures:** The leak is associated with 105-KE Fuel Storage Basin (sitecode 100-K-42) and 100-K-64 Flood Plain.

**Waste Type:** Storage Tank

**Waste Description:** The fuel storage basin effluent included contaminants from fuel cladding failures. Cobalt-60, Strontium-90, Cesium-137 and small amounts of plutonium were noted in the soil beneath the 105-K East basin.

<td>End Date: 1/1/1993</td>
</tr>
<tr>
<td>Description</td>
<td>The site has been remediated and Interim Closed Out. The settling pond was cut into the side of a steep slope leading to the river. A concrete flume was located at the south end of the site. An outlet valve and pipe were located on the west side of the site. It received effluent from the 185-N building drains (SWMU #3). After the solids settled, the liquid discharged to the 1908-NE outfall (SWMU #7). The settling pond was excavated and removed in 2001.</td>
<td></td>
</tr>
<tr>
<td>Location</td>
<td>The Hanford Generating Plant (HGP) Settling Pond was located between the HGP Seal Well building (1908-NE) and the 185-N Building.</td>
<td></td>
</tr>
<tr>
<td>Release</td>
<td>An oil spill occurred on January 2, 1987 that was contained in the settling pond. Clean up of the five gallon oil spill was conducted by United Nuclear Corporation (UNC) and JA Jones in February 1987.</td>
<td></td>
</tr>
<tr>
<td>Process</td>
<td>This unit was constructed to control the Hanford Generating Plant (HGP) waste stream effluents. The effluent flowed into the pond, allowed solids to settle, and the remaining liquid was released to 1908-NE (HGP outfall). A valve was installed on the outlet pipe to prevent the discharge of oil to the outfall. The unit received waste from the HGP condenser pit, service water pumps demineralizer backwash and runoff from the roof and parking lot. An outlet pipe drained the pond directly to 1908-NE (HGP Outfall). The piping from the HGP Building floor drains and sumps to the settling pond was included with the settling pond.</td>
<td></td>
</tr>
<tr>
<td>Waste Type</td>
<td>Equipment</td>
<td></td>
</tr>
<tr>
<td>Waste</td>
<td>The pond operated concurrently with the Hanford Generating Plant (HGP) and received process water from the plant that contained trace oxygen scavenging conditioners such as morpholine, hydrazine and ammonia. Sampling has indicated elevated levels of chromium, lead, nickel, calcium, copper, zinc and ammonia. Trace surface radioactive contamination is detectable.</td>
<td></td>
</tr>
<tr>
<td>Closure Info</td>
<td>The 100-N Reactor provided fuel rods to the plutonium production process at Hanford, but also operated two 430 megawatt turbine generators for the generation of electricity. The Washington Public Supply System, later named Energy Northwest, was responsible for the Hanford Generating Plant located at 100-N Reactor. The Cleanup Verification Package (HGP-CVP-SWMUs 5, 6, 7, 8, 9, &amp; 10) for the Hanford Generating Plant Solid Waste Management units was prepared by Energy Northwest in 2004. Some remedial actions at HGP began in 1992. Other characterization and remediation was completed in 2004. Remedial action activity descriptions include:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>100-N-1 Settling Pond (SWMU#6) - Remediation activities conducted in 2001 removed approximately 0.9 meters (3 ft) of soil and settled solids material from the 100-N-1 Settling Pond (SWMU #6). The excavated material was disposed of at the Environmental Restoration Disposal Facility (ERDF).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>100-N-3 Maintenance Garage French Drain, 100-N-41 Gate House Septic Tank and 100-N-45 Office Building Septic Tank make up SWMU #9. Remediation was determined not to be necessary for the 100-N-3 site and the 100-N-41 and 100-N-45 septic sites. The below grade structures of the drain and septic sites were demolished in place and backfilled with soil in 2004.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>100-N-4 Tile Field (SWMU#5) - Confirmatory sampling activities and data evaluation</td>
<td></td>
</tr>
</tbody>
</table>
determined that remediation was not necessary for the 100-N-4 Tile Field.

100-N-5 Bone Yard (SWMU #10) - Remediation and removal activities for the 100-N-5 Bone Yard (SWMU #10) were primarily conducted in 2001 with the removal of the miscellaneous equipment, metal scrap, and general debris. The limited number of areas with sand blast media, ion exchange resin-like media and areas with soil staining and/or distressed vegetation were remediated in 2003 and 2004. The sand blast, ion exchange resin, and contaminated soil wastes were disposed of at the RABANCO landfill facility in Roosevelt, Washington.

The 100-N-46 Diesel underground storage tank (UST) was excavated and removed in 2001. Soil contaminated with diesel was also excavated from the UST excavation. Contaminated soil was spread over the demolished 1703-N Office Building concrete slab foundation for attenuation. Upon completion of the remedial excavation, the bottom of the excavation was approximately 6.7 meters (22 ft) below the ground surface at the deepest location (southwest corner of excavation).

100-N-52 Gasoline underground storage tank (UST) was excavated and removed in 1992.

1908-NE Outfall (SWMU#7) - The original preferred remedy for the 1908-NE Outfall was Institutional Controls (continued monitoring). A radiological survey of the Outfall seal well and samples of water and sediment were collected from the Outfall seal well in 2001 to assess potential contamination associated with the Outfall. The outfall structure was demolished by the Washington Closure Hanford D&D organization in 2012, eliminating the Institutional Control requirement.

The 1716-NE Maintenance Garage building (SWMU #8), including the building slab and associated floor drain pipelines, were removed in their entirety during the 2003 and 2004 removal action activities. Prior to the removal action all chemical products were removed from the building and either properly disposed of or transferred to another facility for use. The building debris was used as fill for the 185-N Building basement.

**Code:** 100-N-3

**Classification:** Accepted

**Names:** 100-N-3; HGP SWMU #9; Maintenance Garage French Drain; Maintenance Garage Waste Water Treatment Unit

**Reclassification:** Interim Closed Out (6/15/2004)

**Type:** French Drain

**Start Date:** 1/1/1965

**Status:** Inactive

**End Date:**

**Description:** The site has been remediated and Interim Closed Out. The french drain was marked by a 3-meter (10-foot) square barricade and gravel covering a 31-meter (100-foot) square surface. A 1.2-meter (4-foot) diameter steel plate covered the center. (the 100-N-3 garage french drain, the 100-N-41 septic tank and the 100-N-45 septic tank make up Solid Waste Management Unit (SWMU) #9).

**Location:** The site was located in the 100-N Area, at the Washington Public Power Supply System (WPPSS) Hanford Generating Plant Facility, approximately 7.6 meters (25 feet) east of 100-N-78 Hanford Generating Plant (HGP) Maintenance Garage.

**Related Sites/Structures:** The unit received effluent from 100-N-78, the 1716-NE HGP Maintenance Garage.

**Process Description:** The former HGP consisted of two 430-megawatt turbine generators that operated from 1966 until 1986 using steam from the adjacent 100-N production reactor for generation of electricity. The generators were located in the 185-N Building. The site was an ancillary or support facility
to the former Hanford Generating Plant.

**Waste Type:** Water

**Waste Description:** The unit received petroleum wastes.

**Closure Info:** The 100-N Reactor provided fuel rods to the plutonium production process at Hanford, but also operated two 430 megawatt turbine generators for the generation of electricity. The Washington Public Supply System, later named Energy Northwest, was responsible for the Hanford Generating Plant located at 100-N Reactor. The Cleanup Verification Package (HGP-CVP-SWMUs 5, 6, 7, 8, 9, & 10) for the Hanford Generating Plant Solid Waste Management units was prepared by Energy Northwest in 2004. Some remedial actions at HGP began in 1992. Other characterization and remediation was completed in 2004. Remedial action activity descriptions include:

100-N-1 Settling Pond (SWMU#6) - Remediation activities conducted in 2001 removed approximately 0.9 meters (3 ft) of soil and settled solids material from the 100-N-1 Settling Pond (SWMU #6). The excavated material was disposed of at the Environmental Restoration Disposal Facility (ERDF).

100-N-3 Maintenance Garage French Drain, 100-N-41 Gate House Septic Tank and 100-N-45 Office Building Septic Tank make up SWMU #9. Names: 100-N-4; HGP SWMU #5; HGP Tile Field

Type: Drain/Tile Field

Status: Inactive

Start Date: 1/1/1966

Description: The site has been remediated and Interim Closed Out. The tile field received effluent from the 185-N Building drains of the HGP 185-N building chemical laboratory and sanitary drains.

Location: The unit was located between the Hanford Generating Plant (HGP) Seal Well building (1908-NE) and the 185-N Building, upslope and east of the HGP Settling Pond.

Related Sites/Structures: The tile field is associated with septic tank 100-N-95 (remediated in 2013).

Process Description: The former HGP consisted of two 430 megawatt turbine generators that operated from 1966 until 1986 using steam from the adjacent 100-N production reactor for generation of electricity. The generators were formerly located in the 185-N Building. The site was an ancillary or support facility to the former HGP. The site was an ancillary or support facility to the former HGP, and received effluent from the 185-N Building drains of the HGP Sanitary Sewer and lab. The unit was designed to release waste water by allowing it to percolate into the soil.

Waste Type: Soil

Waste Description: The unit received sanitary sewage and lab waste. Testing for corrosion inhibitors hydrazine and morpholine were performed in the lab. It is likely that reagents used for these tests were discharged to the unit.

Closure Info: The 100-N Reactor provided fuel rods to the plutonium production process at Hanford, but also operated two 430 megawatt turbine generators for the generation of electricity. The Washington Public Supply System, later named Energy Northwest, was responsible for the Hanford Generating Plant located at 100-N Reactor. The Cleanup Verification Package (HGP-CVP-SWMUs 5, 6, 7, 8, 9, & 10) for the Hanford Generating Plant Solid Waste Management units was prepared by Energy Northwest in 2004. Some remedial actions at HGP began in 1992. Other characterization and remediation was completed in 2004. Remedial action activity descriptions include:

100-N-1 Settling Pond (SWMU#6) - Remediation activities conducted in 2001 removed approximately 0.9 meters (3 ft) of soil and settled solids material from the 100-N-1 Settling Pond (SWMU #6). The excavated material was disposed of at the Environmental Restoration Disposal Facility (ERDF).

100-N-3 Maintenance Garage French Drain, 100-N-41 Gate House Septic Tank and 100-N-45 Office Building Septic Tank make up SWMU #9. Remediation was determined not to be necessary for the 100-N-3 site and the 100-N-41 and 100-N-45 septic sites. The below grade structures of the drain and septic sites were demolished in place and backfilled with soil in 2004.

100-N-4 Tile Field (SWMU#5) - Confirmatory sampling activities and data evaluation determined that remediation was not necessary for the 100-N-4 Tile Field.

100-N-5 Bone Yard (SWMU #10) - Remediation and removal activities for the 100-N-5 Bone Yard (SWMU #10) were primarily conducted in 2001 with the removal of the miscellaneous equipment, metal scrap, and general debris. The limited number of areas with sand blast media, ion exchange resin-like media and areas with soil staining and/or distressed vegetation were
remediated in 2003 and 2004. The sand blast, ion exchange resin, and contaminated soil wastes were disposed of at the RABANCO landfill facility in Roosevelt, Washington.

The 100-N-46 Diesel underground storage tank (UST) was excavated and removed in 2001. Soil contaminated with diesel was also excavated from the UST excavation. Contaminated soil was spread over the demolished 1703-N Office Building concrete slab foundation for attenuation. Upon completion of the remedial excavation, the bottom of the excavation was approximately 6.7 meters (22 ft) below the ground surface at the deepest location (southwest corner of excavation).

100-N-52 Gasoline underground storage tank (UST) was excavated and removed in 1992.

1908-NE Outfall (SWMU#7) - The original preferred remedy for the 1908-NE Outfall was Institutional Controls (continued monitoring). A radiological survey of the Outfall seal well and samples of water and sediment were collected from the Outfall seal well in 2001 to assess potential contamination associated with the Outfall. The 1716-NE Maintenance Garage building (SWMU #8), including the building slab and associated floor drain pipelines, were removed in their entirety during the 2003 and 2004 removal action activities. Prior to the removal action all chemical products were removed from the building and either properly disposed of or transferred to another facility for use. The building debris was used as fill for the 185-N Building basement.

**Classification:** Accepted

**Reclassification:** Interim Closed Out (6/15/2004)

**Code:** 100-N-5

**Names:** 100-N-5; HGP Bone Yard; HGP Disposal and Storage Area; HGP SWMU #10

**Type:** Storage

**Status:** Inactive

**Description:** The site has been remediated and Interim Closed Out. The waste site was a surface storage yard. Some of the soil was oil stained. Garnet sandblasting grit was also present. Remedial and removal activities occurred in 2001.

**Location:** The unit was located southwest of the Hanford Generating Plant (HGP) Building (185-N) in the 100-N Area. It was inside the HGP security fence.

**Related Sites/Structures:** The site was associated with the Hanford Generating Plant (HGP).

**Process Description:** Material and equipment were stored inside the southwest corner of the Hanford Generating Plant facility fence. Some of the material included scrap metal, electrical equipment, pipes and cables. The unit was located on a level area which had several spots of stressed or absent vegetation.

**Waste Type:** Construction Debris

**Waste Description:** The unit contained scrap iron, brass, copper, electrical components, piping, cable, and miscellaneous pieces of metal equipment. The site also contained oil stains, sand blasting grit, and ion exchange resin beads on the soil.

**Closure Info:** The 100-N Reactor provided fuel rods to the plutonium production process at Hanford, but also operated two 430 megawatt turbine generators for the generation of electricity. The Washington Public Supply System, later named Energy Northwest, was responsible for the Hanford
Generating Plant located at 100-N Reactor. The Cleanup Verification Package (HGP-CVP-SWMUs 5, 6, 7, 8, 9, & 10) for the Hanford Generating Plant Solid Waste Management units was prepared by Energy Northwest in 2004. Some remedial actions at HGP began in 1992. Other characterization and remediation was completed in 2004. Remedial action activity descriptions include:

100-N-1 Settling Pond (SWMU#6) - Remediation activities conducted in 2001 removed approximately 0.9 meters (3 ft) of soil and settled solids material from the 100-N-1 Settling Pond (SWMU #6). The excavated material was disposed of at the Environmental Restoration Disposal Facility (ERDF).

100-N-3 Maintenance Garage French Drain, 100-N-41 Gate House Septic Tank and 100-N-45 Office Building Septic Tank make up SWMU #9. Remediation was determined not to be necessary for the 100-N-3 site and the 100-N-41 and 100-N-45 septic sites. The below grade structures of the drain and septic sites were demolished in place and backfilled with soil in 2004.

100-N-4 Tile Field (SWMU#5) - Confirmatory sampling activities and data evaluation determined that remediation was not necessary for the 100-N-4 Tile Field.

100-N-5 Bone Yard (SWMU #10) - Remediation and removal activities for the 100-N-5 Bone Yard (SWMU #10) were primarily conducted in 2001 with the removal of the miscellaneous equipment, metal scrap, and general debris. The limited number of areas with sand blast media, ion exchange resin-like media and areas with soil staining and/or distressed vegetation were remediated in 2003 and 2004. The sand blast, ion exchange resin, and contaminated soil wastes were disposed of at the RABANCO landfill facility in Roosevelt, Washington.

The 100-N-46 Diesel under ground storage tank (UST) was excavated and removed in 2001. Soil contaminated with diesel was also excavated from the UST excavation. Contaminated soil was spread over the demolished 1703-N Office Building concrete slab foundation for attenuation. Upon completion of the remedial excavation, the bottom of the excavation was approximately 6.7 meters (22 ft) below the ground surface at the deepest location (southwest corner of excavation).

100-N-52 Gasoline underground storage tank (UST) was excavated and removed in 1992.

Hanford Site Waste Management Units Report
February 2015
Description: The waste site has been remediated and Interim Closed Out. In 1994, the site appeared to have been leveled and scraped.

Location: The site is located east of 1120-N and northwest of 124-N-10.

Related Sites/Structures: The site is associated with 100-N-16 and 128-N-1.

Process Description: This site was used to burn miscellaneous trash and debris.

Waste Type: Water

Waste Description: In 1992 soil samples were collected and analyzed for the 100-NR-1 Remedial Investigation/Corrective Measures Study (RI/CMS). Field screening were less than detectable for volatile organic compounds (VOC), total petroleum hydrocarbons (TPH), and polychlorinated biphenyls (PCB). Heavy metals and metal-complexed compounds did not differ from background.

Closure Info: Remediation of 100-N-6, 100-N-16, 100-N-98 area 1, and 128-N-1 waste sites began on August 2, 2010, and was completed on November 28, 2011. A total of approximately 20,334 bank cubic meters (BCM) (26,596 bank cubic yards [BCY]) were excavated and staged for removal to the Environmental Restoration Disposal Facility (ERDF). Between April 16 and 19, 2012, the excavation was expanded to the west to include stained soil Area 2 of the 100-N-98 waste site. Approximately 476 BCM (623 BCY) of soil was removed from 100-N-98 Area 2 and direct loaded for disposal at ERDF. The additional remediation of the spoil pile area (SPA) and the 100-N-6, 100-N-16, 100-N-98, and 128-N-1 waste site excavation generated an additional volume of 5,446 BCM (7,123 BCY) of material for direct load out to ERDF. A total volume of 26,256 BCM (34,342 BCY) was disposed at ERDF, to complete the 100-N-6, 100-N-16, 100-N-98, and 128-N-1 waste site remediation.

The materials removed from the 100-N-6, 100-N-16, 100-N-98, and 128-N-1 waste sites consisted of abandoned wiring, transite pipe, metallic and wood debris, burnt wood, ash, tar, roofing felt, stained soil, a bucket of grout, an open glass bottle, green fibrous material, purple sandy material, a paint ball, drums containing bunker and amber oil, and miscellaneous demolition debris. Anomalous material discovered during remediation included six 208-L (55-gal) drums, small white ceramic balls used as filtering media, and soil with a strong solvent odor.

Names: 100-N-13; Contaminated Soil Solid Waste Site 1

Type: Unplanned Release

Status: Inactive

Classification: Accepted

Reclassification: Interim Closed Out (5/16/2012)

Start Date: End Date:

Description: The waste site has been remediated and interim Closed Out. The area contained miscellaneous construction debris. It had been posted at four corners with "Underground Radioactive Material" signs. Approximately 0.3 to 0.6 meters (1 to 2 feet) of soil had been placed on top of the site. The area contained miscellaneous construction debris. The radiological postings were removed in September 2012.

Location: The site was located in the 100 N area, about 124 meters (405 feet) northeast of the 1120-N Building. It was in the northeast quadrant of the dirt road intersection that is northeast of the 1120-N.
Rev. 24

DOE/RL-88-30

Process Description: In May 1993, a radiation survey identified the presence of cobalt-60 at what became the 100-N-13 waste site. The site was posted at four corners with "Underground Radioactive Material" signs, and approximately 0.3 to 0.6 meters (1 to 2 ft) of soil was placed on the top of the site. It was noted in 1994 that a photograph dated about 1963 showed a dark circular area (possibly a burn pit) in the vicinity of the 100-N-13 waste site.

Waste Type: Equipment

Waste Description: A May 1993 radiation survey identified the presence of cobalt-60 at the site. A photograph from about 1963 shows a dark circular area (possibly a burn pit) in the vicinity of this site. A 1988 photo shows a crane (possibly regulated) parked in the vicinity of this site.

Closure Info: Remedial action at the 100-N-13 waste site was performed between December 27, 2010, and March 7, 2011. Excavation continued until all debris and contamination associated with the waste site had been removed. The 100-N-13 waste site was excavated to a maximum depth of 4.6 meters (15 ft). Approximately 663 bank cubic meters (BCM) (867 bank cubic yards [BCY]) of contaminated soil and debris removed from the excavation and staged in the stockpile area before being loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 160 BCM (209 BCY) of soil was scraped and removed from the 100-N-13 stockpile area and disposed at ERDF between June 23 and 27, 2011.

The debris removed from the 100-N-13 waste site consisted of a small amount of metal debris. Although the radionuclide cobalt-60 is listed in the 100-N Area RDR/RAWP as a COPC for the 100-N-13 waste site, no radiologically contaminated material was detected during remediation activities. No indications of previous spills or releases were discovered during remediation of the 100-N-13 waste site.

Code: 100-N-14

Classification: Accepted

Names: 100-N-14; Contaminated Soil Solid Waste Site 2

Reclassification: Interim Closed Out (4/25/2012)

Type: Dumping Area

Start Date: Interim Closed Out (4/25/2012)

Status: Inactive

End Date: Interim Closed Out (4/25/2012)

Description: The site has been remediated and Interim Closed Out. It had been posted at four corners with "Underground Radioactive Material" signs. Approximately 0.3 to 0.6 meters (1 to 2 feet) of soil has been placed on top of the site. The radiological postings were removed in September 2012.

Location: The site was located in the 100N Area, about 453 meters (1500 feet) east of the 1120-N Building.

Release Description: A May 1993 radiation survey identified the presence of cesium-137 at the site.

Related Sites/Structures: It is associated with 100-N-34 and 100-N-17.

Waste Type: Equipment

Waste Description: Remedial action at the 100-N-14, 100-N-17, and 100-N-34 waste sites was performed between August 5, 2010, and January 4, 2011. Excavation continued to a depth of 10 meters (33 ft) at the lowest point, until all debris and visible contamination associated with the waste sites had been removed. The debris removed from the 100-N-14, 100-N-17, and 100-N-34 waste sites consisted of miscellaneous noncombustible debris including concrete, metal, bricks, vitrified clay pipe, electrical wiring, and asbestos. Approximately 10,527 bank cubic meters (BCM)

Hanford Site Waste Management Units Report
February 2015
(13,769 bank cubic yards [BCY]) of contaminated soil and debris were removed from the 100-N-17 and 100-N-34 combined excavation and staged in staging piles to the east before being loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 905 BCM (1,184 BCY) of contaminated soil and debris were removed from the 100-N-14 waste site excavation and directly loaded into trucks for shipment and disposal at the ERDF. Excavation continued until all debris and contamination associated with the waste sites had been removed. No radiologically contaminated material was discovered during remediation activities. The excavation boundary was expanded beyond the design during remediation due to debris found beyond the excavation limits.

The radiological postings were removed in September 2012.

Hanford Site Waste Management Units Report
February 2015 794
**Status:** Inactive  
**End Date:** 1/1/1989

**Description:** The waste site has been remediated and Interim Closed Out. It was an area that contained evidence of burning including charred wood and burned metal. Vegetation at the site was sparse with a few rabbitbrush plants.

**Location:** The Hanford Generating Plant (HGP) Burn Pit was located approximately 123 meters (404 feet) southwest of the Bonneville Power Administration (BPA) Hanford Substation.

**Process Description:** Combustible materials such as vegetation, office wastes, wood, trash, tools, hardware, and possibly paints and solvents have been burned at this site.

**Waste Type:** Equipment

**Waste Description:** Soil samples were collected from disturbed areas of the pit and analyzed using field screening methods. Samples tested contained less than detectable concentrations of volatile organic compounds (VOCs), heavy metals, total petroleum hydrocarbons (TPH), and polychlorinated biphenyls (PCBs).

**Closure Info:** Several samples were collected to support waste characterization and designation at the 100-N-18 waste site prior to remediation. Three test pits were excavated within the boundary of the waste site and one soil sample was collected from each test pit at approximately 0.9 to 1.5 meters (3 to 5 ft) bgs. The initial remedial action at the 100-N-18 waste site was performed on September 27, 2011. The excavation continued to an approximate depth of 1.5 meters (5 ft) below ground surface (bgs) resulting in approximately 195 bank cubic meters (BCM) (255 bank cubic yards [BCY]) of soil, metal, ash, and wood debris being removed for disposal at the Environmental Restoration Disposal Facility. Debris similar to that previously removed remained just outside of the 100-N-18 Waste Information Data System boundary. Therefore, remediation resumed on November 15, 2011, resulting in an additional 870 BCM (1,138 BCY) of soil and debris being removed for disposal. The final depth of the excavation extended to 1.5 meters (5 ft) bgs at the deepest point. No anomalous material or radiologically contaminated material was discovered during remediation activities.

<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Remediation of the 100-N-22 waste site occurred from April 12 to 18, 2012, and resulted in approximately 665 bank cubic meters (870 bank cubic yards) of soil and debris being removed</td>
<td></td>
</tr>
</tbody>
</table>
and disposed at the Environmental Restoration Disposal Facility. During remediation, it was discovered that the septic tank had previously been removed and its former location filled with dirt. The 100-N-22 waste site was excavated to a depth of approximately 4 meters (13 ft) below ground surface. The debris consisted of the concrete cesspool structure, rock, cast iron and polyvinyl chloride piping, and wiring. No anomalies were discovered during remediation. All material was direct loaded from the excavation for disposal at the Environmental Restoration Disposal Facility; therefore, no waste staging pile area was created. Additionally, there is no overburden soil stockpile associated with the 100-N-22 waste site.

Portions of the 100-N-84:1, 100-N-84:3, 100-N-84:5, and 100-N-84:8 pipeline subsites were co-located with the 100-N-22 waste site.

</tr>
<tr>
<td>Description</td>
<td>The overflow sump has been remediated and Interim Closed Out. It was an open, rectangular, unlined pit with a 61-centimeter (24-inch) overflow pipe protruding from the north side of the pit. The pit received spent resin from the 163-N Demineralized Water Treatment Plant.</td>
</tr>
<tr>
<td>Location</td>
<td>The site was located west of the 116-N-8 Facility (163-N Mixed Waste and Hazardous Waste Container Storage Pad).</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>There are two drain pipes that discharged into this site. Both pipelines are part of the 100-N-84:6 subsite. The larger drain originated from the 183-NB Clearwell and the other originated from the 163-N Demineralization Plant.</td>
</tr>
<tr>
<td>Waste Type</td>
<td>Equipment</td>
</tr>
<tr>
<td>Waste Description:</td>
<td>According to site personnel, the pit was used to dispose of resin generated in the 163-N Demineralized Water Plant. The pit later served as the clearwell overflow up until about 1990. Although it is not used for that purpose anymore, it could be used on an emergency basis. On May 5, 1980 and January 1976 the overflow sump received neutralized waste that was pumped from cleanup actions for an acid spill that occurred on the 108-N/163-N Transfer Line.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Remedial action at the 100-N-23 waste site was performed from July 20 through July 29, 2011. The excavation depth was approximately 4.5 meters (14.8 ft), resulting in approximately 1,922 bank cubic meters (BCM) (2,514 bank cubic yards [BCY]) of contaminated soil, piping, and resin (also referred to as resin beads). All material was direct loaded from the excavation for disposal at the Environmental Restoration Disposal Facility (ERDF). No anomalous material was encountered during the excavation. Global Positioning Environmental Radiological Surveyor (GPERS) surveys were conducted on August 18, 2011, within the 100-N-23 waste site following the site remedial action. No elevated radioactivity was detected. Following analysis of the original excavation verification samples, it was determined that additional remediation was needed within the excavation because of remedial action goal (RAG) exceedances of polychlorinated biphenyls (PCBs) and polycyclic aromatic hydrocarbons (PAH). A total of four additional remediation and sampling campaigns occurred from November 9, 2012, through March 18, 2013, to a depth of approximately 5.8 m (19 ft). During this time, 1,175 BCM (1,537 BCY) of contaminated soil was direct loaded and disposed at the ERDF, for a final waste site disposal volume of 3,097 BCM (4,051 BCY).</td>

*Hanford Site Waste Management Units Report*  
February 2015
Names: 100-N-24; Hydrogen Dry Well Liquid Waste Site; Hydrogen Peroxide Drywell

Reclassification: Interim Closed Out (7/24/2013)

Type: French Drain

Start Date: Interim Closed Out (7/24/2013)

Status: Inactive

End Date: Interim Closed Out (7/24/2013)

Description: The site has been remediated and Interim Closed Out. It was a buried vertical concrete pipe with a 0.83-meter (2.75-foot) diameter steel cover. The hydrogen peroxide drywell was a non-reinforced concrete pipe of 0.83-meters (2.75-feet) above a subchamber 2.53 meters (8.3 feet) in diameter. The subchamber was set in a gravel pocket 3.35 meters (11 feet) in diameter. Welded wire fabric cells 15 centimeters (6 inches) by 10.1 centimeters (4 inches) were within the subchamber.

Location: The site was located south of the 184-N Building and west of the southwest corner of the 153-N Switch Gear Building.

Related Sites/Structures: The hydrogen drywell was connected to a 5-centimeter (2-inch) chemical drain line which extends from the 109-N Building.

Process Description: The hydrogen peroxide drywell was constructed to receive and disperse liquids from the Hydrogen Peroxide Sump Pump to the surrounding soil below ground level.

Waste Type: Equipment

Waste Description: The waste is the predominantly concrete and metal structure of the hydrogen peroxide drywell. The site received 50 percent hydrogen peroxide and water from the hydrogen peroxide sump under the hydrogen peroxide tank located in the 109-N Decontamination Facility. The solution used for washing down of the storage tank area.

Closure Info: The 100-N-61:1 group includes co-located sites 100-N-61:1, 100-N-64:1, 100-N-24, 100-N-29, 100-N-30, 100-N-37 and 100-N-53. Remediation of the 100-N-61:1 grouping of waste sites and the 100-N-53 waste site began in February 2011 and continued through April 2012.

The 100-N-24, 100-N-29, 100-N-30, and 100-N-37 waste sites were located within the remediation boundary and removed during the 100-N-61:1 pipeline remediation. The remaining basement of the 1902-N Building, the 186-N concrete pad, concrete, valves and piping associated with the 163-N sump #2 were located within the remediation boundary and were subsequently removed. A french drain (known as french drain #2) was originally part of the 100-N-103:1 subsite. However, because of its location, the drain was removed with the 100-N-61:1 pipeline remediation. Installation of a haul road was necessary to gain access to the structures. Therefore, the 100-N-53 site and segments of the 100-N-61:1 and 100-N-64:1 pipelines that were located within the roadway boundary were removed and disposed. Verification samples were collected and 100-N-53 was backfilled as part of the haul road installation.

Petroleum-stained soil was observed throughout the excavation, but was determined to be unrelated to the waste site group. Focused verification samples were collected within the stained areas and analyzed for TPH, PAH, and PCBs. Concentrations of TPH and PAH were present in the samples above direct exposure RAGs. The oil staining is considered part of the 100-N-106, Shallow Petroleum-Only Releases waste site and no additional remediation was performed.

Global Positioning Environmental Radiological Surveyor (GPERS) surveys were conducted within the 100-N-61:1 waste site grouping excavation boundary. Radiological measurements slightly above background were observed in the northern portion of the site. Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).
Soil, concrete, piping, and rebar were among the types of material removed from the excavation and disposed at the Environmental Restoration Disposal Facility (ERDF). Prior to the material being loaded out for shipment to ERDF, the material was staged in a combined staging pile area (SPA). Verification sampling of the SPA will be addressed with the 100-N-61:4 waste site closeout.

Excavation of the 100-N-61:1 group extended to an approximate maximum depth of 7 meters (23 ft) below ground surface. The 100-N-53 waste site was excavated to an approximate depth of 3 meters (9.8 ft) below ground surface. An estimated 70,000 bank cubic meters (91,557 bank cubic yards) of soil and debris was removed from the entire excavation. A portion of the soil removed from on top of the pipelines was stockpiled for use as clean backfill and is included in the total volume of material removed. Asbestos was detected in the soil at the SZ3-7 location, and hexavalent chromium was detected above a remedial action goal (RAG) at the SZ4-10 location. Therefore, additional remediation was conducted January 21 through February 5, 2013. Asbestos was detected in nonsoil debris (tar/tar paper) at four locations within the excavation. A visual inspection was conducted and the visible pieces of tar and/or tar paper were removed. The volume of additional material removed is included in the estimated volume.

<tr>
<td>Process Description:</td>
<td>The purpose of this drain is unknown. The nearest structure was the 1105-N Administrative Office Trailer (MO919), from 1975 to 1986. 1105-N was replaced with 1129-N (MO536) in 1986. 1129-N was removed in 1993.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>No above or below grade pipelines were found to have led to the drain. Therefore, it was speculated that the drain was used for water runoff from the nearby office trailer roof or condensate from an air conditioning unit. Remediation of the 100-N-25 waste site was performed between March 27 and 29, 2012. The waste site was excavated to an approximate depth of 4 meters (13 ft) below ground surface resulting in approximately 333 bank cubic meters (436 bank cubic yards) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility. There was no evidence of a french drain found during remediation.</td>

</tbody>
</table>
Location: This underground site was in the 100-N Area, north-northeast of the 13-N Building (signed as Fitters Stock N-13 L).

Release Description: Waste sites 100-N-26 and 120-N-4 were impacted by a raw water pipeline break on December 11, 2008. The regulators and tribes have requested that this release information be noted in WIDS.

During the removal of the concrete pad at the 1524-N Hazardous waste storage facility on December 11, 2008 an unknown 1.5 inch tap into the export water line was inadvertently contacted. A rupture of the 12 inch export water line and a release of at least 50,000 gallons of raw water onto the surrounding area resulted. A temporary berm was constructed around the area using excess clean 100 Area Borrow Pit material to contain the release and control potential spread of radiological contamination associated with the 1524-N pad. Once the water line was turned off the water in the area immediately percolated into the ground.

In-process and post-event surface soil radiological field survey results did not find any contamination spread as a result of the water release. A follow-up review of nearby monitoring wells as well as the standard waste site confirmatory sampling will be used to ascertain potential impacts/conditions.

Process Description: The french drain received condensate from Trapping Station No. 3 along the 10 centimeter (4 in) high pressure steam supply line to the 166-N fuel oil unloading and storage facilities, as shown on drawing H-1-29456. The steam was supplied by the 184-N Stand-by Boiler to the 166-N facilities for heating the fuel oil. Steam condensation took place in the distribution piping due to heat loss. Trapping stations were installed at defined intervals to drain condensate and thereby prevent blockage of the steam line. The steam supply was independent of the reactor operation.

Waste Type: Equipment
Waste Description: The site receives yard steam condensate.

Closure Info: Remedial action at the 100-N-26 waste site was performed on October 27, 2011. The site was excavated to an approximate depth of 3.5 meters (11.5 ft), resulting in complete removal of the french drain structure with approximately 276 bank cubic meters (361 bank cubic yards) of debris, sand, soil, and rocks. All excavated material was direct loaded from the excavation and disposed of at the Environmental Restoration Disposal Facility.

Code: 100-N-28 Classification: Accepted
Names: 100-N-28; Resin Disposal Pit Liquid Waste Site 2 Reclassification: Interim Closed Out (4/3/2013)
Type: Process Pit Start Date:
Status: Inactive End Date:
Description: The site has been remediated and Interim Closed Out. It was a slight depression around a 1.5-meter (5-foot) square concrete structure that has a 0.8-meter (2.5-foot) by 0.63-centimeter (0.25-inch) rusted metal cover. The site was surrounded with four heavy steel posts connected with chain. The steel cover was posted as a confined space.

Location: This unit was located south of the 184-N Building and west of the 153-N Building.

Related Sites/Structures: The Resin Disposal Pit is connected to a 7.6-centimeter (3-inch) chemical drain line which originates in the 109-N Building.
Process Description: The resin disposal pit was designed to receive the spent resin charge from the 109-N Ion Exchanger. The construction of the pit is such that all liquids entered the pit via the chemical drain line and the liquid entrained in the resin were filtered to the soil below the resin disposal pit. The effective volume of the resin disposal pit was 40.36 cubic meters (1,425 cubic feet) and the maximum resin charge in the ion exchanger was 3.12 cubic meters (110 cubic feet). A 7.62-centimeter (3-inch) chemical drain goes from the 109-N Decontamination Facility to the Resin Disposal Pit.

Waste Type: Process Effluent

Waste Description: The waste is the below grade structure, including the lead shield plug, piping to the pit from the 109-N Facility, and the pit structure. Site employees report that the pit was initially used for reactor decontamination waste and may have never actually been used as a resin disposal pit. Documentation (HW-69000-Volume II) states that the Resin Disposal Pit was designed to receive the resin charge from the 109-N Ion Exchanger.

Closure Info: Remediation of the 100-N-28 waste site was performed between January 25 and March 29, 2012. The site was excavated to a depth of 8.4 meters (27.6 ft) below ground surface (bgs) and resulted in the removal of 2,577 BCM (3,371 BCY) of soil and debris. The debris consisted of soil, rock, a concrete resin pit, piping, and wiring. No resin was present in the pit and it is assumed the site was only used for liquid disposal from the 109-N Building. Soil and debris were directly loaded from the 100-N-28 excavation and disposed at the Environmental Restoration Disposal Facility (ERDF).

Remedial actions for the 100-N-61:2, 100-N-62, and 100-N-64:2 sites were performed between April 13, 2011, and March 29, 2012. Excavation depths ranged from 3 meters (9.9 ft) to 8 meters (26.2 ft) bgs. Approximately 24,113 bank cubic meters of contaminated soil and debris associated with the three pipelines was removed from the waste sites and staged in the South Staging Pile Area 1 (SSP Area 1) to the south of the excavation prior to load out for disposal at ERDF. The debris consisted of rock, concrete, piping, and wiring. Verification sampling of the SSP Area 1 will be addressed in the 100-N-61:4 verification work instruction. In addition, overburden (OB) material was stockpiled in three OB piles southwest of the waste sites. The OB piles will also be addressed in the 100-N-61:4 verification work instruction.

Multiple TPH and PAH results collected at the 100-N-61:2, 100-N-62, and 100-N-64:2 excavation exceeded soil RAGs. However, these results were concluded to be cross contamination from petroleum releases unrelated to the waste sites and will be addressed as part of the 100-N-106 (Shallow Petroleum-Only Releases at 100-N; SPOR Releases) waste site and were not used for evaluation in this RSVP.

A valve pit (OSE ID N-244) was discovered at Washington State plane coordinates N149350.37, E571230.54, with asbestos pipe wrapping. The valve pit was a 1 meter (3.3 ft) diameter manhole, with a valve and a 7.6 centimeter (3 in.) pipeline running east to west. Spatial analysis indicated that valve pit N-244 is associated with the 100-N-84:3, potable water line. The valve pit was completely removed and disposed with soil and debris from the 100-N-61:2, 100-N-62, and 100-N-64:2 excavation. No other anomalies were discovered during remediation.

Code: 100-N-29
Names: 100-N-29; Unplanned Release on 25-Centimeter (10-Inch) Blowdown Pipeline #1
Type: Unplanned Release
Status: Inactive
Classification: Accepted
Reclassification: Interim Closed Out (7/24/2013)
Start Date: End Date:
**Description:**
The unplanned release site has been remediated and Interim Closed Out. It was associated with the blowdown pipe connected to the 1300-N Emergency Dump Basin. The area surrounding it was level and graveled with no vegetation. Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

**Location:**
The release site was located near the southwest corner of the 104-N Building between valve BDV 6214 and BDV 801 on the 25-centimeter (10-inch) blowdown pipeline.

**Release Description:**
Through process knowledge, it is known that several water leaks occurred around and adjacent to the dump basin in the early 1980's.

**Related Sites/Structures:**
The 1300-N Emergency Dump Basin (116-N-4), 100-N Reactor, 109-N Building and the 259 centimeter (102 inch) Outfall (NPDES 009) are associated with this Unplanned Release site.

**Waste Type:**
Process Effluent

**Waste Description:**
An inventory table from an unnumbered document is attached to the listed reference.

Contaminants in the Dump Basin liquid include average concentrations of 6.25 E+05 of H-3, 6.12 E+01 of C0-60, 5.70 E+04 of Sr-90, 2.51 E+01 of Zr-95, 5.16 E+01 of Ru-106, 2.16 E+1 of Sb-125, 5.16 E+00 of Cs-134, 9.27 E+02 of Cs-137, 1.62 E-02 of Pu-239 and 1.82 E-01 of Pu.

**Closure Info:**
The 100-N-61:1 group includes co-located sites 100-N-61:1, 100-N-64:1, 100-N-24, 100-N-29, 100-N-30, 100-N-37 and 100-N-53. Remediation of the 100-N-61:1 grouping of waste sites and the 100-N-53 waste site began in February 2011 and continued through April 2012.

The 100-N-24, 100-N-29, 100-N-30, and 100-N-37 waste sites were located within the remediation boundary and removed during the 100-N-61:1 pipeline remediation. The remaining basement of the 1902-N Building, the 186-N concrete pad, concrete, valves and piping associated with the 163-N sump #2 were located within the remediation boundary and were subsequently removed. A french drain (known as french drain #2) was originally part of the 100-N-103:1 subsite. However, because of its location, the drain was removed with the 100-N-61:1 pipeline remediation. Installation of a haul road was necessary to gain access to the structures. Therefore, the 100-N-53 site and segments of the 100-N-61:1 and 100-N-64:1 pipelines that were located within the roadway boundary were removed and disposed.

Verification samples were collected and 100-N-53 was backfilled as part of the haul road installation.

Petroleum-stained soil was observed throughout the excavation, but was determined to be unrelated to the waste site group. Focused verification samples were collected within the stained areas and analyzed for TPH, PAH, and PCBs. Concentrations of TPH and PAH were present in the samples above direct exposure RAGs. The oil staining is considered part of the 100-N-106, Shallow Petroleum-Only Releases waste site and no additional remediation was performed.

Global Positioning Environmental Radiological Surveyor (GPERS) surveys were conducted within the 100-N-61:1 waste site grouping excavation boundary. Radiological measurements slightly above background were observed in the northern portion of the site. Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

Soil, concrete, piping, and rebar were among the types of material removed from the excavation and disposed at the Environmental Restoration Disposal Facility (ERDF). Prior to the material being loaded out for shipment to ERDF, the material was staged in a combined staging pile area (SPA). Verification sampling of the SPA will be addressed with the 100-N-61:4 waste site closeout.
Excavation of the 100-N-61:1 group extended to an approximate maximum depth of 7 meters (23 ft) below ground surface. The 100-N-53 waste site was excavated to an approximate depth of 3 meters (9.8 ft) below ground surface. An estimated 70,000 bank cubic meters (91,557 bank cubic yards) of soil and debris was removed from the entire excavation. A portion of the soil removed from on top of the pipelines was stockpiled for use as clean backfill and is included in the total volume of material removed. Asbestos was detected in the soil at the SZ3-7 location, and hexavalent chromium was detected above a remedial action goal (RAG) at the SZ4-10 location. Therefore, additional remediation was conducted January 21 through February 5, 2013. Asbestos was detected in nonsoil debris (tar/tar paper) at four locations within the excavation. A visual inspection was conducted and the visible pieces of tar and/or tar paper were removed. The volume of additional material removed is included in the estimated volume.

---

**Code:** 100-N-31

**Classification:** Accepted

**Names:** 100-N-31; Unplanned Release on 30-Inch Pipe Line

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The waste site has been remediated and Interim Closed Out. Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. These waste sites are collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.

100-N-31 was a leak from a valve (FLV-858) transferring radioactively contaminated water from the 105-N Reactor to the 1300-N Emergency Dump Basin. The surface area had no vegetation and was covered with gravel.

**Location:** 100-N-31 and the group of eleven adjacent sites were located west of the 105-N/109-N buildings. The 100-N-31 leak was near the northwest corner of the 109-N building.

**Release Description:** Through process knowledge, it is known that several water leaks occurred around and adjacent to the dump basin in the early 1980's.
Rev. 24

DOE/RL-88-30

Related Sites/Structures: The waste site is associated with 100-N Reactor and 1300-N Emergency Dump Basin. It was adjacent to the 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39, UPR-100-N-4 and UPR-100-N-8 waste sites.

Waste Type: Equipment

Waste Description: Through process knowledge, it is known that water was slightly chemically treated with hydrazine and mophaline which are very volatile and most likely not detectable. The water was radioactively contaminated.

Closure Info: Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. This group of waste sites was referred to as the waste sites west of the 105-N/109-N Reactor. The footprints of the 1909-N Waste Disposal Valve Pit, the 107-N facility and the pipe trench between 105-N and 107-N were also located within the boundary of the group.

The eleven collocated waste sites located west of the 105-N/109-N Reactor Building were remediated, either partially or completely, by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the collocated waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N) Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected above background. However, the area with the highest detected activity is associated with residual structures and soils for the 105-N/109-N SSE and is considered part of the 100-N-66, 105-N/109-N Reactor Building Complex waste site. A small area with elevated beta and gamma contamination was detected within the waste sites west of the 105-N/109-N Reactor boundary. Additional soil was removed from this area and disposed at the ERDF. An environmental radiological survey of the area using hand-held instruments verified that the contaminated soils have been removed.

The 1909-N Waste Disposal Valve Pit was removed during general facility demolition in this area by the D4 Project. Due to the proximity and general configuration of demolition and remediation activities on the west side of the reactor, closure of the facility footprint was deferred until nearby waste site remediation by the FR Project occurred. The residual contaminated soil that remained beneath the location of the former 1909-N facility was then removed.

The 107-N basin structure was completely removed by the D4 Project. However, closure of the basin footprint was deferred to the UPR-100-N-12 waste site. Additional soil was removed from the footprint during general waste site remediation in the area. Surveys found no elevated residual radiological activity.
Several segments of the 100-N-84 pipeline subsites were partially located within the remediation boundary. All of the segments of the 100-N-84:2, 100-N-84:4, 100-N-84:5, and 100-N-84:6 pipeline subsites that were within the excavation boundary were removed and disposed at the ERDF. Reclassification of the total 100-N-84:2, 100-N-84:4, 100-N-84:5 and 100-N-84:6 pipeline subsites will be addressed in separate closure documents.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

100-N-32 was a leak from a valve (BDV-800) transferring radioactively contaminated water from the 105-N Reactor to the 1300-N Emergency Dump Basin. The surface area had no vegetation and was covered with gravel.

The waste site has been remediad and Interim Closed Out. The 100-N-31 waste site was located on the west side of the 105-N/109-N Reactor Buildings and adjacent to the 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39 waste sites. These waste sites were collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.

The eleven collocated waste sites located west of the 105-N/109-N Reactor Building were remediad, either partially or completely, by the Deactivation, Decontamination,
Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the collocated waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N) Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected above background. However, the area with the highest detected activity is associated with residual structures and soils for the 105-N/109-N SSE and is considered part of the 100-N-66, 105-N/109-N Reactor Building Complex waste site. A small area with elevated beta and gamma contamination was detected within the waste sites west of the 105-N/109-N Reactor boundary. Additional soil was removed from this area and disposed at the ERDF. An environmental radiological survey of the area using hand-held instruments verified that the contaminated soils have been removed.

The 1909-N Waste Disposal Valve Pit was removed during general facility demolition in this area by the D4 Project. Due to the proximity and general configuration of demolition and remediation activities on the west side of the reactor, closure of the facility footprint was deferred until nearby waste site remediation by the FR Project occurred. The residual contaminated soil that remained beneath the location of the former 1909-N facility was then removed.

The 107-N basin structure was completely removed by the D4 Project. However, closure of the basin footprint was deferred to the UPR-100-N-12 waste site. Additional soil was removed from the footprint during general waste site remediation in the area. Surveys found no elevated residual radiological activity.

Several segments of the 100-N-84 pipeline subsites were partially located within the remediation boundary. All of the segments of the 100-N-84:2, 100-N-84:4, 100-N-84:5, and 100-N-84:6 pipeline subsites that were within the excavation boundary were removed and disposed at the ERDF. Reclassification of the total 100-N-84:2, 100-N-84:4, 100-N-84:5 and 100-N-84:6 pipeline subsites will be addressed in separate closure documents.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

---

**Code:** 100-N-33  
**Classification:** Accepted  
**Names:** 100-N-33; 100-N Military Installation Ash Pit  
**Reclassification:** Interim Closed Out (8/2/2012)  
**Type:** Coal Ash Pit  
**Start Date:**  
**Status:** Inactive  
**End Date:**  
**Description:** The waste site has been remediated and Interim Closed Out. It was an irregularly-shaped area, covered with dark, uniform grain-size ash, perhaps the remnants of coal burning.
Location: The site is located generally southeast of the 100-N Area and southwest of the 100-N Military Artillery Site. The site is south southeast of the 105-N Reactor Building.

Process Description: The source of the material is unknown.

Waste Type: Process Effluent

Waste Description: A description of the waste is not known at this time.

Closure Info: Remediation of the two waste sites was performed between December 27, 2010, and July 19, 2011.

The 100-N-33 waste site was excavated to a depth of approximately 0.5 to 1.0 meter (1.6 to 3.3 ft) below ground surface (bgs). Remediation of the 100-N-33 waste site involved removal of approximately 221 bank cubic meters (BCM) (289 bank cubic yards [BCY]) of ash and soil, which was staged at the southern staging pile or 100-N-33 staging pile before disposal at the Environmental Restoration Disposal Facility (ERDF).

The 100-N-47 waste site was excavated to a depth of approximately 2.0 to 5.5 meters (6.6 to 18.0 ft) bgs. Remediation of the 100-N-47 waste site included excavation of the septic system, all manholes, septic tanks, the drain field, associated piping, and miscellaneous material/debris. The contents of the septic tank were treated with soda lime to raise the pH above 12.0 in order to kill any coliform bacteria, and then the septage was solidified with Waterworks silica gel. The concrete septic tank, solidified contents of the septic tank, and pipeline between the drainfield and manhole/building footprint were direct loaded to ERDF, while the soil and debris from the remainder of the 100-N-47 waste site were staged in the northern staging pile, before being loaded out to ERDF. Approximately 9,776 BCM (12,787 BCY) of soil and miscellaneous debris, including concrete, solidified sewage, and tiles, from the 100-N-47 waste site was disposed at ERDF. No overburden soil stockpiles were associated with the waste sites.

Code: 100-N-34

Names: 100-N-34; Debris Site

Type: Dumping Area

Status: Inactive

Classification: Accepted

Reclassification: Interim Closed Out (4/25/2012)

Start Date: Interim Closed Out (4/25/2012)

End Date:

Description: The 100-N-34 waste site consisted of a debris dumping site that encompassed the smaller 100-N-17 burn pit waste site and adjacent 100-N-14, contaminated soil solid waste site. The site was an irregular shape with gravel/cobble (some in piles), weedy vegetation, and dead tumbleweeds (some in piles) present. Construction debris including asphalt, concrete, and metal pipe were also present.

Location: The 100-N-34 waste site is located outside the 100-N industrial area approximately 803 meters (2,635 ft) east of the 105-N Reactor Building.

Related Sites/Structures: It is associated with burn pits 100-N-14 and 100-N-17

Process Description: This site received debris from 100-N Area construction and operation activities.

Waste Type: Process Effluent
Waste Description:

Closure Info: Remedial action at the 100-N-14, 100-N-17, and 100-N-34 waste sites was performed between August 5, 2010, and January 4, 2011. Excavation continued to a depth of 10 meters (33 ft) at the lowest point, until all debris and visible contamination associated with the waste sites had been removed. The debris removed from the 100-N-14, 100-N-17, and 100-N-34 waste sites consisted of miscellaneous noncombustible debris including concrete, metal, bricks, vitrified clay pipe, electrical wiring, and asbestos. Approximately 10,527 bank cubic meters (BCM) (13,769 bank cubic yards [BCY]) of contaminated soil and debris were removed from the 100-N-17 and 100-N-34 combined excavation and staged in staging piles to the east before being loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 905 BCM (1,184 BCY) of contaminated soil and debris were removed from the 100-N-14 waste site excavation and directly loaded into trucks for shipment and disposal at the ERDF. Excavation continued until all debris and contamination associated with the waste sites had been removed. No radiologically contaminated material was discovered during remediation activities. The excavation boundary was expanded beyond the design during remediation due to debris found beyond the excavation limits.

The radiological postings were removed in September 2012.

<tr>
<td>Description</td>
<td>The waste site has been evaluated and reclassified to Rejected. It was reported releases of oil and hydraulic fluid from equipment located inside the Hanford Generating Plant (HGP) Substation. Two releases occurred in 1989 and were reported and documented. A review of the 1992 RCRA Facility Assessment concluded no further cleanup action was required. In 2014, Bonneville Power Administration concurred that the waste site should be reclassified to Rejected. Note: 100-N-35 was originally described in the WIDS database as the Hanford Generating Plant (HGP) Substation facility. The definition was later changed to address the potential for petroleum/PCB contamination in soil.</td>
</tr>
<tr>
<td>Location</td>
<td>The waste site is located southwest of the 100-N Reactor area.</td>
</tr>
<tr>
<td>Release</td>
<td>On June 6, 1989, oil leaked from equipment (BPA nno. 4001 MOD). The source document does not specify oil type or equipment use. On July 16, 1990, a hydraulic leak from a fitting on B-phase circuit breaker was repaired. Soil sampled near the leak at various times showed polychlorinated biphenyl (PCB) concentrations ranging from less than detectable to 7 milligrams/kilogram (7 parts per million).</td>
</tr>
<tr>
<td>Related Sites/Structures</td>
<td>The site is associated with a construction dump area located outside the facility boundary known as Solid Waste Management Unit (SWMU) #11. See WIDS sites 100-N-19 and 100-N-39.</td>
</tr>
<tr>
<td>Process</td>
<td>The Hanford Generating Plant (185-N Building) produced electricity for the Bonneville Power Association (BPA) grid using steam from the N-Reactor operation. The Hanford Substation distributed the power into the grid. The Hanford Generating Plant operated continuously from April 1966 to December 1986. As of August 2000, the BPA Hanford Substation was still</td>

</table>

Hanford Site Waste Management Units Report
February 2015

808
active. A telephone inquiry to MSA in June 2013 indicated the substation is still active.

**Waste Type:** Soil

**Waste Description:** There is asbestos insulated piping in the basement of the mechanical room. Mineral oil containing polychlorinated biphenyls and solvents is used during routine equipment maintenance.

---

**Code:** 100-N-36  
**Classification:** Accepted

**Names:** 100-N-36; 107-N Oil Stained Pad  
**Reclassification:** Interim Closed Out (4/8/2013)

**Type:** Unplanned Release  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The waste site was remediated along with the demolition of the 107-N Recirculation Facility and has been Interim Closed Out. It consisted of a cement air compressor pad adjacent to the 107-N Building. The concrete pad and adjacent asphalt were stained with lubrication oil from the maintenance of air compressor. The area was covered with asphalt except for the concrete pad that measured approximately 1.2 meters (4 feet) by 2.4 meters (8 feet).

**Location:** The air compressor pad is adjacent to the 107-N Building.

**Related Sites/Structures:** The 107-N Building is associated with the site.

**Waste Type:** Process Effluent

**Waste Description:** The waste consists of non-hazardous petroleum product (oil) from air compressor leaks.

**Closure Info:** The 100-N-36 waste site was within the layback for removal of the 107-N Building. The removal of the 107-N facility basement in 2012 resulted in the incidental remediation of the 100-N-36 waste site. Soils were excavated to a depth of approximately 7 meters (23 ft) below ground surface at the site location. No stained soil was observed. No verification samples were collected.

---

**Code:** 100-N-37  
**Classification:** Accepted

**Names:** 100-N-37; 109-N Asbestos Release  
**Reclassification:** Interim Closed Out (7/24/2013)

**Type:** Unplanned Release  
**Start Date:** 1/16/1995

**Status:** Inactive  
**End Date:**

**Description:** The waste site has been remediated and Interim Closed Out. It was an area where asbestos insulation lagging from an above ground steam line was affected by a rain event. A large chunk of lagging fell to the ground.

**Location:** 100-N-37 was located south of 109-N.

**Release Description:** Heavy rainfall caused a subsidence next to a caisson directly beneath the west elbow of the steam transfer line at the 109-N Building. The same rainfall saturated asbestos insulation lagging on the steam transfer piping causing a large chunk (estimated to weigh 180 to 320 kilograms [400 to 500 pounds]) to fall off. It was apparent that some of the asbestos insulation washed down the subsidence next to the caisson. Surface asbestos material was cleaned up and disposed of. The subsidence was backfilled with clean fill material. No action was taken to remove asbestos contamination from the subsidence.
Related Sites/Structures: The 109-N Building was associated with the site.

Waste Type: Sludge

Waste Description: The 100-N-61:1 group includes co-located sites 100-N-61:1, 100-N-64:1, 100-N-24, 100-N-29, 100-N-30, 100-N-37 and 100-N-53. Remediation of the 100-N-61:1 grouping of waste sites and the 100-N-53 waste site began in February 2011 and continued through April 2012.

The 100-N-24, 100-N-29, 100-N-30, and 100-N-37 waste sites were located within the remediation boundary and removed during the 100-N-61:1 pipeline remediation. The remaining basement of the 1902-N Building, the 186-N concrete pad, concrete, valves and piping associated with the 163-N sump #2 were located within the remediation boundary and were subsequently removed. A french drain (known as french drain #2) was originally part of the 100-N-103:1 subsite. However, because of its location, the drain was removed with the 100-N-61:1 pipeline remediation. Installation of a haul road was necessary to gain access to the structures. Therefore, the 100-N-53 site and segments of the 100-N-61:1 and 100-N-64:1 pipelines that were located within the roadway boundary were removed and disposed. Verification samples were collected and 100-N-53 was backfilled as part of the haul road installation.

Petroleum-stained soil was observed throughout the excavation, but was determined to be unrelated to the waste site group. Focused verification samples were collected within the stained areas and analyzed for TPH, PAH, and PCBs. Concentrations of TPH and PAH were present in the samples above direct exposure RAGs. The oil staining is considered part of the 100-N-106, Shallow Petroleum-Only Releases waste site and no additional remediation was performed.

Global Positioning Environmental Radiological Surveyor (GPERS) surveys were conducted within the 100-N-61:1 waste site grouping excavation boundary. Radiological measurements slightly above background were observed in the northern portion of the site. Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

Soil, concrete, piping, and rebar were among the types of material removed from the excavation and disposed at the Environmental Restoration Disposal Facility (ERDF). Prior to the material being loaded out for shipment to ERDF, the material was staged in a combined staging pile area (SPA). Verification sampling of the SPA will be addressed with the 100-N-61:4 waste site closeout.

Excavation of the 100-N-61:1 group extended to an approximate maximum depth of 7 meters (23 ft) below ground surface. The 100-N-53 waste site was excavated to an approximate depth of 3 meters (9.8 ft) below ground surface. An estimated 70,000 bank cubic meters (91,557 bank cubic yards) of soil and debris was removed from the entire excavation. A portion of the soil removed from on top of the pipelines was stockpiled for use as clean backfill and is included in the total volume of material removed. Asbestos was detected in the soil at the SZ3-7 location, and hexavalent chromium was detected above a remedial action goal (RAG) at the SZ4-10 location. Therefore, additional remediation was conducted January 21 through February 5, 2013. Asbestos was detected in nonsoil debris (tar/tar paper) at four locations within the excavation. A visual inspection was conducted and the visible pieces of tar and/or tar paper were removed. The volume of additional material removed is included in the estimated volume.
The waste site has been remediated and Interim Closed Out. The 100-N-31 waste site was located on the west side of the 105-N/109-N Reactor Buildings and adjacent to the 100-N-32, 100-N-38, 100-N-61 :3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39 waste sites. These waste sites are collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.

100-N-38 was a leak of radioactively contaminated water from the 105-N Reactor to the 1300-N Emergency Dump Basin. The area surrounding the basin had no vegetation and was covered with gravel.

Location: 100-N-38 was located near the northeast corner of the 1300-N Emergency Dump Basin where the 25-centimeter (10-inch) blow down line connected to the basin.

Related Sites/Structures: The 1300-N Emergency Dump Basin (116-N-4) and the 109-N Building are associated with the site.

Process Description: From 1973 to 1987, the Emergency Dump Basin received contaminated liquid generated during the periodic blowdown of the steam generators located in the 109-N Building. This condensate contained low levels of radioactive contaminants.

Waste Type: Equipment

Waste Description: Through process knowledge it is known that several water leaks have occurred around and adjacent to the dump basin in the early 1980's. Contaminants in the Dump Basin liquid include average concentrations of 6.25 E+05 of H-3, 6.12 E+01 of C0-60, 5.70 E+04 of Sr-90, 2.51 E+01 of Zr-95,5.16 E+01 of Ru-106, 2.16 E+01 of Sb-125, 5.16 E+00 of Cs-134, 9.27 E+02 of Cs-137, 1.62 E-02 of Pu-239 and 1.82 E-01 of Pu.

Closure Info: Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. This group of waste sites was referred to as the waste sites west of the 105-N/109-N Reactor. The footprints of the 1909-N Waste Disposal Valve Pit, the 107-N facility and the pipe trench between 105-N and 107-N were also located within the boundary of the group.

The eleven collocated waste sites located west of the 105-N/109-N Reactor Building were remediated, either partially or completely, by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the collocated waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N)
Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected above background. However, the area with the highest detected activity is associated with residual structures and soils for the 105-N/109-N SSE and is considered part of the 100-N-66, 105-N/109-N Reactor Building Complex waste site. A small area with elevated beta and gamma contamination was detected within the waste sites west of the 105-N/109-N Reactor boundary. Additional soil was removed from this area and disposed at the ERDF. An environmental radiological survey of the area using hand-held instruments verified that the contaminated soils have been removed.

The 1909-N Waste Disposal Valve Pit was removed during general facility demolition in this area by the D4 Project. Due to the proximity and general configuration of demolition and remediation activities on the west side of the reactor, closure of the facility footprint was deferred until nearby waste site remediation by the FR Project occurred. The residual contaminated soil that remained beneath the location of the former 1909-N facility was then removed.

The 107-N basin structure was completely removed by the D4 Project. However, closure of the basin footprint was deferred to the UPR-100-N-12 waste site. Additional soil was removed from the footprint during general waste site remediation in the area. Surveys found no elevated residual radiological activity.

Several segments of the 100-N-84 pipeline subsites were partially located within the remediation boundary. All of the segments of the 100-N-84:2, 100-N-84:4, 100-N-84:5, and 100-N-84:6 pipeline subsites that were within the excavation boundary were removed and disposed at the ERDF. Reclassification of the total 100-N-84:2, 100-N-84:4, 100-N-84:5 and 100-N-84:6 pipeline subsites will be addressed in separate closure documents.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

</table>

**Description:** The site has been remediated and Interim Closed Out. The site consisted of a septic system that received effluent from the demolished 1701-NE Gate House. The site was not located in a known contaminated area. (the 100-N-3 garage french drain, the 100-N-41 septic tank and the 100-N-45 septic tank make up Solid Waste Management Unit (SWMU) #9). The septic tank was an open bottomed cesspool constructed of concrete blocks and gravel. The septic structure was demolished in place and backfilled with clean soil.

**Location:** The site was located just off the north corner of the 1701-NE Gate House within the HGP portion of the 100N area.

**Process Description:** The former HGP consisted of two 430-megawatt turbine generators that operated from 1966 until 1986 using steam from the adjacent 100-N production reactor for generation of electricity. The generators were located in the 185-N Building. The site was an ancillary or support facility to the former HGP.
Waste Type: Equipment

Waste Description:
The 100-N Reactor provided fuel rods to the plutonium production process at Hanford, but also operated two 430 megawatt turbine generators for the generation of electricity. The Washington Public Supply System, later named Energy Northwest, was responsible for the Hanford Generating Plant located at 100-N Reactor. The Cleanup Verification Package (HGP-CVP-SWMUs 5, 6, 7, 8, 9, & 10) for the Hanford Generating Plant Solid Waste Management units was prepared by Energy Northwest in 2004. Some remedial actions at HGP began in 1992. Other characterization and remediation was completed in 2004. Remedial action activity descriptions include:

100-N-1 Settling Pond (SWMU#6) - Remediation activities conducted in 2001 removed approximately 0.9 meters (3 ft) of soil and settled solids material from the 100-N-1 Settling Pond (SWMU #6). The excavated material was disposed of at the Environmental Restoration Disposal Facility (ERDF).

100-N-3 Maintenance Garage French Drain, 100-N-41 Gate House Septic Tank and 100-N-45 Office Building Septic Tank make up SWMU #9. Remediation was determined not to be necessary for the 100-N-3 site and the 100-N-41 and 100-N-45 septic sites. The below grade structures of the drain and septic sites were demolished in place and backfilled with soil in 2004.

100-N-4 Tile Field (SWMU#5) - Confirmatory sampling activities and data evaluation determined that remediation was not necessary for the 100-N-4 Tile Field.

100-N-5 Bone Yard (SWMU #10) - Remediation and removal activities for the 100-N-5 Bone Yard (SWMU #10) were primarily conducted in 2001 with the removal of the miscellaneous equipment, metal scrap, and general debris. The limited number of areas with sand blast media, ion exchange resin-like media and areas with soil staining and/or distressed vegetation were remediated in 2003 and 2004. The sand blast, ion exchange resin, and contaminated soil wastes were disposed of at the RABANCO landfill facility in Roosevelt, Washington.

The 100-N-46 Diesel underground storage tank (UST) was excavated and removed in 2001. Soil contaminated with diesel was also excavated from the UST excavation. Contaminated soil was spread over the demolished 1703-N Office Building concrete slab foundation for attenuation. Upon completion of the remedial excavation, the bottom of the excavation was approximately 6.7 meters (22 ft) below the ground surface at the deepest location (southwest corner of excavation).

100-N-52 Gasoline underground storage tank (UST) was excavated and removed in 1992.

1908-NE Outfall (SWMU#7) - The original preferred remedy for the 1908-NE Outfall was Institutional Controls (continued monitoring). A radiological survey of the Outfall seal well and samples of water and sediment were collected from the Outfall seal well in 2001 to assess potential contamination associated with the Outfall. The outfall structure was demolished by the Washington Closure Hanford D&D organization in 2012, eliminating the Institutional Control requirement.

The 1716-NE Maintenance Garage building (SWMU #8), including the building slab and associated floor drain pipelines, were removed in their entirety during the 2003 and 2004 removal action activities. Prior to the removal action all chemical products were removed from the building and either properly disposed of or transferred to another facility for use. The building debris was used as fill for the 185-N Building basement.

<td>The 100-N Reactor provided fuel rods to the plutonium production process at Hanford, but also operated two 430 megawatt turbine generators for the generation of electricity. The Washington Public Supply System, later named Energy Northwest, was responsible for the Hanford Generating Plant located at 100-N Reactor. The Cleanup Verification Package (HGP-CVP-SWMUs 5, 6, 7, 8, 9, &amp; 10) for the Hanford Generating Plant Solid Waste Management units was prepared by Energy Northwest in 2004. Some remedial actions at HGP began in 1992. Other characterization and remediation was completed in 2004. Remedial action activity descriptions include:</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

100-N-1 Settling Pond (SWMU#6) - Remediation activities conducted in 2001 removed approximately 0.9 meters (3 ft) of soil and settled solids material from the 100-N-1 Settling Pond (SWMU #6). The excavated material was disposed of at the Environmental Restoration Disposal Facility (ERDF). |

100-N-3 Maintenance Garage French Drain, 100-N-41 Gate House Septic Tank and 100-N-45 Office Building Septic Tank make up SWMU #9. Remediation was determined not to be necessary for the 100-N-3 site and the 100-N-41 and 100-N-45 septic sites. The below grade structures of the drain and septic sites were demolished in place and backfilled with soil in 2004. |

100-N-4 Tile Field (SWMU#5) - Confirmatory sampling activities and data evaluation determined that remediation was not necessary for the 100-N-4 Tile Field. |

100-N-5 Bone Yard (SWMU #10) - Remediation and removal activities for the 100-N-5 Bone Yard (SWMU #10) were primarily conducted in 2001 with the removal of the miscellaneous equipment, metal scrap, and general debris. The limited number of areas with sand blast media, ion exchange resin-like media and areas with soil staining and/or distressed vegetation were remediated in 2003 and 2004. The sand blast, ion exchange resin, and contaminated soil wastes
were disposed of at the RABANCO landfill facility in Roosevelt, Washington.

The 100-N-46 Diesel under ground storage tank (UST) was excavated and removed in 2001. Soil contaminated with diesel was also excavated from the UST excavation. Contaminated soil was spread over the demolished 1703-N Office Building concrete slab foundation for attenuation. Upon completion of the remedial excavation, the bottom of the excavation was approximately 6.7 meters (22 ft) below the ground surface at the deepest location (southwest corner of excavation).

100-N-52 Gasoline underground storage tank (UST) was excavated and removed in 1992.

1908-NE Outfall (SWMU#7) - The original preferred remedy for the 1908-NE Outfall was Institutional Controls (continued monitoring). A radiological survey of the Outfall seal well and samples of water and sediment were collected from the Outfall seal well in 2001 to assess potential contamination associated with the Outfall. The outfall structure was demolished by the Washington Closure Hanford D&D organization in 2012, eliminating the Institutional Control requirement.

The 1716-NE Maintenance Garage building (SWMU #8), including the building slab and associated floor drain pipelines, were removed in their entirety during the 2003 and 2004 removal action activities. Prior to the removal action all chemical products were removed from the building and either properly disposed of or transferred to another facility for use. The building debris was used as fill for the 185-N Building basement.

</table>
Description: The waste site has been remediated and Interim Closed Out. It was a military installation that included ten separate intact concrete foundations and remnants of at least one other. A number of concrete walkways and remnants of walkways were associated with the foundations. There were remnants of asphalt roadways, parking areas, and piles of broken-up asphalt. There is a 0.6-meter (2-foot) diameter sewer manhole and three 1.2 by 1.2 meter (4 by 4 foot) square concrete hatch covers. These are likely to be underground sanitary waste holding areas.

Scattered debris included wood poles, metal cables, wire, metal pipe, glass, paint cans, fire hose, metal cans, broken up concrete, concrete blocks, wood pallets, bricks, and transite siding. A number of 0.3 meter (1 foot) diameter wooden poles were standing, and some had been cut off at ground level. On one concrete foundation were thirty one bee hive boxes left from a Pacific Northwest Laboratory (PNL) experiment conducted from 1981 to 1984.

Location: The site is located generally southeast of the 100-N-Area. Entrance to the site is from the 100-N access road to the west, approximately 1 kilometer (0.6 mile) before the 100-N Reactor entrance. A row of 6 locust trees is on the south side of the dirt road leading to the site.

Related Sites/Structures: 100-N-91

Closure Info: Remediation of the two waste sites was performed between December 27, 2010, and July 19, 2011.

The 100-N-33 waste site was excavated to a depth of approximately 0.5 to 1.0 meter (1.6 to 3.3 ft) below ground surface (bgs). Remediation of the 100-N-33 waste site involved removal of approximately 221 bank cubic meters (BCM) (289 bank cubic yards [BCY]) of ash and soil, which was staged at the southern staging pile or 100-N-33 staging pile before disposal at the Environmental Restoration Disposal Facility (ERDF).

The 100-N-47 waste site was excavated to a depth of approximately 2.0 to 5.5 meters (6.6 to 18.0 ft) bgs. Remediation of the 100-N-47 waste site included excavation of the septic system, all manholes, septic tanks, the drain field, associated piping, and miscellaneous material/debris. The contents of the septic tank were treated with soda lime to raise the pH above 12.0 in order to kill any coliform bacteria, and then the septage was solidified with Waterworks silica gel. The concrete septic tank, solidified contents of the septic tank, and pipeline between the drainfield and manhole/building footprint were direct loaded to ERDF, while the soil and debris from the remainder of the 100-N-47 waste site were staged in the northern staging pile, before being loaded out to ERDF. Approximately 9,776 BCM (12,787 BCY) of soil and miscellaneous debris, including concrete, solidified sewage, and tiles, from the 100-N-47 waste site was disposed at ERDF. No overburden soil stockpiles were associated with the waste sites.

Code: 100-N-50
Names: 100-N-50; HGP SWMU #4; Turbine Oil Cleaning System; Turbine Oil Filter Unit
Type: Single-Shell Tank
Status: Inactive
Description: The site has been remediated and Interim Closed Out. It consisted of two filtration units located in the basement of the 185-N building. The basement floor of the building is approximately 15.2 meters (50 ft) below surrounding grade. The turbines were supported on large concrete support pedestals extending from the basement floor and foundation to approximately surface grade. The reinforced concrete basement floor and foundation is approximately 1.5 meters (5 ft) thick. The entire 185-N Building aboveground structure was demolished during the 2003 and
2004 activities. The debris from demolition of the building as well as from demolition of other HGP structures was used as fill for the 185-N Building basement.

**Location:** The 100-N-50 Turbine Oil Filter Unit (SWMU #4) was located in the 185-N Building basement along the northeast and southeast walls.

**Release Description:** No releases are known to have occurred from this unit.

**Related Sites/Structures:** 100-N-51 HGP Building Oil Storage Area

**Process Description:** The former HGP consisted of two 430-megawatt turbine generators that operated from 1966 until 1986 using steam from the adjacent 100-N production reactor for generation of electricity. The generators were located in the 185-N Building. The filter unit was used to clean turbine oil located in the basement of the Hanford Generating Plant (HGP) Building. It was surrounded by a concrete berm.

**Waste Type:** Process Effluent

**Waste Description:** The filters were periodically changed, but no information was available on the location of their disposal. This unit likely managed impurities in the turbine oil such as metals.

**Closure Info:** The Hanford Generating Plant (HGP) solid waste management unit (SWMU) removal actions included in this CVP began in 2001 and were completed in 2004. The majority of the removal action activities were completed in 2003 and 2004. The remediation and report were done by Energy Northwest.

The entire 185-N Building aboveground structure was demolished during the 2003 and 2004 activities. The debris from demolition of the building as well as from demolition of other HGP structures was used as fill for the 185-N Building basement. The debris was placed into the building basement from the bottom (15.2 meters [50 ft] below ground surface) to within 7.6 meters (25 ft) of the ground surface. The remaining void spaces among the debris fill were filled using a cement grout controlled density fill. The remaining below grade portion of the basement was backfilled with clean soil. The reinforced concrete turbine pedestals that extend from the basement floor to approximately the ground surface were left in place. Based on agreement with the Washington State Department of Ecology, the portions of the turbine pedestals at the ground surface were covered with 0.9 meter (3 ft) of soil consistent with requirements for other 100 Area facilities. The Removal Action Workplan (DOE-RL 1999) specified removal of structures to a minimum of 0.3 meter (1 ft) below the surrounding grade and other 100 Area action memorandums generally require that a structure be demolished to a minimum of 0.9 meters (3 ft) below the surrounding grade. However, in the case of the turbine pedestals, because of their mass and the amount of steel reinforcement, demolition was deemed impractical. The 0.9 meters (3 ft) of cover for the pedestals was placed to blend in with, and to gently slope with, the surrounding grade.

The 185-N Building is not a SWMU. However, SWMUs #2, 3, and 4 are located within the building. To provide a complete description of the removal action activities for SWMUs #2, 3, and 4, a summary description of the removal action activities conducted for the 185-N Building is below.

**UPR-100-N-37 Transformer Yard (SWMU #1):** Eight of the nine transformers located in the transformer yard were removed prior to the Action Memorandum (EPA 1999). The ninth, smaller, operating transformer, was drained of oil and scrapped during the most recent 2003 and 2004 activities. The oil and transformer were disposed of based on historical data indicating that the transformer oil did not contain PCBs. During removal action activities conducted in 2001, minor areas of soil contaminated with oil were excavated from around each transformer.
pad and properly disposed. During the more recent 2003 and 2004 activities, the concrete pads were demolished, excavated and the concrete rubble used as fill for the demolished 185-N Building basement.

100-N-51 Oil Storage Area (SWMU #2): All stored oil and waste containers were previously removed from the oil storage area and properly disposed of or appropriately used. Miscellaneous concrete stained areas including the sump were cleaned. Cleaning of concrete surfaces included the use of concrete scabbling and water and detergents during the 2001 activities. The 100-N-51 Oil Storage Area (SWMU #2) was located at the bottom of the 185-N Building basement. It has been covered and filled with building debris, a cement grout controlled density fill, and borrow soil.

185-N Building Drains and Sumps (SWMU #3): The 185-N Building basement drains and sumps were emptied and cleaned during the 2001 removal action activities. Cleaning activities involved removal and proper disposal of sludges and liquids. Following removal of the sludges and liquids, the sump concrete and metal surfaces were hand cleaned, pressure washed, and scabbled as needed. During the recent 2003 and 2004 activities three of the sumps contained water. The water was characterized, removed from the sump, and properly disposed. All of the miscellaneous drains were filled with a cement grout controlled density fill during the 2003 and 2004 activities. The sumps were filled with borrow soil and capped with a minimum of 15 cm (6 in.) of cement grout during the 2003 and 2004 activities. Also, the sumps and drains have been covered with building debris fill, cement grout controlled density fill, and borrow soil.

100-N-50 Turbine Oil Filter Unit (SWMU #4): During the 2001 removal action activities, the two steel tank oil filtration units including the internal metal oil filtration screens were drained and cleaned. Residual oil from the units was removed and properly disposed. In addition, the two concrete sumps associated with the filter units were cleaned. Stained concrete was removed from the sumps through chipping and scabbling. These units were located at the bottom of the 185-N Building basement and have been filled and covered with the cement grout controlled density fill.

*Hanford Site Waste Management Units Report*

February 2015

819
Rev. 24

DOE/RL-88-30

**Related Sites/Structures:**
100-N-51B HGP Building Floor Drains and Sump, and 100-N-50 Turbine Oil filter Unit, 185-N Building

**Process Description:**
The former HGP consisted of two 430-megawatt turbine generators that operated from 1966 until 1986 using steam from the adjacent 100-N production reactor for generation of electricity. The generators were formerly located in the 185-N Building.

**Waste Type:**
Process Effluent

**Waste Description:**
Used oil and rags from maintenance activities are stored in drums inside the room.

**Closure Info:**
The Hanford Generating Plant (HGP) solid waste management unit (SWMU) removal actions included in this CVP began in 2001 and were completed in 2004. The majority of the removal action activities were completed in 2003 and 2004. The remediation and report were done by Energy Northwest.

The entire 185-N Building aboveground structure was demolished during the 2003 and 2004 activities. The debris from demolition of the building as well as from demolition of other HGP structures was used as fill for the 185-N Building basement. The debris was placed into the building basement from the bottom (15.2 meters [50 ft] below ground surface) to within 7.6 meters (25 ft) of the ground surface. The remaining void spaces among the debris fill were filled using a cement grout controlled density fill. The remaining below grade portion of the basement was backfilled with clean soil. The reinforced concrete turbine pedestals that extend from the basement floor to approximately the ground surface were left in place. Based on agreement with the Washington State Department of Ecology, the portions of the turbine pedestals at the ground surface were covered with 0.9 meter (3 ft) of soil consistent with requirements for other 100 Area facilities. The Removal Action Workplan (DOE-RL 1999) specified removal of structures to a minimum of 0.3 meter (1 ft) below the surrounding grade and other 100 Area action memorandums generally require that a structure be demolished to a minimum of 0.9 meters (3 ft) below the surrounding grade. However, in the case of the turbine pedestals, because of their mass and the amount of steel reinforcement, demolition was deemed impractical. The 0.9 meters (3 ft) of cover for the pedestals was placed to blend in with, and to gently slope with, the surrounding grade.

The 185-N Building is not a SWMU. However, SWMUs #2, 3, and 4 are located within the building. To provide a complete description of the removal action activities for SWMUs #2, 3, and 4, a summary description of the removal action activities conducted for the 185-N Building is below.

**UPR-100-N-37 Transformer Yard (SWMU #1):** Eight of the nine transformers located in the transformer yard were removed prior to the Action Memorandum (EPA 1999). The ninth, smaller, operating transformer, was drained of oil and scrapped during the most recent 2003 and 2004 activities. The oil and transformer were disposed of based on historical data indicating that the transformer oil did not contain PCBs. During removal action activities conducted in 2001, minor areas of soil contaminated with oil were excavated from around each transformer pad and properly disposed. During the more recent 2003 and 2004 activities, the concrete pads were demolished, excavated and the concrete rubble used as fill for the demolished 185-N Building basement.

**100-N-51 Oil Storage Area (SWMU #2):** All stored oil and waste containers were previously removed from the oil storage area and properly disposed of or appropriately used. Miscellaneous concrete stained areas including the sump were cleaned. Cleaning of concrete surfaces included the use of concrete scabbling and water and detergents during the 2001 activities. The 100-N-51 Oil Storage Area (SWMU #2) was located at the bottom of the 185-N Building basement. It has been covered and filled with building debris, a cement grout.
controlled density fill, and borrow soil.

185-N Building Drains and Sumps (SWMU #3): The 185-N Building basement drains and sumps were emptied and cleaned during the 2001 removal action activities. Cleaning activities involved removal and proper disposal of sludges and liquids. Following removal of the sludges and liquids, the sump concrete and metal surfaces were hand cleaned, pressure washed, and scabbled as needed. During the recent 2003 and 2004 activities three of the sumps contained water. The water was characterized, removed from the sump, and properly disposed. All of the miscellaneous drains were filled with a cement grout controlled density fill during the 2003 and 2004 activities. The sumps were filled with borrow soil and capped with a minimum of 15 cm (6 in.) of cement grout during the 2003 and 2004 activities. Also, the sumps and drains have been covered with building debris fill, cement grout controlled density fill, and borrow soil.

100-N-50 Turbine Oil Filter Unit (SWMU #4): During the 2001 removal action activities, the two steel tank oil filtration units including the internal metal oil filtration screens were drained and cleaned. Residual oil from the units was removed and properly disposed. In addition, the two concrete sumps associated with the filter units were cleaned. Stained concrete was removed from the sumps through chipping and scabbling. These units were located at the bottom of the 185-N Building basement and have been filled and covered with the cement grout controlled density fill.

UPR-100-N-37 Transformer Yard (SWMU #1): Eight of the nine transformers located in the transformer yard were removed prior to the Action Memorandum (EPA 1999). The ninth, smaller, operating transformer, was drained of oil and scrapped during the most recent 2003 and 2004 activities. The oil and transformer were disposed of based on historical data indicating that the transformer oil did not contain PCBs. During removal action activities conducted in 2001, minor areas of soil contaminated with oil were excavated from around each transformer pad and properly disposed. During the more recent 2003 and 2004 activities, the concrete pads were demolished, excavated and the concrete rubble used as fill for the demolished 185-N Building basement.

100-N-51 Oil Storage Area (SWMU #2): All stored oil and waste containers were previously removed from the oil storage area and properly disposed of or appropriately used. Miscellaneous concrete stained areas including the sump were cleaned. Cleaning of concrete surfaces included the use of concrete scabbling and water and detergents during the 2001 activities. The 100-N-51 Oil Storage Area (SWMU #2) was located at the bottom of the 185-N Building basement. It has been covered and filled with building debris, a cement grout controlled density fill, and borrow soil.

185-N Building Drains and Sumps (SWMU #3): The 185-N Building basement drains and sumps were emptied and cleaned during the 2001 removal action activities. Cleaning activities involved removal and proper disposal of sludges and liquids. Following removal of the sludges and liquids, the sump concrete and metal surfaces were hand cleaned, pressure washed, and scabbled as needed. During the recent 2003 and 2004 activities three of the sumps contained water. The water was characterized, removed from the sump, and properly disposed. All of the miscellaneous drains were filled with a cement grout controlled density fill during the 2003 and 2004 activities. The sumps were filled with borrow soil and capped with a minimum of 15 cm (6 in.) of cement grout during the 2003 and 2004 activities. Also, the sumps and drains have been covered with building debris fill, cement grout controlled density fill, and borrow soil.

100-N-50 Turbine Oil Filter Unit (SWMU #4): During the 2001 removal action activities, the two steel tank oil filtration units including the internal metal oil filtration screens were drained and cleaned. Residual oil from the units was removed and properly disposed. In addition, the two concrete sumps associated with the filter units were cleaned. Stained concrete was removed from the sumps through chipping and scabbling. These units were located at the bottom of the 185-N Building basement and have been filled and covered with the cement grout controlled
density fill.

<tr>
<td>The 100-N Reactor provided fuel rods to the plutonium production process at Hanford, but also operated two 430 megawatt turbine generators for the generation of electricity. The Washington Public Supply System, later named Energy Northwest, was responsible for the Hanford Generating Plant located at 100-N Reactor. The Cleanup Verification Package (HGP-CVP-SWMUs 5, 6, 7, 8, 9, &amp; 10) for the Hanford Generating Plant Solid Waste Management units was prepared by Energy Northwest in 2004. Some remedial actions at HGP began in 1992. Other characterization and remediation was completed in 2004. Remedial action activity descriptions include:</td>
</tr>
</tbody>
</table>

100-N-1 Settling Pond (SWMU#6) - Remediation activities conducted in 2001 removed approximately 0.9 meters (3 ft) of soil and settled solids material from the 100-N-1 Settling Pond (SWMU #6). The excavated material was disposed of at the Environmental Restoration Disposal Facility (ERDF).

100-N-3 Maintenance Garage French Drain, 100-N-41 Gate House Septic Tank and 100-N-45 Office Building Septic Tank make up SWMU #9. Remediation was determined not to be necessary for the 100-N-3 site and the 100-N-41 and 100-N-45 septic sites. The below grade structures of the drain and septic sites were demolished in place and backfilled with soil in 2004.

100-N-4 Tile Field (SWMU#5) - Confirmatory sampling activities and data evaluation determined that remediation was not necessary for the 100-N-4 Tile Field.

100-N-5 Bone Yard (SWMU #10) - Remediation and removal activities for the 100-N-5 Bone Yard (SWMU #10) were primarily conducted in 2001 with the removal of the miscellaneous equipment, metal scrap, and general debris. The limited number of areas with sand blast media, ion exchange resin-like media and areas with soil staining and/or distressed vegetation were remediated in 2003 and 2004. The sand blast, ion exchange resin, and contaminated soil wastes
were disposed of at the RABANCO landfill facility in Roosevelt, Washington.

The 100-N-46 Diesel underground storage tank (UST) was excavated and removed in 2001. Soil contaminated with diesel was also excavated from the UST excavation. Contaminated soil was spread over the demolished 1703-N Office Building concrete slab foundation for attenuation. Upon completion of the remedial excavation, the bottom of the excavation was approximately 6.7 meters (22 ft) below the ground surface at the deepest location (southwest corner of excavation).

100-N-52 Gasoline underground storage tank (UST) was excavated and removed in 1992.

1908-NE Outfall (SWMU#7) - The original preferred remedy for the 1908-NE Outfall was Institutional Controls (continued monitoring). A radiological survey of the Outfall seal well and samples of water and sediment were collected from the Outfall seal well in 2001 to assess potential contamination associated with the Outfall. The outfall structure was demolished by the Washington Closure Hanford D&D organization in 2012, eliminating the Institutional Control requirement.

The 1716-NE Maintenance Garage building (SWMU #8), including the building slab and associated floor drain pipelines, were removed in their entirety during the 2003 and 2004 removal action activities. Prior to the removal action all chemical products were removed from the building and either properly disposed of or transferred to another facility for use. The building debris was used as fill for the 185-N Building basement.

### Code: 100-N-53
Classification: Accepted

### Names: 100-N-53; 181-N Building Waste Oil Tank
Reclassification: Interim Closed Out (7/24/2013)

### Type: Storage Tank
Start Date: End Date:

### Status: Inactive

### Description:
The site has been remediating and Interim Closed Out. It was an empty above-ground waste oil tank. The tank was 1.1 meters (3.5 feet) in diameter and 1.2 meters (4.1 feet) high.

### Location:
The site was located in the 100-N Area, 18 meters (60 feet) east of the 181-N Pumphouse, south of the river road.

### Related Sites/Structures:
The 181-N Building is associated with this site.

### Process Description:
The site received waste oil from diesel powered emergency pumps in the 181-N Building.

### Waste Type:
Water

### Waste Description:
The tank has been removed.

### Closure Info:
The 100-N-61:1 group includes co-located sites 100-N-61:1, 100-N-64:1, 100-N-24, 100-N-29, 100-N-30, 100-N-37 and 100-N-53. Remediation of the 100-N-61:1 grouping of waste sites and the 100-N-53 waste site began in February 2011 and continued through April 2012.

The 100-N-24, 100-N-29, 100-N-30, and 100-N-37 waste sites were located within the remediation boundary and removed during the 100-N-61:1 pipeline remediation. The remaining basement of the 1902-N Building, the 186-N concrete pad, concrete, valves and piping associated with the 163-N sump #2 were located within the remediation boundary and were located.
A french drain (known as french drain #2) was originally part of the 100-N-103:1 subsite. However, because of its location, the drain was removed with the 100-N-61:1 pipeline remediation. Installation of a haul road was necessary to gain access to the structures. Therefore, the 100-N-53 site and segments of the 100-N-61:1 and 100-N-64:1 pipelines that were located within the roadway boundary were removed and disposed. Verification samples were collected and 100-N-53 was backfilled as part of the haul road installation.

Petroleum-stained soil was observed throughout the excavation, but was determined to be unrelated to the waste site group. Focused verification samples were collected within the stained areas and analyzed for TPH, PAH, and PCBs. Concentrations of TPH and PAH were present in the samples above direct exposure RAGs. The oil staining is considered part of the 100-N-106, Shallow Petroleum-Only Releases waste site and no additional remediation was performed.

Global Positioning Environmental Radiological Surveyor (GPERS) surveys were conducted within the 100-N-61:1 waste site grouping excavation boundary. Radiological measurements slightly above background were observed in the northern portion of the site. Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

Soil, concrete, piping, and rebar were among the types of material removed from the excavation and disposed at the Environmental Restoration Disposal Facility (ERDF). Prior to the material being loaded out for shipment to ERDF, the material was staged in a combined staging pile area (SPA). Verification sampling of the SPA will be addressed with the 100-N-61:4 waste site closeout.

Excavation of the 100-N-61:1 group extended to an approximate maximum depth of 7 meters (23 ft) below ground surface. The 100-N-53 waste site was excavated to an approximate depth of 3 meters (9.8 ft) below ground surface. An estimated 70,000 bank cubic meters (91,557 bank cubic yards) of soil and debris was removed from the entire excavation. A portion of the soil removed from on top of the pipelines was stockpiled for use as clean backfill and is included in the total volume of material removed. Asbestos was detected in the soil at the SZ3-7 location, and hexavalent chromium was detected above a remedial action goal (RAG) at the SZ4-10 location. Therefore, additional remediation was conducted January 21 through February 5, 2013. Asbestos was detected in nonsoil debris (tar/tar paper) at four locations within the excavation. A visual inspection was conducted and the visible pieces of tar and/or tar paper were removed. The volume of additional material removed is included in the estimated volume.

The site has been remediated and Interim Closed Out. It was a french drain, made of 1.2 meter (4 foot) inner diameter and 1.65 meter (5 foot 5 inch) outer diameter concrete pipe, with a steel cover.

The 151-N building was demolished and completely removed in December 2005, including incidental removal of the 100-N-54 drywell. Following demolition activities, excavation boundaries were surveyed and the site was temporarily backfilled.
**Location:** The site was located in the 100-N Area, just off the south wall of the 151-N Building. It was approximately 130 meters (430 ft) southeast of the 109-N Building.

**Related Sites/Structures:** This site drains a sink in the 151-N Building, which is the Area Electrical Switchgear Building. It is 215 square meters (2,310 square feet), and takes 230 kilovolts down to 13.8 kilovolts.

**Waste Type:** Water

**Waste Description:** The site received waste water from the service sink located inside the 151-N building.

**Closure Info:** Remedial action at the 100-N-54 waste site was conducted on November 4, 2013. The excavation extended to approximately 2 meters (6.6 ft) below ground surface (bgs) resulting in approximately 80 bank cubic meters (BCM) (105 bank cubic yards [BCY]) of soil and debris (transite conduit, concrete, and electrical wire) being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Additional remediation was conducted on March 4 and 5, 2014, due to several (PAH) and semivolatile organic compounds (SVOCs) exceeding direct exposure remedial action goals (RAGs). An additional 346 BCM (453 BCY) of soil was removed from the excavation. The final remediation depth was approximately 3 meters (9.8 ft) bgs, and a total of 426 BCM (558 BCY) of soil and debris was removed and disposed at the ERDF. All material was direct loaded from the waste site. No waste staging pile area was created.

**Code:** 100-N-55  
**Classification:** Accepted

**Names:** 100-N-55; 153-N Building Drywell; Miscellaneous Stream #728  
**Reclassification:** Interim Closed Out (11/5/2012)

**Type:** French Drain  
**Status:** Inactive

**Start Date:** 1/1/1997

**End Date:**

**Description:** The site has been remediated and Interim Closed Out. It was a french drain with a 1.2-meter (4-foot) steel cover. Four yellow steel posts surrounded the drain that was located in a gravel road.

**Location:** The site was located in the 100-N Area, just off the northeast corner of the 153-N Building (Washington State Plane coordinates E 571293.6, N 149367.5).

**Related Sites/Structures:** The 153-N Building is associated with this waste site. French drain 100-N-55 was located within the remediation footprint of UPR-100-N-36.

**Process Description:** The drywell received steam condensate from a condensate pump and drainage from a service sink in the 153-N Building. The 153-N Building was the switchgear building containing an electrical transformer/substation that reduced 13.8 kilovolt current down to 4160 volts.

**Waste Type:** Construction Debris

**Waste Description:** The site receives steam condensate from a condensate pump and drainage from a service sink inside the 153-N Building.

**Closure Info:** Demolition of the 153-N Building was completed in October 2006. The entire facility including the foundation and underground piping was removed to 1.5 meters (5 ft) outside of the building footprint. The site was backfilled and graded to match surrounding terrain. The adjacent 100-N-55 drywell was left intact during demolition operations with minimal disturbance.

The 100-N-55 waste site was remediated incidental to remediation of the co-located waste site, UPR-100-N-36. Remedial action at the UPR-100-N-36 waste site occurred between May 23 and November 11, 2011. This remediation resulted in complete removal of the 100-N-55 waste.
The waste site has been remediated and Interim Closed Out. The 1304-N was a 500,000 gallon, above-ground storage tank with a dome-shaped top.

The site was located in the 100-N Area, between the 105-N Building and the Columbia River and between the 1908-N Sealwell and the 107-N Building.

Four unplanned releases of N-Reactor primary coolant water have occurred from the 1304-N EDT caused by leaking valves associated with the tank and one tank overflow.

The 105-N Building, 1325-N Crib, and 102 Inch Outfall Discharge are related to this site. The site is associated with UPR-100-N-1, UPR-100-N-2, UPR-100-N-29, UPR-100-N-30, and UPR-100-N-32 waste sites.

The 1304-N Emergency Dump Tank was a 4.9E+06-liter (1.3E+06-gallon) steel, above-ground storage tank. The tank is constructed of steel and insulated with asbestos and fiberglass under aluminum sheeting. It replaced the 1300-N Emergency Dump Basin as the storage facility used for emergency blowdown of thermally hot pressurized reactor primary coolant water. The tank maintained a constant volume of 2.6E+06 liters (6.8E+05 gallons) of unheated water for quenching the hot water to prevent it from flashing to steam. Because a small flow of primary coolant was maintained to the 1304-N Emergency Dump Tank to keep interconnecting piping in a thermally warm condition, the quench water normally contained a small inventory of radioactive materials.

The primary objective of the 1304-N Decontamination Project was to reduce the dose rate contribution of the Emergency Dump Tank (EDT) by at least 90% in accordance with the Hanford Federal Facility Agreement and Consent Order (Tri-Party Agreement) Milestone N-16-12F. A secondary objective was to demonstrate the effectiveness of decontamination and paint-removal chemicals manufactured by Corpex and distributed by MELE Associates, the licensed applicator.

Process Effluent

Between March 14, 1995 and September 29, 1995 approximately 5,300 liters (1,400 gallons) of water, 230 liters (60 gallons) of sand, and 165 bags of debris were removed from the tank. The sectioned piping was left inside the tank and will be removed and disposed of during the subsequent final decontamination and demolition of the tank. Results from Ion Chromatography/Inductively Coupled Plasma analysis at the 222-S Laboratory detected levels of lead and chromium content classified the waste as mixed.

The above ground 1304 Emergency Dump Tank and associated piping were removed in 2004.

Remedial action at the 100-N-57, UPR-100-N-1, UPR-100-N-2, UPR-100-N-29, UPR-100-N-30, and UPR-100-N-32 waste sites was performed between February 21 and May 31, 2011. Excavation continued until all debris and contamination associated with the waste sites had been removed. Contaminated soil, concrete, pipeline segments and debris removed during excavation were staged within the South Staging Pile Area 1 (SSP Area 1) prior to shipment to
the ERDF. Approximately 1,848 bank cubic meters (2,417 bank cubic yards) of contaminated soil and debris were removed from the site and disposed at the ERDF. No stained soil or anomalous material was found during the remediation activities.

The debris removed from the waste sites consisted of miscellaneous noncombustible debris and soil. Portions of the 100-N-63:2, 100-N-64, 100-N-84:2, 100-N-84:3, 100-N-84:4, and 100-N-84:5 pipeline waste sites were also removed during 100-N-57 group of waste sites remediation activities. The remaining portions of these pipeline waste sites will be remediated and separate closure documents prepared at a later date.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

**Names:** 100-N-58; 120-N South Settling Pond; 1324-N South Settling Pond; South Pond

**Type:** Pond

**Status:** Inactive

**Start Date:** 1/1/1977  
**End Date:** 1/1/1982

**Description:** The site has been remediated and closed out.

**Location:** The 100-N-58 site was co-located with 120-N-1, 120-N-2 sites in the 100-N Area in the 100-NR-1 Operable Unit of the Hanford Site in southeastern Washington State. These sites are about 100 m (328 ft) southeast of the 163-N Demineralization Plant Building, and are approximately 400 m (1,312 ft) from the Columbia River.

**Related Sites/Structures:** The 163-N Building, 183-N Building, 120-N-2 (1324-N) Surface Impoundment, and 120-N-1 (1324-NA) Percolation Pond are associated with this site.

**Process Description:** In 1977 the 120-N-1, 120-N-2, and 100-N-58 sites were initially constructed as the East Percolation Pond and North and South Settling Ponds, respectively. These unlined ponds received 163-N anion/cation regeneration effluent as well as the 183-N Filtered Water Plant filter backwash effluent. In 1982, because of pond percolation problems, the 183-N filter backwash was rerouted to an effluent disposal pond (130-N-1). During this time period the 100-N-58 site was backfilled.

**Waste Type:** Water

**Waste Description:** The 1324N South Settling Pond received regeneration wastes containing aluminum sulfate, sulfuric acid, sodium hydroxide solutions and cooling water from the 163-N Building and filter backwash water from the 183-N Building.

**Closure Info:** The site was remediating in September/October 2000. A Reclassification form was completed for 100-N-58. However for 120-N-1 and 120-N-2, Washington State Department of Ecology rejected the certification of closure from DOE. A post-closure groundwater plan must be submitted to Ecology and approved prior to approval of the Certification of Closure documentation.

Remedial/corrective action field activities at the 120-N-1, 120-N-2, and 100-N-58 sites were conducted in September 2000, and included the removal and disposal of miscellaneous structural debris-type items. A total of about 120 cubic meters (4,238 cu ft) of material was removed from the sites. The material consisted of about 15 cubic meters (530 cu ft) of concrete, 96 cubic meters (3,390 cu ft) of high-density polyethylene (HDPE) liner, 4 cubic meters (141.3 cu ft) of polyvinyl chloride (PVC) piping, and 0.5 cubic meters (17.7 cu ft) of steel fencing material. The material was disposed of in the inert demolition landfill in the 100-H Area.
The two 20.3-cm (8-in.) diameter influent pipelines were sampled and remain in place.

Closure performance standards were established by the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These performance standards are documented in the 100-NR-1 Treatment, Storage, and Disposal Units Corrective Measures Study/Closure Plan (CMS/CP) (DOE-RL-90-22) and the Remedial Design Report/Remedial Action Work Plan for the 100-NR-1 Treatment, Storage, and Disposal Units (RDR/RAWP) (DOE/RL-2000-16). Permit conditions were established in the Hanford Facility Dangerous Waste Permit (Ecology 1994). While sites 120-N-1, 120-N-2, and 100-N-58 are not included in a Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) record of decision (ROD) corrective action activities have been documented in CVP-2001-00021 (CVP).

The soil investigation conducted at these sites in 1992 and 1993 for the CMS/CP indicated that the site did not require soil remediation. Therefore, the selected remedial/corrective action included the removal and disposal of the miscellaneous site structures, including the 120-N-2 liner system, a small sampling shed, fencing, and other miscellaneous debris. The CMS/CP soil investigation indicated that there generally are no contaminants of concern (COCs) for these waste sites. However, because a former overflow area and the waste site influent pipelines required additional sampling (as specified by the CMS/CP), these sites were included in the Sampling and Analysis Plan for the 100-NR-1 Treatment, Storage, and Disposal Units During Remediation and Closeout (SAP) (DOE-RL-2000-07). The verification samples collected under the sampling and analysis plan were analyzed for generally the same inorganic metals and wet chemical anions listed in the CMS/CP soil investigation. The samples were also analyzed for pH. The analytical results from the additional soil sampling and the pipeline scale sampling are presented in Appendix A of the CVP. The analytical results of the soil samples are consistent with the findings of the CMS/CP: soil concentrations are at or below Hanford Site or Washington State background concentrations.

---

**Code:** 100-N-59  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (1/2/2013)  
**Names:** 100-N-59; Radioactively Contaminated Soil Northeast of 105-NB Building  
**Type:** Unplanned Release  
**Status:** Inactive  
**Start Date:** 1/1/1995  
**End Date:**  
**Description:** The site has been remediated and Interim Closed Out. It was an area where a contaminated, underground pipeline broke. After excavating and repairing the broken pipe, the site was marked with a single Underground Radioactive Material sign. A site visit in August 2000 found that the single post with the Underground Radioactive Material sign was gone, but an Underground Radioactive Material sign was attached to the fence near the waste site.  
**Location:** It was approximately 100 meters (300 ft.) northeast of the 105-NB Building, inside the double fence.  
**Release Description:** In September 1995, a 15 centimeter (6 inch) diameter underground liquid waste pipeline was found to be leaking. An area approximately 0.76 meters (2.5 feet) by 1.4 meters (4.5 feet) was excavated to repair the pipe. The soil below the pipe had a beta/gamma reading of 7,000 disintegrations per minute. A direct reading on the broken pipe found 35,000 disintegrations per minute. After repairing the pipe, the excavation was backfilled with clean dirt and posted with an Underground Radioactive Material sign.  
**Related Sites/Structures:** The site is associated with an underground waste line from the 105-N/109-N facility. (see sitecode 100-N-63:2)
**Process Description:** The soil was radioactively contaminated when a liquid waste line from the 109-N facility broke.

**Waste Type:** Process Effluent

**Waste Description:** The soil was radioactively contaminated when a liquid waste line broke.

**Closure Info:** Remedial action excavation at the 100-N-59 waste site was performed during December 2011 along with the 100-N-63:2 subsite, to a depth of approximately 1.5 meters (5 ft) below ground surface. The soil was loaded out directly for disposal at the Environmental Restoration Disposal Facility. No overburden soil stockpiles are associated with this waste site. Additional soil was removed on March 26, 2012.

<td></td>
</tr>
<tr>
<td>Release Description:</td>
<td>100-N Plant Operations personnel were filling a railroad waste tank car with spent decontamination solutions at a the 1314-N Loading Station. After approximately 26,500 liters (7,000 gallons) of solution had been pumped into the 75,700-liter (20,000-gallon) waste tank car, solution began overflowing from the tank car fittings. The tank car loading pump was turned off, then solution began flowing up through the drain in the catch basin beneath the car. The catch basin filled and overflowed into the adjacent drywell which also filled and overflowed. Approximately 380 liters (100 gallons) of solution flowed out of the drywell, covering a 6 by 6-meter (20 by 20-foot) section of ground inside the Radiation Zone at the loading station. The solution that spilled out of the drywell onto the ground was contained with trenches and earthen dams, then covered with plastic to prevent contamination spread. The solution contained in the catch basin was hosed down to remove loose contamination. Inspection of the loading and vent lines on the top of the waste tank car revealed that a manual valve on the vent line was in the closed position resulting in a pressure buildup in the tank car that caused backflow through the loading line, holding tank, and catch basin. Evaluation revealed that about 280 liters (75 gallons) of solution containing a total of 0.011 curies was discharged to the ground (sub surface) through the drywell.</td>

The 1314-N Liquid Waste Loadout Station was a 9 meter (30 ft) by 18 meter (60 ft) single story, metal-frame building supported on a reinforced concrete slab foundation. It began to operate in 1972. The facility was a transfer station consisting of numerous valves, pumps, underground and overhead piping and couplings, and underground tanks It was located approximately 100 meters (300 ft) from the Columbia River. This facility was used to loadout...
radioactive liquid waste from the 116-N-2 and 107-N facilities into railroad tank cars for shipment to the 200 Areas for processing and disposal. The loadout facility contained a tank car wash station with a sump to collect the wash water. The water drained into a 3,780 liters (1,000 gal) overflow tank. During the filling operation, excess liquid waste was designed to overflow through a closed piping system from the tank car to the overflow tank, which initiated pump shutdown. A 756 liters (200 gal) catch tank was installed to hold liquids that exceeded the capacity of the car wash sump.

Waste Type: Demolition and Inert Waste

Waste Description: The site received spent decontamination solutions from a railroad waste tank car.

Closure Info: The 1314-N building was demolished in 2006. 100-N-60 and UPR-100-N-26 were located within the building footprint. UPR-100-N-13 was located near the 1314-N building, but outside the building footprint.

Remedial action for 100-N-60, UPR-100-N-13 and UPR-100-N-26 was performed between September 21 and November 14, 2011. Approximately 2,459.0 bank cubic meters (BCM) (3,216.3 bank cubic yards [BCY]) of contaminated soil and debris were removed from the 100-N-60 group of waste sites excavation and direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Excavation continued until all debris and contamination associated with the waste site had been removed. No anomalous material was discovered during remediation activities.

The stained soil location was evaluated for TPH and PAH with a focused sample (FS-2), but the sample results were used to support a greater effort to identify the extent of the TPH and PAH contamination in the 100-N Area and were not included in the evaluation of the 100-N-60, UPR-100-N-13, UPR-100-N-26 group of waste sites.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

<td>Description</td>
<td>The 100-N-61 waste site encompassed all underground water pipelines used to transport reactor cooling water between water treatment facilities and the 105-N/109-N Buildings. This included all underground pipelines between buildings and those connected to drainage facilities. It was subdivided into four subsites: 100-N-61:1 Water Treatment and Storage Facilities Underground Pipelines South of 109-N, 100-N-61:2 Water Treatment and Storage Facilities Underground Pipelines East of 109-N, 100-N-61:3 Water Treatment and Storage Facilities Underground Pipelines West of 109-N and 100-N-61:4 Water Treatment and Storage Facilities Underground Pipelines South of 182-N. Each subsite was individually remediated and Interim Closed Out. Therefore the parent site is also Interim Closed Out.</td>
</tr>
<tr>
<td>Location</td>
<td>The site was located where the underground pipelines run from the 181-N River Pump House to the 163-N Water Treatment Plant, the 182-N Pump House and Storage Tanks, and to the 105-N Reactor Building. Also, any underground drainage pipelines running from the water treatment and storage facilities to the riverside outfall structures. Other underground pipelines running to the outfall structures are included in other waste sites and are therefore excluded from this site.</td>

Hanford Site Waste Management Units Report
February 2015
831
**Process Description:** Reactor cooling water was pumped from the Columbia River, settled and treated to remove minerals, then injected into the reactor primary coolant loop at a rate of about 760 liters/minute (200 gallons/minute).

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The waste is steel piping, concrete, and soil (if contaminants are present). Chemical additives to the reactor cooling water included sulfuric acid, sodium hydroxide, aluminum sulfate (alum) with excess hydrated calcium oxide, separan, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine residual was approximately 0.2 milligrams/liter.

**Closure Info:** The 100-N-61:1 group includes co-located sites 100-N-61:1, 100-N-64:1, 100-N-24, 100-N-29, 100-N-30, 100-N-37 and 100-N-53. Remediation of the 100-N-61:1 grouping of waste sites and the 100-N-53 waste site began in February 2011 and continued through April 2012.
The 100-N-24, 100-N-29, 100-N-30, and 100-N-37 waste sites were located within the remediation boundary and removed during the 100-N-61:1 pipeline remediation. The remaining basement of the 1902-N Building, the 186-N concrete pad, concrete, valves and piping associated with the 163-N sump #2 were located within the remediation boundary and were subsequently removed. A french drain (known as french drain #2) was originally part of the 100-N-103:1 subsite. However, because of its location, the drain was removed with the 100-N-61:1 pipeline remediation. Installation of a haul road was necessary to gain access to the structures. Therefore, the 100-N-53 site and segments of the 100-N-61:1 and 100-N-64:1 pipelines that were located within the roadway boundary were removed and disposed. Verification samples were collected and 100-N-53 was backfilled as part of the haul road installation.

Petroleum-stained soil was observed throughout the excavation, but was determined to be unrelated to the waste site group. Focused verification samples were collected within the stained areas and analyzed for TPH, PAH, and PCBs. Concentrations of TPH and PAH were present in the samples above direct exposure RAGs. The oil staining is considered part of the 100-N-106, Shallow Petroleum-Only Releases waste site and no additional remediation was performed.

Global Positioning Environmental Radiological Surveyor (GPERS) surveys were conducted within the 100-N-61:1 waste site grouping excavation boundary. Radiological measurements slightly above background were observed in the northern portion of the site. Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

Soil, concrete, piping, and rebar were among the types of material removed from the excavation and disposed at the Environmental Restoration Disposal Facility (ERDF). Prior to the material being loaded out for shipment to ERDF, the material was staged in a combined staging pile area (SPA). Verification sampling of the SPA will be addressed with the 100-N-61:4 waste site closeout.

Excavation of the 100-N-61:1 group extended to an approximate maximum depth of 7 meters (23 ft) below ground surface. The 100-N-53 waste site was excavated to an approximate depth of 3 meters (9.8 ft) below ground surface. An estimated 70,000 bank cubic meters (91,557 bank cubic yards) of soil and debris was removed from the entire excavation. A portion of the soil removed from on top of the pipelines was stockpiled for use as clean backfill and is included in the total volume of material removed. Asbestos was detected in the soil at the SZ3-7 location, and hexavalent chromium was detected above a remedial action goal (RAG) at the SZ4-10 location. Therefore, additional remediation was conducted January 21 through February 5, 2013. Asbestos was detected in nonsoil debris (tar/tar paper) at four locations within the excavation. A visual inspection was conducted and the visible pieces of tar and/or tar paper were removed. The volume of additional material removed is included in the estimated volume.

**End Date:**
Description: The 100-N-61:2 pipelines have been remediated and Interim Closed Out. They were located parallel to and directly east of the 109-N Heat Exchanger Building. They were used to transport transported raw water to the 109N Building from the 182-N High-Lift Pump House. These pipes varied in size 4 inch to 54 inch diameter and were mainly steel, wrapped in coal tar enamel mastic. The geographical location of the 100-N-61:2 sub-site also coincides with the 100-N-62, 100-N 105-N, 109-N, 163-N, 182-N, 183-N and 184-N Underground Pipelines waste site, which lie underneath.

Location: The pipelines were located east of the 105-N and 109-N buildings.

Related Sites/Structures: Co-located associated waste sites and ancillary facilities include 100-N-62, 100-N-84:1, :2, :3, :4, :5, :6, 100-N-63:2 and 100-N-64:2.

Process Description: These pipelines transported reactor cooling water between the water treatment facilities and the 105-N Reactor Building.

Closure Info: Remediation of the 100-N-28 waste site was performed between January 25 and March 29, 2012. The site was excavated to a depth of 8.4 meters (27.6 ft) below ground surface (bgs) and resulted in the removal of 2,577 BCM (3,371 BCY) of soil and debris. The debris consisted of soil, rock, a concrete resin pit, piping, and wiring. No resin was present in the pit and it is assumed the site was only used for liquid disposal from the 109-N Building. Soil and debris were directly loaded from the 100-N-28 excavation and disposed at the Environmental Restoration Disposal Facility (ERDF).

Remedial actions for the 100-N-61:2, 100-N-62, and 100-N-64:2 sites were performed between April 13, 2011, and March 29, 2012. Excavation depths ranged from 3 meters (9.9 ft) to 8 meters (26.2 ft) bgs. Approximately 24,113 bank cubic meters of contaminated soil and debris associated with the three pipelines was removed from the waste sites and staged in the South Staging Pile Area 1 (SSP Area 1) to the south of the excavation prior to load out for disposal at ERDF. The debris consisted of rock, concrete, piping, and wiring. Verification sampling of the SSP Area 1 will be addressed in the 100-N-61:4 verification work instruction. In addition, overburden (OB) material was stockpiled in three OB piles southwest of the waste sites. The OB piles will also be addressed in the 100-N-61:4 verification work instruction.

Multiple TPH and PAH results collected at the 100-N-61:2, 100-N-62, and 100-N-64:2 excavation exceeded soil RAGs. However, these results were concluded to be cross contamination from petroleum releases unrelated to the waste sites and will be addressed as part of the 100-N-106 (Shallow Petroleum-Only Releases at 100-N; SPOR Releases) waste site and were not used for evaluation in this RSVP.

A valve pit (OSE ID N-244) was discovered at Washington State plane coordinates N149350.37, E571230.54, with asbestos pipe wrapping. The valve pit was a 1 meter (3.3 ft) diameter manhole, with a valve and a 7.6 centimeter (3 in.) pipeline running east to west. Spatial analysis indicated that valve pit N-244 is associated with the 100-N-84:3, potable water line. The valve pit was completely removed and disposed with soil and debris from the 100-N-61:2, 100-N-62, and 100-N-64:2 excavation. No other anomalies were discovered during remediation.

**Description:** The 100-N-61:3 pipelines have been remediated and Interim Closed Out. The 100-N-31 waste site was located on the west side of the 105-N/109-N Reactor Buildings and adjacent to the 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39 waste sites. These waste sites are collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.

100-N-61:3 consisted of a 30 inch diameter emergency raw water supply pipeline from the 182-N High-Lift Pump House, and a 30 inch diameter overflow pipeline located between the 1300-N Emergency Dump Basin and the 1908-N Seal Well Outfall Structure.

**Location:** The 100-N-61:3 pipelines were located west of the 109-N Heat Exchanger Building and 105-N Reactor Building.

**Related Sites/Structures:** Co-located associated waste sites and ancillary facilities include 100-N-84:1, :2, :3, :4, :5, :6, 118-N-1, 100-N-64:3, 100-N-63:2 100-N-32, 100-N-38, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39.

**Process Description:** The 100-N-61 pipelines transported reactor cooling water between water treatment facilities and the 105-N/109-N Buildings.

**Closure Info:** Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. This group of waste sites was referred to as the waste sites west of the 105-N/109-N Reactor. The footprints of the 1909-N Waste Disposal Valve Pit, the 107-N facility and the pipe trench between 105-N and 107-N were also located within the boundary of the group.

The eleven co-located waste sites located west of the 105-N/109-N Reactor Building were remediated, either partially or completely, by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the co-located waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N) Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected above background. However, the area with the highest detected activity is associated with residual structures and soils for the 105-N/109-N SSE and is considered part of the 100-N-66,
105-N/109-N Reactor Building Complex waste site. A small area with elevated beta and gamma contamination was detected within the waste sites west of the 105-N/109-N Reactor boundary. Additional soil was removed from this area and disposed at the ERDF. An environmental radiological survey of the area using hand-held instruments verified that the contaminated soils have been removed.

The 1909-N Waste Disposal Valve Pit was removed during general facility demolition in this area by the D4 Project. Due to the proximity and general configuration of demolition and remediation activities on the west side of the reactor, closure of the facility footprint was deferred until nearby waste site remediation by the FR Project occurred. The residual contaminated soil that remained beneath the location of the former 1909-N facility was then removed.

The 107-N basin structure was completely removed by the D4 Project. However, closure of the basin footprint was deferred to the UPR-100-N-12 waste site. Additional soil was removed from the footprint during general waste site remediation in the area. Surveys found no elevated residual radiological activity.

Several segments of the 100-N-84 pipeline subsites were partially located within the remediation boundary. All of the segments of the 100-N-84:2, 100-N-84:4, 100-N-84:5, and 100-N-84:6 pipeline subsites that were within the excavation boundary were removed and disposed at the ERDF. Reclassification of the total 100-N-84:2, 100-N-84:4, 100-N-84:5 and 100-N-84:6 pipeline subsites will be addressed in separate closure documents.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

DOE/RL-88-30
Rev. 24

Process Description: These pipelines transported raw and filtered water in 4 inch to 42 inch diameter steel pipes.

Closure Info: Remediation of 100-N-61:4 pipelines began after the deactivation, decontamination, decommissioning, and demolition (D4) of the 182-N Building and 1900-N Facility were completed. Several segments of the 100-N-84 pipelines were co-located in the 100-N-61:4 pipeline excavation. The 100-N South Staging Pile (SSP) began operation on February 16, 2011 and received waste from multiple adjacent or collocated waste sites. It was agreed that the SSP would be closed with the 100-N-61:4 waste site. An overburden staging area for multiple waste sites was also evaluated with 100-N-61:4. Some segments of pipelines described in 100-N-84:4 and 100-N-84:6 were co-located, remediated and sampled with the excavation of 100-N-61:4. The 100-N-61:4 and co-located pipelines were remediated between October 8, 2012, and February 4, 2013. Remediation included removal of soil, steel pipe, asbestos tar paper and mastic, concrete, steel debris, and building demolition debris. The lengths of pipeline removed and disposed at the Environmental Restoration Disposal Facility (ERDF) included approximately 565 meters (1,854 ft) for the 100-N-61:4 subsite, 152 meters (499 ft) for the 100-N-84:4 segments, and 199 meters (653 ft) for the 100-N-84:6 segments. Approximately 20,660 bank cubic meters (BCM) (26,950 bank cubic yards [BCY]) of material was removed during the remediation. Most of the material was directly loaded for disposal at the ERDF with only 4,589 BCM (5,986 BCY) staged at the SSP area prior to disposal. The pipeline excavation extended to a maximum depth of approximately 3.5 meters (11.5 ft) bgs.

Radiological surveys were conducted in March 2013. No anomalies were discovered during the remediation activities, but some soil staining was noted on the south wall of the excavation. Stain sampling found petroleum contamination that will be addressed with the 100-N-106 waste site.

Approximately 85,111 BCM (111,023 BCY) of waste material (from multiple waste sites) in the South Staging Pile was disposed at the ERDF in March 2012. In April 2012, 0.2 meters (0.5 ft) of material was scrapped from the surface of where the staging pile had been located. The area was then used to stage waste from the 100-N-61:4 excavation. This staged material was taken to ERDF in December 2012. Results of the staging area sampling found elevated levels of TPH and PAH. Further remediation of the staging area was not done, due to a previous agreement regarding cross contamination of asphaltic materials.

Three separate areas were used to stage overburden from pipeline remediations. Material with visible debris was removed and properly disposed. The overburden piles were sampled in December 2012. It was agreed that material with elevated levels of PAH would not be used as backfill in areas less than 3 meters (9.9 ft) above groundwater.

| Type: | Radioactive Process Sewer |
| Status: | Inactive |
| Start Date: | 1/1/1963 |
| End Date: | 1/1/1987 |
| Description: | This site has been remediated and Interim Closed Out. It included the underground pipelines that transported reactor decontamination chemicals and/or radioactive liquid wastes from the 105-N/109-N Reactor facilities and other pipelines with the potential for radioactive |
contamination that were co-located on the east side of the 105-N/109-N Building complex. These pipelines consist of potentially contaminated underground steam and condensate return pipelines including a radioactive drain, miscellaneous chemical drains, a backwash return pipeline, chemical drain pipelines and chemical supply pipelines (sodium hydroxide, ammonium hydroxide and phosphoric acid).

This site does not include the pipelines that discharge to the 116-N-4 (1300-N), the 1304-N Emergency Dump Tank, pipelines to and from the 107-N and 105-N Buildings, or pipelines from the 105-N/109-N Buildings to the 1908-N Outfall that are addressed by a separate waste site (sitecode 100-N-65).

**Location:** The location of this site was all of the potentially radionuclide contaminated underground pipelines leaving the 105-N/109-N Buildings on the east side (east-west direction) and proceeding in a north-south direction to their respective treatment/disposal sites.

**Related Sites/Structures:** The related structures are the 105-N Reactor Building, the 109-N Heat Exchange Building, the 184-N Powerhouse, the 100-N-23 and the 100-N-24 waste sites.

**Process Description:** Water was taken from the Columbia River and treated extensively to purify it prior to its use as reactor cooling water. In the reactor, the water circulated through the reactor core where it carried away heat to maintain safe core temperatures. This heat was transferred to a secondary system via heat exchangers from which the water returned to the reactor core in a closed loop. The secondary cooling system, also a "closed loop" system, could be maintained in a hot pressurized state from the 184-N Powerhouse when the reactor was down for maintenance or other reasons. Because of this interconnection between the auxiliary steam supply system and the contaminated secondary cooling system, the potential for cross-contamination exists. However, the auxiliary steam supply system was isolated by the use of motor operated valves and a "flow control" mode of operation that precluded back pressure contamination of the auxiliary steam system from the secondary cooling system.

**Waste Type:** Oil

**Waste Description:** The waste is the underground pipelines from the east side of the 105-N and 109-N Buildings to the 184-N Powerhouse, 100-N-23 (Resin Disposal Pit Liquid Waste Site 1) and 100-N-24 (Hydrogen Dry Well Liquid Waste Site) waste sites. The chemical drain lines are known to have been used for the disposal of decontamination chemicals, however, specific chemicals and radionuclide content is currently unknown.

**Closure Info:** Remediation of the 100-N-28 waste site was performed between January 25 and March 29, 2012. The site was excavated to a depth of 8.4 meters (27.6 ft) below ground surface (bgs) and resulted in the removal of 2,577 BCM (3,371 BCY) of soil and debris. The debris consisted of soil, rock, a concrete resin pit, piping, and wiring. No resin was present in the pit and it is assumed the site was only used for liquid disposal from the 109-N Building. Soil and debris were directly loaded from the 100-N-28 excavation and disposed at the Environmental Restoration Disposal Facility (ERDF).

Remedial actions for the 100-N-61:2, 100-N-62, and 100-N-64:2 sites were performed between April 13, 2011, and March 29, 2012. Excavation depths ranged from 3 meters (9.9 ft) to 8 meters (26.2 ft) bgs. Approximately 24,113 bank cubic meters of contaminated soil and debris associated with the three pipelines was removed from the waste sites and staged in the South Staging Pile Area 1 (SSP Area 1) to the south of the excavation prior to load out for disposal at ERDF. The debris consisted of rock, concrete, piping, and wiring. Verification sampling of the SSP Area 1 will be addressed in the 100-N-61:4 verification work instruction. In addition, overburden (OB) material was stockpiled in three OB piles southwest of the waste sites. The OB piles will also be addressed in the 100-N-61:4 verification work instruction.

Multiple TPH and PAH results collected at the 100-N-61:2, 100-N-62, and 100-N-64:2
excavation exceeded soil RAGs. However, these results were concluded to be cross contamination from petroleum releases unrelated to the waste sites and will be addressed as part of the 100-N-106 (Shallow Petroleum-Only Releases at 100-N; SPOR Releases) waste site and were not used for evaluation in this RSVP.

A valve pit (OSE ID N-244) was discovered at Washington State plane coordinates N149350.37, E571230.54, with asbestos pipe wrapping. The valve pit was a 1 meter (3.3 ft) diameter manhole, with a valve and a 7.6 centimeter (3 in.) pipeline running east to west. Spatial analysis indicated that valve pit N-244 is associated with the 100-N-84:3, potable water line. The valve pit was completely removed and disposed with soil and debris from the 100-N-61:2, 100-N-62, and 100-N-64:2 excavation. No other anomalies were discovered during remediation.

**Names:** 100-N-63; 100-N Reactor (1314-N, 116-N-1 and 116-N-3) TSD Underground Pipelines

**Type:** Radioactive Process Sewer

**Status:** Inactive

**Start Date:** 1/1/1963

**End Date:** 1/1/1987

**Description:**

100-N-63 was divided into two subsites. Both subsites were Reclassified to Interim Closed Out. Therefore, the parent site is also considered Interim Closed Out. The waste site encompassed the Treatment, Storage, and Disposal (TSD) underground pipelines that transported reactor cooling water and radioactive liquid wastes from the 105-N Reactor facilities to the 116-N-1 (1301-N), 116-N-3 (1325-N) Crib, and 116-N-2 (1310-N Tank).

The pipelines from 1310-N transfer tank (silo) to the 1310-N (aka 116-N-2 or Golf Ball) are 100-N-63:1. A third 30.5 centimeter (12 inch) chemical drain pipeline returns from 1310-N (Golf Ball) to the 1310-N transfer tank. From the 116-N-1 weir box, a 91.4 centimeter (36 inch) underground pipeline (100-N-63:1) connected the 116-N-1 crib and trench to the 1312-N diversion box and continued to the 116-N-3 crib and trench.

The pipelines in site 100-N-63 that exited the 105-N, 109-N and 1714-NB Buildings on the east, west and north sides are 100-N-63:2. They proceeded north-northeast to their respective treatment/disposal facilities. Pipeline diameter sizes beyond the 1322-N Building varied. A 30.5 centimeter (12-inch) radioactive drain originated on the west side of the 109-N Building as a 25.4 centimeter (10-inch) pipeline. It extended north to a 30.5 centimeter (12 inch) disposal system pipeline located east of the number 3 spacer silo. It proceeded north to a point east of the 1314-N Building and extended east to the 1322-N Building. It could be diverted to either the 1310-N (Golf Ball) via the 1310-N transfer tank or to the 1322-NC building and the 116-N-1 weir box. The final pipeline in this subsite is the 91.4 centimeter (36-inch) contaminated drain/flush pipeline. It originated on the west side of the 105-N Building and passed under the 1722-N building. It continued in a parallel path with the 30.5 centimeters (12-inch) radioactive drain pipeline.

Not included in this waste site are underground pipelines that discharged to the 116-N-4 (1300-N Emergency Dump Basin), 1304-N Emergency Dump Tank, pipelines to and from the 107-N and 105-N Buildings, or pipelines from the 105/109-N Buildings to the 1908-N Outfall that are addressed by 100-N-64 (100-N Reactor 105/109-N Cooling Water Effluent Underground Pipelines) waste site.

**Location:** The location of the underground reactor effluent lines is between the 105-N Reactor Buildings and the 1314-N, 116-N-1, and 116-N-3 waste sites.
Release Description: A diesel fuel spill occurred on 1/10/2010 at the 100-N BioVenting Pilot Test Site at the 100-N Area. Approximately 330 gallons of diesel fuel were released due to an improper connection of the generator to a 1,000 gallon auxiliary fuel tank supporting the project. Spill cleanup activities on 1/10/2010 generated over 310 tons of contaminated soil that were removed and disposed at ERDF. The area of the spill was almost entirely contained within the 100-N-63:2 pipeline WIDS boundary west of the 1310-N Radioactive and Liquid Waste Treatment Facility (Golf Ball).

Agreement with the Washington State Department of Ecology on 2/4/10 determined that further cleanup actions at the site were not necessary at this time as long as the remediation design for the affected portion of the 100-N-63:2 pipeline was revised to encompass the entire area that was affected by the spill. Contractor remediation activities at 100-N are scheduled to begin in July 2010 and remediation of this portion of the waste site is anticipated to occur in late 2010. An update to the WIDS database was requested, documenting the location, including GPS, of the area impacted by the spill. GPS locations and a map of the spill location have been included in the WIDS database for the 100-N-63:2.

Related Sites/Structures: The associated structures include: the 105-N Reactor Building, the 116-N-1 and 116-N-3 Cribs and Trenches, the 1322-N Monitoring and Pilot Plant Complex, the 1314-N Waste Transfer Station, and various valve stations, UPR-100-N-31, Radioactive Effluent Water Spill Near 116-N-1 (1301-N), UN-100-N-31.

Process Description: Water was taken from the Columbia River and treated extensively to purify it before its use as reactor cooling water. In the reactor, the water circulated through the reactor core where it carried away heat to maintain the core temperature at a safe level. This heat was yielded in a heat exchanger from which the water returned to the core in a closed loop. A small quantity of cooling water was bled off (about 760 liters/minute [200 gallons/minute]) and was replaced with fresh water from the water treatment plant. The bleed-off water and liquid wastes from other sources including decontamination stations and radioactive drains was transported to either the crib disposal system or to a storage and transportation system for disposal.

Waste Type: Chemicals

Waste Description: The waste is the contaminated underground pipelines. The following radionuclides were released from the reactor to the 116-N-1 and/or 116-N-3 Cribs and Trenches, passing through the underground pipelines. Residual contaminants of some radionuclides may be expected to remain in the underground pipelines. These include: tritium, zinc-65, iodine-131, plutonium-238, phosphorous-32, strontium-89/90, xenon-133, plutonium-239/240, chromium-51, zirconium-niobium-95, cesium-134/137, neptunium-239, manganese-54, molybdenum-technetium-99, barium-140, iron-59, ruthenium-103/106, cerium-141, cobalt-58/60, antimony-124/125, and cerium-praseodymium-144. Additionally, decontamination chemicals are known to have passed through the underground pipelines, including phosphoric acid and diethylthiourea.

Classification: Accepted
Reclassification: Interim Closed Out (10/1/2013)
Start Date: End Date:

Description: The 100-N-63:2 subsite has been remediated and Reclassified to Interim Closed Out. The 100-N-63:2 subsite encompassed the TSD underground pipelines that transported reactor cooling water and radioactive and chemical liquid wastes from the 105-N Reactor facilities to the 116-N-1 (1301-N Crib and Trench) and the 91.4 cm (36 in.) process drain that emptied into the 100-
N-77 (100-N River Effluent Pipeline). The 100-N-63:2 pipelines originated on the north, east, and west sides of the 105-N Reactor Building and ran to either the 116-N-1 or the 100-N-77 effluent pipeline. The 100-N-63:2 subsite also includes the area where a diesel fuel spill occurred on January 10, 2010, at the 100-N Bioventing Pilot Test Site. The 100-N-77 effluent pipeline and the diesel fuel spill are not associated with the 100-N-63:2 TSD pipeline under the RCRA Permit (Ecology 2012), but are included in the evaluation of the 100-N-63:2 subsite cleanup.

The 100-N-63:2 waste site pipelines were located throughout the 100-N Area and were co-located with a number of other pipeline waste sites, including but not limited to the 100-N-84, 100-N Miscellaneous Pipelines waste site. During remediation of the 100-N-63:2 waste site, co-located waste sites were also partially or fully remediated.

**Location:**

The 100-N-63:2 waste site pipelines are located throughout the 100-N Area and are co-located with a number of other pipeline waste sites including but not limited to the 100-N-84, 100-N Miscellaneous Pipelines waste site. The pipelines originated on the north, east and west sides of the 105-N Reactor Building and ran to either the 116-N-1 Crib or the 100-N-77 effluent pipeline.

**Related Sites/Structures:**

100-N-63:2 is associated with the 100-N-77 and 100-N-84 pipeline sites and UPR-100-N-17.

**Waste Type:** Chemicals

**Waste Description:** The waste is the contaminated underground pipelines.

**Closure Info:**

The 100-N-63:2 subsite was remediated between June 2009 and May 2013, with all remaining RCRA TSD pipelines being completely removed. Excavation included the removal of the pipelines and the underlying contaminated soil. During the remediation of the 100-N-63:2 pipeline subsite, co-located sites were also either fully or partially removed. Independent site-specific closure documents will be prepared for co-located waste sites per agreement with Ecology. If the boundary of a co-located waste site extended beyond the 100-N-63:2 excavation boundaries, remediation of that waste site may require additional remediation independent of the 100-N-63:2 subsite. Several land bridges were constructed over the 100-N-63:2 excavation using clean fill to provide essential access within the 100-N Area. The remediation also included the area where a diesel spill occurred on January 10, 2010, at the 100-N Bioventing Well Island in the 100-N Area. Approximately 1,247 liters (330 gal) of diesel fuel was released due to an improper connection of the generator to a 3,780 liters (1,000-gal) auxiliary fuel tank supporting the project. Spill cleanup activities on January 10, 2010, generated over 310 tons of contaminated soil that were removed and disposed at ERDF. The area of the spill was almost entirely contained within the 100-N-63:2 pipeline boundary, west of the 116-N-2 waste site (1310-N Radioactive and Liquid Waste Treatment Facility [Golf Ball]).

The remedial action at the 116-N-2 (1310-N Golf Ball) was performed between March 1, 2011, and April 26, 2012 and removed several sections of 100-N-63:2 pipelines, with the exception of one pipeline section that remained on a side slope in the northern part of the excavation. This pipeline was a 7.6 meter (25 ft) long section of 30 cm (12 in.) diameter pipe that was remediated between March 22 and April 18, 2013.

The excavation depth varied from 0.9 to 5.5 meters (3 to 18 ft), below ground surface, depending on the depth of pipeline and the volume of the underlying contaminated soil. Approximately 2,465 meters (8,088 ft) of piping was removed from the 100-N-63:2 excavation. An estimated total volume of 39,753 bank cubic meters (51,995 bank cubic yards) of contaminated soil and pipelines was excavated and disposed of at the Environmental Restoration Disposal Facility. There were no staging pile areas (SPAs) or overburden piles.
associated with the 100-N-63:2 subsite excavation.

**The SubSite is Part Of:**

**Code:** 100-N-63

**Names:** 100-N-63; 100-N Reactor (1314-N, 116-N-1 and 116-N-3) TSD Underground Pipelines

---

**Code:** 100-N-64

**Classification:** Accepted

**Names:** 100-N-64; 100-N Reactor 105/109-N Cooling Water Effluent Underground Pipelines

**Type:** Radioactive Process Sewer

**Status:** Inactive

**Start Date:** 1/1/1963

**End Date:** 1/1/1987

**Description:** The site was divided into three subsites based on geographical locations. The subsites are 100-N-64:1 Cooling Water Effluent Underground Pipelines South of 109-N, 100-N-64:2 Cooling Water Effluent Underground Pipelines East of 109-N and 100-N-64:3 Cooling Water Effluent Underground Pipelines West of 109-N. All the subsites have been remediated and reclassified to Interim Closed Out. Therefore, the parent site is also considered Interim Closed Out.

100-N-64 includes those underground pipelines that transported reactor cooling water from the 105-N Reactor facilities to the 116-N-4 (1300-N), the 1304-N Emergency Dump Basin and Tank respectively, the 107-N Filter Building and the pipelines from these facilities to the 1908-N Outfall Structure. The site does include overflow lines to the 1908-N Outfall Structure, but does not include the 1908-N Outfall Structure. It does not include the underground lines that discharged to the 1301-N (116-N-1) and/or 1325-N (116-N-3) Cribs. (see sitecode 100-N-63).

The 107-N Building includes return pipelines as well as other process pipelines contained in a concrete encasement between the 105-N and 107-N Buildings. This encasement houses 0.26-meter (10-inch) and 0.46-meter (18-inch) demineralized water lines, a 0.3-meter (12-inch) filtered water line, 1.3-centimeter (0.5-inch) instrument air, 5.1-centimeter (2-inch) steam, 15-centimeter (6-inch) fire, line and telephone, instrument, power, and fire alarm lines. The encasement is about 30 meters (98 feet) long. (The remaining underground pipelines associated with the 1300-N and 1304-N include a 0.76-meter [30-inch] flush line, a 0.61-meter [24-inch] vent, a 0.76-meter [30-inch] overflow, a 25.4-centimeter [10-inch] blowdown, and a connection to the 25.4-centimeter [10-inch] radioactive drain line that becomes the 0.3-meter [12-inch] radioactive drain line that are not included with this waste site.)

**Location:** This site was the underground pipelines running between the 105/109-N Buildings to the 116-N-4 (1300-N), the 1304-N Emergency Dump Basin and Tank, the 107-N Filter Building to the 1908-N Outfall Structure. The pipelines exited the 105-N Reactor Building on the west side and extended to the west to their respective treatment/disposal facilities.

**Related Sites/Structures:** The associated structures are the 105-N and 109-N Reactor Buildings. The TSD pipelines are in site 100-N-63.

**Process Description:** The Emergency Dump Basin (116-N-4/1300-N) and the Emergency Dump Tank (1304-N) were designed to receive "single-pass" reactor cooling water in the case of an emergency. Both systems were used to periodically receive steam blowdown. The 1304-N Tank replaced the 1300-N Basin. This steam condensate normally contained low levels of radionuclide contamination and fission products. Overflow and drain lines to the 1908-N Outfall Structure are include in this waste site. However, the outfall structure is a separate waste site.

**Waste Type:** Oil
The waste is the contaminated underground pipelines. The following radionuclides were released from the reactor through the underground pipelines to the 116-N-4 (1300-N), 1304-N Emergency Dump Basin and Tank, the 107-N Filter Building and to the 1908-N Outfall Structure. Residual contaminants of some may be expected to remain in the underground pipelines. These include: sodium-24, niobium-95, iodine-131, chromium-51, zirconium-95, tellurium-132, technetium-99, manganese-54, iron-59, ruthenium-103, cerium-144, and cobalt-60. Because of radioactive decay, only manganese-54, cobalt-60, and cerium-144 are expected to remain.

This Site has the Following SubSites:

Code: 100-N-64:1
Names: 100-N-64:1; 109-N South side pipelines of the 100-N Reactor 105/109-N Cooling Water Effluent Underground Pipelines

Code: 100-N-64:2
Names: 100-N-64:2; 109-N East side pipelines of the 100-N Reactor 105/109-N Cooling Water Effluent Underground Pipelines

Code: 100-N-64:3
Names: 100-N-64:3; 109-N West side pipelines of the 100-N Reactor 105/109-N Cooling Water Effluent Underground Pipelines

The 100-N-64:1 subsite has been remediated and Interim Closed Out. They were 10 inch diameter pipelines, located directly south of the 109N Heat Exchanger Building. They were used as blowdown lines from the 109N Heat Exchanger Building to the 1908-N Seal Well Outfall Structure.

This site is the location of underground pipelines running between the 105/109-N Buildings to the 116-N-4 (1300-N), the 1304-N Emergency Dump Basin and Tank, the 107-N Filter Building to the 1908-N Outfall Structure. The pipelines exit the 105-N Reactor Building on the west side and extend to the west to their respective treatment/disposal facilities.

Co-located associated waste sites and ancillary facilities include: 100-N-37, 100-N-29, 100-N-30, 100-N-61:1, 100-N-103:1 (french drain on east side of 1902N), 100-N-84:1, :2, :3, :4, :5, :6, :7, Sump #2 (part of 100-N-84:5). The 186N (slab) pipeline ends at 163N and 183N foundations. The foundations were left in place by the D4 project.

The pipelines transported reactor cooling water to the 1300-N Emergency Dump Basin.

The 100-N-24, 100-N-29, 100-N-30, and 100-N-37 waste sites were located within the remediation boundary and removed during the 100-N-61:1 pipeline remediation. The remaining basement of the 1902-N Building, the 186-N concrete pad, concrete, valves and piping
associated with the 163-N sump #2 were located within the remediation boundary and were subsequently removed. A french drain (known as french drain #2) was originally part of the 100-N-103:1 subsite. However, because of its location, the drain was removed with the 100-N-61:1 pipeline remediation. Installation of a haul road was necessary to gain access to the structures. Therefore, the 100-N-53 site and segments of the 100-N-61:1 and 100-N-64:1 pipelines that were located within the roadway boundary were removed and disposed. Verification samples were collected and 100-N-53 was backfilled as part of the haul road installation.

Petroleum-stained soil was observed throughout the excavation, but was determined to be unrelated to the waste site group. Focused verification samples were collected within the stained areas and analyzed for TPH, PAH, and PCBs. Concentrations of TPH and PAH were present in the samples above direct exposure RAGs. The oil staining is considered part of the 100-N-106, Shallow Petroleum-Only Releases waste site and no additional remediation was performed.

Global Positioning Environmental Radiological Surveyor (GPERS) surveys were conducted within the 100-N-61:1 waste site grouping excavation boundary. Radiological measurements slightly above background were observed in the northern portion of the site. Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

Soil, concrete, piping, and rebar were among the types of material removed from the excavation and disposed at the Environmental Restoration Disposal Facility (ERDF). Prior to the material being loaded out for shipment to ERDF, the material was staged in a combined staging pile area (SPA). Verification sampling of the SPA will be addressed with the 100-N-61:4 waste site closeout.

Excavation of the 100-N-61:1 group extended to an approximate maximum depth of 7 meters (23 ft) below ground surface. The 100-N-53 waste site was excavated to an approximate depth of 3 meters (9.8 ft) below ground surface. An estimated 70,000 bank cubic meters (91,557 bank cubic yards) of soil and debris was removed from the entire excavation. A portion of the soil removed from on top of the pipelines was stockpiled for use as clean backfill and is included in the total volume of material removed. Asbestos was detected in the soil at the SZ3-7 location, and hexavalent chromium was detected above a remedial action goal (RAG) at the SZ4-10 location. Therefore, additional remediation was conducted January 21 through February 5, 2013. Asbestos was detected in nonsoil debris (tar/tar paper) at four locations within the excavation. A visual inspection was conducted and the visible pieces of tar and/or tar paper were removed. The volume of additional material removed is included in the estimated volume.

Exchanger Building. The geographical location of the 100-N-61:2 sub-site also coincides with the 100-N-62, 100-N 105-N, 109-N, 163-N, 182-N, 183-N and 184-N Underground Pipelines waste site, that lie underneath.

**Related Sites/Structures:** Co-located associated waste sites and ancillary facilities include 100-N-62, 100-N-84:1, :2, :3, :4, :5, :6, 100-N-61:2 and 100-N-63:2.

**Process Description:** The Emergency Dump Basin (116-N-4/1300-N) and the Emergency Dump Tank (1304-N) were designed to receive "single-pass" reactor cooling water in the case of an emergency. Both systems were used to periodically receive steam blowdown. This steam condensate normally contained low levels of radionuclide contamination and fission products. Overflow and drain lines to the 1908-N Outfall Structure are also included in this waste site.

**Closure Info:** Remediation of the 100-N-28 waste site was performed between January 25 and March 29, 2012. The site was excavated to a depth of 8.4 meters (27.6 ft) below ground surface (bgs) and resulted in the removal of 2,577 BCM (3,371 BCY) of soil and debris. The debris consisted of soil, rock, a concrete resin pit, piping, and wiring. No resin was present in the pit and it is assumed the site was only used for liquid disposal from the 109-N Building. Soil and debris were directly loaded from the 100-N-28 excavation and disposed at the Environmental Restoration Disposal Facility (ERDF).

Remedial actions for the 100-N-61:2, 100-N-62, and 100-N-64:2 sites were performed between April 13, 2011, and March 29, 2012. Excavation depths ranged from 3 meters (9.9 ft) to 8 meters (26.2 ft) bgs. Approximately 24,113 bank cubic meters of contaminated soil and debris associated with the three pipelines was removed from the waste sites and staged in the South Staging Pile Area 1 (SSP Area 1) to the south of the excavation prior to load out for disposal at ERDF. The debris consisted of rock, concrete, piping, and wiring. Verification sampling of the SSP Area 1 will be addressed in the 100-N-61:4 verification work instruction. In addition, overburden (OB) material was stockpiled in three OB piles southwest of the waste sites. The OB piles will also be addressed in the 100-N-61:4 verification work instruction.

Multiple TPH and PAH results collected at the 100-N-61:2, 100-N-62, and 100-N-64:2 excavation exceeded soil RAGs. However, these results were concluded to be cross contamination from petroleum releases unrelated to the waste sites and will be addressed as part of the 100-N-106 (Shallow Petroleum-Only Releases at 100-N; SPOR Releases) waste site and were not used for evaluation in this RSVP.

A valve pit (OSE ID N-244) was discovered at Washington State plane coordinates N49350.37, E571230.54, with asbestos pipe wrapping. The valve pit was a 1 meter (3.3 ft) diameter manhole, with a valve and a 7.6 centimeter (3 in.) pipeline running east to west. Spatial analysis indicated that valve pit N-244 is associated with the 100-N-84:3, potable water line. The valve pit was completely removed and disposed with soil and debris from the 100-N-61:2, 100-N-62, and 100-N-64:2 excavation. No other anomalies were discovered during remediation.

**The SubSite is Part Of:**

- **Code:** 100-N-64
- **Names:** 100-N-64; 100-N Reactor 105/109-N Cooling Water Effluent Underground Pipelines

**Code:** 100-N-64:3

**Classification:** Accepted

**Names:** 100-N-64:3; 109-N West side pipelines of the 100-N Reactor 105/109-N Cooling Water Effluent Underground Pipelines

**Reclassification:** Interim Closed Out (9/6/2013)

**Type:** Radioactive Process Sewer

**Start Date:**
Inactive Status: End Date:

Description: This sub-site has been remediated and Interim Closed Out. The 100-N-31 waste site was located on the west side of the 105-N/109-N Reactor Buildings and adjacent to the 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39 waste sites. These waste sites are collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.

100-N-64:3 consisted of pipelines ranging from 2 inches to 32 inches in diameter. The pipelines were used to transport vent, flush, blow-down, filtered, fire line, and demineralized water between the 109-N Building and the 1304-N Emergency Dump Tank, 1300-N Emergency Dump Basin, 107-N Basin Recirculation Facility and the 1303-N Radioactive Dummy Burial Facility/Spacer Silos. It also included utility lines contained in a concrete trench. The hot spot contamination in the northern portion of the 116-N-4 Emergency Dump Basin excavation was deferred to 100-N-64:3.

Location: The 100-N-64:3 pipelines were located west of the 109-N Heat Exchanger Building and 105-N Reactor Building.

Related Sites/Structures: Co-located associated waste sites and ancillary facilities include: 116-N-4, 100-N-84:1,:2,:3,:4,:5,:6, 118-N-1, 100-N-31 100-N-32, 100-N-38, 100-N-61:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-3.

Closure Info: Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. This group of waste sites was referred to as the waste sites west of the 105-N/109-N Reactor. The footprints of the 1909-N Waste Disposal Valve Pit, the 107-N facility and the pipe trench between 105-N and 107-N were also located within the boundary of the group.

The eleven collocated waste sites located west of the 105-N/109-N Reactor Building were remediated, either partially or completely, by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the collocated waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N) Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected above background. However, the area with the highest detected activity is associated with residual structures and soils for the 105-N/109-N SSE and is considered part of the 100-N-66, 105-N/109-N Reactor Building Complex waste site. A small area with elevated beta and gamma contamination was detected within the waste sites west of the 105-N/109-N Reactor boundary. Additional soil was removed from this area and disposed at the ERDF. An environmental radiological survey of the area using hand-held instruments verified that the contaminated soils...
have been removed.

The 1909-N Waste Disposal Valve Pit was removed during general facility demolition in this area by the D4 Project. Due to the proximity and general configuration of demolition and remediation activities on the west side of the reactor, closure of the facility footprint was deferred until nearby waste site remediation by the FR Project occurred. The residual contaminated soil that remained beneath the location of the former 1909-N facility was then removed.

The 107-N basin structure was completely removed by the D4 Project. However, closure of the basin footprint was deferred to the UPR-100-N-12 waste site. Additional soil was removed from the footprint during general waste site remediation in the area. Surveys found no elevated residual radiological activity.

Several segments of the 100-N-84 pipeline subsites were partially located within the remediation boundary. All of the segments of the 100-N-84:2, 100-N-84:4, 100-N-84:5, and 100-N-84:6 pipeline subsites that were within the excavation boundary were removed and disposed at the ERDF. Reclassification of the total 100-N-84:2, 100-N-84:4, 100-N-84:5 and 100-N-84:6 pipeline subsites will be addressed in separate closure documents.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

| Code:       | 100-N-65 |
| Classification: | Accepted |
| Reclassification: | None |

| Names: | 100-N-65; Diesel Oil Interceptor Trench; UPR-100-N-17 Interceptor Trench |
| Type: | Trench |
| Status: | Inactive |
| Start Date: | 1/1/1966 |
| End Date: | |
| Description: | The site is a trench that was excavated along the Columbia River bank to intercept diesel oil before it could reach the river. The trench was excavated as a result of an unplanned release of 303,000 liters (80,000 gallons) of diesel fuel that leaked from a pipeline within 166-N Tank Farm (See UPR-100-N-17). Several smaller unplanned releases also contributed to the need for the trench (See UPR-100-N-19 and UPR-100-N-20). Oil trapped in the trench was ignited and burned. A significant portion of the oil was thus removed before it could reach the river. In 1994, the trench was backfilled with material to the top of the adjacent berm. |
| Location: | The trench was located on the riverbank, northeast of 166-N Tank Farm. |
| Related Sites/Structures: | The site was related to the 166-N Tank Farm, the Fuel Oil Unloading Trench, and the Fuel Oil Day Tanks (184-N Powerhouse). |
| Process Description: | The trench was excavated along the Columbia River bank to intercept diesel oil before it could reach the river. |
| Waste Type: | Water |
| Waste Description: | The waste was diesel oil from spills in the 100-N Area diesel oil storage facilities. |
**Code:** 100-N-67  
**Classification:** Accepted  
**Names:** 100-N-67; HGP Dumping Area  
**Reclassification:** Interim No Action (9/11/2000)  
**Type:** Dumping Area  
**Status:** Inactive  
**Description:** The site has been evaluated and determined to require No Action. It is a pile of metal banding material, barbed wire, wire rope, concrete, and pipe. Some of the materials are partially buried.  
**Location:** The site is located approximately 250 meters (820 feet) west of the Bonneville Power Administration (BPA) substation and Hanford Generating Plant facility fence. It is between the facility fence and the Columbia River. It is directly under the western BPA powerlines that cross the Columbia River.  
**Process Description:** The waste appears to have been generated from the construction of the Bonneville Power Administration (BPA) powerlines.  
**Waste Type:** Chemical Release  
**Waste Description:** The site contains metal banding material, barbed wire, pipe, and concrete.  
**Closure Info:** In September 2000, Waste Site Reclassification Form 2000-057 declared the metal and concrete debris was not hazardous and reclassified the site to No Action.

**Code:** 100-N-68  
**Classification:** Accepted  
**Names:** 100-N-68; N Basin Low Level Radioactive Water Spill  
**Reclassification:** Interim Closed Out (9/6/2013)  
**Type:** Unplanned Release  
**Status:** Inactive  
**Start Date:** 1/7/1998  
**End Date:** 2/20/1998  
**Description:** The site has been remediated and Interim Closed Out. The 100-N-31 waste site was located on the west side of the 105-N/109-N Reactor Buildings and adjacent to the 100-N-32, 100-N-38, 100-N-61 :3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39 waste sites. These waste sites are collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.  
100-N-68 was a release of contaminated water onto the floor of the 105-N building that seeped under the roll up doors and onto the ground outside. The release area had been posted with Contaminated Area signs. In 1998, the contamination was temporarily stabilized with a fixative, tarps and plywood. Later it was stabilized with asphalt.  
**Location:** The site was located just outside the N Basin Transfer area, west of the 105-N Building.  
**Release Description:** On January 7, 1998, at approximately 0810 hours, a Decontamination and Decommissioning (D&D) worker in the 105-N Basin discovered water spraying from a hose connected to the Final Transfer Filtration (FTF) system. The worker immediately shut off the FTF system and notified management.  
The event investigation determined the intake hose to the FTF system had split sometime between 2:00-4:00 am, causing contaminated water from the basin to be released to the floor. The estimated amount of water released from the basin is approximately 1.36E+05 liters (36,000 gallons). The basin drains captured most of the water, however an estimated 7,600
Process Description:
The filtration system at the 100-N Fuel Storage Basin (FSB) experienced a leak through a split hose of about 36,000 gallons of radioactively contaminated water on the morning of January 7, 1998. Approximately 2,000 gallons flowed outside the FSB enclosure. The final transfer filtration system was used to reduce the turbidity of the FSB water while decontamination and decommissioning (D&D) workers recovered items from the basin. The FTF was used to remove particulates from the basin water to increase water clarity.

Waste Type: Equipment

Waste Description: Using current analytical data on the N Basin water, the total curies released in the spill/leak for all of the radionuclides was calculated to be 0.42 curies. No reportable quantities were exceeded.

Closure Info: Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. This group of waste sites was referred to as the waste sites west of the 105-N/109-N Reactor. The footprints of the 1909-N Waste Disposal Valve Pit, the 107-N facility and the pipe trench between 105-N and 107-N were also located within the boundary of the group.

The eleven collocated waste sites located west of the 105-N/109-N Reactor Building were remediated, either partially or completely, by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the collocated waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N) Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected above background. </table>
Waste Type: Chemicals
Waste Description: The waste includes the pipeline and the potentially contaminated scale and sediment contained within it.

Code: 100-N-78
Names: 100-N-78; 1716-NE Maintenance Garage; HGP SWMU #8
Type: Maintenance Shop
Status: Inactive
Start Date: Interim Closed Out (6/15/2004)
End Date: Accepted

Description: The site has been remediated and Interim Closed Out. The 1716-NE Maintenance Garage was used for vehicle maintenance. The garage had three vehicle bays, each containing a floor drain that led to the 100-N-3 Maintenance Garage French Drain (SWMU #9).

Location: The 1716-NE Maintenance Garage (SWMU #8) was located to the east of the former 185-N Building.

Related Sites/Structures: The garage is associated with the 100-N-52 Gasoline Storage Tank (UST).

Process Description: The former HGP consisted of two 430-megawatt turbine generators that operated from 1966 until 1986 using steam from the adjacent 100-N production reactor for generation of electricity. The generators were located in the 185-N Building. The site was an ancillary or support facility to the former HGP.

Closure Info: The 100-N Reactor provided fuel rods to the plutonium production process at Hanford, but also operated two 430 megawatt turbine generators for the generation of electricity. The Washington Public Supply System, later named Energy Northwest, was responsible for the Hanford Generating Plant located at 100-N Reactor. The Cleanup Verification Package (HGP-CVP-SWMUs 5, 6, 7, 8, 9, & 10) for the Hanford Generating Plant Solid Waste Management units was prepared by Energy Northwest in 2004. Some remedial actions at HGP began in 1992. Other characterization and remediation was completed in 2004. Remedial action activity descriptions include:

100-N-1 Settling Pond (SWMU#6) - Remediation activities conducted in 2001 removed approximately 0.9 meters (3 ft) of soil and settled solids material from the 100-N-1 Settling Pond (SWMU #6). The excavated material was disposed of at the Environmental Restoration Disposal Facility (ERDF).

100-N-3 Maintenance Garage French Drain, 100-N-41 Gate House Septic Tank and 100-N-45 Office Building Septic Tank make up SWMU #9. Remediation was determined not to be necessary for the 100-N-3 site and the 100-N-41 and 100-N-45 septic sites. The below grade structures of the drain and septic sites were demolished in place and backfilled with soil in 2004.

100-N-4 Tile Field (SWMU#5) - Confirmatory sampling activities and data evaluation determined that remediation was not necessary for the 100-N-4 Tile Field.

100-N-5 Bone Yard (SWMU #10) - Remediation and removal activities for the 100-N-5 Bone Yard (SWMU #10) were primarily conducted in 2001 with the removal of the miscellaneous equipment, metal scrap, and general debris. The limited number of areas with sand blast media, ion exchange resin-like media and areas with soil staining and/or distressed vegetation were remediated in 2003 and 2004. The sand blast, ion exchange resin, and contaminated soil wastes were disposed of at the RABANCO landfill facility in Roosevelt, Washington.
The 100-N-46 Diesel underground storage tank (UST) was excavated and removed in 2001. Soil contaminated with diesel was also excavated from the UST excavation. Contaminated soil was spread over the demolished 1703-N Office Building concrete slab foundation for attenuation. Upon completion of the remedial excavation, the bottom of the excavation was approximately 6.7 meters (22 ft) below the ground surface at the deepest location (southwest corner of excavation).

100-N-52 Gasoline underground storage tank (UST) was excavated and removed in 1992.

1908-NE Outfall (SWMU#7) - The original preferred remedy for the 1908-NE Outfall was Institutional Controls (continued monitoring). A radiological survey of the Outfall seal well and samples of water and sediment were collected from the Outfall seal well in 2001 to assess potential contamination associated with the Outfall. The outfall structure was demolished by the Washington Closure Hanford D&D organization in 2012, eliminating the Institutional Control requirement.

The 1716-NE Maintenance Garage building (SWMU #8), including the building slab and associated floor drain pipelines, were removed in their entirety during the 2003 and 2004 removal action activities. Prior to the removal action all chemical products were removed from the building and either properly disposed of or transferred to another facility for use. The building debris was used as fill for the 185-N Building basement.

### Classification:

- **Code:** 100-N-80
- **Classification:** Accepted
- **Names:** 100-N-80; River Line from 1908-NE Outfall
- **Reclassification:** None
- **Type:** Process Sewer
- **Start Date:**
- **End Date:**
- **Status:** Inactive

### Description:

This site includes one, 335-centimeters (132 inches) (2 centimeter (0.75 inch) wall thickness) steel pipeline, extending from the face of the 1908-NE Outfall into the main channel of the Columbia River.

### Location:

The 1908-NE Outfall is located in the 100-N Area, approximately 61 meters (200 feet) downstream of the 181-NE River Pumphouse on the Columbia River at river mile 379.6. The 100-N-80 river effluent pipeline extends from, and is perpendicular to, the face of the 1908-NE outfall structure. The pipeline extends 313 meters (1,028 feet) from the outfall face to its discharge point in the Columbia River.

### Related Sites/Structures:

The site is associated with the 1908-NE Outfall and the 100-N-1 Settling Pond.

### Process Description:

The river effluent pipeline received single pass raw river water which had passed through the Hanford Generating Plant (HGP) condensers, as well as waste water from the 100-N-1 Settling Basin. The pipeline contains seven, 20 centimeter (8 inch) vents along its length, and discharges to the river via four, 3.4 meter (11 feet) outlets. The pipeline is buried along its entire length to a depth of at least 1.2 meters (4 feet) with soil, gravel, and riprap.

### Waste Type:

- **Oil**

### Waste Description:

The waste includes the pipeline and the potentially contaminated scale and sediment contained within it. The contaminants of concern include cobalt-60, cesium-137, and petroleum hydrocarbons (diesel and heavy oil range hydrocarbons).
DOE/RL-88-30
Rev. 24

Code: 100-N-81
Classification: Accepted

Names: 100-N-81; 100-N Kaiser Shops Garnet Sandblasting Material
Reclassification: Interim Closed Out (5/7/2014)

Type: Dumping Area
Start Date:

Status: Inactive
End Date:

Description: The site was remediated and Interim Closed Out. It consisted of garnet sand and any underlying contaminated soil surrounding the former 1517-N Paint Shop. The garnet sand was purple and covered an area approximately 577 square meters (690 square yards).

Location: The waste site was located at the 1517-N Paint Shop in the Kaiser Shop Area. The Paint Shop was located about 300 meters (1,000 feet) east of the 105-N Reactor facility.

Related Sites/Structures: The garnet sandblasting operations were likely in support of the 1517-N Fixed Metal Paint Shop mission.

Process Description: The 1517-N Paint Shop was constructed in 1982 (HW-5000, 4/30/1982). It was originally operated by the J.A. Jones Construction Services Company. Kaiser Engineering Hanford (KEH) assumed responsibility for the Paint Shop in 1987 (HW-5000, 6/16/1987). Respiratory protection equipment was stored in part of the building at some point during its operation (CCN 125281). The paint shop was used to store supplies for the craft services painters. Materials needed for various outside jobs are taken from the shop to the job site only in quantities equal to the amount needed for that job or day's work. Unused materials are returned to the shop at the end of each day (WHC-SP-0460). Paint, solvents, and oils were used at the Paint Shop. There were two waste accumulation areas, one for waste paint and the other for waste oil (DOE/RL-90-22). There was also an associated sandblasting area. An air compressor located east of the paint shop leaked nonhazardous lubrication oil over the years; the surrounding soil is oil-stained. The extent of contamination is unknown. Six drums of contaminated soil were removed (DOE/RL-90-22). The 1517-N building was demolished in January 2006. Prior to demolition, the extent of the discarded sandblasting grit (garnet sand) was mapped using a global positioning system (GPS). The mapped area in conjunction with a 2004 aerial photograph (04080084-57cn) was used to establish the waste site boundary. The garnet material was stockpiled into the northeast corner of the Kaiser Shop Area in order to prevent its spread during demolition activities (CCN 126707). This stockpiled material falls within the waste site boundary.

Waste Type: Misc. Trash and Debris

Waste Description: The waste is a red colored granular material. In 2005 a grab sample of the sandblasting waste material was analyzed for metals (J10VC5). The material contained chromium at a level (45.0 mg/kg) exceeding the soil cleanup level (18.5 mg/kg) for protection of groundwater and protection of the river. Contaminants of potential concern have not been established at this time.

Closure Info: Remedial action at the 100-N-81 waste site was performed between October 22 and October 31, 2013. The excavation depth ranged from 1 to 2 meters (3.3 to 6.6 ft) bgs resulting in approximately 1,200 bank cubic meters (1,570 bank cubic yards) of soil and debris (garnet sand, concrete, wood, and steel chain-link fencing) removed for disposal at the Environmental Restoration Disposal Facility (ERDF). All material was direct loaded from the excavation into trucks for disposal at the ERDF. Therefore, no waste staging pile area was created and no overburden soil pile associated with the waste site. A boundary survey was conducted following remedial action activities. A glass anomaly was encountered approximately 30 meters (98 ft) north of the 100-N-81 site boundary.

Code: 100-N-82
Classification: Accepted

Hanford Site Waste Management Units Report
February 2015 854
Names: 100-N-82; 100-N Decontamination Pad

Type: Unplanned Release

Status: Inactive

Description: The waste site has been remediated and Interim Closed Out. It included the decontamination pad and any underlying soil contamination was found. The decontamination pad had a reinforced (rebar) concrete slab with a center drainage trench and sump. The slab sloped toward the center concrete drainage trench where the water was trapped in the sump. A HDPE liner cover had been installed on top of the decontamination pad to prevent rainwater from entering the trench and sump area (CCN-107899). It was posted with radiological warning signs.

Location: The decontamination pad was located approximately 245 meters (804 ft) northeast of the 1120-N Building.

Related Sites/Structures: The site was related to 1301-N (Sitecode 116-N-1) and 1325-N (Sitecode 116-N-3) cribs and trenches.

Process Description: The decontamination pad was constructed in 2000. It was constructed to support 100-N vehicles and equipment performing remediation work associated with sites 116-N-1 (1301 Crib/Trench) and 116-N-3 Crib/Trench. When a vehicle drove onto the pad, a self-contained steam cleaner, water tank, and pump with suction and discharge hoses was used to decontaminate the vehicle. Runoff water would enter the trench and sump, and, as needed, wash water would be pumped to a tank truck for removal. The pad was covered with a liner upon demobilization to prevent rainwater from entering the trench and sump (CCN-107899).

Waste Type: Oil

Waste Description: The waste is a contaminated concrete pad. Contaminants of potential concern (COPCs) include Co-60, Cs-134, Cs-137, Pu-238, Pu-239, H-3 and Ru-106.

Closure Info: Remediation of the 100-N-82, 100-N Decontamination Pad was performed between March 19 and March 24, 2014. Approximately 194 bank cubic meters (254 bank cubic yards) of excavated materials were removed and direct loaded for disposal at the Environmental Restoration Disposal Facility. The depth of the excavation was approximately 1.5 meters (4.9 ft). Excavated materials included plastic tarp, concrete, railroad ties, steel, rebar, soil, and other miscellaneous debris. The sump located near the center of the decontamination pad was also removed. No soil staining or anomalies were observed during and after the excavation. No overburden materials were salvaged from the 100-N-82 waste site excavation. There was no overburden pile associated with the 100-N-82 waste site. A 100-N-82 waste site walk around boundary was used to determine the footprint for the 100-N-82 waste site and develop the verification sampling design.

A Global Positioning Environmental Radiological Surveyor (GPERS) survey was conducted within the 100-N-82 waste site open excavation. No radiological contamination was detected above background.

---

Names: 100-N-83; Two Contamination Areas Found Near 116-N-1

Type: Unplanned Release

Status: Inactive

Description: The site consists of two radiologically contaminated areas identified during remediation of 116-N-1 Crib and Trench. The first area is located where an uncontaminated soil stockpile was
previously removed. The second area is relatively undisturbed located near and around the eastern end of the former 116-N-1 Trench.

**Location:** The two areas are located along the northeast excavation boundary of the 116-N-1 Crib and Trench. They are bound to the north and east by the security fence shown on drawing 0100N-DD-C0190.

**Waste Type:** Oil

**Waste Description:** The waste is radiologically contaminated soils. The contaminants of potential concern are radiological contaminants.

**Type:** Radioactive Process Sewer

**Status:** Inactive

**Description:** The parent site is also considered Interim Closed Out. The waste site consisted of all miscellaneous pipelines in the 100-N Area that were identified during the WCH Orphan Site Evaluation (OSE) process that were not associated with an existing waste site. The miscellaneous pipelines supported the reactor operation and related support facilities throughout the N-Area. The waste site had been divided into ten subsites to allow a phased remediation strategy. 100-N-84 includes product pipelines, service water pipelines, sewers and associated features (manholes, storm drains, valve boxes, etc.).

The waste site has nine subsites: 100-N-84:1, 100-N Area Raw Water Pipelines; 100-N-84:2, 100-N Area Fuel and Foam Pipelines; 100-N-84:3, 100-N Area Filtered and Potable Water Pipelines; 100-N-84:4, 100-N Area Steam and Condensate Pipeline; 100-N-84:5, 100-N Area Sanitary Pipelines; 100-N-84:6. 100-N Area Chemical and Process Sewer Pipelines; 100-N-84:7, 100-N Area Unidentified and Other Miscellaneous Pipelines; 100-N-84:8, 100-N Area Unidentified Pipelines within Planned Excavations. The tenth subsite, 100-N-84:9, 100-N Area Active Raw Water Pipelines and 100-N-84:10, Miscellaneous Pipelines within the Bioventing Well Island was consolidated with 100-N-107.

**Location:** The pipeline segments are located within the 100-N Area.

**Process Description:** Specific process descriptions are contained in the subsite descriptions.

**This Site has the Following SubSites:**

- **Code:** 100-N-84:1
  - **Names:** 100-N-84:1; 100-N Area Raw Water Pipelines

- **Code:** 100-N-84:2
  - **Names:** 100-N-84:2; 100-N Area Fuel and Foam Pipelines

- **Code:** 100-N-84:3
  - **Names:** 100-N-84:3; 100-N Area Filter and Potable Water Pipelines

- **Code:** 100-N-84:4
  - **Names:** 100-N-84:4; 100-N Area Steam and Condensate Pipelines

- **Code:** 100-N-84:5
  - **Names:** 100-N-84:5; 100-N Area Sanitary Pipelines
The subsite has been evaluated and determined to require No Action. It consists of the inactive 100-N Area raw water pipelines including: low pressure water, raw water, raw water return, raw water supply, raw water supply high and low pressure, emergency The lines are raw water supply, sprinkler, vent, fire line, irrigation, fog, and fish line pipelines. They located in various throughout the 100-N Area.

The 100-N Area raw water system was built in 1963 with additional portions added as new support buildings were constructed. Raw water was pumped from the Columbia River at the 181-N Pump House to the 185-N Hanford Generating Plant, the 109-N Heat Exchanger Building, the 182-N High-Lift Pump House, and the 184-N Power House. These large delivery pipelines are not part of the 100-N-84 waste site. The subsite includes pipelines between the 105-N Reactor Building and it's supporting facilities.

The pipelines exiting the 182-N Building transferred raw water to the 105-N, 109-N, 163-N and 183-N Buildings. At the 182-N Building, raw water was passed through screens before it was stored in 18.6 meter (61 ft) deep, independent pump suction wells for future distribution. Raw water supplied to the 109-N Heat Exchange Buildings supported the dump-condensers, graphite cooling heat exchangers and turbine surface-condensers. Additionally, raw water was supplied to the 182-N Building emergency raw water tank and various heat exchangers, along with the 100-N Area irrigation and fire systems. The fire system pipelines originating at the 182-N supported the 185-N Hanford Generating Plant and substation located outside of the 100-N Fenced area. Raw water from the 109-N and 184-N buildings could also be returned to the Columbia river through the Sealwell.

The pipelines located between the 109-N, 182-N, 163-N and the 183-N Buildings lay within the 100-N-61 water treatment pipeline removal excavation footprint (H-1-89933). This area was excavated and backfilled in 2008 through 2009. Raw water lines collocated with 105-N Reactor Treatment Storage and Disposal Underground Pipelines along the east side of the 109-N and 105-N Buildings lay within the 100-N-63 excavation footprint (H-1-89933). This area was excavated and backfilled in 2009.

The large majority of the pipelines being located in and around the 182-N High-Lift Pump House, 163 Demineralization Plan, 183-N Water Filter Plant, 184-N Power House, the 185-N Hanford Generating Plant, 109-N Heat Exchanger Building and many office buildings and trailers located to the south and south east of the 105-N Reactor Building. One additional 12-
inch raw water line, used for temporary construction, is located in the northeastern portion of the 100-N area and connects to the export water pipeline.

Closure Info: Confirmatory samples were collected from test pits at nine locations on the 100-N-84:1 subsite between March 8 and July 19, 2012 to support an evaluation to determine if residual contaminant concentrations in the soil meet cleanup criteria. The 100-N-84:9 pipelines are still active while the 100-N-84:1 pipelines have been taken out of service and/or removed. Both subsite pipelines carried the same type of raw water. Therefore the confirmatory sampling conducted at the inactive 100-N-84:1 has been used to evaluate and support the 100-N-84:9 reclassification.

The SubSite is Part Of:

Code: 100-N-84
Names: 100-N-84; 100-N 100-N Miscellaneous Pipelines

Code: 100-N-84:2
Names: 100-N-84:2; 100-N Area Fuel and Foam Pipelines
Type: Radioactive Process Sewer
Status: Inactive
Description: The subsite has been remediated and Interim Closed Out. It included the fuel oil and fire suppression foam, underground pipelines located on the northwest and west side of the 105-N Reactor Building. In addition to the pipelines, the subsite also included a fuel oil unloading facility that was used to unload both fuel oil (No. 6 fuel oil also known as Bunker C) and diesel oil (No. 2 fuel oil).

The fire suppression foam lines that supported the diesel oil tanks and pipelines were co-located with the diesel oil pipelines near the 166-N Building. The northwest portions of the 100-N-84:2 pipelines were located within the 100-N-63 excavation footprint (H-1-89933).

Location: Fuel and fire suppression foam underground pipelines were located in the 100-N Area, on the northwest and west side of the 105-N Reactor Building.

Related Sites/Structures: UPR-100-N-17, UPR-100-N-18, UPR-100-N-19, UPR-100-N-20, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, UPR-100-N-36, UPR-100-N-42, and UPR-100-N-43.

Process Description: Diesel oil was used to fire the igniters in the boilers and to fuel the diesel-driven emergency low-lift, high-lift, and fog spray pumps. Bunker C was used as fuel for the 184-N boilers. Bunker C fuel oil was stored in a 5,204,925 liters (1,375,000-gal) capacity above-ground storage tank and transferred through underground lines to the two 184-N fuel oil day tanks. Two fuel oil unloading, storage and transfer systems were used in the 100-N Area. Diesel oil unloaded from rail cars at the 166-N unloading station was transferred for storage to the one of four aboveground storage tanks within the 1715-N Building. The diesel oil was then transferred through a 10.2 cm (4-in) underground supply pipeline to the 184-N Building day tank or through 5.1 cm (2-in) and 10.2 cm (4-in) underground pipelines to the three 56,781 liters (15,000 gal) day tanks outside of the 182-N building. The diesel fuel from the 182-N day tanks was used to support the 182-N and 181-N diesel oil systems. Number 6 fuel oil (also known as Bunker C fuel oil) was unloaded from rail cars at the 1900-N unloading station and transferred to the 166-N Building for storage in a 5,204,941 liters (1,375,000 gal) capacity aboveground storage tank. The No. 6 fuel oil was transferred through underground pipelines from 166-N to two 184-N fuel oil day tanks.

Waste Type: Demolition and Inert Waste
Waste Description: The waste is the pipeline (if present), scale, sediment, or liquid present within the pipelines, and the underlying soil.

Closure Info: Demolition of the 166-N facilities included removal of the fuel oil (Bunker C) tank in January 2006 and removal of the 166-N Pump House and the 166-N Unloading Station in April 2006. The four 1715-N diesel tanks were removed during prior demolition work approximately 10 years earlier, leaving the tank foundations to be removed during the 2006 demolition. The contaminated soil associated with the 166-N facilities to the Field Remediation (FR) Closure Project for remediation.

The D4 Closure Project removed many of the 100-N-84:2 pipelines during facility demolition work that began in 2006 and continued through 2012. In some instances, the pipelines were removed at locations where they entered buildings and tanks. Field remediation of co-located waste sites removed portions of some pipelines during waste site excavation. Prior to removal, the pipelines were drained and the oil collected for waste disposition. It is estimated that over the past 7 years, approximately 3,030 L (800 gal) each of diesel and Bunker C had been drained from the pipelines.

Remediation of the 100-N-84:2 subsite began April 6, 2013, and was completed in March 21, 2014. The depth of the excavation after removal of the pipelines varied based upon the amount of excavation necessary to remove soil staining and petroleum contamination. In general, the pipeline excavations did not extend deeper than 4.9 meters (16 ft) below surface grade. Approximately 41,710 bank cubic meters (54,555 bank cubic yards) of petroleum-contaminated soil was removed for disposal at the Environmental Restoration Disposal Facility (ERDF).

No petroleum contamination or evidence of any release of petroleum was observed in soil associated with the 100-N-84:2 pipelines that ran from the fuel unloading station to the 181-N and 182-N facilities. In agreement with the Washington State Department of Ecology and the U.S. Department of Energy, the excavation associated with the pipelines in this area could be backfilled and no verification sampling was needed.

Significant petroleum-stained soil was present below 4.6 meters (15 ft) depth at the location where the 100-N-84:2 Bunker C and diesel pipelines entered the 166-N pump house and the Bunker C storage tank. A test pit was excavated and sampled on November 20, 2013, to a depth of approximately 9.4 meters (31 ft) bgs, at the location of the worst staining, to evaluate the vertical extent of petroleum contamination and support decisions concerning the need for additional remediation. Heavily stained petroleum-contaminated soil was noted in the material that was excavated from this test pit and the contamination continued to be present at the base of the test pit (9.4 meters [31 ft] bgs). This petroleum contamination is suspected to be mostly Bunker C and may include weathered, aged diesel. This information was used to support assignment of this portion of the 100-N-84:2 subsite, located below 4.6 meters (15 ft), to the UPR-100-N-17 waste site for in situ bioremediation. The soil contamination in Test Pit #4 was located near the UPR-100-N-17 bioventing wells and was within the air injection radius of influence for the bioremediation system.

The waste site was divided into three sample Areas. Test Pits 1, 2 and 3 were excavated within Area 2, where the highest concentrations and staining of petroleum was observed at the base of the excavation. Test Pit 4 was excavated in Area 3, where heavily stained petroleum-contaminated soil was observed on the floor of the excavation.

Petroleum contamination was not detected above cleanup criteria in soil samples below a depth of approximately 6.7 meters (22 ft) in Test Pits 1, 2, and 3. The petroleum had not migrated deeper than 6.7 meters (22 ft) below ground surface at test pits 1, 2, and 3, indicating that petroleum was not present in groundwater at these test pit locations. However, the petroleum contamination remained present with depth in soil samples collected from Test Pit 4.
The SubSite is Part Of:

Code: 100-N-84
Names: 100-N-84; 100-N Miscellaneous Pipelines

Code: 100-N-84:3
Names: 100-N-84:3; 100-N Area Filter and Potable Water Pipelines
Type: Radioactive Process Sewer
Status: Inactive

Description: The 100-N-84:3 subsite has been evaluated and determined to require No Action. The 100-N Area filter and potable water pipelines include makeup water, filter water, demineralized water, and potable water pipelines.

Location: Filtered water lines are located to the north and south of the 105-N reactor Building. The potable water lines are located mainly to the southwest of the 105 reactor building connecting to the 105-N support facilities.

Process Description: Raw water was supplied to 183-N Filter Plant Building for pretreatment and filtration. The 183-N filter plant supplied sanitary water to the entire 100-N Area. The plant also supplied filtered water to various buildings throughout the 100 N Area for use where treated water was not desirable or required. During treatment, liquid alum (aluminum sulphate), Separan (polyacrylamide coagulant), and liquid chlorine were added. Chlorine was added for the control of slime and algae and may have been used to assist in coagulation, odor, and iron removal problems.

During treatment, liquid alum (aluminum sulphate), Separan (polyacrylamide coagulant), and liquid chlorine were added. Chlorine was added for the control of slime and algae and may have been used to assist in coagulation, odor, and iron removal problems. The alum used at 183-N contained trace amounts of naturally occurring radium-226, radium-228, and thorium-228, which may have resulted in formation of Technologically Enhanced Naturally Occurring Radioactive Material (TENORM). Previously, to determine if TENORM was present, a number of samples downstream of the 183-N chemical mixing tank were collected and subsequently evaluated in the document Post Demolition Summary Report for the 163-N Water Demineralization Plant, 183-N Water Treatment Plant, 183-NA Pump House, 183-NB Clearwell, and the 183-NC Filter Backwash Sump. The evaluation of those samples found no detectable amounts of radioactive contamination.

Demineralized water from 163-N Building was used as makeup water feed for the pretreatment system in 183-N building, while raw water was used for chemical mixing in the 182-N and 183-N Buildings prior to being added to the water. The chemical feed systems were maintained using proportional ratios with the water flow. Demineralized water was used to prevent mineral deposits what would foul pipeline systems. Chlorine was added for the control of slime and algae, and may have been used to assist in coagulation, odor and iron removal problems. Alum was used as the principle coagulant during pretreatment. 100-N-84:3 pipelines located between the 109-N, 182-N, 163-N and the 183-N Buildings lay within the 100-N-61 water treatment pipeline removal excavation footprint (H-1-89932). This area was excavated and backfilled in 2008 through 2009. The north west portions of the 100-N-84:3 pipelines are located within the 100-N-63 excavation footprint (H-1-89933).

Waste Type: Chemical Release
Waste Description: The waste is the pipeline (if present), scale, sediment, or liquid present within the pipelines, and the underlying soil.
Closure Info: The 100-N-84:3 pipelines located between the 109-N, 163-N, 181-N, 182-N, 183-N, and 184-N Buildings are co-located with 100-N-61 (100-N Water Treatment and Storage Facilities Underground Pipelines), the 100-N-62 (100-N, 105-N, 109-N, 183-N, and 184-N underground pipelines) and 100-N-63 (100-N Reactor Treatment Storage and Disposal Underground Pipelines). The portions of the 100-N-84:3 pipelines that lay within the 100-N-61 and 100-N-63 excavation footprint will be removed during the excavation of these sites and were not identified for confirmatory sampling during the 100-N-84:3 activities.

Eleven Test Pits were dug. Confirmatory samples were collected from Test Pits 3, 6, 8, and 10. No indications of previous spills or releases associated with the 100-N-84:3 pipelines were detected during confirmatory sampling. The 100-N-84:3 data set indicates elevated polycyclic aromatic hydrocarbons (PAH) in samples from two of the collection areas. The ground surface in much of the 100-N Area was covered with asphalt. Remnants of asphalt are visible on the surface and in excavations in various areas and are thought to be responsible for the PAH results. Also, many of the pipelines are covered in an asphalt mastic coating. Mechanical methods recently employed to access sample materials may also have resulted in small particles of asphalt becoming incorporated in the samples.

The SubSite is Part Of:

Code: 100-N-84
Names: 100-N-84; 100-N 100-N Miscellaneous Pipelines

Code: 100-N-84:4
Names: 100-N-84:4; 100-N Area Steam and Condensate Pipelines
Type: Radioactive Process Sewer
Status: Inactive
Classification: Accepted
Reclassification: Interim Closed Out (9/9/2014)
Start Date: End Date:

Description: The subsite has been remediated and Interim Closed Out. It included the 100-N Area steam, condensate, injection and vacuum pump water pipelines located near the reactor building and support facilities. 100-N-103:1 French Drains 9, 10 and 11 were deferred to 100-N-84:4 because they were within the planned pipeline remediation footprint or were removed during previous demolition and removal of the 105-N control room structure. The French drain #9 structure was removed during demolition of the 105-N Control Room structure.

Location: The steam and condensate pipelines are concentrated around the 105-N Reactor building to support facilities and the 185-N Hanford Generating Plant.

Related Sites/Structures: Some of the 100-N-84:4 pipelines are associated with 100-N-61:4.

Process Description: The 100-N Reactor excess steam was used to generate electricity from 1966 to January 7, 1987. Condensate from the dump condensers was routed back to steam generators for regeneration. The main steam system was designed to distribute steam generated from generators on the roof of the 109-N Building as high, medium and low pressure steam. High pressures steam was exported through a 71 cm (28-in) pipeline to the 184-N Building to support the turbine generator and miscellaneous services. Medium pressure steam was distributed from 109-N for area heating (105-N, 182-N, 163-N, 183-N, 108-N, 1704-N, 1716-N, and 1734-N) and additional miscellaneous services. Low pressure steam was exported to the 184-N and 153-N Buildings for unit heaters and convectors. Stand-by boilers located 184-N were maintained independent of reactor operation supplying steam to the 184-N day tanks, the 166-N fuel unloading facilities and for the 109-N emergency seal water turbines. Once the steam had been utilized in each building condensate return pipelines exported the 184-N Building condenser receiver where it is re-circulated de-aerating heater for reuse. 109-N Building was equipped...
with a condensate diversion station controlling the levels in the de-aerated water storage tank.

A 10" condensate emergency drain could be used to release condensate from 109N to the 0.17 meters (66-in) raw water pipelines downstream of the Sealwell.

Waste Type: Misc. Trash and Debris
Waste Description: The waste is the pipeline (if present), scale, sediment, or liquid present within the pipelines, and the underlying soil.

Closure Info: Confirmatory sampling was conducted in June and July 2011. No elevated radionuclides or industrial hygiene readings were detected at any of the eight test pits. Therefore, volatile organic analysis, gamma energy analysis, and gross alpha and gross beta analyses were not performed for any of the confirmatory samples.

Three french drains (formerly part of the 100-N-103:1) were added to the 100-N-84:4 subsite because they were within the planned layback of the 100-N-84:4 pipeline remediation. French drain 9 was removed during demolition activities performed in 2009. French drains 10 and 11 were removed and disposed with the remediation of the 100-N-84:4 pipeline subsite. Several segments of the 100-N-84:4 pipeline subsite were removed with previous waste site remediations. These segments were evaluated in the RSVP-2011-118 document.

The remediation of the 100-N-84:4 subsite was performed from December 2, 2013, through February 24, 2014. The depth of the remediation ranged from approximately 1.5 to 5 meters (4.9 to 16.4 ft) below ground surface, resulting in approximately 4,100 bank cubic meters (5,363 bank cubic yards) of soil and pipeline debris being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). All waste material was loaded directly from the excavation into ERDF containers for disposal. No waste staging pile or overburden areas were created for the 100-N-84:4 subsite. Several in-process soil samples were collected from the 100-N-84:4 pipeline subsite during and at the completion of site remediation.

The SubSite is Part Of:
Code: 100-N-84
Names: 100-N-84; 100-N Miscellaneous Pipelines

Description: The subsite has been remediated and Interim Closed Out. It included the 100-N Area sanitary pipelines that includes sanitary water, sewer, storm drains, and drain field pipelines. These pipelines included a variety of diameters of pipe ranging from 0.75 in. to 20 in. and were composed of cast iron, concrete, vitrified clay, or steel.

Location: The 100-N-84:5 pipelines are located throughout the 100-N Area's 100-NR-1 operable unit.

Process Description: The 100-N Area was serviced by ten separate sewer systems consisting of one cesspool, one lagoon, one septic tank with an associated tile field, two septic tanks with seepage pits, and five septic tanks associated with drain fields. The septic tanks, pits, cesspools and lagoon are identified as the 124-N-1 through 124-N-10 waste sites. Waste sites 124-N-5, 124-N-6, 124-N-7, 124-N-8 have been reclassified as "rejected". The feed and drainage pipelines associated with these waste sites are included in 100-N-84:5.

Waste Type: Oil
Waste Description: The waste is the pipeline (if present), scale, sediment, or liquid present within the pipelines, and the underlying soil.

Closure Info: Portions of the 100-N-84:5 subsite were removed by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project in support of the demolition and removal of the 100-N river structures. Installation of a haul road was necessary to gain access to the structures. Therefore, segments of the 100-N-84:5 pipelines that were located within the roadway boundary were removed and disposed. The segments of pipeline associated with the Bonneville Power Administration (BPA) substation are active and expected to remain active for many years. These segments of pipeline were removed from the 100-N-84:5 subsite description. They will be dispositioned with the BPA substation at a future time.

The Field Remediation Closure Project continued the remediation of the 100-N-84:5 subsite from July 8, 2013, through February 28, 2014. The depth of the remediation ranged from approximately 1.5 to 4 meters (4.9 to 13 ft) below ground surface. Approximately 13,534 bank cubic meters (17,702 bank cubic yards) of soil and pipeline debris being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Some waste material was staged prior for loadout and disposal. A waste staging pile area (SPA) was generated. No overburden material was stockpiled for use as clean backfill. Two segments of the 100-N-84:8 subsite (segments 8 and 12) were located within the 100-N-84:5 subsite excavation. Both segments were removed and disposed at ERDF. Two pneumatic cylinders were found during the waste site remediation. These items were not considered anomalies and were disposed at ERDF. No anomalous material or stained soil was observed during the remediation.

Several segments of the 100-N-84:5 pipelines were approved to be left in place. These pipeline segments were not remediated and subsequently were not included in the verification sample design. Several in-process soil samples were collected from the 100-N-84:5 pipeline subsite during and at the completion of site remediation.

The SubSite is Part Of:

<td>Description</td>
<td>The subsite has been remediated and Interim Closed Out. It included the 100-N Area Chemical and Process Sewer Pipelines. The lines carried chemical waste, a dummy disposal line and a radioactive drain line. The 100-N-103:1 French Drain 1 is also addressed with the pipelines in 100-N-84:6. The pipelines associated with the 100-N-23 resin pit are part of the 100-N-84:6 subsite.</td>
</tr>
<tr>
<td>Location</td>
<td>The 100-N-84:6 waste site pipelines were centrally located between the 100-N Area process buildings (105-N, 109-N, 182-N, 183-N, 184-N, and 163-N).</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>Only one pipeline was visually observed at 100-N-23 during site walkdowns done in 2011. Some of the 100-N-84:6 pipelines are associated with 100-N-61:4.</td>
</tr>
<tr>
<td>Process Description</td>
<td>The 100-N-84:6 pipelines originate from the 109-N Heat Exchanger Building, the 105-N Reactor Building, the 163-N Demineralization Plant, 182-N High-Lift Pump House, 183-N Filter Plant, and 184-N Power House. Various chemicals were utilized in these buildings.</td>

Hanford Site Waste Management Units Report
February 2015
Phosphoric, ascorbic and citric acids, and potassium permanganate were used in the 109-N and 105-N Buildings decontamination processes (WHC-SP-0460). Ammonium hydroxide, morpholine and lithium hydroxide were added to control cooling water pH. Hydrazine was added to reduce oxygen concentrations in cooling water (WHC-SP-0460). The addition of these chemicals and the core's cooling water system design allowed the water to recycled instead of using raw water as a once through coolant (DOE/RL-90-22).

Sulfuric acid and sodium hydroxide from supply tanks in 163-N Building were primarily consumed in the demineralizer plant. A 93% sulfuric acid solution was used to regenerate the cation resin used at the 163-N Building while a 50% sodium hydroxide solution was use to regenerate the anion resin. The 8-inch acid drain from 163-N connected into the 100-N river channel discharge line to the Columbia River. Sodium sulfite was used as a deoxygenizing chemical for low pressure filter water (182-N). Sodium dichromate was added to filtered water supply and raw water supply for cooling coils in the 105-N Reactor Building.

Radioactive drains at 109-N collect from the coolant systems, hot water quality laboratory, service bay hot shop. The 105-N and 109-N drains run to the 1301-N Liquid Waste Disposal Crib. 100-N-84:6 pipelines located between the 109-N, 182-N, 163-N and the 183-N Buildings lay within the 100-N-61 water treatment pipeline removal excavation footprint (H-1-89932). This area was excavated and backfilled in 2008 through 2009. A small portion of the 100-N-84:6 pipelines also lay within the adjacent 100-N-64 planned excavation (H-1-89934).

Waste Type: Construction Debris
Waste Description: The waste is the pipeline (if present),scale, sediment, or liquid present within the pipelines, and the underlying soil.
Closure Info: Portions of the 100-N-84:6 subsite were removed by the Deactivation, Decontamination, Decommissioning, and Demolition Project (D4) in support of the removal of the 100-N river structures. Installation of a haul road was necessary to gain access to the structures. Segments of the 100-N-84:6 pipeline that were located within the roadway boundary were removed and disposed. A verification soil sample (J1J4H9) and a duplicate sample (J1J4J0) were collected per an approved sampling agreement with the Washington State Department of Ecology (Ecology) and the excavation was backfilled. Several segments of the 100-N-84:6 pipeline subsite were removed with previous waste site remediations. Two segments of the 100-N-84:6 pipelines were approved to be left in place per an agreement with Ecology. Segment 16 of the 100-N-84:8 pipeline subsite was removed and disposed with the 100-N-84:6 remediation.

French drain 1 (formerly part of the 100-N-103:1), was removed during the demolition of the 108-N Building. The french drain was added to the 100-N-84:6 pipeline subsite because it was within the planned excavation footprint of the 100-N-84:6 pipeline remediation.

Remediation of the 100-N-84:6 subsite continued from April 10, 2013 through March 4, 2014. The depth of the remediation ranged from approximately 1.0 to 2.0 meters (3.3 to 6.7 ft) below ground surface, resulting in approximately 3,447 bank cubic meters (4,509 bank cubic yards) of soil and pipeline debris being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). The pipeline debris includes steel pipe, concrete, rebar, wood, Gilsulate bedding material, asphalt, wire, and asbestos. Figure 4 shows the 100-N-84:6 pipeline remediation where it intersects with the UPR-100-N-31 waste site. There were no overburden soil stockpiles or waste staging pile areas associated with the 100-N-84:6 subsite.

Two empty, smashed, and rusted drums and a section of irrigation pipeline covered in friable asbestos insulation were encountered during the remediation. These items were not considered anomalies and were disposed of at ERDF. No anomalous material or stained soil was observed during the remediation.
The SubSite is Part Of:
Code: 100-N-84
Names: 100-N-84; 100-N Miscellaneous Pipelines

Code: 100-N-84:7
Names: 100-N-84:7; 100-N Area unidentified and Other Miscellaneous Pipelines
Type: Radioactive Process Sewer
Status: Inactive
Classification: Accepted
Reclassification: Interim No Action (5/16/2012)
Start Date: Interim No Action (5/16/2012)
End Date: Interim No Action (5/16/2012)

Description: This subsite has been evaluated and reclassified to No Action. The 100-N-84:7 waste site pipelines include sections of various diameter pipelines located within the 100-NR-1 operable unit in and around the 105-N Reactor Building. These sections described as unidentified or multitube could not be positively identified based on review of historical documentation. The pipelines described as multitube are lateral airlines that extend from the 184-N Building to pressure reducing stations. They supplied dry, oil-free, compressed air to the control and instrumentation systems for the water pretreatment plant and the demineralization plant as part of the instrument control air system.

An above ground feature, labeled N-213, was observed during the 100-N Orphan Site Evaluation (OSR-2009-0001). Since it was co-located with the 100-N-84 pipelines, it was decided to incorporate this feature into this subsite.

Location: The 100-N-84:7 pipelines are located throughout the 100-N Area's 100-NR-1 operable in and around the 105-N Reactor Building.

Waste Type: Barrels/Drums/Buckets/Cans
Waste Description: The waste is the pipeline (if present), scale, sediment, or liquid present within the pipelines, and the underlying soil.

Closure Info: Confirmatory sampling was performed in fifteen test pits, between June 27 and July 2, 2011. Suspect asbestos material was found in Test Pit 3. Diesel fumes were noted in Test Pit 5. No samples were collected from Test Pits 2, 4, 7, 8, 10, 11, 12, 13, 14 or 15.

Subsequent to the sample design preparation, additional information regarding the process history of the multitubes that make up a portion of the 100-N-84:7 subsite test pits was obtained. The multitubes are part of an instrument CAS designed to supply dry, oil-free compressed air to the control and instrumentation systems for the water pretreatment plant and the demineralization plant. Therefore, the multitube test pit locations were removed from the confirmatory sampling activities because they were not considered dangerous or hazardous waste. These test pits included 6, 11, 12, 13, and 15.

The 100-N-84:7 pipelines are located throughout the 100-N Area. Due to changing conditions from ongoing other remediation and facilities demolition activities, some pipeline segments were identified to be removed from this scope and combined with other waste sites scheduled for remove, treat, and dispose (RTD) actions. Therefore, test pits include 4, 7, 8, and 14 were excluded.

The pipeline segment at Test Pit 7 was inaccessible for confirmatory sampling due to field activities, and was subsequently removed with the 117-N building.

The pipeline segments at Test Pit 4 and Test Pit 8 will be removed with the remediation of the 100-N-84:5 pipeline waste site.
The pipe at the Test Pit 5 location was uncovered at a depth of approximately 1.2 meters (4 ft). Diesel fumes were noted when the pipe was cut. However, there was nothing inside the pipe to sample. A soil sample (JIJDF9) was collected at a depth of approximately 1.5 meters (5 ft) and analyzed for ICP metals, mercury, hexavalent chromium, SVOCs, polycyclic aromatic hydrocarbons, total petroleum hydrocarbons (TPHs), PCBs, pesticides, volatile organic compounds, gross alpha, gross beta, and by gamma energy analysis. The sample results exceeded direct exposure soil cleanup levels for benzo(a)pyrene. In addition, the groundwater and river protection RAGs were exceeded for benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, and chrysene. The pipe within Test Pit 5 is in the vicinity of the 100-N-84:2 pipeline subsite, which is scheduled for RTD. The pipeline segment from Test Pit 5 will be removed and documented with the 100-N-84:2 pipeline. The Test Pit 14 location will also be included with the 100-N-84:2 pipeline waste site.

The analytical results indicate that the residual concentrations of contaminants considered at the test pits meet the RAOs for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the confirmatory sampling results support a reclassification of the 100-N-84:7 subsite to No Action.
throughout the area north and east of the 105-N Reactor Building. On historical drawings, these pipeline segments are labeled as "Unidentified" or had no labeling. Eleven of the 17 pipeline segments are located within completed or planned excavations. The remaining pipeline segments are associated with systems that serviced administrative offices or buildings that did not store or generate any hazardous or radioactive substances. Based on the review of historical drawings, process knowledge of adjacent waste sites and buildings, and the general location of these segments, it was concluded that contamination would not exist within these pipeline segments. Therefore, the remaining 100-N-84:8 subsite pipeline segments (6, 7, 9, 10, 11, and 13) are being left in place with No Action required.

It was determined that confirmatory sampling test pit excavations of the short sections of pipelines would result in the majority of the length of the pipeline segments being excavated. Therefore, the 100-N-84:8 subsite was recommended for remove, treat, and dispose without confirmatory sampling evaluation. However, because most of the pipeline segments are being removed with other excavations and it was concluded that contamination would not exist within the remaining pipeline segments, no action is required.

Pipe Segments that were removed with other waste site excavations include segments 1,2,3,4,5,8,12,14,15,16 and 17.

Pipe Segments 6, 7, 9, 10, 11 and 13 were left in place with No Action required.

**The SubSite is Part Of:**

**Code:** 100-N-84  
**Names:** 100-N-84; 100-N 100-N Miscellaneous Pipelines

**Description:** The subsite has been evaluated and determined to require No Action. The 100-N Area active raw water pipelines range in size from 6 to 12 inches in diameter and are used for fire protection. The 100-N export water line (12 inch) is fed from the main 42 inch raw water export line located between 100-B and 100-D Areas. Smaller pipeline segments connect this line to various fire hydrants located in the 100-N industrial area.

**Location:** The 100-N-84:9 pipelines are located east of the 105-N Building.

**Process Description:** Raw water was pumped from the Columbia River and supplied to the fire protection pipelines.

**Waste Type:** Stormwater Runoff

**Waste Description:** The waste is the pipeline (if present), scale, sediment, or liquid present within the pipelines, and the underlying soil.

**Closure Info:** Confirmatory samples were collected from test pits at nine locations on the 100-N-84:1 subsite between March 8 and July 19, 2012 to support an evaluation to determine if residual contaminant concentrations in the soil meet cleanup criteria. The 100-N-84:9 pipelines are still active while the 100-N-84:1 pipelines have been taken out of service and/or removed. Both subsite pipelines carried the same type of raw water. Therefore the confirmatory sampling conducted at the inactive 100-N-84:1 has been used to evaluate and support the 100-N-84:9
The SubSite is Part Of:
Code: 100-N-84
Names: 100-N-84; 100-N 100-N Miscellaneous Pipelines

Code: 100-N-84:10
Names: 100-N-84:10; Miscellaneous Pipelines within the Bioventing Well Island
Type: Radioactive Process Sewer
Status: Inactive
Description: Subsite 10 was consolidated into the 100-N-107 waste site. It is the miscellaneous pipelines located in the Bioventing Wells island.

This Site Was Consolidated With:
Code: 100-N-107
Names: 100-N-107; Bioventing Well Islands; Soil Contamination Adjacent to Bioventing Wells

The SubSite is Part Of:
Code: 100-N-85
Names: 100-N-85; 100-N 100-N Miscellaneous Pipelines

This site consisted of a self-service gasoline station with two fuel pumps, a meter card station, an above ground tank, two underground tanks, and a compressor house. The waste site consists of soil contaminated with gasoline and diesel which remained after the removal of two underground fuel storage tanks located at the former 1716-NA Service Station.

Location: The tanks were located approximately 31.2 m (102.4 ft) northwest of 1100-N (H-1-45007, sheet 42).

Process Description: A self-service gasoline station (1716-NA) was established about 1972 to provide fuel for plant vehicles (1716NA). The original tank (100-N-SS-27) reportedly was installed in 1967 (WCH 147703 and WHC-SD-L044-CDR-001, Rev. 0). If the tank was originally installed in 1967 then it may have been located at the 1716-NE Garage Facility. This facility included a Gas Attendant's Building and gasoline pumps according to the official Hanford Atomic Product Operation Buildings List (HW-5000 7/25/1967). The same facility does not list the Gas Attendant's Building following the establishment of 1716-NA. Presumably the Gas Attendant's Building and gasoline pumps were relocated to the self service gasoline station at that time. The 1716-NE Garage Facility had a waste site (100-N-52) associated with a gasoline storage tank. A second gasoline tank (100N-SS-28) was installed at 1716-NA about 1976 (H-1-15635). Tank 100-N-SS-27 was an 11,356 L (3000 gal), single wall, 0.48 cm (3/16 in) carbon steel tank with asphalt coating, buried approximately 1.8 m (6 ft) below grade. The tank was used for regular leaded gasoline storage until 1987 when it began storing unleaded gasoline. The tank was removed from service in June 1990 when it failed a tightness test and a leak was found near the top of the tank. It was subsequently removed from the ground on December 18, 1990, and
confirmed to be a release site. The underlying soil was sampled on the same day, and field screening with an organic vapor monitor revealed 200-350 ppm concentration of organic vapor. Approximately 7.6 m (25 ft) of supply pipeline was also removed (WHC-SD-EN-TI-136). Tank 100-N-SS-28 was a 7571 L (2000 gal), single wall, 0.48 cm (3/16 in) carbon steel tank, buried 1 m (3 ft) below grade (H-1-15635). The tank was originally used for diesel fuel storage and later converted to gasoline. It was removed from the ground on July 17, 1991 (WHC-SD-EN-TI-136). Contamination was believed to be the result of occasionally overfilling these tanks, a loose pipe connection on the delivery line leading from the tank to the pump island, as well as a reported release of 337 L (89 gal) on January 18, 1988 (WHC-SD-EN-TI-136, appendix C-1). The soil is contaminated to a depth of at least 11 m (36 ft) below grade, although the actual depth is not known (WHC-SD-EN-TI-136). The lateral extent of the contamination is not documented.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The waste is soil contaminated with gasoline and/or diesel fuel from underground storage tanks and associated piping. Soil samples obtained from beneath the tanks indicated toluene (4.7 mg/kg), diesel range organics (1,000 mg/kg) and kerosene range organics (3,085 mg/kg) contamination (WHC-SD-EN-TI-136, Table 2).

---

**Code:** 100-N-86

**Classification:** Accepted

**Names:** 100-N-86; 151-N Substation Transformer and Oil Circuit Breakers

**Reclassification:** Interim Closed Out (3/4/2014)

**Type:** Electrical Substation

**Start Date:**

**Status:** Inactive

**End Date:**

**Description:** The site has been remediated and Interim Closed Out. It consisted of concrete support pedestals for a 230-13.8 kv transformer, the concrete pad for three oil circuit breakers (OCBs) and any underlying contaminated soils. The 151-N Substation contained various electrical equipment and a control building surrounded by a fence.

**Location:**

The 230 to 13.8 kv transformer and OCBs were located south of Trinity Drive and east of Timber Road. The OCBs were 265 meters (870 ft) southeast of the 105-N Reactor and the transformer was located 225 meters (738 ft) southeast of the 105-N Reactor. The oil Circuit Breakers were centered at coordinates E571374.21 N149310.86. The transformer was centered at coordinates E571328.21 N149328.45.

**Related Sites/Structures:** 151-N Substation

**Process Description:**

The 151-N Substation was the primary source for "off-site" electrical power for the 100-N Area. The substation was fed by Bonneville Power Administration Midway Switching Station. The 230 kv electrical feed passed through a bank of OCBs to the 230-13.8 kv main power transformer. The 13.8 kv lines went from the low side terminals of the transformer to the 151-N Building. There were three OCBs, one for each phase of electric power.

Construction of the 151-N Substation was completed in November 1961 (HW-83918). The substation continued to serve the 100-N area until it was decommissioned in 1998. The transformer and OCBs were isolated in March 1998. Based on aerial photographs, they were removed between November 2001 and May 2002. The transformer pedestals and OCB pad remained in place. The control building and 13.8-4.16 kv transformer were demolished and removed by the D4 Project in 2006 (D4-100N-0002). The excavation extended to the south pedestal for the 230 kv transformer.
Analogous sites at other reactor operational areas have had releases of polychlorinated biphenyls (PCBs) and petroleum hydrocarbons to the underlying soil, due to routine maintenance and accidental releases during their operations.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The waste is potentially contaminated concrete and underlying soils.

**Closure Info:** The transformers and oil circuit breakers were isolated in March 1998 and were removed between November 2001 and May 2002. The transformer pedestal and oil circuit breakers pad remained in place. Between December 2005 and March 2006, portions of the concrete support pedestals were removed by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) project during the demolition of the 151-N Building.

In April 2012, while removing the 151-N Building slab and foundation, D4 also removed the transformer support pedestals that were adjacent to and north of the former 151-N Building. The pedestals were removed to 1 meter (3 ft) bgs. A radiological survey was conducted in May 2012. No gamma-emitting radiological contamination above background was detected. The Field Remediation project resumed remedial action on May 14, 2013 and continued through June 6, 2013. In-process soil samples collected in the west excavation detected polycyclic aromatic hydrocarbons (PAH) above RAGs. Therefore remediation continued on the southern slope of the westernmost excavation on July 29 and 30, 2013. Additional in-process samples were collected following the completion of field remediation.

The excavation extended to approximately 1.5 to 3 meters (4.9 to 9.8 ft) bgs, resulting in approximately 725 bank cubic meters (948 bank cubic yards) of soil and debris being disposed at the Environmental Restoration Disposal Facility (ERDF). No anomalous material or soil staining was encountered during the waste site remediation. The railroad tracks and treated railroad ties that were located adjacent to the 100-N-86 waste site excavation have been removed as miscellaneous restoration items.

---

**Code:** 100-N-87  
**Classification:** Accepted

**Names:** 100-N-87, 116-N Ventilation Stack Piping and French Drain  
**Reclassification:** Interim Closed Out (7/2/2013)

**Type:** French Drain  
**Start Date:** 1/1/1961

**Status:** Inactive  
**End Date:** 1/1/1991

**Description:** The site has been remediated and Interim Closed Out. It consisted of the stack drain piping and french drain for the 116-N ventilation Stack.

**Location:** The 116-N Exhaust Stack was located approximately 95 meters (312 ft) north of the 105-N Reactor Building. The french drain was located approximately 13 meters (43 ft) east of 116-N.

**Related Sites/Structures:** 105-N Reactor Building, 117-N Filter Building

**Process Description:** The 116-N Exhaust Stack was constructed in 1961 and was in use until the N-Reactor was ordered permanently shut down in 1991. The stack was designed to control worker exposure to airborne radioactive contaminants from the reactor by discharging them high into the atmosphere. Air from all five ventilation confinement zones in the 105-N Reactor Building was routed through moisture separators, high efficiency particulate filters, and charcoal absorbers in the 117-N Filter Building to remove airborne contamination. The filtered air was discharged to the stack. Moisture and other condensates in the filtered air stream would plate out on the inside of the stack. The stack foundation contained a floor drain that discharged the condensate to a
French drain through a 5.08 centimeter (2 in) galvanized iron pipe.

**Waste Type:** Chemical Release

**Waste Description:** The waste consists of the drain piping, french drains and underlying gravel and soil.

**Closure Info:** Remedial action at the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 waste sites was performed during January and February 2011. Remediation involved removal of the foundations of the 116-N stack, the 119-N and 119-NA structures, and the underlying soil. Excavation continued until the french drain, associated piping, and contaminated soil and debris were removed. This excavation exceeded the depth that would be required to remove the 100-N-102:1, UPR-100-N-9, and UPR-100-N-14 waste sites. According to drawing H-1-46389, the depth of the 100-N-102:1 subsite, and therefore the unplanned release waste sites UPR-100-N-9 and UPR-100-N-14, was at 0.76 meters (2.5 ft) bgs. The final excavation depth was approximately 8.5 meters (28 ft) bgs. Because the excavation and removal of the 116-N stack foundation was previously performed by the D4 Project, the exact volume of material removed is unknown.

The debris removed included soil, concrete, piping, and other debris associated with the 116-N, 119-N, and 119-NA structures and french drain. All material from these waste sites was disposed at the Environmental Restoration Disposal Facility (ERDF). No anomalous material was encountered during the excavation.

In March 2012, the D4 Project constructed a ramp across the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 excavation to provide access and to support remediation activities at 1303-N (118-N-1) waste site. The ramp material was excavated on September 28, 2012, and also disposed of at ERDF. A walk around the site boundary confirmed that all fill material used to build the ramp had been removed. After the excavation of the ramp material, a gamma survey was performed on October 3, 2012, within the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 excavation. The gamma survey results indicated readings above background at two locations. Additional remediation was performed to address areas where the GPERS survey results indicated elevated radiological results. Follow up surveys on October 17, 2012 and October 19, 2012 indicated no elevated readings above background.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

**Code:** 100-N-88  
**Classification:** Accepted

**Names:** 100-N-88; 1143-N French Drain  
**Reclassification:** Interim Closed Out (7/2/2013)

**Type:** French Drain  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site has been remediated and Interim Closed Out. It was a 0.61 meter (24 in) catch basin (french drain), associated 5.1 centimeter (2 in) diameter drain pipeline and the underlying soil. A sink inside the 1143-N Paint Shop discharged to this site. The potential existed for the french drain to receive paint solvents and other hazardous liquids from the activities within the building. The sink was removed about 1997, and discharges to this site ceased.

**Location:** The 1143-N Carpenter/Paint Shop was approximately 360 meters (1181 ft) southwest of the 105-N Reactor building. The french drain was located approximately 3.5 meters (11.5 ft) southwest of the 1143-N Carpenter/Paint Shop.

**Related Sites/Structures:** 1143-N Carpenter/Paint Shop
The south half of 1143-N Building was used as a paint shop after the building was built in the early 1980's until the mid-1990's, when it was converted to a heavy equipment mechanics shop. The french drain received wastewater from a sink located in the south half of the shop from the early 1980's until 1997.

Waste Type: Barrels/Drums/Buckets/Cans
Waste Description: Soil within and beneath the french drain and associated pipeline, potentially wetted with hazardous solvents and lead-based paints. COPCs consist of paint solvents and lead-based paints.

Closure Info: Remedial action at the 100-N-88 waste site was performed on February 28, 2012, as a part of the 1143-N Building remediation through the D4 Project. The excavation for the 100-N-88 waste site continued to an approximate depth of 1.3 meters (4.3 ft) over an area of 30.6 square meters (329.4 sq. ft.). All material (soil, concrete, gravel, and steel pipe) was directly loaded from the excavation into Environmental Restoration Disposal Facility (ERDF) containers for disposal at ERDF. There are no overburden piles or waste staging pile areas associated with the 100-N-88 waste site. No anomalous materials were encountered during the excavation.

Code: 100-N-89
Names: 100-N-89; 117-NVH French Drain
Type: French Drain
Status: Inactive
Description: The french drain has been remediated and Interim Closed Out. It was a 61 cm (24 in) concrete pipe buried to a depth of 91 cm (36 in). The top of the pipe was at grade and it was filled with gravel. An additional 46 cm (18 in) of gravel was beneath the pipe. A metal plate covered the pipe (H-1-50093).
Location: The French drain was located on the west side and adjacent to the 117-NVH Valve House. It was approximately 112 meters (367 ft) north of the 105-N Reactor. It was within the excavation footprint when the 100-N-63 pipelines are remediated.
Related Sites/Structures: Two 100-N-63, 100-N Reactor Underground Pipelines were located west of the French drain. A 91 cm (36 in) contaminated drain (CD) line was about 2 meter (6.5 ft) west and a 30.5 cm (12 in) radioactive drain (RDR) line was about 2.6 m (8.5 ft) to the west (H-1-45007, sheet 44).
 heeft Structures associated with the French drain included 117-N Filter House and the 117-NVH Valve House. A 25.4 cm (10 in) nitrogen inerting system (NIS) pipe, associated with the construction of the post-Chernobyl upgrades to N Reactor, was buried to the west of the French drain (H-1-50223).
Process Description: The french drain received discharge from back flushing an in-line screen on the 10 cm (4 in) raw water supply line in the 117-NVH Valve House (H-1-50092). The discharge to the french drain was an above-grade 3.8 cm (1.5 in.) high-pressure raw water supply pipeline from the 10 cm (4 inch) raw water supply back flush pipeline.
Waste Type: Sanitary Sewage
Waste Description: The waste includes the concrete pipe and gravel (french drain) and underlying soils if determined to be contaminated. The french drain reportedly received raw water back flushed from an inline screen on the raw water supply. There are no contaminants of potential concern associated with raw water.
Closure Info: The 100-N-89 french drain was removed by the Decontamination, Decommissioning,
Deactivation, and Demolition (D4) Project during removal of the 117-NVH Valve Control House Building in April 2011. The waste was disposed at the Environmental Restoration Disposal Facility (ERDF). Radiological surveys were performed at an area north of the 118-N-1 spacer silo waste site to support evaluation of remediation of the nearby 100-N-63:2 pipelines detected radiological contamination associated with the 100-N-63:2 waste site that included identification of radiological contamination at the 100-N-89 waste site location. As a result, additional soil remediation was performed between May 22 and 30, 2013, to remove this residual radiological contamination. Approximately 1,448 bank cubic meters (1,894 bank cubic yards) of contaminated soil was removed during the subsequent 100-N-63:2 soil remediation. Additional soil was removed from below the former 100-N-89 french drain and 117-NVH Building locations during subsequent remediation of the 117-N Air Filter House. This additional soil removal was completed in September 2011. The excavation depth below the french drain was approximately 4.5 meters (14.8 ft) below surface grade. All material was disposed at ERDF.

The final excavation depth at the former location of the 100-N-89 french drain is approximately 5.5 meters (18.0 ft) below surface grade. The base of the french drain was approximately 1.4 m (4.5 ft) below surface grade. No anomalies were encountered or observed during the excavation.

<tr>
<td>Closure Info:</td>
<td>The 100-N-90 Rod Caves were completely removed by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project in March 2011 as part of removal of the 117-N Exhaust Air Filter House and the 117-NVH Valve Control House. Two post-demolition Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in October 2011. Radiological contamination was identified within the 117-NVH facility footprint and the</td>
</tr>
</tbody>
</table>
northern portion of the 117-N facility footprint. Therefore, the facility footprints were then excavated to a deeper extent and the previously contaminated portions of these footprints were resurveyed in December 2012. The soil below the 100-N-90 waste site was excavated to a depth of approximately 7 meters (23 ft) below surface grade as part of the 117-N and 117-NVH facility removal. Radiological surveys for beta and gamma contamination did not identify radiological contamination below the 100-N-90 waste site. Therefore, no verification samples were required and the 100-N-90 waste is reclassified as Interim Closed Out.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

<tr>
<td>Closure Info: The 100-N-91 waste site was remediated by hand digging on November 12, 2013, based on the recommendation of the remove, treat, and dispose report. Less than 1 bank cubic meters (1.3 bank cubic yards) of soil was collected in plastic bags for disposal at the Environmental Restoration Disposal Facility. There was no staging pile area or overburden soil stockpile associated with the 100-N-91 waste site excavation. Debris consisting of small dry-cell batteries and pieces of batteries was excavated by hand digging at the 100-N-91 waste site. No other anomalous material or staining was encountered during excavation. The final depth of the 100-N-91 waste site excavation is approximately 0.5 meter (1.5 ft). Following remediation, a boundary walk-around survey of the 100-N-91 waste site excavation was not performed due to the very small size of the hand-dug excavation. The post-excavation footprint was a small, circular hole of approximately 0.9 meter (3 ft) in diameter resulting in an excavated waste site area of less than 1 square meter (10.8 sq. ft.).</td>

<td>Names: 100-N-92; 100-N Stain Area #1</td>
<td>Reclassification: Interim No Action (4/5/2012)</td>
</tr>
<tr>
<td>Type: Dumping Area</td>
<td>Start Date:</td>
</tr>
</tbody>
</table>
This site was determined to be a No Action site. The site consisted of a 3 meter (10 feet) diameter area stained with a white substance resembling dried paint and two 4 liter (1 gallon) cans. Confirmatory sampling of the 100-N-92 waste site was performed on January 26, 2011. The results indicated that the waste site achieved compliance with the remedial action objectives (RAOs) and remedial action goals (RAGs) for the 100-N-92 waste site. Therefore, remediation was not necessary.

This feature is located approximately 1200 meters southeast of the 105-N Reactor building and 123 meters southwest of 100-N-47 (Military Artillery Site Solid Waste Site). The coordinates for the area are E571851 N148367.

The waste site may be associated with the 100-N Military Artillery Site Solid Waste Site (sitecode 100-N-47).

Site COPCs consist of volatile organic compounds and lead. The waste consists of the stained soil and debris.

Three soil samples (one beneath each paint can and one beneath the white substance and one duplicate) were collected from the surface of the 100-N-92 waste site. In addition, a solid sample of the white substance shown was also collected. No additional debris was observed during sampling, other than the paint cans and the black wire noted on May 19, 2010. No sign of oil staining was noted, so total petroleum hydrocarbons (TPH) and polycyclic aromatic hydrocarbons (PAH) analyses were not performed. No radiological activity was detected at this waste site; therefore, radionuclide analysis of the samples was not performed. Based on confirmatory sampling results at the 100-N-92 waste site, remedial action was determined to be unnecessary. The confirmatory sampling data has been used to document this waste site to be reclassified as a No Action site.

The waste site was remediated and Interim Closed Out. The site consisted of potentially contaminated soil. It also included concrete, metal, glass debris, stained soil, suspected friable asbestos, and garnet sand with areas lacking in vegetation.

The stain was associated with the 100-N-19 borrow pit.

The 100-N-19 pit used for disposal of nonhazardous debris from the 100-N Area and the Hanford Generating Plant (HGP).
Closure Info: Remedial action at the 100-N-93 waste site was performed between March 26, 2013, and March 21, 2014. The depth of the remediation ranged from 4.6 to 6.1 meters (15 to 20 ft) below ground surface resulting in approximately 35,551 bank cubic meters (46,499 bank cubic yards) of soil and debris being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). The debris consisted of lead-acid batteries, asbestos, miscellaneous steel, burnt wood, glass, concrete, empty steel drums, wire, garnet sand, and communications cable. All waste material was loaded directly from the waste site into the ERDF disposal containers. No waste staging pile area or overburden soil stockpiles were created. No anomalous materials were encountered during the remediation.

<td>This septic system was located approximately 4 meters from the NE corner of the Hanford Generating Plant (HGP) tile field (100-N-4).</td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The septic tank is associated with 100-N-4 (HGP tile field also called SWMU #5).</td>
<td></td>
</tr>
</tbody>
</table>
Process Description: The septic tank supplied influent to 100-N-4 (Hanford Generating Plant (HGP) tile field). The tank received sanitary waste and lab waste influent from the 185-N building via a 20 cm (8 in) cast iron pipe (H-6-4025 sht. 1 rev. 1). The tank did not receive effluent from the 185-N building drains and sumps, which are identified as SWMU # 3 (per document HGP-CVP-SWMUs 5, 6, 7, 8, 9 & 10 Rev. 0, June 2004). Testing for corrosion inhibitors hydrazine and morpholine were performed in the 185-N lab. It is likely that the tank received these reagents (see sitecode 100-N-4).

Closure Info: Remedial action at the 100-N-95 waste site was performed between April 29 and June 11, 2013, and continued to a maximum depth of approximately 4.0 meters (13.1 ft) below ground surface resulting in the removal of approximately 1,385 bank cubic meters (BCM) (1,812 bank cubic yards [BCY]) of contaminated soil, cast iron pipe, lead bells, and rebar. All material was direct loaded from the excavation for disposal at the Environmental Restoration Disposal Facility (ERDF). No anomalous material was encountered during the excavation. The maximum excavation depth was 4 meters (13 ft). In-process soil samples were collected from the 100-N-95 waste site between April and June 2013.

<td>Process Description:</td>
<td>The &quot;Army Agreement&quot; of 1951 provided for the disposal of refuse by the Army as follows: &quot;Army will dispose of its trash and garbage in a manner acceptable to the Atomic Energy Commission (AEC). The Army may make disposal pits off Army land, as necessary, at locations designated by AEC and such pits shall be subject to AEC inspection.&quot; (CCN# 589754). The 1957 aerial photo of the military site shows disturbances to the southwest of the military camp outside what appears to be the perimeter fence. These disturbances are suspect disposal pits. The military camp was in use by the Army from 1951 to 1958. In 2008 aerial photos (115-rgb.tif and 116-rgb.tif) heavy equipment blade marks are visible which indicate the disposal pits have been backfilled.</td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Equipment</td>
</tr>
<tr>
<td>Waste Description:</td>
<td>The waste consists of solid waste generated by the military camp. Site COPCs were listed as volatile organics, semivolatile organics, polychlorinated biphenyls and metals.</td>
</tr>
</tbody>
</table>
The waste site has been remediated and Interim Closed Out. It consisted of underlying soil and 3 oil filters. There was no vegetation growing within the release area.

This feature was located approximately 56 meters (184 ft) west of the southwest corner of the 100-D Area perimeter, near Pumphouse Road.

Equipment

The waste includes discarded oil filters and potentially contaminated soil. Site COPCs consist of metals, polyaromatic hydrocarbons, total petroleum hydrocarbons, and polychlorinated biphenyls.

A characterization sample was collected on April 22, 2013, prior to the start of remediation. Waste site remediation began on November 12, 2013, and continued through January 8, 2014. Because the waste site was located in a culturally sensitive area, it was remediated by hand digging. The material was placed into plastic bags for disposal. The plastic bags were hand carried to the nearest access road to be disposed in an Environmental Restoration Disposal Facility (ERDF) container.

The remediation extended approximately 0.61 meters (2 ft) below ground surface, resulting in approximately 1.3 bank cubic meters (1.7 bank cubic yards) of soil and debris being removed and disposed at ERDF. No anomalous material was encountered during the remediation of the site. All visibly stained soil was removed.

Two in-process soil samples were collected on November 13, 2013, and analyzed for the site COPCs to determine if remedial action activities were complete and if the site was ready for verification sampling. Total petroleum hydrocarbons (TPH) exceeded the RAG in both samples collected; therefore, remediation continued to remove the residual contaminated soil.

On January 8, 2014, two additional in-process soil samples were collected from the same locations as the previous in-process samples to determine if the residual contaminated soil had been removed. The samples were analyzed for TPH only. The results indicated that the contaminated soil had been removed. Therefore, the remediation was determined to be complete on January 8, 2014.

The waste site has been remediated and Interim Closed Out. The site consisted of two locations where the surface was stained and no vegetation was growing in the affected area. One location (OSE -N-193) consisted of multiple stained spots in a 30 meter (98.4 feet) diameter area. The other location (OSE -N-194) was a single stained spot approximately 3 meter (9.8 feet) in diameter.

The larger stained area was located approximately 33 meters northwest of 128-N-1 (Burn Pit). The smaller stained area was located approximately 34 meters northeast of 128-N-1.

Misc. Trash and Debris

The waste consists of the stained soil.
**Closure Info:** Remediation of 100-N-6, 100-N-16, 100-N-98 area 1, and 128-N-1 waste sites began on August 2, 2010, and was completed on November 28, 2011. A total of approximately 20,334 bank cubic meters (BCM) (26,596 bank cubic yards [BCY]) were excavated and staged for removal to the Environmental Restoration Disposal Facility (ERDF). Between April 16 and 19, 2012, the excavation was expanded to the west to include stained soil Area 2 of the 100-N-98 waste site. Approximately 476 BCM (623 BCY) of soil was removed from 100-N-98 Area 2 and direct loaded for disposal at ERDF. The additional remediation of the spoil pile area (SPA) and the 100-N-6, 100-N-16, 100-N-98, and 128-N-1 waste site excavation generated an additional volume of 5,446 BCM (7,123 BCY) of material for direct load out to ERDF. A total volume of 26,256 BCM (34,342 BCY) was disposed at ERDF, to complete the 100-N-6, 100-N-16, 100-N-98, and 128-N-1 waste site remediation.

The materials removed from the 100-N-6, 100-N-16, 100-N-98, and 128-N-1 waste sites consisted of abandoned wiring, transite pipe, metallic and wood debris, burnt wood, ash, tar, roofing felt, stained soil, a bucket of grout, an open glass bottle, green fibrous material, purple sandy material, a paint ball, drums containing bunker and amber oil, and miscellaneous demolition debris. Anomalous material discovered during remediation included six 208-L (55-gal) drums, small white ceramic balls used as filtering media, and soil with a strong solvent odor.

### Reclassification: Interim Closed Out (6/12/2014)

#### Names:
| 100-N-100; 100-N Oil Filters #4 |

#### Type:
Unplanned Release

#### Status:
Inactive

#### Description:
This site was remediated and Interim Closed Out. It consisted of petroleum based material released to the ground surface and the underlying soils. The soil was crusted and no vegetation was growing in the affected area. There were 4 oil filters at this location.

#### Location:
The site was located approximately 190 meters west of the north side of 116-N-1 at coordinates N150010.8 E571544.1.

#### Waste Type:
Process Effluent

#### Waste Description:
The waste includes discarded oil filters and potentially contaminated soils. Site COPCs consists of metals, polyaromatic hydrocarbons, total petroleum hydrocarbons, and polychlorinated biphenyls.

#### Closure Info:
Remedial action of the 100-N-100 waste site was performed on November 13, 2013, and February 27, 2014. Due to cultural sensitivity of the area, the waste site was remediated by hand digging. The maximum depth of the excavation was 0.5 meters (1.5 ft) below ground surface and resulted in the removal of less than 1.0 bank cubic meters (1.3 bank cubic yards) of soil and debris. The debris consisted of oil filters in two distinct locations. The contaminated soil and debris were directly loaded into plastic bags and carried out for disposal at the Environmental Restoration Disposal Facility (ERDF). Oil-stained soil was observed during the excavation, and all oil-stained soil was removed and disposed at ERDF. No anomalous material was encountered during excavation.

The results of the initial verification sampling indicated exceedances of direct exposure RAGs for TPH. Therefore, additional remediation and sampling was conducted on February 27, 2014.

---

### Reclassification: Interim Closed Out (5/27/2014)

#### Code:
100-N-101

#### Names:
| 100-N-101; 100-N Stain Area #4 |

#### Type:
Unplanned Release

#### Status:
Inactive

#### Description:
The site has been remediated and Interim Closed Out. It consisted of an area of multiple stained soil spots with no growing vegetation. It was an area covering approximately 10 meters (33 ft) in diameter.

#### Location:
The waste site was located east of the 105-N reactor, approximately 13 meters SW of the 100-N-13 site at coordinates N149379.8 E571718.7.

#### Waste Type:
Water

#### Waste Description:
The waste consists of the stained soil.

#### Closure Info:
Confirmatory sampling was performed at the 100-N-101 waste site on January 24, 2011.

The 100-N-101 waste site was remediated on November 5, 2013. Approximately 64 bank cubic meters (BCM) (84 bank cubic yards [BCY]) of soil was direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). There is no staging pile area or overburden soil stockpile associated with the 100-N-101 waste site excavation. No debris was uncovered at the 100-N-101 waste site. No anomalous material or staining was encountered.
during excavation. The final depth of the 100-N-101 waste site excavation is approximately 1 meters (3.3 ft) below ground surface. Following remediation, a boundary walk-around survey of the 100-N-101 waste site excavation was performed.

| Code:          | 100-N-102                          | Classification: | Accepted |

| Description:  | This site consists three of potentially contaminated french drains, the associated piping and surrounding soil known as location 1A, 1B and 3. The waste site was divided into two subsites. Subsite 1 has been Interim Closed Out. Subsite 2 was determined to require No Action. Since both subsites have been reclassified, the Parent Site is also considered complete and is reclassified. In order to facilitate closure of the removed portions, the 100-N-102 site was divided into two subsites: |
|               | 100-N-102:1, 100-N Potentially Contaminated French Drains and Drain lines, Group 1. It has been excavated along with 100-N-87 and Interim Closed Out. |
|               | 100-N-102:2, 100-N Potentially Contaminated French Drains and Drain Lines, Group 2. It consists of two french drains, known as location 1B and location 3. It has been evaluated and reclassified to No Action. |
|               | Note: The second french drain (166-N Pump House Dry Well), originally described in 100-N-102:2 as location 2, has been removed from this subsite. This drain was within the excavation footprint of the UPR-100-N-18 waste site excavation. It was completely removed as part of the UPR-100-N-18 remediation activity. See UPR-100-N-18 for details. |
| Location:     | The 119-N Exhaust Air Monitoring Building Absorption Pit is centered at E571244/N149685. The French Drain outside the mobile office is centered at E571366/N149478. |
| Process Description: | Subsite 1 - 119-N Exhaust Air Monitoring Building Absorption Pit - |
|               | Although the 116-N Ventilation Stack began operation in 1961, its exhaust stream was not continuously sampled until the construction of the 119-N Exhaust Air Monitoring Building in 1971. The sample stream was filtered, then cooled in a condenser. The 5 GPM cooling water stream for this condenser initially discharged via a 2-inch line to the 36-inch contaminated transfer line between the 105-N Lift Station and the 1301-N Crib. Back pressure from this lift station transfer line backed up the cooling water discharge line and resulted in UPR-100-N-14 in August 1974. The corrective action for this UPR was to construct a new cooling water discharge line and earth absorption pit, and abandon the old line (DC-3322). While this was being done, another release (UPR-100-N-9) occurred from the cooling water discharge line in October 1974, nearer the lift station transfer line. Then in 1984, the 119-NA Air Sample Monitoring Stack Sampler Building was constructed to assist with monitoring the stack exhaust for tritium. Excess tritium effluent condensate was also routed via a floor drain to the |
absorption pit (H-1-36322), until permanent reactor shut down in the early 1990's.

Subsite 2, French Drain Outside Mobile Office -

H-1-45007, sht 35, shows the french drain adjacent to a buried power line conduit. No lines are shown connecting to it, so sources of discharge to this drain are unknown. The trailers immediately adjacent to the french drain were used for offices and classrooms with restroom facilities and a kitchen.

This Site has the Following SubSites:

<tr>
<td>Closure Info: Remedial action at the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 waste sites was performed during January and February 2011. Remediation involved removal of the foundations of the 116-N stack, the 119-N and 119-NA structures, and the underlying soil.</td>
<td></td>
</tr>
</tbody>
</table>
Excavation continued until the french drain, associated piping, and contaminated soil and debris were removed. This excavation exceeded the depth that would be required to remove the 100-N-102:1, UPR-100-N-9, and UPR-100-N-14 waste sites. According to drawing H-1-46389, the depth of the 100-N-102:1 subsite, and therefore the unplanned release waste sites UPR-100-N-9 and UPR-100-N-14, was at 0.76 meters (2.5 ft) bgs. The final excavation depth was approximately 8.5 meters (28 ft) bgs. Because the excavation and removal of the 116-N stack foundation was previously performed by the D4 Project, the exact volume of material removed is unknown.

The debris removed included soil, concrete, piping, and other debris associated with the 116-N, 119-N, and 119-NA structures and french drain. All material from these waste sites was disposed at the Environmental Restoration Disposal Facility (ERDF). No anomalous material was encountered during the excavation.

In March 2012, the D4 Project constructed a ramp across the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 excavation to provide access and to support remediation activities at 1303-N (118-N-1) waste site. The ramp material was excavated on September 28, 2012, and also disposed of at ERDF. A walk around the site boundary confirmed that all fill material used to build the ramp had been removed. After the excavation of the ramp material, a gamma survey was performed on October 3, 2012, within the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 excavation. The gamma survey results indicated readings above background at two locations. Additional remediation was performed to address areas where the GPERS survey results indicated elevated radiological results. Follow up surveys on October 17, 2012 and October 19, 2012 indicated no elevated readings above background.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

The SubSite is Part Of:

Code: 100-N-102
Names: 100-N-102; Potentially Contaminated French Drains and Drain Lines; 100-N Potentially Contaminated French Drains

Code: 100-N-102:2
Names: 100-N-102:2; Potentially Contaminated French Drains and Drain Lines, Group 2; 100-N Potentially Contaminated French Drains, Group 2

Type: French Drain
Status: Inactive

Description: The subsite has been evaluated and reclassified to No Action. It consists of two potentially contaminated french drains and associated piping (known as location 1B and Location 3).

One french drain had an absorption pit and two drain lines, located generally to the north of the former 116-N Ventilation Stack location. These components were associated with the former 119-N and 119-NA Sample Buildings, which sampled potentially contaminated exhaust air and associated condensate from the 116-N Stack. The stack and sample buildings have been demolished, and the line to the absorption pit was capped. The french drain and remaining piping are included in this subsite. It is described as location 1B.

The other french drain was located west of the former 1126-NA Mobile Office. It had had no identified associated piping. The mobile office, as well as other nearby buildings, have been demolished. It is described as location 3.
Location: The first drain is located near the 119-N Exhaust Air Monitoring Building Absorption Pit, centered at 571244E 149685N. It is described as location 1A. The second French Drain is located outside the 1126-NA mobile office, centered at coordinates E571366 N149478. It is described as location 3.

Closure Info: The 100-N-102:2 subsite consisted of two locations, 1B and 3, that were identified in the Confirmatory Work Instruction (CWI) as potential french drains.

Subsite 2 was reclassified with Waste Site Reclassification Form (WSRF) 2012-001. It addresses only the 100-N-102:2 subsite, which consists of two locations, 1B and 3.

Location 1B was excavated to 4.6 meters (15 ft) for confirmatory sampling, but no indication of a french drain structure, staining, debris, undisturbed soil, or contamination was found. The excavation was increased to 6.1 meters (20 ft), also with no indication of a french drain structure, staining or contamination. An evaluation of this location indicated that the structure was either removed with the 100-N-87 waste site remediation, or it was never present. In accordance with the CWI, location 1B was not sampled.

Excavation for confirmatory sampling at location 3 began, but was stopped when live 220 Kv electrical lines were encountered within the excavation. No samples were collected at location 3 due to safety concerns. Prior to the cessation of activities, the top of the french drain was uncovered. This french drain consists of a metal 55 gallon drum to which a pipe is attached. The drum was filled with cobbled. This french drain is associated with a temporary administrative office and classroom trailer (MO 1126-N). An office and classroom trailer would have been supplied with steam for heating but would not be expected to have any chemical or radiological processes associated with the trailer and therefore with the french drain. French drains were constructed with the compatibility of the discharge taken into consideration. Steel would not have been used for acidic or other chemically active discharges because the metal is incompatible with those liquids. Chemically active liquids would have been disposed in clay pipes. The metal of construction of this french drain is consistent with french drains designed for steam condensate. This is also consistent with the historical description of the french drain at location 3 which is identified as servicing the 1126-N Mobile Office and classroom. This type of steam condensate french drain presents a very limited risk for contamination.

The SubSite is Part Of:

Code: 100-N-102
Names: 100-N-102; Potentially Contaminated French Drains and Drain Lines; 100-N Potentially Contaminated French Drains

Code: 100-N-103
Names: 100-N-103; 100-N Steam Condensate French Drains
Type: French Drain
Status: Inactive
Description: The waste site consists of 12 steam condensate french drains and their associated below grade piping components discovered during the Orphan Site Evaluation Report (OSR) historical review. It included subsites 100-N-103:1, 100-N Steam Condensate French Drains (eleven
inactive drains) and 100-N-103:2, 100-N Steam Condensate French Drains (one active drain). Both subsites have been addressed, so the parent site has also been reclassified. Some of the drywells and their associated pipelines fall within a planned excavation of other waste sites. These french drains will be dispositioned during remediation of those waste sites.

**Location:** Refer to the subsites for locations of the french drains.

**Process Description:** Steam was typically used at all facilities for heating purposes. As a non-contact system the steam remained uncontaminated. The steam transport process utilized a high pressure supply line and a low pressure return or discharge line. It was necessary to bleed both the supply and return lines to prevent condensate build up. The condensate was typically blown off from the above grade piping system into a below grade, covered french drain. French drain diameters and construction material varied depending on steam piping size, service capacity pounds per hour, and expected flow rate received.

**This Site has the Following SubSites:**

**Code:** 100-N-103:1

**Names:** 100-N-103:1; 100-N Steam Condensate French Drains (inactive)

**Code:** 100-N-103:2

**Names:** 100-N-103:2; 609-E-1; 100-N Steam Condensate French Drains (active)

Subsite 1 consists of 11, inactive steam condensate french drains and their associated below grade piping components.

The site descriptions for each of the 11 steam condensate french drains (FD) are:

**FD1.** The site was a french drain with a 1.9-cm (0.75-in.) clean medium pressure steam return line from the 108-N Building (H-1-29247). This french drain was removed during the demolition of the 108-N building. 100-N-103:1 French Drain 1 will be addressed with the pipelines in 100-N-84:6 (and 100-N-61). French Drain 1 is not considered a No Action component.

**FD2.** The site is a 7.6-cm (3-in.) french drain, 2.8-m (9.2-ft) to wall. The site is associated with the 1902-N building, which housed clean export water valving and piping (H-1-45007, sht 22). (removed with 100-N-61)

**FD3.** The site is a 0.61-m (24-in.) primary flash pipe with a 1.9-cm (0.75-in.) diameter, 13-m (43-ft) long medium pressure steam condensate pipeline from the wall of the 184-NC Building (H-1-45007, sht 28, 29). Confirmatory activities determined FD-3 was removed completely during the demolition of the 184-N Building in 2008.

**FD4.** The site is a 0.9-m (36-in.) french drain with a 6-m (20-ft) long pipe to the wall of the 1701-N clean badgehouse (H-1-45007, sht 27).
FD5. The site is a 0.9-m (36-in.) dry well abandoned in 1985, replaced by a 1.2-m (48-in.) dry well, and received steam condensate from 184-N, 184-NA, and 184-N day tanks. (H-1-45007, sht 29; H-1-48915 shs 1 and 2). Confirmatory activities determined this dry well was removed during the demolition of the 184-N Building in 2008.

FD6. The site is a 1.2-m (48-in.) dry well that replaced a 0.9-m (36-in.) dry well in 1985, and received steam condensate from 184-N, 184-NA, and 184-N day tanks. A 7.6-cm (3-in.) pipe enters the dry well (H-1-45007, sht 29). (removed with UPR-100-N-19 remedial excavation)

FD7. The site is a 0.61-m (24-in.) dry well with a 1.3-cm (0.5-in.) diameter, 31.5-m (103-ft) long steam condensate pipeline to the 1101-N wall, and a potable water line from the 1100-N office building (H-1-45007, sht 28). Confirmatory activities determined the structure at this location was a valve box. There was no dry well at the excavation.

FD8. The site is a dry well with a 30-m (98-ft) long, 2.54-cm (1.5-in.) diameter line connecting from the 1100-N Building (H-1-45007, sht 35, H-1-44195). There is a manhole with a valve and pipe inside immediately adjacent to the french drain.

FD9. The site is a 1.2-m (48-in.) dry well with a 10-cm (4-in.) floor drain from an equipment access pit, and a 10-cm (4-in.) cast iron floor drain line from a clean office area at the 105 N Building (H-1-28877, H-1-27705). (French Drain 9 has also been deferred for disposition with 100-N-84:4. This french drain structure was actually removed during demolition of the 105-N Control Room structure.)

FD10. The site is a dry well with a 10-cm (4-in.) steam condensate pipeline from the 105 N Building and another 10-cm (4-in.) steam condensate pipeline from clean operations in 1712-N (H-1-45007, sht 43). (disposition with remediation of 100-N-84:4)

FD11. The site is a dry well with a 7.6-cm (3-in.) low pressure steam condensate pipeline from the 1734-N gas bottle storage building (H-1-45007, sht 43). (disposition with remediation of 100-N-84:4)

Location: The 100-N-103 Steam Condensate French Drains are located in the 100 NR-1 Operable Unit of the Hanford Site, near the 108-N chemical unloading facility, 1902-N export water tie-in building, 184-N powerhouse, 1701-N Gatehouse, 1100-N and 1101-N Office Buildings, 105-N Reactor, 1712-N Insulation Shop, and the 1734-N gas storage bottle building.

Waste Type: Misc. Trash and Debris

Waste Description: The waste will include the pipelines and any potential contaminated soil.

Closure Info: Confirmatory sampling for the 100-N-103:1 subsite was performed between August 29, 2011, and September 19, 2011, to support a determination that residual contaminant concentrations at this site meet the cleanup criteria specified in the RDR/RAWP (DOE/RL-2006b) and the N-Area ROD (EPA 1999).

The french drains identified at each of the locations within the 100-N-103:1 subsite were selected for sampling, with six exceptions. Excavation was being undertaken at the locations of drain numbers 1, 2, 6, and 9 for the purpose of remediating the 100-N-61:1, UPR-100-N-19 waste sites and building demolitions in the vicinity during the confirmatory sampling effort. Access to these french drain locations was not available. The remediations removed the french drains as debris within the field remediation excavation boundaries. Therefore, no confirmatory sampling was performed at these locations. French drains 10 and 11 will be removed in the excavation for the scheduled remediation of the 100-N-84:4 pipeline subsite. These french drains will be dispositioned within the closeout documentation for the 100-N-61:1, UPR-100-N-
19, and 100-N-84:4 waste sites, as appropriate.

Geophysical surveys performed at the french drain locations during confirmatory sampling activities revealed that french drain numbers 3 and 5 had been removed in their entirety during the demolition of the 184-N building. Test pits were excavated at the locations of french drain numbers 4 and 8.

The confirmatory sampling results support a reclassification of the 100-N-103:1 subsite to No Action.

The SubSite is Part Of:
Code: 100-N-103

<tr>
<td><strong>Related Sites/Structures:</strong></td>
<td>The site is associated 100-N-63, 100-N Reactor (1314-N, 116-N-1 and 116-N-3) TSD Underground Pipelines and UPR-100-N-31.</td>
<td></td>
</tr>
<tr>
<td><strong>Process Description:</strong></td>
<td>The crib and trench received radiologically contaminated water from the 105-N Reactor basin floor drains and the 109-N floor drains. The effluent contained activation and fission products as well as small quantities of corrosive liquids and laboratory chemicals. At times, the effluent consisted of water from the primary reactor coolant system, the periphery reactor cooling system and decontamination wastes from these systems. The crib and trench operated in tandem until 1985, when the 116-N-3 Crib became the primary liquid disposal facility for the N Reactor, and the 116-N-1 Crib and Trench were taken out of service.</td>
<td></td>
</tr>
<tr>
<td><strong>Waste Type:</strong></td>
<td>Asbestos (non-friable)</td>
<td></td>
</tr>
<tr>
<td><strong>Waste Description:</strong></td>
<td>The unit received radioactive water containing activation and fission products and small quantities of corrosive liquids and laboratory chemicals at an average flow rate of approximately 5,680 liters per minute (1,500 gallons per minute) (note: the 8 million liters assumes the crib effluent was steady 24 hours per day). The crib received radioactive effluent streams from the 105-N and 109-N Buildings. After 1965, the trench received the same wastes as the crib. Operational contaminant inventory records from 1964 through 1985 show a total of 3,000 curies of tritium, 2,300 curies of cobalt-60, 1,900 curies of strontium-90, 2,600 curies of cesium-137, and 23 curies of plutonium-239 being released to the crib and trench. An estimate of dangerous wastes from the decontamination of the primary coolant system discharged annually include 2,800 kilogram (6,100 pounds) of hydrazine test solution, 2,800 kilograms (6,100 pound) of ammonia test solution, 3,500 kilograms (7,800 pounds) of chloride test solution and 1,800 kilograms (3,900 pounds) of fluoride test solution per year of operation. No actual amounts are available. The estimates include common floor drains that discharged to the crib.</td>
<td></td>
</tr>
<tr>
<td><strong>Closure Info:</strong></td>
<td>Remedial action at the site began in April 2002 and concluded in October 2005. Excavation of</td>
<td></td>
</tr>
</tbody>
</table>
the site involved removing the overburden materials, debris, the contaminated and uncontaminated structure, and underlying contaminated soil. Approximately 8 meters (26.2 ft) of piping was also removed between the crib and the 1315-N valve station during excavation of the sidewall of the crib. Closeout of this segment of piping was addressed using the verification sampling for the crib. The contamination within the boundaries of the UPR-100-N-31 waste site was also removed, but the unplanned release waste site is not proposed to be Interim Closed Out because of contaminant plumes that impacted active facilities and cannot be excavated until the active facilities are closed or relocated. Approximately 333,528 metric tons (387,652 tons) of contaminated materials were disposed at ERDF. The crib was excavated to a depth of 6.5 meters (21 feet). The trench was excavated to a depth of 4.5 meters (14.8 feet).

Note: The original CVP-2006-004, Revision 0, was submitted to Ecology in 2006. Ecology rejected the Waste Site Reclassification Form at that time due to the verification sample results exceeding Washington Administrative Code (WAC) 173-303-610 (2)(b)(i) closure performance standards for hexavalent chromium of 2.0 mg/kg (based on WAC 173-340, amended 1996). In 2008, DOE agreed to submit a revised CVP. This revised cleanup verification package (CVP-2006-004, Rev. 1) further documents completion of remedial action for the 116-N-1 Crib and Trench. The revised CVP-2006-0004 Rev. 1 applies only to the 116-N-1 Crib and Trench, which does not encompass the entire 1301-N TSD unit boundary.

<tr>
<td>Related Sites/Structures:</td>
<td>116-N-2 is associated with portions of the 100-N-63 piping.</td>
</tr>
<tr>
<td>Process Description:</td>
<td>The 116-N-2 Tank was used to temporarily store and neutralize acidic decontamination waste from the internal decontamination of the N Reactor primary loop through an underground pipeline. An additional, small scale transfer line enters the tank from the N Reactor Building. The primary loop was decontaminated every three to five years. Each decontamination event resulted in approximately 2.3E+06 liters (6.0E+05 gallons) of contaminated solution. The decontamination solutions contained approximately 80,000 liters (21,000 gallons) of 70% phosphoric acid and 180 kilograms (400 pounds) of diethylthiourea. The solutions were neutralized in the tank. From 1968 to 1972, the neutralized solutions were pumped into trucks parked on the east side of the containment area and transported to 200 Area for disposal. After 1972, the solution was sent to the 1314-N Liquid Waste Loadout Station. The solutions were also discharged to the 116-N-1 Crib, if necessary.</td>

</tbody>
</table>
storage tanks. The liquid in the tank was neutralized with sodium hydroxide. Three unplanned releases of decontamination solution occurred at this site which cumulatively totaled 3.43E+05 liters (90,600 gallons).

**Closure Info:** Remedial action of the 116-N-2 (Golf Ball) waste site was performed between March 1, 2011 and April 26, 2012. Equipment decontamination was conducted within the southeast corner of the waste site excavation, and that area was remediated May 7 and 8, 2012. The maximum depth of the excavation was 13 meters (42.7 ft) bgs and resulted in the removal of approximately 11,144 bank cubic meters (BCM) (14,576 bank cubic yards [BCY]) of soil and debris. The debris consisted of rock, sand, and piping material. The contaminated soil and debris were directly loaded out for disposal at the Environmental Restoration Disposal Facility (ERDF). Also removed with the 116-N-2 excavation were the UPR-100-N-5 and UPR-100-N-25 waste sites, as well as portions of the 100-N-84 and 100-N-63 pipelines. A section of the 100-N-63:2 pipeline remained on a side slope in the northern part of the excavation until it was remediated between March 22, and 25, 2013. No anomalous material was found during remediation. No in-process samples were collected for the 116-N-2 grouping of waste sites.

Clean padding material (soil and gravel) had been previously placed on the ground surface south of the excavation to cover radiological contamination that resulted from the previous D4 activities to remove the golf ball and silo structures. The padding material and approximately 2 meters (6.5 ft) of soil below the padding was scraped and removed for disposal at ERDF.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The 116-N-3 Crib (1325-N LWDF) was designed for the disposal of liquid waste percolation through the soil column. It was built to replace the 116-N-1 Crib and first received N Reactor effluent in 1983. The 116-N-3 Trench was activated in September 1985 to provide additional disposal capacity. Effluent reportedly never overflowed beyond the first earthen dam in the trench. The LWDF has not received waste since February 1987 and was closed under interim status. The process design capacity for the 1325-N LWDF was 1.64E+07 liters (4.32E+06 gallons) per day. The design capacity reflected the maximum volume of water discharged daily, rather than the physical capacity of the unit. This unit consisted of a rectangular concrete crib that measured 76.25 by 73.20 meters (250 by 240 feet) and a percolation trench. The trench, located on the northeast side of the crib, measured 3 meters (10 ft) wide, 2.1 meters (7 ft) deep, and 915 meters (3,000 ft) in length. It was divided into four equal sections by three earthen dams. The trench was also covered with...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
concrete panels. Effluent was delivered to the 116-N-3 Crib through a 448 meter (1,468 foot) long by 0.9 meter (Diameter Nominal [DN] 900) (36 inch) diameter pipeline that entered the crib at the southwest end. A covered concrete by-pass structure ran parallel to the pipeline and connected to the crib at the southwest end. The by-pass structure was built at the same time as the 1312-N Retention Basin (also known as the Liquid Effluent Retention Facility or LERF).

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** This unit received radioactive activation and fission products and small quantities (below regulatory limits) of corrosive liquids and laboratory chemicals. Dangerous waste code numbers include: F003, D002, D006, D007, D008, D009, U133, WC02, and WT02.

**Closure Info:** A portion of the pipeline 100-N-63:1 was remediated with the 116-N-3 Crib and Interim Closed Out in CVP-2002-00002. For purposes of the CVP and consistent with the permitted TSD site designation, the 116-N-3 Crib and Trench, the 100-N-63:1 Pipeline, and the bypass structure are collectively referred to as the 116-N-3 site.

Remediation at the 116-N-3 site began on July 21, 2000. Excavation of the site involved removing the overburden materials, debris, the contaminated and uncontaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. The pipeline bypass (100-N-63:1) trenches were excavated completely and clean backfill was used to provide a temporary road for utilities and crossing. Contaminated materials were disposed of at the ERDF. On December 21, 2001, the excavation was completed. Only the portion of the trench near the crib was excavated. Effluent in the trench percolated into the soil column before overflowing the first earthen dam. Thus, the remainder of the trench beyond the first dam was not affected by waste disposal activities and did not require remediation. The excavation for the entire 116-N-3 site was approximately 21,980 square meters (236,590 sq. ft.) in area. Soils were removed beneath the crib and trench to a minimum of 1.5 meters (5 ft) below the engineered structures. Approximately 140,270 metric tons (154,578 tons) of material from the site were disposed of at the ERDF.

**Code:** 116-N-4  
**Classification:** Accepted

**Names:** 116-N-4; 1300-N Emergency Dump Basin  
**Reclassification:** Interim Closed Out (5/14/2013)

**Type:** Retention Basin  
**Start Date:** 1/1/1963

**Status:** Inactive  
**End Date:** 1/1/1987

**Description:** The waste site has been remediated and Interim Closed Out. It consisted of the 1300-N Emergency dump basin. The 116-N-4 Emergency Dump Basin was a rectangular shaped, outdoor, concrete storage basin with a 10.7-centimeter (0.188-inch) carbon steel liner. During the basin demolition in 2011, hot spot contamination and a potential plume was identified on the north end of the basin excavation. This contamination was deferred to the 100-N-64:33 (105/109-N Cooling Water Effluent Underground Pipelines) site. Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

**Location:** The basin was located on the west side of the 109-N Building and the 105-N Reactor Building.

**Release Description:** The basin leaked to the soil at the northeast and northwest corners of the basin during the early 1980s.

**Related Sites/Structures:** The basin is associated with suspected unplanned releases 100-N-29, 100-N-30 and 100-N-38. It is also associated with 100-N-64:3, due to the hot spot contamination found on the north side of the basin.

**Process Description:** The 116-N-4 Emergency Dump Basin (EDB) was originally designed to receive emergency single pass cooling water from N Reactor. In the late 1960's the unit was determined to be

**Hanford Site Waste Management Units Report**
February 2015  
891
insufficient for its original purpose because it did not have adequate capacity for the volume of coolant used during an emergency cooling operation. It was replaced with the 1304-N Emergency Dump Tank (EDT) in 1973. The EDT was never used for its original purpose. Instead, 116-N-4 received contaminated liquid generated during the periodic blowdown of the steam generators located in the 109-N Building from 1973 to 1987. This condensate contained low levels of radioactive contaminants. It also received radioactive waste from the N Reactor Lift Station. Since the shutdown of N Reactor in 1987, approximately 2.0E+06 liters (7.5E+05 gallons) of water has been maintained in the basin to cover the layer of sludge in the bottom of the basin to prevent it from drying and causing airborne contamination. Non-filtered river water has been added as needed to maintain an adequate water level.

**Waste Type:** Construction Debris

**Waste Description:** Sediments were sampled in 1995 and found to contain radionuclides exceeding Westinghouse Hanford Company Category I limits and heavy metal concentrations below Resource Conservation and Recovery Act (RCRA) limits. The site is, therefore, radiologically contaminated but is not a mixed waste site. Radionuclide and heavy metal characterization is provided in BHI-00731. Since basin leakage has occurred, additional contaminants may be expected in the soils beneath the basin. Contaminants in the Dump Basin liquid include average concentrations of 6.25 E+05 of H-3, 6.12 E+01 of Co-60, 5.70 E+04 of Sr-90, 2.51 E+01 of Zr-95, <5.16 E+01 of Ru-106, 2.16 E+01 of Sb-125, >5.16 E+00 of Cs-134, 9.27 E+02 of Cs-137, 1.62 E-02 of Pu-239 and 1.82 E-01 of Pu.

**Closure Info:** DOE agreed to defer the remediation of the "hot spots" plume (north end of the 116-N-4) to occur during the excavation of the collocated 100-N-64 and UPR-100-N-7 waste sites. The northern portion of the 116-N-4 waste site was reassigned to waste site 100-N-64:3 (105/109-N Cooling Water Effluent Underground Pipelines) on April 16, 2013 per the agreement.

Remedial action at the 116-N-4 Emergency Dump Basin (EDB) waste site was performed between March 21 and June 29, 2011. Due to safety issues involved in removing the fuel storage basin, the northern section of the 116-N-4 waste site was not remediated and was deferred to the 100-N-64 waste site excavation (WCH 2011c). Excavation continued until all debris and contamination associated with the waste site had been removed. Approximately 413 bank cubic meters (BCM) (540 bank cubic yards [BCY]) of contaminated soil and debris was direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately, 1,680 BCM (2,197 BCY) of contaminated soil and debris was stockpiled and later loaded out for disposal at the (ERDF). Approximately 1,105 BCM (1,445 BCY) of additional contaminated soil was later direct loaded for disposal at the ERDF for a final disposal volume of 3,198 BCM (4,182 BCY). No stained soil or anomalous material were discovered during remediation activities.

During remediation of the 116-N-4 EDB, it was recommended to include excavation only to a depth necessary to remove the west and south walls and the basin steel structure. The north and east walls (closest to the 105-N/109-N Buildings) were left in place to prevent an unstable condition of other structures, including the 105-N/109-N Buildings and adjacent piping (sitecode 100-N-64). The east wall was eventually removed during the excavation of the 116-N-4 EDB. The remaining contamination from the north and east walls was removed during deactivation, decontamination, decommissioning, and demolition (D4) removal of the fuel storage basin, which was completed in spring 2012. The west excavation boundary of borders the 100-N-57, 1304-N Emergency Dump Tank waste site excavation and is included in the 100-N-57 work instruction. Unplanned releases associated with the 116-N-4 waste site will be reclassified separately.

**Code:** 118-N-1  
**Classification:** Accepted  
**Names:** 118-N-1; 1303-N Radioactive Dummy Burial  
**Reclassification:** Interim Closed Out (8/16/2013)
Type: Silo
Status: Inactive
Start Date: 1/1/1963
End Date: 1/1/1995

Description: The site has been remediated and Interim Closed Out. The 1303-N Spacer Silos consisted of three buried silos used for temporary storage of irradiated metallic fuel rod spacers removed from the 105-N Reactor. The silos were covered and surrounded with an earth berm and had a 30.5 meters (100 ft) reinforced concrete retaining wall along the west side. The soil berm had scant vegetation growing on it and a single vent stack protruded from the mound. A chain link fence surrounded the site on three sides and was posted with "Contamination Area, Underground Radioactivity and Soil Contamination Area" signs. The western side was barricaded with a 2.1 meter (7 foot) concrete wall. Following surface stabilization in 1998, the site was posted with Underground Radioactive Material signs. The silos were demolished in 2012.

Location: The site was located outside the northwest corner of the 105-N Building, approximately 30 meters (98 feet) northwest of the 105-N Transfer Area.

Related Sites/Structures: The spacer transfer line (dummy disposal line) became part of 100-N-84:6. UPR-100-N-3 and UPR-100-N-12 were documented leaks in the spacer transfer line.

Process Description: The site contained three concrete silos, each 4.9 meters (16 feet) in diameter. Periodically, the contents were shipped to the 200 Area Burial Grounds for permanent disposal. Two of the silos are open bottomed.

Silo 1 began operation in 1963 and was a 30.5 centimeter (12 inch) thick reinforced concrete culvert 4 meters (13 ft) in diameter and 7.6 meters (25 ft) long, buried upright and extending about 7.1 meters (20 ft) below grade. Approximately 0.9 meters (3 ft) of packed aluminum turnings were placed at the base of silo 1. Silos 2 and 3 were added in 1967 and were corrugated, galvanized-steel culverts 5.2 meters (17 ft) in diameter and 10.7 meters (35 ft) long that extended 9.1 meters (30 ft) below grade. All three silos were standing vertically on end with the top 1.5 meters (5 ft) being above grade with concrete covers.

When a silo was completely full, the spacers were removed and shipped to the 200 Area burial grounds for disposal.

Waste Type: Batteries

Waste Description: This site received byproduct radioactive metallic fuel spacers from the reactor. Quantities were variable based upon reactor operation levels. The radioactively contaminated fuel spacers were temporarily stored in the underground silos and then shipped to the 200 Area Low-Level Burial Grounds for disposal. All spacers were removed from the silos in September 1995.

Closure Info: The 118-N-1 silos were remediated in 2012. Approximately 8,680 bank cubic meters of soil was removed by the Field Remediation project from January 4, 2013, through March 22, 2013. Radiological surveys were performed after the soil was removed. All waste was direct loaded during the excavation and disposed at the ERDF. No anomalies were encountered during the remedial action activities.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

<tr>
<td>Related Sites/Structures:</td>
<td>The 163-N Building, 183-N Building, 120-N-2 (1324-N) Surface Impoundment, and 100-N-58 (1324-N South Settling Pond) are associated with this site.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>In 1977 the 120-N-1, 120-N-2, and 100-N-58 sites were initially constructed as the East Percolation Pond and North and South Settling Ponds, respectively. These unlined ponds received 163-N anion/cation regeneration effluent as well as the 183-N Filtered Water Plant filter backwash effluent. In 1982, because of pond percolation problems, the 183-N filter backwash was rerouted to an effluent disposal pond (130-N-1). During this time period the 100-N-58 site was backfilled. Liquid wastes were transferred to the north and south settling ponds where particulates were allowed to settle out. After the solids, primarily from the filter backwash effluent, had settled the contents of the settling ponds were transferred to the percolation pond. Between 1983 and 1986, the settling ponds were closed and the percolation pond was enlarged. The regeneration effluent was then discharged directly to the percolation pond through a 20-centimeter (8-inch) diameter PVC valved pipeline. The filter backwash effluent was then discharged to the 130-N-1 Filter Backwash Disposal Pond through a rerouted 40-centimeter (16-inch) diameter PVC pipeline that ran under the 100-N-58 South Settling Pond. The south settling pond was backfilled. Effluent was treated in the percolation pond by the alternate addition of acidic (cation) column regeneration effluent and alkaline anion column regeneration effluent. This alternate addition of low and high pH effluent served to neutralize the effluents. The percolation pond also made use of the buffering capacity and calcareous nature of the soil underlying it to neutralize these corrosive wastes.</td>
<td></td>

</table>
Remedial/corrective action field activities at the 120-N-1, 120-N-2, and 100-N-58 sites were conducted in September 2000, and included the removal and disposal of miscellaneous structural debris-type items. A total of about 120 cubic meters (4,238 cu ft) of material was removed from the sites. The material consisted of about 15 cubic meters (530 cu ft) of concrete, 96 cubic meters (3,390 cu ft) of high-density polyethylene (HDPE) liner, 4 cubic meters (141.3 cu ft) of polyvinyl chloride (PVC) piping, and 0.5 cubic meters (17.7 cu ft) of steel fencing material. The material was disposed of in the inert demolition landfill in the 100-H Area. Waste designation and disposal documentation is kept in project files. The two 20.3-cm (8-in.) diameter influent pipelines were sampled and remain in place.

Closure performance standards were established by the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These performance standards are documented in the 100-NR-1 Treatment, Storage, and Disposal Units Corrective Measures Study/Closure Plan (CMS/CP) (DOE-RL-90-22) and the Remedial Design Report/Remedial Action Work Plan for the 100-NR-1 Treatment, Storage, and Disposal Units (RDR/RAWP) (DOE/RL-2000-16). Permit conditions were established in the Hanford Facility Dangerous Waste Permit (Ecology 1994). While sites 120-N-1, 120-N-2, and 100-N-58 are not included in a Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) record of decision (ROD) corrective action activities have been documented in CVP-2001-00021 (CVP).

The soil investigation conducted at these sites in 1992 and 1993 for the CMS/CP indicated that the site did not require soil remediation. Therefore, the selected remedial/corrective action included the removal and disposal of the miscellaneous site structures, including the 120-N-2 liner system, a small sampling shed, fencing, and other miscellaneous debris. The CMS/CP soil investigation indicated that there generally are no contaminants of concern (COCs) for these waste sites. However, because a former overflow area and the waste site influent pipelines required additional sampling (as specified by the CMS/CP), these sites were included in the Sampling and Analysis Plan for the 100-NR-1 Treatment, Storage, and Disposal Units During Remediation and Closeout (SAP) (DOE-RL-2000-07). The verification samples collected under the sampling and analysis plan were analyzed for generally the same inorganic metals and wet chemical anions listed in the CMS/CP soil investigation. The samples were also analyzed for pH. The analytical results from the additional soil sampling and the pipeline scale sampling are presented in Appendix A of the CVP. The analytical results of the soil samples are consistent with the findings of the CMS/CP: soil concentrations are at or below Hanford Site or Washington State background concentrations.

**Description:** The site was remediated in September/October 2000. The remedial activity for sites 100-N-58, 120-N-1 and 120-N-2 was documented in CVP-2001-00021. A Reclassification form was completed for 100-N-58. However for 120-N-1 and 120-N-2, Washington State Department of Ecology rejected the certification of closure from DOE. A post-closure groundwater plan must be submitted to Ecology and approved prior to approval of the Certification of Closure documentation.

**Location:** The 120-N-2 site was co-located with 120-N-1 and 100-N-58 sites in the 100-N Area in the 100-NR-1 Operable Unit of the Hanford Site in southeastern Washington State. These sites are
about 100 meters (328 ft) southeast of the 163-N Demineralization Plant Building, and are approximately 400 meters (1,312 ft) from the Columbia River.

**Related Sites/Structures:** The 163-N Building, 183-N Building, 100-N-58 (1324-N) South Settling Pond and 120-N-1 (1324-NA) Percolation Pond are associated with this site.

**Process Description:** In 1977 the 120-N-1, 120-N-2, and 100-N-58 sites were initially constructed as the East Percolation Pond and North and South Settling Ponds, respectively. These unlined ponds received 163-N anion/cation regeneration effluent as well as the 183-N Filtered Water Plant filter backwash effluent. In 1982, because of pond percolation problems, the 183-N filter backwash was rerouted to an effluent disposal pond (130-N-1). During this time period the 100-N-58 site was backfilled. Prior to 1982, approximately 1.63E+06 liters/day (4.3E+05 gallons/day) of acidic and caustic effluents were transferred by underground lines to the 120-N-2 Surface Impoundment to be neutralized. Caustic anion regeneration effluent was generally neutralized in the facility by the addition of acidic cation regeneration effluent. Acid cation regeneration effluent was similarly neutralized by the addition of caustic anion regeneration effluent. Once neutralization was complete, the neutralized effluent was discharged to the 120-N-1 Percolation Pond via a 30-centimeter (12-inch) polyvinyl chloride (PVC) drainline and/or a 30-centimeter (12-inch) PVC overflow line.

**Waste Type:** Batteries

**Waste Description:** The 1324-N Surface Impoundment received corrosive regeneration effluent and process and cooling water from the 163-N Demineralization Plant. Analytical results from surface soils and sediment test pit sampling are reported in DOE/RL-90-22.

**Closure Info:** The site was remediated in September/October 2000. A Reclassification form was completed for 100-N-58. However for 120-N-1 and 120-N-2, Washington State Department of Ecology rejected the certification of closure from DOE. A post-closure groundwater plan must be submitted to Ecology and approved prior to approval of the Certification of Closure documentation.

Remedial/corrective action field activities at the 120-N-1, 120-N-2, and 100-N-58 sites were conducted in September 2000, and included the removal and disposal of miscellaneous structural debris-type items. A total of about 120 cubic meters (4,238 cu ft) of material was removed from the sites. The material consisted of about 15 cubic meters (530 cu ft) of concrete, 96 cubic meters (3,390 cu ft) of high-density polyethylene (HDPE) liner, 4 cubic meters (141.3 cu ft) of polyvinyl chloride (PVC) piping, and 0.5 cubic meters (17.7 cu ft) of steel fencing material. The material was disposed of in the inert demolition landfill in the 100-H Area. Waste designation and disposal documentation is kept in project files. The two 20.3-cm (8-in.) diameter influent pipelines were sampled and remain in place.

Closure performance standards were established by the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These performance standards are documented in the 100-NR-1 Treatment, Storage, and Disposal Units Corrective Measures Study/Closure Plan (CMS/CP) (DOE-RL-90-22) and the Remedial Design Report/Remedial Action Work Plan for the 100-NR-1 Treatment, Storage, and Disposal Units (RDR/RAWP) (DOE/RL-2000-16). Permit conditions were established in the Hanford Facility Dangerous Waste Permit (Ecology 1994). While sites 120-N-1, 120-N-2, and 100-N-58 are not included in a Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) record of decision (ROD) corrective action activities have been documented in CVP-2001-00021 (CVP).

The soil investigation conducted at these sites in 1992 and 1993 for the CMS/CP indicated that the site did not require soil remediation. Therefore, the selected remedial/corrective action included the removal and disposal of the miscellaneous site structures, including the 120-N-2
liner system, a small sampling shed, fencing, and other miscellaneous debris. The CMS/CP soil investigation indicated that there generally are no contaminants of concern (COCs) for these waste sites. However, because a former overflow area and the waste site influent pipelines required additional sampling (as specified by the CMS/CP), these sites were included in the Sampling and Analysis Plan for the 100-NR-1 Treatment, Storage, and Disposal Units During Remediation and Closeout (SAP) (DOE-RL-2000-07). The verification samples collected under the sampling and analysis plan were analyzed for generally the same inorganic metals and wet chemical anions listed in the CMS/CP soil investigation. The samples were also analyzed for pH. The analytical results from the additional soil sampling and the pipeline scale sampling are presented in Appendix A of the CVP. The analytical results of the soil samples are consistent with the findings of the CMS/CP: soil concentrations are at or below Hanford Site or Washington State background concentrations.

<tr>
<td>Waste Description:</td>
<td>The unit received unknown amounts of corrosive liquids, such as sodium hydroxide and sulfuric acid.</td>
</tr>
</tbody>
</table>
| Closure Info:   | Remedial action at the 120-N-3 waste site was performed August 10, 2011, through January 31, 2012. The excavation continued to a depth of 5 meters (16.4 ft) below ground surface resulting in approximately 3,917 bank cubic meters (5,123 bank cubic yards) of contaminated soil and debris removed for disposal at the Environmental Restoration Disposal Facility (ERDF). All material was direct-loaded from the excavation. No waste staging pile areas are associated with the site. The waste material removed from the 120-N-3 waste site consisted of soil, concrete, and rebar. No anomalous materials were encountered during the excavation. There are no overburden piles or waste staging pile areas associated with the 120-N-3 waste site. During remediation of the 120-N-3 waste site, suspect oil-stained soil was observed on the east sidewall of the excavation. This staining was determined not related to the 120-N-3 waste site,
but informational in-process soil samples were collected from the stained area. This stained area will be addressed with 100-N-106.

<tr>
<td>Description:</td>
<td>The waste site was remediated and Interim Closed Out. The 1310-N Hazardous Waste Storage Area was a concrete pad approximately 20 by 25 meters (70 by 80 feet), surrounded with a concrete berm (curb) and locked chain-link fence. Outside the pad the ground surface is gravel. A small open shed is in the southwest corner of the pad. The site was posted as a Radioactive Materials Area, and is also posted &quot;Contaminated Lead Storage Area (For Re-Use).&quot; In April 2000, the area contained several wrapped objects marked with radioactive warning signs.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The site is located immediately south of the 1310-N Facility.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Release</td>
<td>Waste sites 100-N-26 and 120-N-4 were impacted by a raw water pipeline break on December 11, 2008. The regulators and tribes have requested that this release information be noted in WIDS.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Description:</td>
<td>During the removal of the concrete pad at the 1524-N Hazardous waste storage facility on December 11, 2008 a 1.5 inch feed line from the export water line was inadvertently contacted during the excavation of the concrete pad. A rupture of the 12 inch export water line and a release of at least 50,000 gallons of raw water onto the surrounding area resulted. A temporary berm was constructed around the area using excess clean 100 Area Borrow Pit material to contain the release and control potential spread of radiological contamination associated with the 1524-N pad. Once the water line was turned off the water in the area immediately percolated into the ground. In-process and post-event surface soil radiological field survey results did not find any contamination spread as a result of the water release. A follow-up review of nearby monitoring wells as well as the standard waste site confirmatory sampling will be used to ascertain potential impacts/conditions.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process</td>
<td>The unit stored waste held in drums and containers from 1985 to 1989. The waste oil drums have been removed. The pad is (in April 12, 2000) was used to store lead lined burial casks and radioactive materials.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Description:</td>
<td>The concrete pad comprising the 120-N-4 waste site was removed and disposed to the Environmental Restoration Disposal Facility (ERDF) between December 2008 and February 2009. During the removal of the concrete pad on December 11, 2008, a 1.5 inch feed line from the export water line was inadvertently contacted during the excavation of the concrete pad. A rupture of the 12 inch export water line and a release of at least 50,000 gallons of raw water onto the surrounding area resulted. A temporary berm was constructed around the area to contain the release and control potential spread of radiological contamination associated with the 1524-N pad. Once the water line was turned off the water in the area immediately percolated into the ground. The soil underlying the concrete pad was evaluated for residual contamination.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Between October 8 and October 10, 2013, 956 bank cubic meters (BCM) of material from the 120-N-4 site was directly loaded out for disposal at ERDF. Along with this, approximately 1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
BCM of wire and concrete debris were removed. This excavation was approximately 1 meter (3.3 ft) deep. No anomalies were discovered.

</tbody>
</table>
of the 163-N Water Treatment Building.

**Related Sites/Structures:** This site supported the 163-N Water Treatment Building.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** This unit receives approximately 5,300 liters per day (1,400 gallons per day) of sanitary sewage.

**Closure Info:** The 124-N-1 Sanitary Sewer System consisted of a septic tank and a cesspool. The septic tank was removed by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project in June and September 2009 and disposed at the Environmental Restoration Disposal Facility (ERDF). Removal of the cesspool structure and excavation of underlying soils associated with the entire septic system was performed on November 28, 2012 and continued through February 8, 2013. In addition, the portion of the 100-N-84:5 sanitary pipeline that connected the septic tank with the cesspool was removed.

Red-stained soil observed during the initial excavation was sampled on December 6, 2012, and additional soil was removed from the excavation. Approximately 721 bank cubic meters of contaminated soil and debris was directly loaded out for disposal to ERDF.

One anomaly was encountered during the remedial action activities. The anomaly was a 1.2 meter by 1.2 meter by 2.1 meter (4 ft by 4 ft by 7 ft) concrete box that was found to be empty and was disposed to ERDF.

---

**Code:** 124-N-2  
**Classification:** Accepted

**Names:** 124-N-2; 124-N-2 Septic Tank; 1607-N2; 100-N Sanitary Sewer System No. 2  
**Reclassification:** Interim Closed Out (8/21/2013)

**Type:** Septic Tank  
**Start Date:** 1/1/1963

**Status:** Inactive  
**End Date:** 1/1/1987

**Description:** The waste site has been remediated and Interim Closed Out. It was a septic tank and seepage pit. The seepage pit provided approximately 18.4 square meters (200 square feet) of infiltration surface area and 8,700 liters (2,300 gallons) of fluid storage.

**Location:** The site was located southeast of the 182-N Building.

**Process Description:** This unit received sanitary sewage from the 182-N Building. The seepage pit provided approximately 18.4 square meters (200 sq. ft.) of infiltration surface area and 8,700 liters (2,300 gal) of fluid storage. During the period of operation, the septic tank received an estimated 757 liters/day (200 gal/day) of sanitary sewage from the 182-N Building.

**Waste Type:** Equipment

**Waste Description:** During the period of operation, this unit received an estimated 757 liters/day (200 gallons/day) of sanitary sewage from the 182-N Building.

**Closure Info:** The 124-N-2 waste site was remediated between April 12, 2012, and April 18, 2012, along with the remediation of the 182-N Building by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project. The septic tank excavation extended approximately 1.7 meters (5.6 ft) below the original ground surface. Materials from the 124-N-2 waste site could not be physically separated from the 182-N Building materials. Therefore, an accurate total volume excavated from the 124-N-2 waste site is unknown. A volume of approximately 240 BCM (314 BCY) of material is estimated to have been excavated from the
124-N-2 waste site by the D4 Project. Materials removed from the excavation included the demolished seepage pit, concrete, soil, and rocks. Additional remediation of the 124-N-2 waste site was performed by the Field Remediation (FR) Project between January 21 and 30, 2013. Approximately 371 BCM (485 BCY) of material was excavated from the 124-N-2 waste site for direct disposal at the ERDF.

On March 28, 2013, remediation at the 124-N-2 waste site resumed to further excavate the entire footprint of the 124-N-2 waste site. The excavation was expanded to the east to remove the adjacent 100-N-84:4 pipelines and to allow the 124-N-2 excavation to proceed to a greater depth. The 124-N-2 excavation was completed on April 25, 2013, and final depth of the excavation is approximately 4.9 to 5.1 meters (16 to 17 ft below ground surface), with some locations extending deeper. The 100-N-84:5, 100-N Area Sanitary Pipeline segments were partially removed within the 124-N-2 excavation area during the remediation effort and were addressed with the 124-N-2 waste site verification sampling.

Approximately 1,185 BCM (1,550 BCY) of additional material was removed from the 124-N-2 excavation. All excavated materials and pipelines were removed for direct disposal at the ERDF.

</thead>
<tbody>
<tr>
<td>124-N-3</td>
<td>Accepted</td>
<td>Interim Closed Out (7/18/2013)</td>
</tr>
</tbody>
</table>

**Names:**
- 124-N-3 Septic Tank
- 1607-N3
- 100-N Sanitary Sewer System No. 3

**Type:** Septic Tank

**Status:** Inactive

**Start Date:** 1/1/1982

**Process Description:**
The unit is a cesspool consisting of a 1,900-liter (500-gallon) precast concrete perforated pipe with a solid cover, resting on a 0.61-meter (2-foot) thick pad of crushed stone. There are no surface indications of the cesspool's location since there is no above-ground access port to the pit.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** When operational, this unit received approximately 170 liters/day (45 gallons/day) of sanitary sewage.

**Closure Info:** Remedial action at the 124-N-3 waste site was performed in August 2012 by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the adjacent 107-N Basin Recirculation Facility. The cesspool structure was completely removed during remediation of the 124-N-3 waste site and the adjoining 107-N Basin Recirculation Facility. A Global Positioning Environmental Radiological Surveyor (GPERS) survey was conducted on December 14, 2012, within the 107-N Building footprint and the 124-N-3 excavation footprint. Radiological contamination remained within the footprint. Therefore, the area was deferred to the Field Remediation project for final cleanup.

The 124-N-3 waste site underwent additional remediation to remove contaminated soil and debris in January 2013. An additional 14 bank cubic meters (18 bank cubic yards) of soil was removed at the 124-N-3 waste site by the Field Remediation Project. The original grade at the 124-N-3 waste site prior to remediation activities was 140 meters (459 ft) above mean sea level. The final grade at the completion of remedial action activities is 135 meters (443 ft) above...
mean sea level resulting in a 5 meter (16 ft) deep excavation. The assumed maximum depth of
the cesspool structure was 4.3 meter (14 ft), based on the available records and typical design.

<td>The unit received approximately 136,400 liters/day (30,000 gallons/day) of sanitary sewage.</td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Remedial action at the 124-N-4 waste site was performed between October 28, 2010, and February 16, 2011. Approximately 8,713 bank cubic meters (BCM) (11,396 bank cubic yards [BCY]) of contaminated soil and debris were removed from the 124-N-4 excavation and direct loaded or staged in staging piles prior to being disposed at the Environmental Restoration Disposal Facility (ERDF). Excavation continued until all debris and contamination associated with the waste site had been removed. No radiologically contaminated material was discovered during remediation activities. The two 124-N-4 septic tanks were sampled on October 13, 2010, to estimate the amount of lime and Water Works absorbent needed to treat and solidify the tank contents prior to remediation. Remedial actions at the 124-N-4 waste site started on October 28, 2010. The tanks were treated and solidified on November 8 and 9, 2010. Once the contents were solidified, the septic tanks were rubblized in place and loaded out for disposal at the Environmental Restoration Disposal Facility (ERDF). Loadout of the 124-N-4 excavation was completed on February 16, 2011.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The 124-N-4 excavation reached a maximum depth of 8 meters (26 ft) below the surrounding ground surface. The septic tank excavations extended approximately 4 meters (13 ft) below the original surface, and the tile field was excavated to approximately 3 meters (10 ft) below the original tile field surface. The remedial action included removal of the four diversion boxes, the 100-N-84:5 pipelines that connected the septic tank to the diversion boxes, and those pipelines from the septic tanks up to the manhole located by the southernmost septic tank. Active power lines extended above the tile field's eastern side between two power poles located near the</td>
<td></td>
</tr>
</tbody>
</table>
northeast and southeast corners of the waste site boundary. Due to a need to stabilize the power poles, an estimated 9-meters (30-ft) area surrounding the poles was left in place at the edge of the excavation.

**Names:**
- 124-N-9 Septic Tank
- 1607-N9 Septic Tank
- 100-N Sanitary Sewer System No. 9

**Type:** Septic Tank

**Status:** Inactive

**Description:**
The septic system has been remediated and Interim Closed Out. It consisted of two septic tanks and one drainfield that received sanitary waste from the 1120N building. They were located inside an area that was delineated by light posts and chain.

**Location:**
The unit was located approximately 46 meters (150 feet) northeast of the 1120-N Building.

**Process Description:**
The site consisted of 2 septic tanks and a drain field. Each tank has a volume of 11,360 liters (3,000 gallons), and the drain field has an infiltration surface area of 325 square meters (3,500 square feet). The 1120-N Building housed training facilities and offices and also served as a warehouse. For a brief period of time a radiological counting facility was housed in the building. Storage in the warehouse section included janitorial supplies, pest control supplies, sign shop supplies, and radioactive sources. The radioactive sources were calibration standards used to calibrate the equipment used in the radiological counting facility. Floor drains in the 1120-N facility emptied into a 10 cm (4 in.) polyvinyl chloride (PVC) sewer that bypassed the septic tanks and emptied directly to the drain field. Effluent from the restroom drained into a 10 cm (4 in.) PVC sewer that drained into the septic tanks before being discharged to the drain field.

**Waste Type:** Oil

**Waste Description:**
This unit receives approximately 8,300 liters/day (2,200 gallons/day) of sanitary sewage.

**Closure Info:**
Remedial action at the 124-N-9 waste site was performed between August 15 and August 23, 2012. Approximately 975 bank cubic meters (BCM) (1,275 bank cubic yards [BCY]) of soil, rock, concrete, and piping were removed and disposed at the Environmental Restoration Disposal Facility (ERDF). The removed sections of piping between the septic tanks and the drain field are part of the 100-N-84:5 and the 100-N-84:6 waste sites. The excavation was performed to approximately 0.3 meters (1 ft) below the structure of the septic tanks and drain field and is a maximum of approximately 2.8 meters (9.2 ft) deep in the area of the septic tanks and a minimum of 1 meter (3.3 ft) deep in the area of the drain field.

**Names:**
- 124-N-10 Sanitary Sewer System
- 1607-N10 Sanitary Sewer System No. 10
- 100-N Central Sewer System No. 10
- 1904-NA Sanitary Lift Station No. 1
- Project H-677
- 100-N Sewage Lagoon

**Type:** Sewage Lagoon

**Status:** Inactive

**Description:**
The 124-N-10 site has been remediated and Interim Closed Out. It encompassed the footprints of the 1904-N lagoons and the 1904-NA lift stations. 124-N-10 consisted of a three pond
sewage lagoon facility (1904-N), a server trunk pipeline and other pipelines, two lift stations (1904-NA), new manholes and associated sewer system instrumentation. The sewer system was deactivated. Demolition began in December 2012 and continued through April 2013. It serviced a minimum of 27 buildings.

Location: The site was located 1 mile northwest of the intersection of N Avenue and Route 4 North cutoff. The sanitary sewer system was parallel with and north of the railroad tracks that intersect N Avenue.

Process Description: This system processed domestic human sewage. Three sewer ponds (or lagoons), identified in the drawings, included a lined aeration pond, a lined stabilization pond, and an unlined infiltration pond, had a total combined length of 822.75 ft by 220 ft wide. The system was designed for a maximum of 2,500 employees and a maximum design flow of 789,000 L (50,000 gal) per day. It began operation in February 1987.

Waste Type: Soil

Waste Description: The maximum design flow for this septic system is 50,000 gallons per day. It is designed for a maximum of 2,500 employees. The site has received domestic wastewater sewage from the 100-N Area and domestic sewage pumped from septic tanks throughout the Hanford Site. Incidental solids (rags, scum, and other debris) are removed from the system and disposed of as solid waste at an approved disposal site. The discharge from the infiltration pond percolates down to the groundwater.

Closure Info: Demolition of the 1904-N and 1904-NA facilities was performed from December 2012 through April 2013 by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) project. The depth of the excavation ranged from approximately 1 meter (3 ft) to 3 meters (9.8 ft) below ground surface. Approximately 18,000 bank cubic meters (23,500 bank cubic yards) of soil and debris was disposed at the Environmental Restoration Disposal Facility (ERDF). All physical components of the 1904-N and the 1904-NA facilities have been removed. Waste characterization samples and in-process soil samples were collected prior to and during the removal of the facilities and the underlying soil. Hexavalent chromium was detected in an in-process soil sample above a remedial action goal (RAG). Therefore, additional soil was removed from the soil sample location.

Following D4 activities, the Field Remediation (FR) project collected in-process soil samples to determine if additional soil remediation was necessary from the 124-N-10 waste site prior to initiating verification sampling activities. The sample results indicated that the waste removal conducted by D4 was sufficient. Therefore, no additional material was removed by the FR project. No anomalies or stained soil were encountered during demolition and removal of the facilities and underlying soil. All material removed from the waste site was direct loaded for disposal at the ERDF. No staging pile areas were associated with the 124-N-10 waste site remediation.

Code: 128-N-1 Classification: Accepted
Names: 128-N-1; 128-N-1 Burning Pit; 100-N Burning Pit Reclassification: Interim Closed Out (4/10/2013)
Type: Burn Pit Start Date: 1/1/1963
Status: Inactive End Date: 1/1/1989
Description: The waste site has been remediated and Interim Closed Out. The site was an area with evidence of burning, in the form of burnt trash and cans. Most of the site had been backfilled.
Location: The site was located approximately 460 meters (1,500 feet) northeast of the 1120-N Building, and was southeast of 116-N-3.
Process Description: Combustible materials, such as nuisance vegetation and combustible wastes (office waste, tools and hardware, and potentially paints and solvents), have been burned at this site. After the establishment of the Hanford Central Landfill in the early 1973, the pit was used only for burning nuisance vegetation.

Waste Type: Equipment

Waste Description: Combustible materials, such as nuisance vegetation and combustible wastes (office waste, tools and hardware, and potentially paints and solvents), have been burned at this site. The quantity of material burned at the site is unknown. Since the establishment of the Hanford Central Landfill (in the early 1970's), this unit has been used for burning nuisance vegetation only.

Closure Info: Remediation of 100-N-6, 100-N-16, 100-N-98 area 1, and 128-N-1 waste sites began on August 2, 2010, and was completed on November 28, 2011. A total of approximately 20,334 bank cubic meters (BCM) (26,596 bank cubic yards [BCY]) were excavated and staged for removal to the Environmental Restoration Disposal Facility (ERDF). Between April 16 and 19, 2012, the excavation was expanded to the west to include stained soil Area 2 of the 100-N-98 waste site. Approximately 476 BCM (623 BCY) of soil was removed from 100-N-98 Area 2 and direct loaded for disposal at ERDF. The additional remediation of the spoil pile area (SPA) and the 100-N-6, 100-N-16, 100-N-98, and 128-N-1 waste site excavation generated an additional volume of 5,446 BCM (7,123 BCY) of material for direct load out to ERDF. A total volume of 26,256 BCM (34,342 BCY) was disposed at ERDF, to complete the 100-N-6, 100-N-16, 100-N-98, and 128-N-1 waste site remediation.

The materials removed from the 100-N-6, 100-N-16, 100-N-98, and 128-N-1 waste sites consisted of abandoned wiring, transite pipe, metallic and wood debris, burnt wood, ash, tar, roofing felt, stained soil, a bucket of grout, an open glass bottle, green fibrous material, purple sandy material, a paint ball, drums containing bunker and amber oil, and miscellaneous demolition debris. Anomalous material discovered during remediation included six 208-L (55-gal) drums, small white ceramic balls used as filtering media, and soil with a strong solvent odor.

Code: 130-N-1
Names: 130-N-1; 183-N Backwash Discharge Pond; 183-N Filter Backwash Pond; 126-N-1
Type: Pond
Status: Inactive
Description: 130-N-1 was divided into two subsites: 130-N-1:1, 183-N Northeastern Backwash Discharge Pond and 130-N-1:2, 183-N Southwestern Backwash Discharge Pond. Both subsites have been evaluated. Subsite 1 was remediated and Interim Closed Out. Subsite 2 was evaluated and determined to require No Action. Since both subsites have been reclassified, the parent site is also considered Interim Closed Out.

The site consisted of an irregularly shaped natural marsh-like pond that received filter backwash water from the 183-N Filtration Plant. The pond was originally constructed in 1982, utilizing a natural depression and was known as the Backwash Lake. The construction activities included building a dike to protect a railroad spur that ran along the southern end of the depression and excavating channels to facilitate drainage. The Backwash Lake was put into operation in 1983. It was later referred to as the 183-N Backwash Discharge Pond. The effluent discharge pipe was capped on June 27, 2000.
Location: The site is located approximately 0.4 kilometers (0.25 miles) southeast of the 1324-N Facility.

Related Sites/Structures:

Process Description: The 183-N Water Treatment Plant was constructed in 1963 to support operations of the 100-N Reactor. The water filtration plant provided treated water for cooling purposes, water for auxiliary support systems, and potable water for administrative buildings and offices. The filter backwash was originally discharged to the River via the 1908-N Outfall until September 2, 1977 when it was diverted to the 163/183N facility discharge pond area (100-N-58, 120-N-1 and 120-N-2). The settling ponds were small unlined basins which were used mainly to settle out solids from the filter backwash. By late 1981 it was apparent that annual dredging of the settling ponds was not sufficient to prevent flooding. 130-N-1 was constructed in 1982 to receive the filter backwash waste stream to reduce the particulate loading on the settling ponds. It began receiving effluent in 1983.

When the pond was active, the State Waste Discharge permit application, (1994), identified four wastewater streams that were routed to the 183-N Backwash Discharge Pond (DOE/RL-94-23).

1 - The Coagulator Drains Wastewater stream, derived from the annual draining and washing of the coagulator basins.

2 - The Filter Backwash Wastewater stream, consisting of backwash from the multimedia gravity filters.

3 - The Non-Contact Cooling Water stream, from an air compressor in the 184-N Building and a fire pump in the 182-N Building.

4 - The Stormwater from the 163-N Demineralizer Sump stream, from the 163-N Trench Sump and the 108-N Neutralizing Sump.

The 183-N Backwash Discharge Pond was became inactive after the 183-N Potable Water Plant was shutdown. The effluent discharge pipe was capped on June 27, 2000.

Waste Type: Soil

Waste Description: The unit receives filter backwash containing polyacrylamide and aluminum sulfate.

This Site has the Following SubSites:

Code: 130-N-1:1
Names: 130-N-1:1; 183-N Northeastern Backwash Discharge Pond

Code: 130-N-1:2
Names: 130-N-1:2; 183-N Southwestern Backwash Discharge Pond

Code: 130-N-1:1
Names: 130-N-1:1; 183-N Northeastern Backwash Discharge Pond

Classification: Accepted

Reclassification: Interim Closed Out (9/12/2013)

Type: Pond

Status: Inactive

Start Date: 

End Date: 6/27/2000

Description: 130-N-1 Subsite 1 has been remediated and Interim Closed Out. It was the northeastern half of
the 183-N Backwash Discharge Pond. The northeastern half was described in the original discharge permit application as having three adjoining portions; a rectangular portion, a neck, and a dry pond. The effluent discharge pipe was capped on June 27, 2000.

**Location:**
The site is located approximately 0.4 kilometers (0.25 miles) southeast of the 1324-N Facility.

**Related Sites/Structures:**
130-N-1 received waste via the 100-N-58 pipeline.

**Process Description:**
The 183-N Water Treatment Plant was constructed in 1963 to support operations of the 100-N Reactor. The water filtration plant provided treated water for cooling purposes, water for auxiliary support systems, and potable water for administrative buildings and offices. The filter backwash was originally discharged to the River via the 1908-N Outfall until September 2, 1977 when it was diverted to the 163/183N facility discharge pond area (100-N-58, 120-N-1 and 120-N-2). The settling ponds were small unlined basins which were used mainly to settle out solids from the filter backwash. By late 1981 it was apparent that annual dredging of the settling ponds was not sufficient to prevent flooding. 130-N-1 was constructed in 1982 to receive the filter backwash waste stream to reduce the particulate loading on the settling ponds. It began receiving effluent in 1983. When the pond was active, the State Waste Discharge permit application, (1994), identified four wastewater streams that were routed to the 183-N Backwash Discharge Pond (DOE/RL-94-23).

**Closure Info:**
Excavation of the soils associated with the entire 130-N-1:1 subsite was performed by the Field Remediation Project beginning on January 15, 2013, and finishing on April 8, 2013. Approximately 1.7 meters (5 ft) of soil was removed from the excavation and disposed at the Environmental Restoration Disposal Facility (ERDF). Approximately 12,217 bank cubic meters was direct loaded to ERDF. No anomalies were encountered during the excavation and the effluent discharge pipe was cut below grade and buried during this time. Any remaining effluent discharge pipe below grade is related to the 100-N-58 waste site. According to the closure document for the 100-N-58 waste site (CVP-2001-00021), all remaining pipelines were closed out and left in place.

**The SubSite is Part Of:**
- 130-N-1
- 183-N Backwash Discharge Pond
- 183-N Filter Backwash Pond
- 126-N-1

</tbody>
</table>

**Location:**

**Related Sites/Structures:**
130-N-1 received waste via the 100-N-58 pipeline.

**Process Description:**
The pond was originally constructed in 1982 by utilizing a natural depression and was known as the Backwash Lake. The construction activities included building a dike to protect a railroad
spur that ran along the southern end of the depression and excavating channels to facilitate drainage. The Backwash Lake was put into operation in 1983. It was later referred to as the 183-N Backwash Discharge Pond, presumably because the area that received water was significantly smaller than originally designed.

The southwestern half of the 183-N Backwash Discharge Pond received little (if any) effluent. The 130-N-1 pond began receiving effluent in 1983 via the 100-N-58 pipeline, which discharged to the northern end of the pond area.

1 - Coagulator Drains Wastewater, derived from the annual draining and washing of the coagulator basins.

2 - Filter Backwash Wastewater, consisting of backwash from the multimedia gravity filters.

3 - Non-Contact Cooling Water, from an air compressor in the 184-N Building and a fire pump in the 182-N Building.

4 - Collection of Stormwater from the 163-N Demineralizer Sump, 163-N Trench Sump, and 108-N Neutralizing Sump.

Closure Info: Three in-process samples were collected in the 130-N-1:2 southwestern pond on October 22, 2012. The samples were collected in the lowest elevation (140 meters [459.3 ft] above sea level), near the effluent entry point of the subsite 2 area, where contamination was most likely to occur. The sample results indicated that no excavation was required.

The SubSite is Part Of:
Code: 130-N-1
Names: 130-N-1; 183-N Backwash Discharge Pond; 183-N Filter Backwash Pond; 126-N-1

Code: 1908-N
Names: 1908-N; 1908-N Outfall
Type: Outfall
Status: Inactive
Classification: Accepted
Reclassification: Interim Closed Out (9/6/2012)
Start Date: 1/1/1963
End Date:
Description: The waste site structure has been demolished and Interim Closed Out. It consisted of an open-topped, compartmentalized, reinforced concrete outfall structure. A 260 centimeter (102 inch) line discharged into the southeast face of the structure. A 260 centimeter (102 inch) pipeline exited the northwest side of the structure and discharged to the Columbia River. The 1908-N above and below grade structure was removed except for a section of the north wall, that was encased in the concrete monolith.

Location: The 1908-N Sealwell (Outfall) was located west of the 109-N Building, west of the 1300-N Emergency Dump Basin and south of the 1301-N Emergency Dump Tank on a steep bank which leads to the river.

Related Sites/Structures: The outfall structure is associated with 100-N-77 (a 259-centimeter (102-inch) River Effluent pipeline), 100-N-79 (an emergency outfall flume) and the 1300-N Emergency Dump Basin 76-centimeter (30 inch) overflow line.

Process Description: The site was an outfall structure (seal well) that was used as a sump for several discharge lines and to drop the liquid discharge level for overflow to the river. The outfall also discharged to a
flume which was used as an alternative to the river pipelines. An unknown level of radioactive contamination exists within the structure because the discharge lines were associated with the reactor secondary steam system.

The outfall received more than 2 million cubic meters per day of single pass raw river water from the Circulating Raw Water (CRW) System, and discharged it to the river. The CRW supplied once-through untreated river water to 16 dump condensers and 7 surface condensers.

Waste Type: Misc. Trash and Debris

Waste Description: The 1908-N Sealwell received raw river water used to cool the secondary cooling water for the N Reactor. An unknown level of radioactive contamination exists within the structure because the discharge lines were associated with the reactor's secondary steam system. Therefore, while no specific COPCs have been identified, the outfall structure has potential radioactive contamination.

Closure Info: Radiological scoping surveys were performed on the 1908-N facility prior to and during demolition. These surveys did not identify contamination. A certified asbestos inspection was conducted on June 19, 2006. No samples were taken, but a visual inspection of 1908-N was conducted and no Potential ACM was visible during the inspection. There were no samples taken of the 1908-N for waste characterization/designation purposes. Two samples were taken of the lean concrete monolith to identify whether or not the monolith could be left in place.

Demolition of the 1908-N Outfall was performed March 2012 through June 2012. The entire above and below grade structure was removed, including the concrete floor, with the exception of a below-grade portion of the north wall that was encased within a lean concrete monolith. The concrete monolith remaining after demolition of the structure was sampled on April 26, 1012, to support a decision for leaving this concrete monolith in place. An evaluation of the results of this sampling indicated that residual contaminant concentrations in the concrete do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of the site. The results also demonstrate that residual contaminant concentrations in the concrete are protective of groundwater and the Columbia River. The Sampling Determination Form included with the Facility Status Change Form documents that there is no indication that any portion of the 1908-N facility or the underlying soil was ever contaminated and that analytical results for the sample collected from the concrete monolith is sufficient to support closeout of this waste site. The removal action was performed in accordance with the Removal Action Work Plan (RAWP) for 100-N Area Ancillary Facilities (DOE-RL-2002-70, Rev. 3) and included removal and disposal of demolition debris at the ERDF.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

</tr>
</tbody>
</table>
and required Institutional Controls to monitor the structure. Demolition of the structure in 2012 eliminated the requirement for the monitoring Institutional Control.

**Location:**
The unit was located in the 100-N Area, approximately 61 meters (200 feet) downstream from the 181-NE River Pumphouse Building on the Columbia River at river mile 379.6.

**Related Sites/Structures:**
The site was associated with the 100-N-1 Settling Basin, and the 100-N-80 River Effluent Pipeline.

**Process Description:**
The outfall received single pass raw river water which had passed through the Hanford Generating Plant (HGP) condensers, as well as waste water from the 100-N-1 Settling Basin.

**Waste Type:**
Soil

**Waste Description:**
The unit was designed to provide controlled waste water releases from the Hanford Generating Plant (HGP) facility. The unit was permitted under the National Pollutant Discharge Elimination System (NPDES). Releases to the outfall included coolant water, any releases from the HGP building sump prior to the late 1960s, and discharges from the HGP Settling Pond. The contaminants of potential concern include strontium-90, cobalt-60, cesium-137, arsenic, barium, cadmium, chromium, lead, selenium, silver, mercury, and PCBs.

**Closure Info:**
The 100-N Reactor provided fuel rods to the plutonium production process at Hanford, but also operated two 430 megawatt turbine generators for the generation of electricity. The Washington Public Supply System, later named Energy Northwest, was responsible for the Hanford Generating Plant located at 100-N Reactor. The Cleanup Verification Package (HGP-CVP-SWMUs 5, 6, 7, 8, 9, & 10) for the Hanford Generating Plant Solid Waste Management units was prepared by Energy Northwest in 2004. Some remedial actions at HGP began in 1992. Other characterization and remediation was completed in 2004. Remedial action activity descriptions include:

- **100-N-1 Settling Pond (SWMU#6)** - Remediation activities conducted in 2001 removed approximately 0.9 meters (3 ft) of soil and settled solids material from the 100-N-1 Settling Pond (SWMU #6). The excavated material was disposed of at the Environmental Restoration Disposal Facility (ERDF).

- **100-N-3 Maintenance Garage French Drain, 100-N-41 Gate House Septic Tank and 100-N-45 Office Building Septic Tank** make up SWMU #9. Remediation was determined not to be necessary for the 100-N-3 site and the 100-N-41 and 100-N-45 septic sites. The below grade structures of the drain and septic sites were demolished in place and backfilled with soil in 2004.

- **100-N-4 Tile Field (SWMU#5)** - Confirmatory sampling activities and data evaluation determined that remediation was not necessary for the 100-N-4 Tile Field.

- **100-N-5 Bone Yard (SWMU #10)** - Remediation and removal activities for the 100-N-5 Bone Yard (SWMU #10) were primarily conducted in 2001 with the removal of the miscellaneous equipment, metal scrap, and general debris. The limited number of areas with sand blast media, ion exchange resin-like media and areas with soil staining and/or distressed vegetation were remediated in 2003 and 2004. The sand blast, ion exchange resin, and contaminated soil wastes were disposed of at the RABANCO landfill facility in Roosevelt, Washington.

The 100-N-46 Diesel under ground storage tank (UST) was excavated and removed in 2001. Soil contaminated with diesel was also excavated from the UST excavation. Contaminated soil was spread over the demolished 1703-N Office Building concrete slab foundation for attenuation. Upon completion of the remedial excavation, the bottom of the excavation was approximately 6.7 meters (22 ft) below the ground surface at the deepest location (southwest corner of excavation).
100-N-52 Gasoline underground storage tank (UST) was excavated and removed in 1992.

1908-NE Outfall (SWMU#7) - The original preferred remedy for the 1908-NE Outfall was Institutional Controls (continued monitoring). A radiological survey of the Outfall seal well and samples of water and sediment were collected from the Outfall seal well in 2001 to assess potential contamination associated with the Outfall. The outfall structure was demolished by the Washington Closure Hanford D&D organization in 2012, eliminating the Institutional Control requirement.

The 1716-NE Maintenance Garage building (SWMU #8), including the building slab and associated floor drain pipelines, were removed in their entirety during the 2003 and 2004 removal action activities. Prior to the removal action all chemical products were removed from the building and either properly disposed of or transferred to another facility for use. The building debris was used as fill for the 185-N Building basement.

An additional Waste Site Reclassification Form (#2012-088) was approved in November 2012. The outfall was interim closed in 2004; however, no remedial or demolition activities were performed at the outfall and an institutional control to preclude unauthorized human entry into the structure was applied. Subsequently, decontamination, demolition, and disposal was performed in 2011 through 2012 that included removal of contaminated sediment and demolition and removal of the upper portion of the outfall structure to a depth of 0.9 m (3 ft) below grade. The remaining structure was then backfilled to grade with clean fill material. Sediment and concrete removed from the structure was disposed at the Environmental Restoration and Disposal Facility (ERDF).

The concrete sample results supported a decision to demolish and remove the outfall to a depth of 0.9 meters (3 ft) below grade, with subsequent backfill of the structure with clean fill material. The removal action also allows for removal of the Institutional Control requirement, since unauthorized human entry into the structure is no longer possible due to backfill of the remaining below-grade structure with clean fill material.

<td></td>
<td>This waste site has been remediated. It consisted of relatively flat ground covered with fine gravel chips with little or no vegetation. The 600-35 waste site was a non-radiologically contaminated waste site that consisted of a 15-meter (50-ft)-diameter area of wood and metal debris, including a partially crushed topless drum laying on its side and a discarded 12 volt lead-acid battery. A well-head (number 87-55) and the 100-N export water line were noted on the southern edge and along the east-west line of the site, respectively. On May 8, 2008, a field evaluation of the site was made by the Orphan Sites Evaluation team. The team described the site as a 15 meter (50 ft) diameter area of wood and metal debris, including a T-handled valve and vent pipe.</td>

<td>This site consists of a 1.83 meter (six foot) diameter dry well and associated inlet piping, which</td>
</tr>
</tbody>
</table>

**Location:** The 600-35 waste site is located outside the 100-N industrial area in a depression just west of Route 4 N between the 100-N and 100-D Areas. The center of the 600-35 waste site is at Washington State Plane coordinates N149940, E572956. The unit is located in a depression just west of Route 4 N between 100-N and 100-D, about 610 meters (2,000 feet) south of junction of the Route 2 N and Route 4 N.

**Process Description:** This site appears to be a former rock crushing/screening operation area and borrow pit (on the northern edge) with evidence of some dumping.

**Waste Type:** Chemicals

**Waste Description:** Miscellaneous surface debris was the only waste identified at this site. This debris includes a ladder, an 20-centimeter (8-inch) diameter steel pipe, metal scrap wire rope, miscellaneous wood debris, pieces of aluminum, and a container lid (no markings). A deteriorated 12 volt lead-acid battery of the type used in heavy equipment. A 208-liter (55-gallon) drum (no marking) was observed approximately 76 meters (250 feet) west of the site.

**Closure Info:** Remedial action at the 600-35 waste site was performed between August 2 and 29, 2010. The debris removed from the 600-35 waste site consisted of miscellaneous metal and wood debris. Excavation continued until all debris and contamination associated with the waste site had been removed. Excavated material was stockpiled and transported to ERDF in December 2010. A 12-volt lead-acid battery and a crushed drum, previously identified, were not found during remediation. It is assumed the battery and drum were removed after the orphan sites evaluation in May 2008. No indications of previous spills or releases were detected during remediation at the 600-35 waste site. Six in-process soil samples were collected at various locations from the excavator bucket, for waste designation purposes, as soil was being removed.
was part of the original 1960 construction, located west of the 609 Building. The dry well is located 0.61 meters (2 ft) below grade. It is constructed of concrete blocks laid on their sides with 1.3 cm (0.5 in) minimum openings between joints. The open bottom contains a 0.3 meters (1 ft) coarse gravel fill. The opening at the top is secured by a cast iron manhole cover. The 10 cm (4 in) inlet pipe enters the dry well 3 meters (10 ft) above its bottom elevation. The dry well is believed to still be in use, but has been paved over with an asphalt parking lot.

**Location:** The underground drywell (site is covered with asphalt parking lot) is approximately 6 meters (19.7 ft) west of the center of the 609 Building's west wall at approximately E572202.54 N145349.19.

**Process Description:** The dry well was designed to collect rain water draining from the roof, as well as floor drain waste from the entire building. All liquid wastes originating from the routine use and maintenance of the fire station vehicles were flushed to this dry well.

---

### Code: 600-340  
**Classification:** Accepted

**Names:** 600-340; 100 area Fire Station Soil Stained Areas  
**Reclassification:** Interim Closed Out (6/18/2014)

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The waste site was remediated and Interim Closed Out. It consisted of two locations, one with discolored top soil and the other with a white granular stain surface area.

**Location:** The two areas were located at coordinates E572161.02 N145395.78 and E572213.75 N145447.13, approximately 16 meters (52.5 ft) northwest of the 100 Area Fire Station.

**Closure Info:** Ground penetrating radar and electromagnetic induction data were collected over the two stained locations. The entire area surveyed contained scattered surface and near surface debris. Confirmatory sampling was performed at the 600-340 waste site on January 19, 2011. The staining and debris was observed and excavated well beyond the Waste Information Data System (WIDS) and Stewardship Information System mapped waste site boundaries. The excavation was extended to the southeast to encompass additional burned material and stained soil observed during site remediation. The remediation continued until all visible burned debris and stained soil was removed.

The 600-340 waste site was remediated between June 19 and September 10, 2013, based on the results of confirmatory sampling. The debris removed from the 600-340 waste site consisted of stained soil, broken glass, burned construction debris, asbestos-containing materials, wire, metal, and other debris. Approximately 1,472 bank cubic meters (BCM) (1,925 bank cubic yards [BCY]) of soil and debris were direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). There is no staging pile area or overburden soil stockpile associated with the 600-340 waste site excavation. No anomalous material was encountered during excavation.

---

### Code: 600-347  
**Classification:** Accepted

**Names:** 600-347; 100 Area Fire Station Burn Pit  
**Reclassification:** Interim No Action (11/21/2011)

**Type:** Burn Pit

**Status:** Inactive

**Description:** The site consists of an engineered burn pit. The dimensions of the burn pit are 6 m (20 ft) by 3
The site consists of two locations. The first site is the underlying soil from the original 1894 L (500 gallon) fire station gasoline tank removed in late 1987. The second site is a 7571 L (2000 gallon) diesel fuel oil tank and underlying soil used to supply the 609 Building hot water boiler.

Location: E572205.40 N145329.93
E572208.86 N145356.60

Reclassification: 628-2; 100 Area Fire Station Burn Pit
Burn Pit
Inactive

Names: 628-2; 100 Area Fire Station Burn Pit

Type: Burn Pit

Status: Inactive

Description: This site has been remediated and Interim Closed Out. It was an unmarked pit composed of sand and dirt with sparse vegetation showing signs of stress. The site had ash, debris, and soil discoloration.

Location: This site was located 130 meters (426.5 feet) north of the 100 Area Fire Station.

Process Description: The original information indicates that mainly motor oil and diesel fuel contaminated with water or deemed unusable was burned here. However, there is no supporting written documentation.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: The waste site contains motor oil, diesel fuel, and toluene. Other chemicals were potentially burned at the site.

Closure Info: A geophysical investigation was conducted on September 22, 2011. An area measuring 12 by 14 meters (39 by 46 ft) had a significant amount of concentrated debris.

The 628-2 waste site was remediated between June 24 and July 9, 2013. The debris removed from the 628-2 waste site consisted of broken glass, burned construction debris, asbestos-containing materials, wire, metal, and other debris. The estimated volume of excavated materials was approximately 709 bank cubic meters (927 bank cubic yards). Materials were
temporarily staged within the 628-2 excavation, prior to removal to the Environmental Restoration Disposal Facility. There were no staging pile areas or overburden piles associated with the 628-2 waste site excavation. No anomalous material was encountered during excavation.

| Description:    | The Unplanned Release has been remediated and Interim Closed Out. The site was an unplanned release covering an area of ground estimated at 20,000 square feet (1,858 square meters). |

| Location:       | The site extended from the 1304-N Emergency Dump Tank to the front of the 181-N River Water Pump House, approximately 45 meters (147 feet) from the Columbia River. |

| Release Description: | On March 27, 1974 an estimated 113,550 liters (30,000 gallons) of radioactive water leaked onto the ground due to a line leak from the inlet valve box near the 1304-N Emergency Dump Tank. The water flowed down the bank from the Emergency Dump Tank, covered the roadway below the tank, and extended to the front of the 181-N Building. An estimated 139 square meters (1,500 square feet) was contaminated outside the 100-N area security fence. The security fence is considered the site boundary. |

| Related Sites/Structures: | The site is associated with 1322-N Valve Pit, 105-N Lift Station, 1301-N Crib, a 91 centimeter (36 inch) underground pipeline, 1304-N Emergency Dump Tank, and a 76 centimeter (30 inch) underground pipeline. |

| Waste Type: | Storage Tank |

| Waste Description: | The leak consisted of filtered water in the estimated amount of 113,550 liters (30,000 gallons) containing 0.2 Curies of radioactive constituents. |

| Closure Info: | The above ground 1304 Emergency Dump Tank and associated piping were removed in 2004. Remedial action at the 100-N-57, UPR-100-N-1, UPR-100-N-2, UPR-100-N-29, UPR-100-N-30, and UPR-100-N-32 waste sites was performed between February 21 and May 31, 2011. Excavation continued until all debris and contamination associated with the waste sites had been removed. Contaminated soil, concrete, pipeline segments and debris removed during excavation were staged within the South Staging Pile Area 1 (SSP Area 1) prior to shipment to the ERDF. Approximately 1,848 bank cubic meters (2,417 bank cubic yards) of contaminated soil and debris were removed from the site and disposed at the ERDF. No stained soil or anomalous material was found during the remediation activities. The debris removed from the waste sites consisted of miscellaneous noncombustible debris and soil. Portions of the 100-N-63:2, 100-N-64, 100-N-84:2, 100-N-84:3, 100-N-84:4, and 100-N-84:5 pipelines waste sites were also removed during 100-N-57 group of waste sites remediation activities. The remaining portions of these pipeline waste sites will be remediated and separate closure documents prepared at a later date. Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935). |
Reclassification: UPR-100-N-2; 100-N FLV-858 Valve Leak; UN-100-N-2

Unplanned Release

Inactive

Start Date: 2/19/1980
End Date: 2/19/1980

Type: Unplanned Release

Status: Inactive

Classification: Accepted

Reclassification: Interim Closed Out (3/20/2013)

Description: The Unplanned Release has been remediated and Interim Closed Out. The site was an area of ground covering estimated at 28 square meters (300 square feet).

Location: The release was located in the 100 N Area, on the northeast corner of Emergency Dump Basin (116-N-4), below grade.

Release Description: The release occurred on February 19, 1980, with an estimated 113,550 L (30,000 gal) of contaminated reactor effluent being leaked to a crack in a 2.5 cm (1 in.) relief drain line. The FLV858 valve leaked mildly contaminated reactor effluent from a point 3 meters (10 feet) below grade. The leak rate was estimated at 38 liters/minute (10 gallons/minute) and was determined to be due to corrosion of the valve. Estimated surface area affected is 28 square meters (300 square feet).

Related Sites/ Structures: The site is associated with the 105-N Building.

Waste Type: Process Effluent

Waste Description: The release consisted of primary coolant water containing less than 1 curie of beta/gamma.

Closure Info: The above ground 1304 Emergency Dump Tank and associated piping were removed in 2004. Remedial action at the 100-N-57, UPR-100-N-1, UPR-100-N-2, UPR-100-N-29, UPR-100-N-30, and UPR-100-N-32 waste sites was performed between February 21 and May 31, 2011. Excavation continued until all debris and contamination associated with the waste sites had been removed. Contaminated soil, concrete, pipeline segments and debris removed during excavation were staged within the South Staging Pile Area 1 (SSP Area 1) prior to shipment to the ERDF. Approximately 1,848 bank cubic meters (2,417 bank cubic yards) of contaminated soil and debris were removed from the site and disposed at the ERDF. No stained soil or anomalous material was found during the remediation activities.

The debris removed from the waste sites consisted of miscellaneous noncombustible debris and soil. Portions of the 100-N-63:2, 100-N-64, 100-N-84:2, 100-N-84:3, 100-N-84:4, and 100-N-84:5 pipelines waste sites were also removed during 100-N-57 group of waste sites remediation activities. The remaining portions of these pipeline waste sites will be remediated and separate closure documents prepared at a later date.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).
Description: The release site has been remediated and Interim Closed Out. The 100-N-31 waste site was located on the west side of the 105-N/109-N Reactor Buildings and adjacent to the 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39 waste sites. These waste sites are collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.

The release was first discovered as a 1.2 meter (4-foot) diameter and 0.8 meter (2.5 foot) deep sink hole within a radiation control zone, caused by a pipe leak.

Location: The release occurred in the 100-N Area near the north side of the 105-N Lift Station. It was about 4.7 meters (15.4 feet) northeast of the 1722-N Decontamination Hot Shop. This is same the location where the UPR-100-N-10 and UPR-100-N-12 releases occurred.

Release Description: A leak developed in the dummy fuel spacer transfer line, a 7.6-centimeter (3-inch) reinforced plastic pipe extending from the 100-N Fuel Storage Basin to the dummy disposal pit. The leak rate was estimated to be 74.6 liters (25 gallons) per minute. It was not known how long the leak had been occurring. However, due to the size of the sink hole, it was judged to have occurred within the week prior to identification. The volume of water that leaked to the soil was estimated to be approximately 1,362,744 liters (350,000 gal).

Related Sites/Structures: The site is associated with the 100-N Area Spacer Silos (118-N), the 105-N Fuel Storage Basin, 100-N-31 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39.

Waste Type: Storage Tank

Waste Description: The release consisted of storage basin water with an estimated radionuclide release of 0.07 curies of cobalt-60, 0.8 curies of strontium-90, 0.25 curies of cesium-137, 0.14 curies of cerium/praseodymium-144, 0.0004 curies of plutonium-239, and 1.0 curies of tritium (assumed).

Closure Info: Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. This group of waste sites was referred to as the waste sites west of the 105-N/109-N Reactor. The footprints of the 1909-N Waste Disposal Valve Pit, the 107-N facility and the pipe trench between 105-N and 107-N were also located within the boundary of the group.

The eleven collocated waste sites located west of the 105-N/109-N Reactor Building were remediated, either partially or completely, by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the collocated waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N) Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected.
above background. However, the area with the highest detected activity is associated with residual structures and soils for the 105-N/109-N SSE and is considered part of the 100-N-66, 105-N/109-N Reactor Building Complex waste site. A small area with elevated beta and gamma contamination was detected within the waste sites west of the 105-N/109-N Reactor boundary. Additional soil was removed from this area and disposed at the ERDF. An environmental radiological survey of the area using hand-held instruments verified that the contaminated soils have been removed.

The 1909-N Waste Disposal Valve Pit was removed during general facility demolition in this area by the D4 Project. Due to the proximity and general configuration of demolition and remediation activities on the west side of the reactor, closure of the facility footprint was deferred until nearby waste site remediation by the FR Project occurred. The residual contaminated soil that remained beneath the location of the former 1909-N facility was then removed.

The 107-N basin structure was completely removed by the D4 Project. However, closure of the basin footprint was deferred to the UPR-100-N-12 waste site. Additional soil was removed from the footprint during general waste site remediation in the area. Surveys found no elevated residual radiological activity.

Several segments of the 100-N-84 pipeline subsites were partially located within the remediation boundary. All of the segments of the 100-N-84:2, 100-N-84:4, 100-N-84:5, and 100-N-84:6 pipeline subsites that were within the excavation boundary were removed and disposed at the ERDF. Reclassification of the total 100-N-84:2, 100-N-84:4, 100-N-84:5 and 100-N-84:6 pipeline subsites will be addressed in separate closure documents.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

### Code: UPR-100-N-4

**Classification:** Accepted  
**Reclassification:** Interim Closed Out (8/31/2013)

**Names:** UPR-100-N-4; 1322-A Sump Overflow; UN-100-N-4

**Type:** Unplanned Release  
**Start Date:** 5/7/1977  
**End Date:** 5/7/1977

**Status:** Inactive

**Description:** The waste site has been remediated and Interim Closed Out. It was an overflow of contaminated water at the 1322-NA (Effluent Water Pilot Plant) that affected the floor inside the building and ground near the front and rear doors outside the building. The site also includes the drainage tank in Building 1322-N (Waste Treatment Pilot Plant Facility).

**Location:** The 1322 Buildings are about 195 meters (640 feet) northeast of the 105-N (Reactor Facility).

**Release Description:** The 1322-N Drainage Tank top vent sprayed low-level radioactive water. The 1322-NA sink drain backed up and flowed over the 15-centimeter (6-inch) curb and onto the ground in the front and back of the building. The release occurred on May 7, 1977.

**Related Sites/Structures:** The site is associated with UPR-100-N-8, UPR-100-N-31 and Buildings 105-N, 1322-N, and 1322-NA.

**Waste Type:** Storage Tank

**Waste Description:** The site received low-level radioactive water. The total activity was 0.5 millicuries.

**Closure Info:** The 1322N, 1322NA, 1322NB, and 1322NC above-ground buildings and slabs in the vicinity...
of the unplanned releases were removed during the 100-N deactivation, decommission, decontamination, and demolition (D4) activities. The removal included an excavation that measured approximately 3.7 meters (12 ft) deep. The UPR-100-N-4 and UPR-100-N-8 waste sites are associated with the 1322-N/NA Buildings. The UPR-100-N-31 waste site is associated with the 116-N-1 (1301-N) Crib and Trench. Because the locations of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 unplanned release sites were in close proximity to each other and no information was available to delineate the boundary of each release, the three sites were combined into one excavation. The excavation for remediation of the combined unplanned release sites was immediately adjacent to the former 116-N-1 (1301-N) remediation site. Further remediation of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 waste site soils was performed between December 13, 2011 and March 19, 2012, resulting in a combined excavation approximately 7 meters (23 ft) deep.

Approximately 5,683 bank cubic meters (BCM) (7,433 bank cubic yards [BCY]) of additional contaminated soil, rocks, and concrete was removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Additional contaminated soil was removed from areas SZ-6, SZ-8, and SZ-9 between January 30, 2013 and February 4, 2013, resulting in an additional 189 BCM (247 BCY) of contaminated soil removed for disposal at ERDF. Areas of stained soil remained in the deep zone (more than 4.6 meters [15 ft] below ground surface [bgs]) following the completion of the remedial action activities. All material was direct loaded from the excavation for disposal at ERDF. No overburden piles or anomalies were associated with the remediation.

During remediation of the unplanned release sites, increasing radiological activity was observed with depth approaching soils underlying the former 116-N-1 crib. Deep zone sample results from the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 remediation are also consistent with residual contamination in the 116-N-1 deep zone. This suggests that the contamination encountered was residual from 116-N-1 left in place in the deep zone, and that deep zone remediation of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 waste sites is considered complete. The liquid waste effluents associated with the UPR-100-N-31 and 116-N-1 waste sites are the same.

</table>
Waste Type: Storage Tank

Waste Description: The leak consisted of 340,650 liters (90,000 gallons) of radioactive wastewater containing decontaminated chemicals. The waste contained approximately 35 curies of activity, of which 26 curies were cobalt-60. The solution had a pH of approximately 9.

Closure Info: Remedial action of the 116-N-2 (Golf Ball) waste site was performed between March 1, 2011 and April 26, 2012. Equipment decontamination was conducted within the southeast corner of the waste site excavation, and that area was remediated May 7 and 8, 2012. The maximum depth of the excavation was 13 meters (42.7 ft) bgs and resulted in the removal of approximately 11,144 bank cubic meters (BCM) (14,576 bank cubic yards [BCY]) of soil and debris. The debris consisted of rock, sand, and piping material. The contaminated soil and debris were directly loaded out for disposal at the Environmental Restoration Disposal Facility (ERDF). Also removed with the 116-N-2 excavation were the UPR-100-N-5 and UPR-100-N-25 waste sites, as well as portions of the 100-N-84 and 100-N-63 pipelines. A section of the 100-N-63:2 pipeline remained on a side slope in the northern part of the excavation until it was remediated between March 22, and 25, 2013. No anomalous material was found during remediation. No in-process samples were collected for the 116-N-2 grouping of waste sites.

Clean padding material (soil and gravel) had been previously placed on the ground surface south of the excavation to cover radiological contamination that resulted from the previous D4 activities to remove the golf ball and silo structures. The padding material and approximately 2 meters (6.5 ft) of soil below the padding was scraped and removed for disposal at ERDF.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

Code: UPR-100-N-6

Classification: Accepted

Reclassification: Interim Closed Out (1/2/2013)

Names: UPR-100-N-6; 1 1/2 Inch Chemical Decontam. Waste Drain Line Leaks; Chemical Decontamination Waste Drain Line Leak; UN-100-N-6; UN-116-N-6

Type: Unplanned Release

Start Date: 9/10/1985

End Date: 9/10/1985

Status: Inactive

Description: The waste site has been remediated and Interim Closed Out. It was a release from a 1.5 inch diameter, chemical decontamination waste drain line. The release leaked radiologically contaminated water into the surrounding soil. The line was 0.9 meters (3 feet) below grade.

Location: The release site was located between the north wall of the 1714-NB building and the 1310-N tank.

Release Description: The buried 3.8-centimeter (1.5 inch) line leaked radiologically contaminated water in the general area between buildings 1714-N and 1310-N. The release occurred on September 10, 1985. The release consisted of approximately 6,813 liters (1,800 gal) of radiologically contaminated water containing an estimated 0.2 Ci of cobalt-60, 0.04 Ci of manganese-54, 0.003 Ci of ruthenium-103, and 0.003 Ci of cesium-137. Approximately 16.7 cubic meters (590 cubic feet) of contaminated soil reading 7,000 to 25,000 counts per minute was removed from four locations along the line. The excavations were backfilled with clean soil.

Related Sites/Structures: This drain line interconnects with 105-N and 1310-N (Chemical Waste Storage Tank) and 100-N-62:2.

Process Description: This site is a 3.8 centimeter (1.5 inch) waste line, buried 0.9 meters (3 feet) below grade. This chemical decontamination waste drain line runs between the 105-N reactor building and the
1310-N (Chemical Waste Storage Tank).

**Waste Type:** Storage Tank  
**Waste Description:** The release consisted of approximately 6,813 liters (1,800 gallons) of radiologically contaminated water containing an estimated 0.2 curies cobalt-60, 0.04 curies manganese-54, 0.003 curies ruthenium-103, and 0.003 curies of cesium-137.

**Closure Info:** Remedial action at the UPR-100-N-6 waste site to remove the pipeline and associated contaminated soil was performed between September 20, 2011, and April 18, 2012. All excavated materials were direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Excavation continued until all debris and contamination associated with collocated waste sites had been removed. The depth of the excavation was approximately 2.4 to 3.7 meters (8 to 12 ft) below ground surface. All excavated materials were direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF).

Because the UPR-100-N-6 waste site originated from 100-N-63:2 pipeline leaks and the excavation was performed to remediate both waste sites simultaneously. The volume of material removed for the UPR-100-N-6 waste site alone was not calculated. The volumes disposed from this excavation are included in the 100-N-63:2 waste site closeout documents.

**Code:** UPR-100-N-7  
**Classification:** Accepted  
**Names:** UPR-100-N-7; Ten-Inch Radioactive Drain Return Line Leak; UN-100-N-7; UN-116-N-7  
**Reclassification:** Interim Closed Out (9/6/2013)  
**Type:** Unplanned Release  
**Status:** Inactive  
**Start Date:** 4/29/1985  
**End Date:** 5/1/1985  
**Description:** The release site has been remediated and Interim Closed Out. The 100-N-31 waste site was located on the west side of the 105-N/109-N Reactor Buildings and adjacent to the 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39 waste sites. These waste sites are collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.

It was a leak that occurred in a buried 25.4-centimeter (10-inch) drain line between the 109-N Building and the 1909-N Valve Pit. The release occurred on April 29, 1985.

**Location:** The site is located near the northwest corner of the 109-N Building. The leak occurred in a section of 25.4 centimeter (10-inch) diameter radioactive drain return pipe located between the 109-N Building and the 1909-N Valve Pit.

**Release Description:** Adjacent groundwater monitoring wells detected increased levels of iodine-131, indicating a nearby leak to the water table. Approximately 1,907,842 liters (504,000 gallons) had leaked. The release occurred on April 29, 1985.

**Related Sites/Structures:** The 25.4 centimeter (10 inch) Radioactive Drain Return (RDR) line connected to the 109-N Building and the 1909 Valve Pit. The release site is associated with 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39.

**Waste Type:** Process Effluent  
**Waste Description:** The release consisted of approximately 1,907,042 liters (504,053 gallons) of radiologically contaminated N-Reactor cooling water containing an estimated 1.0 curies sodium-24, 0.5 curies cobalt-60, 0.09 curies ruthenium-103, 0.4 curies chromium-51, 0.2 curies zirconium-95, 0.3...
curies tellurium-132, 0.30 curies manganese-54, 0.1 curies niobium-95, 0.5 curies iodine-131, 1.2 curies iron-59, 0.2 curies cerium-141, 0.2 curies cerium-144, and 0.8 curies technecium-99.

Closure Info: Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. This group of waste sites was referred to as the waste sites west of the 105-N/109-N Reactor. The footprints of the 1909-N Waste Disposal Valve Pit, the 107-N facility and the pipe trench between 105-N and 107-N were also located within the boundary of the group.

The eleven collocated waste sites located west of the 105-N/109-N Reactor Building were remediated, either partially or completely, by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the collocated waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N) Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected above background. However, the area with the highest detected activity is associated with residual structures and soils for the 105-N/109-N SSE and is considered part of the 100-N-66, 105-N/109-N Reactor Building Complex waste site. A small area with elevated beta and gamma contamination was detected within the waste sites west of the 105-N/109-N Reactor boundary. Additional soil was removed from this area and disposed at the ERDF. An environmental radiological survey of the area using hand-held instruments verified that the contaminated soils have been removed.

The 1909-N Waste Disposal Valve Pit was removed during general facility demolition in this area by the D4 Project. Due to the proximity and general configuration of demolition and remediation activities on the west side of the reactor, closure of the facility footprint was deferred until nearby waste site remediation by the FR Project occurred. The residual contaminated soil that remained beneath the location of the former 1909-N facility was then removed.

The 107-N basin structure was completely removed by the D4 Project. However, closure of the basin footprint was deferred to the UPR-100-N-12 waste site. Additional soil was removed from the footprint during general waste site remediation in the area. Surveys found no elevated residual radiological activity.

Several segments of the 100-N-84 pipeline subsites were partially located within the remediation boundary. All of the segments of the 100-N-84:2, 100-N-84:4, 100-N-84:5, and 100-N-84:6 pipeline subsites that were within the excavation boundary were removed and disposed at the ERDF. Reclassification of the total 100-N-84:2, 100-N-84:4, 100-N-84:5 and 100-N-84:6 pipeline subsites will be addressed in separate closure documents.

Following remediation, the radiological postings were removed - per WCH Internal Memos.
The waste site has been remediated and Interim Closed Out. It was an overflow of contaminated water at the 1322-NA (Effluent Water Pilot Plant) that affected the area (approximately 2.3 square meters [25 sq. ft]) surrounding the sump, floor, various pieces of equipment, and the ground just outside the rear door (south door).

Location: The 1322-NA Building was located approximately 195 meters (640 feet) northeast of the 105-N Reactor Facility. The release took place in the soil immediately outside the south door of 1322-NA Effluent Water Pilot Plant. This is partly on the same location as UPR-100-N-4.

Release Description: The 0.3-centimeter (1/8-inch) tygon sample tube came off the 91-centimeter (36-inch) radioactive drain return line sampler sample line and up to 379 liters (100 gallons) of radioactive water was released to the soil.

Related Sites/Structures: The site is associated with UPR-100-N-4, UPR-100-N-31 and Buildings 105-N, 1322-N, and 1322-NA.

Waste Type: Animal Waste

Waste Description: The release contained up to 379 liters (100 gallons) of radioactive water contaminated with mixed fission and activation products to a level of 1,000,000 picocuries/liter. The total activity was 0.5 millicuries.

Closure Info: The 1322N, 1322NA, 1322NB, and 1322NC above-ground buildings and slabs in the vicinity of the unplanned releases were removed during the 100-N deactivation, decommission, decontamination, and demolition (D4) activities. The removal included an excavation that measured approximately 3.7 meters (12 ft) deep. The UPR-100-N-4 and UPR-100-N-8 waste sites are associated with the 1322-N/NA Buildings. The UPR-100-N-31 waste site is associated with the 116-N-1 (1301-N) Crib and Trench. Because the locations of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 unplanned release sites were in close proximity to each other and no information was available to delineate the boundary of each release, the three sites were combined into one excavation. The excavation for remediation of the combined unplanned release sites was immediately adjacent to the former 116-N-1 (1301-N) remediation site. Further remediation of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 waste site soils was performed between December 13, 2011 and March 19, 2012, resulting in a combined excavation approximately 7 meters (23 ft) deep.

Approximately 5,683 bank cubic meters (BCM) (7,433 bank cubic yards [BCY]) of additional contaminated soil, rocks, and concrete was removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Additional contaminated soil was removed from areas SZ-6, SZ-8, and SZ-9 between January 30, 2013 and February 4, 2013, resulting in an additional 189 BCM (247 BCY) of contaminated soil removed for disposal at ERDF. Areas of stained soil remained in the deep zone (more than 4.6 meters [15 ft] below ground surface [bgs]) following the completion of the remedial action activities. All material was direct loaded from the excavation for disposal at ERDF. No overburden piles or anomalies were associated with the remediation.

During remediation of the unplanned release sites, increasing radiological activity was observed.
with depth approaching soils underlying the former 116-N-1 crib. Deep zone sample results from the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 remediation are also consistent with residual contamination in the 116-N-1 deep zone. This suggests that the contamination encountered was residual from 116-N-1 left in place in the deep zone, and that deep zone remediation of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 waste sites is considered complete. The liquid waste effluents associated with the UPR-100-N-31 and 116-N-1 waste sites are the same.

</tr>
<tr>
<td>Closure Info:</td>
<td>Remedial action at the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 waste sites was performed during January and February 2011. Remediation involved removal of the foundations of the 116-N stack, the 119-N and 119-NA structures, and the underlying soil. Excavation continued until the french drain, associated piping, and contaminated soil and debris were removed. This excavation exceeded the depth that would be required to remove the 100-N-102:1, UPR-100-N-9, and UPR-100-N-14 waste sites. According to drawing H-1-46389, the depth of the 100-N-102:1 subsite, and therefore the unplanned release waste sites UPR-100-N-9 and UPR-100-N-14, was at 0.76 meters (2.5 ft) bgs. The final excavation depth was approximately 8.5 meters (28 ft) bgs. Because the excavation and removal of the 116-N stack foundation was previously performed by the D4 Project, the exact volume of material removed is unknown. The debris removed included soil, concrete, piping, and other debris associated with the 116-N, 119-N, and 119-NA structures and french drain. All material from these waste sites was disposed at the Environmental Restoration Disposal Facility (ERDF). No anomalous material was encountered during the excavation.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
In March 2012, the D4 Project constructed a ramp across the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 excavation to provide access and to support remediation activities at 1303-N (118-N-1) waste site. The ramp material was excavated on September 28, 2012, and also disposed of at ERDF. A walk around the site boundary confirmed that all fill material used to build the ramp had been removed. After the excavation of the ramp material, a gamma survey was performed on October 3, 2012, within the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 excavation. The gamma survey results indicated readings above background at two locations. Additional remediation was performed to address areas where the GPERS survey results indicated elevated radiological results. Follow up surveys on October 17, 2012 and October 19, 2012 indicated no elevated readings above background.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

**Reclassification:**

- UPR-100-N-10; 100-N Area 105-N Check Valve; Lift Station Gravity Drain Line Leak; UN-100-N-10
- Unplanned Release
- Status: Inactive

**Start Date:** 5/13/1975  
**End Date:** 5/13/1975

**Description:** The waste site has been remediated and Interim Closed Out. The 100-N-31 waste site was located on the west side of the 105-N/109-N Reactor Buildings and adjacent to the 100-N-32, 100-N-38, 100-N-61 :3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39 waste sites. These waste sites are collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.

**UPR-100-N-10** was a release of contaminated water from a drain line to the ground. The leak occurred in an area previously marked as a radiation zone.

**Location:** The leak occurred in the 100-N Area near the north side of the 105-N Lift Station, about 4.7 meters (15.4 feet) northeast of the 1722-N Decontamination Hot Shop, and about 160 meters (530 ft) from the Columbia River. This was the same the location as the UPR-100-N-3 and UPR-100-N-12 releases.

**Release Description:** Approximately 379 liters (100 gallons) of contaminated water leaked to the ground during preparations for the removal of a check valve in the gravity drain line to the lift station on May 13, 1975.

**Related Sites/Structures:** The leak is associated with the 105-N Reactor Facility, UPR-100-N-3 and UPR-100-N-12.

**Waste Type:** Process Effluent  
**Waste Description:** The release contained 0.001 curies of mixed fission and activation products.

**Closure Info:** Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. This group of waste sites was referred to as the waste sites west of the 105-N/109-N Reactor. The footprints of the 1909-N Waste Disposal Valve Pit, the 107-N facility and the pipe trench between 105-N and 107-N were also located within the boundary of the group.
The eleven collocated waste sites located west of the 105-N/109-N Reactor Building were remediated, either partially or completely, by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the collocated waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N) Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected above background. However, the area with the highest detected activity is associated with residual structures and soils for the 105-N/109-N SSE and is considered part of the 100-N-66, 105-N/109-N Reactor Building Complex waste site. A small area with elevated beta and gamma contamination was detected within the waste sites west of the 105-N/109-N Reactor boundary. Additional soil was removed from this area and disposed at the ERDF. An environmental radiological survey of the area using hand-held instruments verified that the contaminated soils have been removed.

The 1009-N Waste Disposal Valve Pit was removed during general facility demolition in this area by the D4 Project. Due to the proximity and general configuration of demolition and remediation activities on the west side of the reactor, closure of the facility footprint was deferred until nearby waste site remediation by the FR Project occurred. The residual contaminated soil that remained beneath the location of the former 1009-N facility was then removed.

The 107-N basin structure was completely removed by the D4 Project. However, closure of the basin footprint was deferred to the UPR-100-N-12 waste site. Additional soil was removed from the footprint during general waste site remediation in the area. Surveys found no elevated residual radiological activity.

Several segments of the 100-N-84 pipeline subsites were partially located within the remediation boundary. All of the segments of the 100-N-84:2, 100-N-84:4, 100-N-84:5, and 100-N-84:6 pipeline subsites that were within the excavation boundary were removed and disposed at the ERDF. Reclassification of the total 100-N-84:2, 100-N-84:4, 100-N-84:5 and 100-N-84:6 pipeline subsites will be addressed in separate closure documents.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

Hanford Site Waste Management Units Report
February 2015
926
Status: Inactive  End Date: 10/3/1975

Description: The waste site has been remediated. The contaminated site consisted of asphalt road, shoulder/roadside, and field area.

Location: The site was located on the east side of Highway 4 North, approximately 45.7 meters (150 feet) southeast of the center line of 100-N access road.

Release Description: A contaminated 227-kilogram (500-pound) valve bonnet, wooden box, and plastic wrapping fell from a truck onto the road and into a field adjacent to the roadway. The wooden box broke open spreading spot contamination on the roadway and in the field. Contamination levels on roadway blacktop at the point of impact was 1,000 mrads/hr (1 rad/hr). Contamination on roadway adjacent to where valve hit was 20,000 to 50,000 counts per minute. The area where valve came to rest measured 5 rads to 10 rads per hour. The area adjacent to where valve came to rest measured 25,000 to 50,000 counts per minute.

Related Sites/Structures: The release is associated with the 105-N Reactor Facility.

Waste Type: Process Effluent

Waste Description: Five to 10 rads per hour were measured where the valve bonnet came to rest in the field.

Measurements of 1,000 millirads per hour were taken where it hit the road; 20,000 to 5,000 counts per minute on 18.6 square meters (200 square feet) of road; and 25,000 to 50,000 on the surface of the field adjacent to the valve bonnet.

Closure Info: Remediation of the UPR-100-N-11 waste site was completed on November 16, 2010, to a depth of approximately 0.5 meters (1.6 ft). The field area and part of the roadside ditch were the target of remedial actions for the UPR-100-N-11 waste site, which excavated an area approximately 11 by 5 meters (36 by 16 ft). The contaminated soil was direct loaded from the excavation.

Radiological surveys were conducted during remediation using hand-held radiological detection instruments. Additionally, a Global Positioning Environmental Radiological Surveyor (GPERS) survey was conducted within the UPR-100-N-11 excavation upon completion of remedial activities. No elevated radiological activity was detected by either of the survey methods. None of the current, existing roadway was removed, because the 1975 occurrence report provided a large amount of detail on removal of the roadway contamination. No stains or other anomalies were observed during field activities.

Code: UPR-100-N-12  Classification: Accepted

Names: UPR-100-N-12; Spacer Transport Line Leak; UN-100-N-12  Reclassification: Interim Closed Out (9/6/2013)

Type: Unplanned Release  Start Date: 1/1/1979

Status: Inactive  End Date: 3/13/1979

Description: The release site has been remediated and Interim Closed Out. The 100-N-31 waste site was located on the west side of the 105-N/109-N Reactor Buildings and adjacent to the 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39 waste sites. These waste sites are collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.

UPR-100-N-12 was first identified as a 0.6 by 0.9 meter (2 by 3 foot) diameter and 0.46 meter (1.5 foot) deep sink hole cause by a pipe leak.

Location: The site is located in the 100-N Area near the north side of the 105-N Lift Station, about 5
meters (15 feet) west of the 1722-N Decontamination Hot Shop, and about 160 meters (530 ft.) from the Columbia River. This was also the same location as the UPR-100-N-3 and UPR-100-N-10 releases.

**Release Description:** The dummy fuel spacer transfer line, (7.6 centimeter (3 inch) reinforced Bonstrand plastic pipe) extended from the 100-N Fuel Storage Basin to the dummy disposal pit. The maximum leak rate was estimated to be 284 liters (75 gallons) per minute. It is not known how long the leak had been occurring. The approximate maximum time the valve could have been open was 55 hours. The estimated release was 946,000 liters (250,000 gal) of fuel storage basin water. The water was originally from the fuel storage basin and had been used to help transport fuel spacers through thespacer transport line. Dummy spacers were transferred December 4,5,10,11,12,13,14, and January 8. The release was reported March 13, 1979.

**Related Sites/Structures:** The release is associated with the 100-N Area Spacer Silos (118-N) and 105-N Fuel Storage Basin, UPR-100-N-3 and UPR-100-N-10.

**Waste Type:** Process Effluent

**Waste Description:** The release consisted of 946,000 liters (250,000 gallons) of storage basin water containing 0.19 curies of cobalt-60, 0.4 curies of cesium-137, and 0.00057 curies of plutonium-239/240. The water was originally from the fuel storage basin and had been used to help dislodge fuel spacers through the spacer transport line. Excavated soil was checked for radioactivity and read 50 to 100 millirem per hour.

**Closure Info:** Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. This group of waste sites was referred to as the waste sites west of the 105-N/109-N Reactor. The footprints of the 1909-N Waste Disposal Valve Pit, the 107-N facility and the pipe trench between 105-N and 107-N were also located within the boundary of the group.

The eleven collocated waste sites located west of the 105-N/109-N Reactor Building were remediated, either partially or completely, by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the collocated waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N) Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected above background. However, the area with the highest detected activity is associated with residual structures and soils for the 105-N/109-N SSE and is considered part of the 100-N-66, 105-N/109-N Reactor Building Complex waste site. A small area with elevated beta and gamma contamination was detected within the waste sites west of the 105-N/109-N Reactor boundary. Additional soil was removed from this area and disposed at the ERDF. An environmental radiological survey of the area using hand-held instruments verified that the contaminated soils have been removed.
The 1909-N Waste Disposal Valve Pit was removed during general facility demolition in this area by the D4 Project. Due to the proximity and general configuration of demolition and remediation activities on the west side of the reactor, closure of the facility footprint was deferred until nearby waste site remediation by the FR Project occurred. The residual contaminated soil that remained beneath the location of the former 1909-N facility was then removed.

The 107-N basin structure was completely removed by the D4 Project. However, closure of the basin footprint was deferred to the UPR-100-N-12 waste site. Additional soil was removed from the footprint during general waste site remediation in the area. Surveys found no elevated residual radiological activity.

Several segments of the 100-N-84 pipeline subsites were partially located within the remediation boundary. All of the segments of the 100-N-84:2, 100-N-84:4, 100-N-84:5, and 100-N-84:6 pipeline subsites that were within the excavation boundary were removed and disposed at the ERDF. Reclassification of the total 100-N-84:2, 100-N-84:4, 100-N-84:5 and 100-N-84:6 pipeline subsites will be addressed in separate closure documents.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

<td>Description: The Unplanned Release has been remedi ed and Interim Closed Out. It consisted of a release of liquid, radioactively contaminated, spent decontamination solution.</td>
<td></td>
</tr>
<tr>
<td>Location: The release was located near the northeast corner of the 1314-N building, inside the posted radiation zone at the 1314-N Liquid Waste Loadout Station.</td>
<td></td>
</tr>
<tr>
<td>Release Description: This release was documented on Unusual Occurrence Report number 73-39. The release occurred on September 24, 1973 and was reported on October 3, 1973. The solution began overflowing from the tank car fittings after approximately 26,500 liters (7,000 gal) had been pumped into the 75,700 liters (20,000 gal) tank car during filling operations. The tank car loading pump was turned off, but the solution began to back flow through the drain in the catch basin beneath the tank car. The catch basin then began to overflow into the adjacent drywell, the capacity of which was also exceeded. The resulting drywell overflow caused the solution to cover a 1.9 square meters (20 ft²) of ground inside the radiation zone at the loading station. Approximately 380 liters (100 gal) of solution was released to the ground with a total activity on the ground surface estimated at 0.015 curies. Evaluation revealed that approximately 280 liters (75 gal) of solution containing 0.011 curies was discharged to the ground through the drywell. An unknown amount of contaminated soil was removed, packaged, and shipped to the 200 Area burial ground for disposal. Clean fill material was used to cover a portion of the contaminated soil that remained.</td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures: This release is associated with the 116-N-2 Radioactive Chemical Treatment and Storage Facility, 107-N Spent Fuel Basin Recirculation Facility and the 100-N-60 french drain.</td>
<td></td>
</tr>
<tr>
<td>Process Description: The 1314-N Liquid Waste Loadout Station was a 9 meter (30 ft) by 18 meter (60 ft) single story, metal-frame building supported on a reinforced concrete slab foundation. It began to operate in 1972. The facility was a transfer station consisting of numerous valves, pumps, underground and overhead piping and couplings, and underground tanks It was located</td>
<td></td>
</tr>
</tbody>
</table>
approximately 100 meters (300 ft) from the Columbia River. This facility was used to loadout radioactive liquid waste from the 116-N-2 and 107-N facilities into railroad tank cars for shipment to the 200 Areas for processing and disposal. The loadout facility contained a tank car wash station with a sump to collect the wash water. The water drained into a 3,780 liters (1,000 gal) overflow tank. During the filling operation, excess liquid waste was designed to overflow through a closed piping system from the tank car to the overflow tank, which initiated pump shutdown. A 756 liters (200 gal) catch tank was installed to hold liquids that exceeded the capacity of the car wash sump.

**Waste Type:** Process Effluent

**Waste Description:** The release consisted of 289 liters (75 gallons) of spent decontamination solution containing 0.011 curies.

**Closure Info:**

The 1314-N building was demolished in 2006. 100-N-60 and UPR-100-N-26 were located within the building footprint. UPR-100-N-13 was located near the 1314-N building, but outside the building footprint.

Remedial action for 100-N-60, UPR-100-N-13 and UPR-100-N-26 was performed between September 21 and November 14, 2011. Approximately 2,459.0 bank cubic meters (BCM) (3,216.3 bank cubic yards [BCY]) of contaminated soil and debris were removed from the 100-N-60 group of waste sites excavation and direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Excavation continued until all debris and contamination associated with the waste site had been removed. No anomalous material was discovered during remediation activities.

The stained soil location was evaluated for TPH and PAH with a focused sample (FS-2), but the sample results were used to support a greater effort to identify the extent of the TPH and PAH contamination in the 100-N Area and were not included in the evaluation of the 100-N-60, UPR-100-N-13, UPR-100-N-26 group of waste sites.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

**Code:** UPR-100-N-14  
**Classification:** Accepted

**Names:** UPR-100-N-14; 119-N Drain System Leak; UN-100-N-14  
**Reclassification:** Interim Closed Out (7/2/2013)

**Type:** Unplanned Release  
**Start Date:** 8/5/1974

**Status:** Inactive  
**End Date:**

**Description:** The site has been remediated and Interim Closed Out. The waste site is the soil near the 119-N Sample Building that was affected during a release of radioactively contaminated water.

**Location:** This site is on the north and east sides of the 116-N Air Stack, and approximately 100 meters (330 feet) north of the 105-N Reactor Building.

**Release Description:** While maintenance personnel were working on the 119-N drain system, to correct loss of coolant flow in a condensate collection sampler, backflow from the drain occurred. Effluent water was discharged to the ground near the building. This release occurred on August 5, 1974 and is documented on Unusual Occurrence Report number 74-24.

**Waste Type:** Chemicals

**Waste Description:** The release consisted of effluent water containing 0.0008 curies of beta/gamma activity.
Closure Info: Remedial action at the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 waste sites was performed during January and February 2011. Remediation involved removal of the foundations of the 116-N stack, the 119-N and 119-NA structures, and the underlying soil. Excavation continued until the french drain, associated piping, and contaminated soil and debris were removed. This excavation exceeded the depth that would be required to remove the 100-N-102:1, UPR-100-N-9, and UPR-100-N-14 waste sites. According to drawing H-1-46389, the depth of the 100-N-102:1 subsite, and therefore the unplanned release waste sites UPR-100-N-9 and UPR-100-N-14, was at 0.76 meters (2.5 ft) bgs. The final excavation depth was approximately 8.5 meters (28 ft) bgs. Because the excavation and removal of the 116-N stack foundation was previously performed by the D4 Project, the exact volume of material removed is unknown.

The debris removed included soil, concrete, piping, and other debris associated with the 116-N, 119-N, and 119-NA structures and french drain. All material from these waste sites was disposed at the Environmental Restoration Disposal Facility (ERDF). No anomalous material was encountered during the excavation.

In March 2012, the D4 Project constructed a ramp across the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 excavation to provide access and to support remediation activities at 1303-N (118-N-1) waste site. The ramp material was excavated on September 28, 2012, and also disposed of at ERDF. A walk around the site boundary confirmed that all fill material used to build the ramp had been removed. After the excavation of the ramp material, a gamma survey was performed on October 3, 2012, within the 100-N-87, 100-N-102:1, UPR-100-N-14, and UPR-100-N-9 excavation. The gamma survey results indicated readings above background at two locations. Additional remediation was performed to address areas where the GPERS survey results indicated elevated radiological results. Follow up surveys on October 17, 2012 and October 19, 2012 indicated no elevated readings above background.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

### Classification:
- **Code:** UPR-100-N-17
- **Names:** UPR-100-N-17; 166-N Diesel Oil Supply Line Leak; UN-100-N-17
- **Type:** Unplanned Release
- **Status:** Inactive
- **Start Date:** 8/1/1966
- **End Date:** 8/1/1966
- **Description:** The site is an unplanned release of diesel oil that occurred at the 166-N Tank Farm. Number 2 and number 6 diesel oil was introduced into the soil over time. In August 1966, approximately 302,833 kiloliters (80,000 gallons) of diesel oil was released from a transfer valve.
- **Location:** The 166-N Tank Farm is located between the 116-N Air Stack and the 116-N-2 Facility (Golf Ball).
- **Release Description:** External corrosion of a 10.2 centimeter (4 inch) diesel oil supply line, between the oil storage tank and the west dike, caused the line to leak and release diesel oil to the soil in August 1966. The oil drained through the soil to groundwater, where it migrated toward the Columbia River.
- **Related Sites/Structures:** 100-N-106, 100-N-107
- **Waste Type:** Barrels/Drums/Buckets/Cans

Hanford Site Waste Management Units Report

<td></td>
</tr>
<tr>
<td>Closure Info: Remediation of the UPR-100-N-18, UPR-100-N-20 and UPR-100-N-24 waste sites was combined in a single excavation. Excavation of the Unplanned Release waste sites was performed between June 27, 2011, and March 26, 2013, resulting in a combined excavation approximately 4.6 meters (15 ft) deep. Approximately 12,062 bank cubic meters (15,777 bank cubic yards) of contaminated soil and debris was removed and disposed to ERDF. The materials removed and disposed to ERDF included those that had been staged at the ex-situ bioremediation Spoil Pile Area (SPA). During removal of materials from the SPA area it was discovered that debris from the previously demolished 1723-N Warehouse was located in the subsurface. The 1723-N debris included asphaltic materials related to a parking lot at that location. The analysis of samples collected after the removal of materials from the ex-situ SPA would have been problematic due to the presence of the 1723-N related asphalt. Therefore an agreement was reached with EPA and DOE to close the ex-situ SPA based on a visual inspection of the area, verifying the UPR-100-N-18/20/24 materials had all been removed. The SPA area is therefore closed. The UPR-N-18/20/24 waste sites excavation removed the contaminated soil to a depth of 4.6 meters (15 ft) below ground surface. Potentially contaminated soils remaining below 4.6 meters (15 ft) are considered part of the UPR-100-N-17 waste site and will be evaluated separately. A portion of the UPR-100-N-18/20/24 waste site on the northern side of the excavation remains in place to provide protection for the in situ bioremediation wells associated with the UPR-100-N-17 waste site. This area is referred to as the &quot;well island&quot; and will be addressed separately.</td>

</table>
### Waste Site Description

**Location:** The release occurred at the 184-N Fuel Oil Day Tank.

**Release Description:** The day tank was overfilled, and fuel oil spilled onto the ground in April 1984.

**Related Sites/Structures:** These releases are also associated with UPR-100-N-42.

**Waste Type:** Chemicals

**Waste Description:** The release consisted of No. 6 fuel oil.

**Closure Info:** Remediation of the UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43 waste sites was performed between June and December 2011, resulting in a combined excavation approximately 5 meters (16.4 ft) deep. Approximately 4,577 bank cubic meters (5,986 bank cubic yards) of contaminated soil and debris was removed and disposed at the Environmental Restoration Disposal Facility (ERDF). French drain #6 formerly associated with the 100-N-103:1 subsite was removed during the remediation of the UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43 waste sites and disposed at ERDF. French drain #6 was administratively removed from the 100-N-103:1 subsite and included as part of the UPR-100-N-19 waste site. The unplanned release sites are collectively referred to as the UPR-100-N-19 waste site grouping. The excavation removed the contaminated soil to a depth of 5 meters (16.4 ft) below ground surface. Potentially contaminated soil remains below 5 meters (16.4 ft) and is considered part of the UPR-100-N-42 waste site. This will be evaluated separately and is excluded from the UPR-100-N-19 scope.

Additional remediation was conducted following initial verification sampling because elevated total petroleum hydrocarbons (TPH) were detected above the RAG in part of the site. Well 199-N-16 was decommissioned and removed as part of the additional soil remediation.

---

**Code:** UPR-100-N-20

**Status:** Inactive

**End Date:**

**Description:** This waste site has been remediated and Interim Closed Out. It was approximately 757 liters of diesel oil that drained to the soil. In 1985, the contaminated soil was removed and properly disposed (per WHC-SD-EN-TI-251).

**Location:** The release site was located near Tank 1 in the 166-N Tank Farm.

**Release Description:** External corrosion caused the 5-centimeter (2-inch) diesel oil return line to leak in June 1985.

**Related Sites/Structures:** Contamination below 4.6 meters (15 feet) is considered to be part of waste site UPR-100-N-17.

**Waste Type:** Sanitary Sewage

---

**Classification:** Accepted

**Reclassification:** Interim Closed Out (8/21/2013)

**Start Date:** 6/1/1985

**End Date:** 6/1/1985
Waste Description: The release consisted of Number 2 diesel oil.

Closure Info: Remediation of the UPR-100-N-18, UPR-100-N-20 and UPR-100-N-24 waste sites was combined in a single excavation. Excavation of the Unplanned Release waste sites was performed between June 27, 2011, and March 26, 2013, resulting in a combined excavation approximately 4.6 meters (15 ft) deep. Approximately 12,062 bank cubic meters (15,777 bank cubic yards) of contaminated soil and debris was removed and disposed to ERDF.

The materials removed and disposed to ERDF included those that had been staged at the ex-situ bioremediation Spoil Pile Area (SPA). During removal of materials from the SPA area it was discovered that debris from the previously demolished 1723-N Warehouse was located in the subsurface. The 1723-N debris included asphaltic materials related to a parking lot at that location. The analysis of samples collected after the removal of materials from the ex-situ SPA would have been problematic due to the presence of the 1723-N related asphalt. Therefore an agreement was reached with EPA and DOE to close the ex-situ SPA based on a visual inspection of the area, verifying the UPR-100-N-18/20/24 materials had all been removed. The SPA area is therefore closed.

The UPR-18/20/24 waste sites excavation removed the contaminated soil to a depth of 4.6 meters (15 ft) below ground surface. Potentially contaminated soils remaining below 4.6 meters (15 ft) are considered part of the UPR-100-N-17 waste site and will be evaluated separately. A portion of the UPR-100-N-18/20/24 waste site on the northern side of the excavation remains in place to provide protection for the in situ bioremediation wells associated with the UPR-100-N-17 waste site. This area is referred to as the "well island" and will be addressed separately.

Code: UPR-100-N-21
Names: UPR-100-N-21; 184-N Diesel Oil Day Tank Overflow; UN-100-N-21; UN-116-N-21
Type: Unplanned Release
Status: Inactive
Start Date: 4/25/1986
End Date: 4/25/1986
Description: The release consisted of Number 2 diesel oil.
Location: The site was located at the 184-N Diesel Oil Day Tank.
Release Description: Failure of the tank-level annunciator caused overfilling of the day tank during an oil transfer on April 25, 1986.
Waste Type: Chemicals
Closure Info: Remediation of the UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43 waste sites was performed between June and December 2011, resulting in a combined excavation approximately 5 meters (16.4 ft) deep. Approximately 4,577 bank cubic meters (5,986 bank cubic yards) of contaminated soil and debris was removed and disposed at the Environmental Restoration Disposal Facility (ERDF). French drain #6 formerly associated with the 100-N-103:1 subsite was removed during the remediation of the UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43 waste sites and disposed at ERDF. French drain #6 was administratively removed from the 100-N-103:1 subsite and included as part of the UPR-100-N-19 waste site. The unplanned release sites are collectively referred to as the UPR-100-N-19 waste site grouping. The excavation removed the 
contaminated soil to a depth of 5 meters (16.4 ft) below ground surface. Potentially contaminated soil remains below 5 meters (16.4 ft) and is considered part of the UPR-100-N-42 waste site. This will be evaluated separately and is excluded from the UPR-100-N-19 scope.

Additional remediation was conducted following initial verification sampling because elevated total petroleum hydrocarbons (TPH) were detected above the RAG in part of the site. Well 199-N-16 was decommissioned and removed as part of the additional soil remediation.

Location: The site was located near the Diesel Oil Day Tank for the 184-N Power House.

Release Description: External corrosion of the piping system was the cause of the leak on January 10, 1987. The leak was detected through inventory discrepancy.

Waste Type: Water

Waste Description: The release consisted of Number 2 diesel oil.

Closure Info: Remediation of the UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43 waste sites was performed between June and December 2011, resulting in a combined excavation approximately 5 meters (16.4 ft) deep. Approximately 4,577 bank cubic meters (5,986 bank cubic yards) of contaminated soil and debris was removed and disposed at the Environmental Restoration Disposal Facility (ERDF). French drain #6 formerly associated with the 100-N-103:1 subsite was removed during the remediation of the UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43 waste sites and disposed at ERDF. French drain #6 was administratively removed from the 100-N-103:1 subsite and included as part of the UPR-100-N-19 waste site. The unplanned release sites are collectively referred to as the UPR-100-N-19 waste site grouping. The excavation removed the contaminated soil to a depth of 5 meters (16.4 ft) below ground surface. Potentially contaminated soil remains below 5 meters (16.4 ft) and is considered part of the UPR-100-N-42 waste site. This will be evaluated separately and is excluded from the UPR-100-N-19 scope.

Additional remediation was conducted following initial verification sampling because elevated total petroleum hydrocarbons (TPH) were detected above the RAG in part of the site. Well 199-N-16 was decommissioned and removed as part of the additional soil remediation.
combined in a single excavation. Excavation of the Unplanned Release waste sites was performed between June 27, 2011, and March 26, 2013, resulting in a combined excavation approximately 4.6 meters (15 ft) deep. Approximately 12,062 bank cubic meters (15,777 bank cubic yards) of contaminated soil and debris was removed and disposed to ERDF.

The materials removed and disposed to ERDF included those that had been staged at the ex-situ bioremediation Spoil Pile Area (SPA). During removal of materials from the SPA area it was discovered that debris from the previously demolished 1723-N Warehouse was located in the subsurface. The 1723-N debris included asphalitic materials related to a parking lot at that location. The analysis of samples collected after the removal of materials from the ex-situ SPA would have been problematic due to the presence of the 1723-N related asphalt. Therefore an agreement was reached with EPA and DOE to close the ex-situ SPA based on a visual inspection of the area, verifying the UPR-100-N-18/20/24 materials had all been removed. The SPA area is therefore closed.

The UPR-N-18/20/24 waste sites excavation removed the contaminated soil to a depth of 4.6 meters (15 ft) below ground surface. Potentially contaminated soils remaining below 4.6 meters (15 ft) are considered part of the UPR-100-N-17 waste site and will be evaluated separately. A portion of the UPR-100-N-18/20/24 waste site on the northern side of the excavation remains in place to provide protection for the in situ bioremediation wells associated with the UPR-100-N-17 waste site. This area is referred to as the "well island" and will be addressed separately.

<tr>
<td>Release Description:</td>
<td>On May 15, 1975, the annual chemical decontamination of the N Reactor primary piping was initiated. During this process, radioactive material is flushed from the primary system to the 1301-N storage tank. An operator was stationed at an open manhole (on top of the tank) to confirm that water was entering the tank. Upon observing water flow, the manhole cover was supposed to be replaced to prevent the release of unfiltered air from the tank. As the operator was beginning to replace the manhole cover, a forceful spray of water came out of the manhole. The surge lasted approximately one minute. An estimated 378 to 1900 liters (100 to 500 gallons) of contaminated water was released to the ground inside the posted Radiation Zone. Smearable contamination up to 20,000 counts per minute was found.</td>
<td></td>
<td></td>

</tbody>
</table>
the waste site excavation, and that area was remediated May 7 and 8, 2012. The maximum depth of the excavation was 13 meters (42.7 ft) bgs and resulted in the removal of approximately 11,144 bank cubic meters (BCM) (14,576 bank cubic yards [BCY]) of soil and debris. The debris consisted of rock, sand, and piping material. The contaminated soil and debris were directly loaded out for disposal at the Environmental Restoration Disposal Facility (ERDF). Also removed with the 116-N-2 excavation were the UPR-100-N-5 and UPR-100-N-25 waste sites, as well as portions of the 100-N-84 and 100-N-63 pipelines. A section of the 100-N-63:2 pipeline remained on a side slope in the northern part of the excavation until it was remediated between March 22, and 25, 2013. No anomalous material was found during remediation. No in-process samples were collected for the 116-N-2 grouping of waste sites.

Clean padding material (soil and gravel) had been previously placed on the ground surface south of the excavation to cover radiological contamination that resulted from the previous D4 activities to remove the golf ball and silo structures. The padding material and approximately 2 meters (6.5 ft) of soil below the padding was scraped and removed for disposal at ERDF.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

<td></td>
</tr>
<tr>
<td>Related Sites/ Structures:</td>
<td>The Unplanned Release is associated with the 100-N-60 French Drain.</td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The 1314-N Liquid Waste Loadout Station was a 9 meter (30 ft) by 18 meter (60 ft) single story, metal-frame building supported on a reinforced concrete slab foundation. It began to operate in 1972. The facility was a transfer station consisting of numerous valves, pumps, underground and overhead piping and couplings, and underground tanks. It was located approximately 100 meters (300 ft) from the Columbia River. This facility was used to loadout radioactive liquid waste from the 116-N-2 and 107-N facilities into railroad tank cars for shipment to the 200 Areas for processing and disposal. The loadout facility contained a tank car wash station with a sump to collect the wash water. The water drained into a 3,780 liters (1,000 gal) overflow tank. During the filling operation, excess liquid waste was designed to overflow through a closed piping system from the tank car to the overflow tank, which initiated pump shutdown. A 756 liters (200 gal) catch tank was installed to hold liquids that exceeded the capacity of the car wash sump.</td>
<td></td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Stormwater Runoff</td>
<td></td>
</tr>
</tbody>
</table>
Waste Description: The release consisted of reactor decontamination solution containing phosphoric acid and diethylthiourea.

Closure Info: The 1314-N building was demolished in 2006. 100-N-60 and UPR-100-N-26 were located within the building footprint. UPR-100-N-13 was located near the 1314-N building, but outside the building footprint.

Remedial action for 100-N-60, UPR-100-N-13 and UPR-100-N-26 was performed between September 21 and November 14, 2011. Approximately 2,459.0 bank cubic meters (BCM) (3,216.3 bank cubic yards [BCY]) of contaminated soil and debris were removed from the 100-N-60 group of waste sites excavation and direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Excavation continued until all debris and contamination associated with the waste site had been removed. No anomalous material was discovered during remediation activities.

The stained soil location was evaluated for TPH and PAH with a focused sample (FS-2), but the sample results were used to support a greater effort to identify the extent of the TPH and PAH contamination in the 100-N Area and were not included in the evaluation of the 100-N-60, UPR-100-N-13, UPR-100-N-26 group of waste sites.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

UPR-100-N-29; 1304-N Dump Tank; Emergency Dump Tank Bypass Line Leak; UN-100-N-29

Start Date: 4/23/1974
End Date: 4/23/1974

The Unplanned Release has been remediated and Interim Closed Out. The site was approximately 378 liters (100 gallons) of primary reactor coolant water that was released to the soil in 1974. The contaminated soil was removed and sent to the 200 Area burial ground for disposal. The excavation was then backfilled with clean fill.

Location: The release occurred on the east side of the 1304-N Emergency Dump Tank.

Release Description: A leaking check valve caused a release of primary coolant water on April 23, 1974. An estimated 378 L (100 gal) of contaminated primary coolant water was released from a leaking check valve. An area approximately 10.8 square meters (120 sq ft) was contaminated by the release. The contaminated soil was removed and shipped to a 200 Area burial ground for disposal. Following soil disposal, the site was covered with clean fill material.

Waste Type: Chemicals

Waste Description: The leak consisted of primary coolant water containing radioactive fission and activation products, mostly manganese-56 and sodium-24.

Closure Info: The above ground 1304 Emergency Dump Tank and associated piping were removed in 2004.

Remedial action at the 100-N-57, UPR-100-N-1, UPR-100-N-2, UPR-100-N-29, UPR-100-N-30, and UPR-100-N-32 waste sites was performed between February 21 and May 31, 2011. Excavation continued until all debris and contamination associated with the waste sites had been removed. Contaminated soil, concrete, pipeline segments and debris removed during excavation were staged within the South Staging Pile Area 1 (SSP Area 1) prior to shipment to the ERDF. Approximately 1,848 bank cubic meters (2,417 bank cubic yards) of contaminated...
soil and debris were removed from the site and disposed at the ERDF. No stained soil or anomalous material was found during the remediation activities.

The debris removed from the waste sites consisted of miscellaneous noncombustible debris and soil. Portions of the 100-N-63:2, 100-N-64, 100-N-84:2, 100-N-84:3, 100-N-84:4, and 100-N-84:5 pipelines waste sites were also removed during 100-N-57 group of waste sites remediation activities. The remaining portions of these pipeline waste sites will be remediated and separate closure documents prepared at a later date.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

Reclassification: Interim Closed Out (8/31/2013)

**Type:** Unplanned Release  
**Status:** Inactive

**Description:** The waste site has been remediated and Interim Closed Out. It was a release of radioactively contaminated water to the soil on the west side of the 116-N-1 crib.

**Location:** The release occurred on the west side of the berm just west of the 1301-N (116-N-1) Liquid Waste Disposal Facility.

**Release Description:** While sample lines were being installed in a 15-centimeter (6-inch) steel casing through the berm on the west side of the 1301-N Crib, the water level in the crib was raised 38 to 46 centimeters (15 to 18 inches) as a result of an Emergency Dump Tank drawdown test. Due to the increased water level, approximately 3785 liters (1000 gallons) of effluent was released, containing 186 square meters (2025 square feet) of soil.

**Related Sites/Structures:** The 116-N-1 Crib and Trench was the originator of the liquid. Also related was 100-N-63, UPR-100-N-4, UPR-100-N-8 and the 100-N Reactor (1314-N, 116-N-1 and 116-N-3) TSD Underground Pipelines.

**Waste Type:** Water

**Waste Description:** The release consisted of radioactive effluent containing fission and activation products. The gross beta/gamma concentration of the spilled water was 700 disintegrations/minute/milliliter.

**Closure Info:** The 1322N, 1322NA, 1322NB, and 1322NC above-ground buildings and slabs in the vicinity of the unplanned releases were removed during the 100-N deactivation, decommission, decontamination, and demolition (D4) activities. The removal included an excavation that measured approximately 3.7 meters (12 ft) deep. The UPR-100-N-4 and UPR-100-N-8 waste sites are associated with the 1322-N/NA Buildings. The UPR-100-N-31 waste site is associated with the 116-N-1 (1301-N) Crib and Trench. Because the locations of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 unplanned release sites were in close proximity to each other and no information was available to delineate the boundary of each release, the three sites were combined into one excavation. The excavation for remediation of the combined unplanned release sites was immediately adjacent to the former 116-N-1 (1301-N) remediation site. Further remediation of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 waste site soils was performed between December 13, 2011 and March 19, 2012, resulting in a combined excavation approximately 7 meters (23 ft) deep.

Approximately 5,683 bank cubic meters (BCM) (7,433 bank cubic yards [BCY]) of additional contaminated soil, rocks, and concrete was removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Additional contaminated soil was removed from areas SZ-6, SZ-8, and SZ-9 between January 30, 2013 and February 4, 2013, resulting in an additional 189 BCM (247 BCY) of contaminated soil removed for disposal at ERDF. Areas of stained soil remained in the deep zone (more than 4.6 meters [15 ft] below ground surface [bgs]) following the completion of the remedial action activities. All material was direct loaded from the excavation for disposal at ERDF. No overburden piles or anomalies were associated with the remediation.

During remediation of the unplanned release sites, increasing radiological activity was observed with depth approaching soils underlying the former 116-N-1 crib. Deep zone sample results

---

<td>Location:</td>
<td>The release occurred on the west side of the berm just west of the 1301-N (116-N-1) Liquid Waste Disposal Facility.</td>
</tr>
<tr>
<td>Release Description:</td>
<td>While sample lines were being installed in a 15-centimeter (6-inch) steel casing through the berm on the west side of the 1301-N Crib, the water level in the crib was raised 38 to 46 centimeters (15 to 18 inches) as a result of an Emergency Dump Tank drawdown test. Due to the increased water level, approximately 3785 liters (1000 gallons) of effluent was released, containing 186 square meters (2025 square feet) of soil.</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The 116-N-1 Crib and Trench was the originator of the liquid. Also related was 100-N-63, UPR-100-N-4, UPR-100-N-8 and the 100-N Reactor (1314-N, 116-N-1 and 116-N-3) TSD Underground Pipelines.</td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Water</td>
</tr>
<tr>
<td>Waste Description:</td>
<td>The release consisted of radioactive effluent containing fission and activation products. The gross beta/gamma concentration of the spilled water was 700 disintegrations/minute/milliliter.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The 1322N, 1322NA, 1322NB, and 1322NC above-ground buildings and slabs in the vicinity of the unplanned releases were removed during the 100-N deactivation, decommission, decontamination, and demolition (D4) activities. The removal included an excavation that measured approximately 3.7 meters (12 ft) deep. The UPR-100-N-4 and UPR-100-N-8 waste sites are associated with the 1322-N/NA Buildings. The UPR-100-N-31 waste site is associated with the 116-N-1 (1301-N) Crib and Trench. Because the locations of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 unplanned release sites were in close proximity to each other and no information was available to delineate the boundary of each release, the three sites were combined into one excavation. The excavation for remediation of the combined unplanned release sites was immediately adjacent to the former 116-N-1 (1301-N) remediation site. Further remediation of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 waste site soils was performed between December 13, 2011 and March 19, 2012, resulting in a combined excavation approximately 7 meters (23 ft) deep. Approximately 5,683 bank cubic meters (BCM) (7,433 bank cubic yards [BCY]) of additional contaminated soil, rocks, and concrete was removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Additional contaminated soil was removed from areas SZ-6, SZ-8, and SZ-9 between January 30, 2013 and February 4, 2013, resulting in an additional 189 BCM (247 BCY) of contaminated soil removed for disposal at ERDF. Areas of stained soil remained in the deep zone (more than 4.6 meters [15 ft] below ground surface [bgs]) following the completion of the remedial action activities. All material was direct loaded from the excavation for disposal at ERDF. No overburden piles or anomalies were associated with the remediation. During remediation of the unplanned release sites, increasing radiological activity was observed with depth approaching soils underlying the former 116-N-1 crib. Deep zone sample results</td>
</tr>
</tbody>
</table>
from the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 remediation are also consistent with residual contamination in the 116-N-1 deep zone. This suggests that the contamination encountered was residual from 116-N-1 left in place in the deep zone, and that deep zone remediation of the UPR-100-N-4, UPR-100-N-8, and UPR-100-N-31 waste sites is considered complete. The liquid waste effluents associated with the UPR-100-N-31 and 116-N-1 waste sites are the same.

<tr>
<td>Description:</td>
<td>The Unplanned Release has been remediated and Interim Closed Out. Approximately 3,785 liters of effluent water was released to the soil in 1974. Most of the contaminated soil was removed in 1974. The remaining contamination was covered with clean fill.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The release occurred on the southeast side of the 1304-N Emergency Dump Tank.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Release Description:</td>
<td>A leaking check valve in the Emergency Dump Tank bypass line released radioactive effluent water to the ground. An estimated 3,785 liters (1,000 gal) of contaminated effluent being released. A majority of the contaminated soil was removed and disposed at a 200 Area burial ground. The remaining soil that had been contaminated by the release was left in place and covered with clean fill material. The effluent water was analyzed at the release location to provide an estimate of the activity of the release. It was estimated that the radioactive material had an activity of less than 10 micro curies. A mud sample reading was 20,000 counts/minute. The release occurred on September 16, 1974.</td>

<tr>
<td>Waste Description:</td>
<td>The release consisted of radioactive effluent water containing fission and activation products. A mud sample read 20,000 counts/minute. The water was analyzed for gross activity. It was estimated that less than 10 millicuries of radioactive material remained on the ground.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The above ground 1304 Emergency Dump Tank and associated piping were removed in 2004. Remedial action at the 100-N-57, UPR-100-N-1, UPR-100-N-2, UPR-100-N-29, UPR-100-N-30, and UPR-100-N-32 waste sites was performed between February 21 and May 31, 2011. Excavation continued until all debris and contamination associated with the waste sites had been removed. Contaminated soil, concrete, pipeline segments and debris removed during excavation were staged within the South Staging Pile Area 1 (SSP Area 1) prior to shipment to the ERDF. Approximately 1,848 bank cubic meters (2,417 bank cubic yards) of contaminated soil and debris were removed from the site and disposed at the ERDF. No stained soil or anomalous material was found during the remediation activities. The debris removed from the waste sites consisted of miscellaneous noncombustible debris and soil. Portions of the 100-N-63:2, 100-N-64, 100-N-84:2, 100-N-84:3, 100-N-84:4, and 100-N-84:5 pipelines waste sites were also removed during 100-N-57 group of waste sites remediation activities. The remaining portions of these pipeline waste sites will be remediated and separate closure documents prepared at a later date. Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).</td>

### Unplanned Release

- **Code:** UPR-100-N-35  
  **Name(s):** UPR-100-N-35; 100-N Fuel Basin Drainage System Leak; 105-N Fuel Storage Basin Drainage System Leak; UN-100-N-35; UN-116-N-35  
  **Type:** Unplanned Release  
  **Status:** Inactive  
  **Start Date:** 2/28/1986  
  **End Date:** 11/1/1986  
  **Classification:** Accepted  
  **Reclassification:** Consolidated (4/10/2013)

**Description:**
This Unplanned Release has been consolidated with 100-N-66 (105N/109N Complex). The release occurred in a crack in the south concrete wall of the lift station pipe tunnel at the 105-N Reactor Building. The pipe tunnel and lift station will remain in place when the 105-N reactor building is placed in the Safe Storage Enclosure (SSE).

**Location:**
This leak occurred on the south side of the pipe tunnel (north side of the Fuel Storage Basin). It affected the western end of the 105-N Reactor core.

**Release Description:**
Routine sampling of the 100-N Area groundwater wells detected slightly elevated levels of iodine-131. Drawdown tests on the basin determined that the leak was not from the basin. Further tests and investigations determined the intermittent leak to be coming from a sub-basin drain line approximately 8.5 meters (28 feet) below the ground. The leak, estimated to be less than 11 liters (3 gallons) per minute, occurred only during feed and bleed (addition of water) of the 100-N Fuel Basin.

**Waste Type:** Chemicals

**Waste Description:**
The release consisted of radioactively contaminated water containing an estimated 1.6 curies manganese-5, 0.4 curies cobalt-60, 0.3 curies niobium-95, 0.1 curies iodine-131, 0.4 curies cesium-137 and 0.3 curies cerium-144.

### This Site Was Consolidated With:

- **Code:** 100-N-66  
  **Names:** 100-N-66; 105-N/109-N Reactor Building Complex

---

### Unplanned Release

- **Code:** UPR-100-N-36  
  **Name(s):** UPR-100-N-36; 184N; 184N Annex; Diesel Generator Area Unplanned Release  
  **Type:** Unplanned Release  
  **Status:** Inactive  
  **Start Date:**  
  **End Date:**  
  **Classification:** Accepted  
  **Reclassification:** Interim Closed Out (2/26/2013)

**Description:**
The waste site has been remediated and Interim Closed Out. It was a diesel release in a graveled area previously affected by a history of spills.

**Location:**
The site is located between Buildings 153N and 184N.

**Release Description:**
Numerous spills of diesel fuel and motor oil used for normal operation and maintenance occurred over a 13 year period. During this period, the site was used as a diesel air compressor staging area.

**Related Sites/Structures:**
French drain 100-N-55 was located within the remediation footprint of UPR-100-N-36. A separate closure document was prepared to address the 100-N-55 french drain.

**Waste Type:** Chemicals

**Waste Description:**
Evidence of spills include stained gravel and a strong smell of petroleum products in the soil beneath (noted during an excavation).
Closure Info: Remedial action at the UPR-100-N-36 waste site was performed between May 23, 2011, and November 15, 2011, resulting in an excavation approximately 4.5 meters (14.8 ft) below ground surface. Approximately 8,400 bank cubic meters (BCM) (10,987 bank cubic yards [BCY]) of contaminated soil and debris were removed for disposal at the ERDF. Initially, the soil and debris were placed in a staging pile area to be evaluated for bioremediation. However, based on sampling results and the debris present (concrete, piping, and chunks of hard black material), the material was disposed. The staging pile area is currently in use by multiple waste sites. Therefore, the staging pile area will not be addressed in this closure document but rather will be closed with the UPR-100-N-18 waste site. All soil and debris from remediation of UPR-100-N-36 was disposed at the ERDF. Therefore, no overburden pile is associated with the site. No anomalous materials were encountered during the remediation.

<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>Dielectric fluid consisting of mineral oil has seeped onto the ground. Washington Public Power Supply System (WPPSS) personnel have verbally stated that polychlorinated biphenyls (PCBs) have never been used in the transformers. However, the RCRA Facility assessment report states that, based on the dates of operation, the presence of PCB's is suspect.</td>
<td></td>
</tr>
</tbody>
</table>

Closure Info: The Hanford Generating Plant (HGP) solid waste management unit (SWMU) removal actions included in this CVP began in 2001 and were completed in 2004. The majority of the removal action activities were completed in 2003 and 2004. The remediation and report were done by Energy Northwest.

The entire 185-N Building aboveground structure was demolished during the 2003 and 2004 activities. The debris from demolition of the building as well as from demolition of other HGP structures was used as fill for the 185-N Building basement. The debris was placed into the building basement from the bottom (15.2 meters [50 ft] below ground surface) to within 7.6 meters (25 ft) of the ground surface. The remaining void spaces among the debris fill were filled using a cement grout controlled density fill. The remaining below grade portion of the basement was backfilled with clean soil. The reinforced concrete turbine pedestals that extend from the basement floor to approximately the ground surface were left in place. Based on agreement with the Washington State Department of Ecology, the portions of the turbine pedestals at the ground surface were covered with 0.9 meter (3 ft) of soil consistent with
requirements for other 100 Area facilities. The Removal Action Workplan (DOE-RL 1999) specified removal of structures to a minimum of 0.3 meter (1 ft) below the surrounding grade and other 100 Area action memorandums generally require that a structure be demolished to a minimum of 0.9 meters (3 ft) below the surrounding grade. However, in the case of the turbine pedestals, because of their mass and the amount of steel reinforcement, demolition was deemed impractical. The 0.9 meters (3 ft) of cover for the pedestals was placed to blend in with, and to gently slope with, the surrounding grade.

The 185-N Building is not a SWMU. However, SWMUs #2, 3, and 4 are located within the building. To provide a complete description of the removal action activities for SWMUs #2, 3, and 4, a summary description of the removal action activities conducted for the 185-N Building is below.

UPR-100-N-37 Transformer Yard (SWMU #1): Eight of the nine transformers located in the transformer yard were removed prior to the Action Memorandum (EPA 1999). The ninth, smaller, operating transformer, was drained of oil and scrapped during the most recent 2003 and 2004 activities. The oil and transformer were disposed of based on historical data indicating that the transformer oil did not contain PCBs. During removal action activities conducted in 2001, minor areas of soil contaminated with oil were excavated from around each transformer pad and properly disposed. During the more recent 2003 and 2004 activities, the concrete pads were demolished, excavated and the concrete rubble used as fill for the demolished 185-N Building basement.

100-N-51 Oil Storage Area (SWMU #2): All stored oil and waste containers were previously removed from the oil storage area and properly disposed of or appropriately used. Miscellaneous concrete stained areas including the sump were cleaned. Cleaning of concrete surfaces included the use of concrete scabbling and water and detergents during the 2001 activities. The 100-N-51 Oil Storage Area (SWMU #2) was located at the bottom of the 185-N Building basement. It has been covered and filled with building debris, a cement grout controlled density fill, and borrow soil.

185-N Building Drains and Sumps (SWMU #3): The 185-N Building basement drains and sumps were emptied and cleaned during the 2001 removal action activities. Cleaning activities involved removal and proper disposal of sludges and liquids. Following removal of the sludges and liquids, the sump concrete and metal surfaces were hand cleaned, pressure washed, and scabbled as needed. During the recent 2003 and 2004 activities three of the sumps contained water. The water was characterized, removed from the sump, and properly disposed. All of the miscellaneous drains were filled with a cement grout controlled density fill during the 2003 and 2004 activities. The sumps were filled with borrow soil and capped with a minimum of 15 cm (6 in.) of cement grout during the 2003 and 2004 activities. Also, the sumps and drains have been covered with building debris fill, cement grout controlled density fill, and borrow soil.

100-N-50 Turbine Oil Filter Unit (SWMU #4): During the 2001 removal action activities, the two steel tank oil filtration units including the internal metal oil filtration screens were drained and cleaned. Residual oil from the units was removed and properly disposed. In addition, the two concrete sumps associated with the filter units were cleaned. Stained concrete was removed from the sumps through chipping and scabbling. These units were located at the bottom of the 185-N Building basement and have been filled and covered with the cement grout controlled density fill.

Hanford Site Waste Management Units Report
February 2015
Unplanned Release

Type: Unplanned Release
Status: Inactive

Description: The release site has been remediated and Interim Closed Out. The 100-N-31 waste site was located on the west side of the 105-N/109-N Reactor Buildings and adjacent to the 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39 waste sites. These waste sites are collectively referred to as the waste sites west of the 105-N/109-N Reactor. The remediation of these waste sites resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. The eleven sites were Interim Closed out in a single document.

UPR-100-N-39 consisted of contaminated soil and concrete from an unplanned release of contaminated water outside the Corridor 22 doorway of the 105-N Reactor.

Location: The release site was located outside the Corridor 22 doorway, on the west side of the 105-N Reactor Building. Corridor 22 doorway was located near the helium low pressure storage tanks and the 105-NE Fission Product Filter Trap.

Release Description: In 1983 or 1984, several hundred liters of radioactively contaminated water was spilled outside Corridor 22. Scrub water from the Fission Product Filter Trap overflowed and discharged to the ground and concrete. The concrete was painted to fix the contamination and an indeterminate amount of the contaminated soil was removed.

Related Sites/Structures: The 105-N Fission Product Filter Trap is associated with the site.

Waste Type: Chemicals
Waste Description: Several hundred liters of radioactively contaminated water from the Fission Product Filter Trap overflowed and discharged to the ground.

Closure Info: Eleven waste sites located west of the 105-N/109-N Reactor Building were remediated as a group. The eleven waste sites included 100-N-31, 100-N-32, 100-N-38, 100-N-61:3, 100-N-64:3, 100-N-68, UPR-100-N-3, UPR-100-N-7, UPR-100-N-10, UPR-100-N-12, and UPR-100-N-39. This group of waste sites was referred to as the waste sites west of the 105-N/109-N Reactor. The footprints of the 1909-N Waste Disposal Valve Pit, the 107-N facility and the pipe trench between 105-N and 107-N were also located within the boundary of the group.

The eleven collocated waste sites located west of the 105-N/109-N Reactor Building were remediated, either partially or completely, by the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Project during the demolition and removal of the portions of the 105-N/109-N Buildings, located outside of the safe storage enclosure (SSE).

The Field Remediation (FR) Project resumed remedial action activities west of the 105-N/109-N Reactor in November 2012. Contaminated soil, structural concrete and rebar, and piping were removed from the collocated waste sites west of the 105-N/109-N Reactor and disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation continued through March 2013 to an approximate maximum depth of 9.5 meters (31 ft) below surface grade. No anomalous materials were encountered during remediation. The remediation resulted in one large excavation with no demarcation of the individual sites, with the exception of the UPR-100-N-39 waste site. Some segments of the 100-N-61:3 and 100-N-64:3 pipelines were removed with remedial action at the 100-N-57, (1304-N) Emergency Dump Tank and 116-N-4, (1300-N) Emergency Dump Basin waste sites.

After the remediation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed in March 2013. Some beta and gamma contamination was detected above background. However, the area with the highest detected activity is associated with
residual structures and soils for the 105-N/109-N SSE and is considered part of the 100-N-66, 105-N/109-N Reactor Building Complex waste site. A small area with elevated beta and gamma contamination was detected within the waste sites west of the 105-N/109-N Reactor boundary. Additional soil was removed from this area and disposed at the ERDF. An environmental radiological survey of the area using hand-held instruments verified that the contaminated soils have been removed.

The 1909-N Waste Disposal Valve Pit was removed during general facility demolition in this area by the D4 Project. Due to the proximity and general configuration of demolition and remediation activities on the west side of the reactor, closure of the facility footprint was deferred until nearby waste site remediation by the FR Project occurred. The residual contaminated soil that remained beneath the location of the former 1909-N facility was then removed.

The 107-N basin structure was completely removed by the D4 Project. However, closure of the basin footprint was deferred to the UPR-100-N-12 waste site. Additional soil was removed from the footprint during general waste site remediation in the area. Surveys found no elevated residual radiological activity.

Several segments of the 100-N-84 pipeline subsites were partially located within the remediation boundary. All of the segments of the 100-N-84:2, 100-N-84:4, 100-N-84:5, and 100-N-84:6 pipeline subsites that were within the excavation boundary were removed and disposed at the ERDF. Reclassification of the total 100-N-84:2, 100-N-84:4, 100-N-84:5 and 100-N-84:6 pipeline subsites will be addressed in separate closure documents.

Following remediation, the radiological postings were removed - per WCH Internal Memos (CCN 176583 and 175935).

</tbody>
</table>
Waste Description: The site received diesel oil.

Closure Info: The UPR-100-N-42 waste site addresses potential petroleum contamination that may be present in the deep vadose zone, at a depth below 4.6 meters (15 ft). Associated shallow releases included UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23 and UPR-100-N-43. Verification sampling of the associated shallow zone releases was conducted on June 14, 2012 and documented in the Remaining Sites Verification Package for the UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43 waste sites (RSVP-2013-025 through 029). The results indicated that remediation of the petroleum-contaminated soil in the shallow zone was complete with the exception of some residual petroleum contamination exceeding soil remedial action goals (RAGs) located on the north excavation sidewall near the 199-N-16 groundwater monitoring well. Remediation of the associated shallow zone petroleum waste sites, that overlie the UPR-100-N-42 deep zone waste site (UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43), was performed from June 7 through October 10, 2011. Additional remediation on the north excavation sidewall was performed in January 2013, resulting in a combined excavation approximately 5 meters (16.4 ft) deep.

Well 199-N-16 (total depth 80 ft) was decommissioned on December 18, 2012. Groundwater samples were collected on November 6, 2012, prior to decommissioning the well. Petroleum contamination was not detected in the groundwater samples.

Verification sampling to support closure of the UPR-100-N-42 waste site was performed in three phases. Phase I sampling was performed on September 19, 2012, and consisted of sampling the floor of the excavation remaining after remediation of overlying shallow zone petroleum remediated waste sites to support evaluation of the lateral distribution of potential residual petroleum contamination at the UPR-100-N-42 waste site. The results of Phase I verification sampling were then used to establish the location of a test pit for Phase II verification sampling near sample locations showing elevated concentrations of petroleum contamination. Phase II sampling was performed on February 13, 2013, to evaluate the vertical distribution of potential petroleum contamination below the floor of the excavation. The test pit was excavated to a final depth of approximately 5 meters (16.4 ft) below the excavation floor. Phase III verification sampling was performed from September 25 through October 1, 2013, and consisted of installing two vertical push probes to provide additional information concerning potential petroleum contamination below the excavation floor. The results of the verification sampling indicate the UPR-100-N-42 waste site meets remedial action objectives and remedial action goals (RAGs) established by the 100-N Area ROD (EPA 1999) and that in-situ bioremediation of the deep zone (greater than 4.6 meters [15 ft]) was not required.

The selected action involved (1) excavating the shallow zone petroleum unplanned release sites waste sites (UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43), (2) disposing of contaminated excavation materials at ERDF, (3) demonstrating through verification sampling that cleanup goals have been achieved, and (4) proposing the site for reclassification as Interim Closed Out.

to the 166-N Storage tanks by a 10 centimeter (4 inch) underground supply line.

**Location:**
The leak occurred at three locations along the pipeline, but the three locations were not provided in the historical documentation. The WIDS site is mapped as one data point, about 49 meters (160 feet) southeast of the 105-N Reactor Building, between the 184-N Building and the 184-N Day Tank Area.

**Release Description:**
A diesel oil leak occurred at three locations along the pipeline from 166-N to 184-N Buildings at three different flange joints. The exact location of these flange joints is not given in the referenced descriptions. The release was reported on April 26, 1989.

**Waste Type:**
Oil

**Waste Description:**
The spill was diesel oil from the diesel oil supply line to the 184-N Day Tank.

**Closure Info:**
Remediation of the UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43 waste sites was performed between June and December 2011, resulting in a combined excavation approximately 5 meters (16.4 ft) deep. Approximately 4,577 bank cubic meters (5,986 bank cubic yards) of contaminated soil and debris was removed and disposed at the Environmental Restoration Disposal Facility (ERDF). French drain #6 formerly associated with the 100-N-103:1 subsite was removed during the remediation of the UPR-100-N-19, UPR-100-N-21, UPR-100-N-22, UPR-100-N-23, and UPR-100-N-43 waste sites and disposed at ERDF. French drain #6 was administratively removed from the 100-N-103:1 subsite and included as part of the UPR-100-N-19 waste site. The unplanned release sites are collectively referred to as the UPR-100-N-19 waste site grouping. The excavation removed the contaminated soil to a depth of 5 meters (16.4 ft) below ground surface. Potentially contaminated soil remains below 5 meters (16.4 ft) and is considered part of the UPR-100-N-42 waste site. This will be evaluated separately and is excluded from the UPR-100-N-19 scope.

Additional remediation was conducted following initial verification sampling because elevated total petroleum hydrocarbons (TPH) were detected above the RAG in part of the site. Well 199-N-16 was decommissioned and removed as part of the additional soil remediation.

**Process Description:**

The 216-B-14, 216-B-15, 216-B-16, 216-B-17, 216-B-18 and 216-B-19 cribs received tri-butyl phosphate waste from the U-Plant Uranium Recovery operations and scavenged tank farm waste via underground pipelines. From 1952 to 1958, waste containing uranium and fission products, produced by the bismuth phosphate separations process, were removed from underground storage tanks and reprocessed at 221-U Plant to recover the uranium from the waste. After the uranium was removed, the cesium and strontium content of the effluent was precipitated by adding ferrocyanide. The addition of ferrocyanide to the waste was called "scavenging". The supernate liquor was released to the ground in the BC Cribs and Trenches. 

The unit is a dispersion structure, 3.0 by 3.0 by 0.9 meters (10 by 10 by 3 feet) high, made of wood, cinder block, and steel, over a 1.5-meter (5-foot) bed of 7.6-centimeter (3-inch) gravel, with a 35.6-centimeter (14-inch) inlet pipe located 1.8 meters (6 feet) below grade. The bottom dimensions of the excavation are 12.2 by 12.2 meters (40 by 40 feet) and 3.96 meters (13 feet) deep. The side slope is 2:1.

**Waste Type:** Process Effluent

**Waste Description:** The site received the scavenged tributyl phosphate (TBP) supernatant waste from 221-U Building during uranium recovery operations. The waste is high in salt and is neutral to basic. The waste contained inorganic compounds such as ferrocyanide, nitrate and phosphate.
Process Description: The 216-B-14, 216-B-15, 216-B-16, 216-B-17, 216-B-18 and 216-B-19 cribs received tri-butyl phosphate waste from the U-Plant Uranium Recovery operations and scavenged tank farm waste via underground pipelines. *Hanford Site Waste Management Units Report*

February 2015  
957
unit. The backfilled trenches have been covered with clean soil and posted as Underground Radioactive Material. Concrete AC 540 markers outline the area where the trenches are located, but do not identify specific trench locations.

**Location:** The site is directly south of the 216-B-25 Trench, south of the 200 East Area (across Route 4S) in the BC Crib Area. The BC Cribs and Trenches are located inside the BC Controlled Area.

**Release Description:** See UPR-200-E-83

**Related Sites/Structures:** The trench is associated with the U Plant uranium recovery process and UPR-200-E-83.

**Process Description:** From 1952 to 1958, waste containing uranium and fission products, produced by the bismuth phosphate separations process, were removed from underground storage tanks and reprocessed at 221-U to recover the uranium from the waste. After the uranium was removed, the cesium and strontium content of the effluent was reduced by precipitation. The supernate liquor was released to the ground in the BC Cribs and Trenches. A total of 16 unlined trenches, 216-B-20 through 216-B-34 and 216-B-52 received waste from the Uranium Recovery Process. Trenches 216-B-53A, 216-B-53B, 216-B-54 and 216-B-58 received laboratory and PRTR waste from 300 Area. Although some documentation states the trench is divided into eight 19-meter (62.5-foot) sections by 1.2-meter (4-foot) high earthen dams with a 1.5:1 side slope, a 1956 photograph shows the trench was divided into only three sections by earth dams.

**Waste Type:** Storage Tank

**Waste Description:** The site received the scavenged tributyl phosphate (TBP) supernatant waste from 221-U Building. The waste is high in salt and is neutral to basic. It contained inorganic compounds such as ferrocyanide, phosphate and nitrate.

---

**Code:** 216-B-27  
**Classification:** Accepted  
**Reclassification:** None  
**Type:** Trench  
**Start Date:** 1/1/1957  
**End Date:** 1/1/1957

**Code:** 216-B-28  
**Classification:** Accepted

**Names:** 216-B-28; 216-B-28 Trench; 216-BC-15 Trench  
**Reclassification:** None

**Type:** Trench  
**Start Date:** 1/1/1957

**Status:** Inactive  
**End Date:** 1/1/1957

**Description:** The BC trenches were surface stabilized as a unit. The backfilled trenches have been covered with clean soil and posted as Underground Radioactive Material. Concrete AC 540 markers outline the area where the trenches are located, but do not identify specific trench locations. The trench construction divided it into eight 19-meter (62.5-foot) sections, separated by 1.2-meter (4-foot) high earthen dams. It has a 1.5:1 side slope.

**Location:** The unit is directly south of the 216-B-27 Trench, south of the 200 East Area (across Route 4S) in the BC Crib Area. The BC Cribs and Trenches are located inside the BC Controlled Area.

**Release Description:** See UPR-200-E-83

**Related Sites/Structures:** This trench is related to UPR-200-E-83.

**Process Description:** From 1952 to 1958, waste containing uranium and fission products, produced by the bismuth phosphate separations process, were removed from underground storage tanks and reprocessed at 221-U to recover the uranium from the waste. After the uranium was removed, the cesium and strontium content of the effluent was reduced by precipitation. The supernate liquor was released to the ground in the BC Cribs and Trenches. A total of 16 unlined trenches, 216-B-20 through 216-B-34 and 216-B-52 received waste from the Uranium Recovery Process. Trenches 216-B-53A, 216-B-53B, 216-B-54 and 216-B-58 received laboratory and PRTR waste from 300 Area. The following are related to the unit: eight 7.62-centimeter (3-inch) Schedule 40 pipes, approximately 6.7 meters (22 feet) long, placed along the side slope, 19.2 meters (63 feet) apart; eight 7.62-centimeter (3-inch) gate valves for the above pipes, at ground level; wooden cover composed of three 2 by 4s, spaced 3 meters (10 feet) apart, running the length of the unit, with 1 by 6s crossing the width, 1.2 meters (4 feet) apart; 4 by 4 support stakes, 0.76 meters (2 feet 6 inches) long, spaced 2.4 meters (8 feet) apart to secure the wooden cover to the unit.

**Waste Type:** Equipment

**Waste Description:** The site received the scavenged tributyl phosphate (TBP) supernatant waste from 221-U Building. The waste is high in salt and is neutral to basic. The waste contained inorganic compounds such as ferrocyanide, nitrate and phosphate.

Status:

End Date: 1/1/1957

Description: The BC trenches were surface stabilized as a unit. The backfilled trenches have been covered with clean soil and posted as Underground Radioactive Material. Concrete AC 540 markers outline the area where the trenches are located, but do not identify specific trench locations. The site is a trench that was used for disposal of medium-activity liquid waste. The trench has been backfilled and the area has been surface stabilized. The trench was a long narrow excavation with a 1:1.75 side slope. It was divided crosswise into two equal sections by an earthen dam. The dam was 1.5 meters (5 feet) high and 1.5 meters (5 feet) wide at the top. A 10.2 centimeter (4 inch) Schedule 40 pipe ran along the top edge of the trench. Four 7.62-centimeter (3-inch) Schedule 40 pipe sections extended laterally from the 10.2-centimeter (4-inch) pipe, down the side slope into the trench. Liquid discharge into the trench was controlled by gate valves located at the top of the lateral lines. A cover, constructed of 1 by 6 and 2 by 4 wood framing and sisalkraft paper, extended the length of the trench. The vertical distance from the cover to the trench bottom was a minimum of 1.5 meters (5 feet).

Location: The trench is located south of the 200 East Area (across Route 4S) in the BC Crib Area. The BC Cribs and Trenches are located inside the BC Controlled Area.

Related Sites/Structures: The trench is associated with 221-U uranium recovery process and UPR-200-E-83.

Process Description: From 1952 to 1958, waste containing uranium and fission products, produced by the bismuth phosphate separations process, were removed from underground storage tanks and reprocessed at 221-U to recover the uranium from the waste. After the uranium was removed, the cesium and strontium content of the effluent was reduced by precipitation. The supernate liquor was released to the ground in the BC Cribs and Trenches. A total of 16 unlined trenches, 216-B-20 through 216-B-34 and 216-B-52 received waste from the Uranium Recovery Process. Trenches 216-B-53A, 216-B-53B, 216-B-54 and 216-B-58 received laboratory and PRTR waste from 300 Area.

Waste Type: Process Effluent

Waste Description: The site received the scavenged tributyl phosphate (TBP) supernatant waste from the 221-U Building. The waste is high in salt and is neutral to basic. It contained inorganic compounds such as ferrocyanide, nitrate and phosphate.

Code: 216-B-30

Names: 216-B-30; 216-B-30 Trench; 216-BC-17 Trench

Type: Trench

Status: Inactive

Start Date: 1/1/1957

### Location:
The unit is immediately north of the 216-B-23 Trench, south of the 200 East Area (across Route 4S) in the BC Crib Area.

### Related Sites/Structures:
The site is associated with 221-U and UPR-200-E-83.

### Process Description:
From 1952 to 1958, waste containing uranium and fission products, produced by the bismuth phosphate separations process, were removed from underground storage tanks and reprocessed at 221-U to recover the uranium from the waste. After the uranium was removed, the cesium and strontium content of the effluent was reduced by precipitation. The supernate liquor was released to the ground in the BC Cribs and Trenches. A total of 16 unlined trenches, 216-B-20 through 216-B-52 received waste from the Uranium Recovery Process. Trenches 216-B-53A, 216-B-53B, 216-B-54 and 216-B-58 received laboratory and PRTR waste from 300 Area. The unit is divided in half by an earthen dam at the center. The dam is 1.5 meters (5 foot) high and 1.5 meters (5 foot) wide at the top. The side slope of the trench is 1:25:1.

### Waste Type:
Chemicals

### Waste Description:
The site received scavenged waste from the uranium recovery process in 221-U (tributyl phosphate [TBP] solvent extraction). The waste is high in salt and is neutral to basic. It
contained inorganic compounds such as ferrocyanide, nitrate and phosphate.

<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The trench was active during October and November 1965. The site received waste from a liquid release at the Plutonium Recycle Test Reactor (PRTR) in the 300 Area. Contaminated liquid was transported to the 200 Area via tanker trucks. Use of the trench discontinued when specific retention capacity was reached. Of all the specific retention trenches at this location, only 216-B-53A is considered to be a TRU waste site, containing 100 grams of plutonium. The trench was divided into two sections by an earthen dam at the center. The dam was 1.5 meters (5 feet) high and 12.7 centimeter (5 inches) wide at the top. The side slope of the open trench was 1.75:1.</td>

</table>
Controlled Area (UPR-200-E-83).

The trench is divided into two sections by an earthen dam at the center. The dam is 1.5 meters (5 feet) high and 12.7 centimeter (5 inch) wide at the top. The side slope is 1.75:1.

**Location:** The trench is located south of the 200 East Area (across Route 4S) in the BC Crib Area. The trench is inside the BC Controlled Area.

**Release Description:** See UPR-200-E-83

**Related Sites/Structures:** The trench is associated with 300 Area laboratory waste and the 340 facility.

**Process Description:** Liquid waste from the 300 Area laboratory facilities was sent to the 340 facility via the process sewer. Waste that was above the release limits for the 300 Area Process Ponds was sent by tanker truck to the 200 Area for disposal.

**Waste Type:** Asbestos (friable)

**Waste Description:** The site received liquid waste from the 300 Area Hanford Laboratory Operations. The waste is low in salt and is neutral to basic.

**Description:** The BC trenches were surface stabilized as a unit. The backfilled trenches have been covered with clean soil and posted as Underground Radioactive Material. Concrete AC 540 markers outline the area where the trenches are located, but do not identify specific trench locations. The trench is located inside the Radiologically Controlled Area boundaries known as the BC Controlled Area (UPR-200-E-83).

**Location:** The trench is located south of the 200 East Area (across Route 4S). The trench is within the BC Controlled Area.

**Release Description:** In 1969, contaminated Russian thistles were found growing on trenches 216-B-53A, 216-B-53B and 216-B-54. The weeds had a maximum dose rate of 1500 millirem per hour. The contaminated weeds were removed and buried. Action was taken to inhibit weed growth on the trenches.

**Related Sites/Structures:** The trench is associated with the 300 Area laboratory facilities and the 340 facility.

**Process Description:** Liquid waste from the 300 Area laboratory facilities was sent to the 340 facility via the process sewer. Waste that was above the release limits for the 300 Area Process Ponds was sent by tanker truck to the 200 Area for disposal. Although some reference documents state the trench was active from 1963 to 1965, ARH-947 and ARH-2806 state the trench was activated in March 1963 and removed from service in October 1963. The trench was divided into two sections by an earthen dam at the center. The dam was 1.5 meters (5 feet) high and 12.7 centimeter (5 inches) wide at the top. The side slope of the open trench was 1.75:1.

**Waste Type:** Equipment

**Waste Description:** The site received waste from the Hanford Laboratory Operations (BNWL) in the 300 Area. The waste is low in salt and is neutral to basic.
**Code:** 216-B-58  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 216-B-58; 216-B-58 Trench; 216-B-59 Crib  
**Type:** Trench  
**Status:** Inactive  
**Start Date:** 1/1/1965  
**End Date:** 1/1/1967  
**Description:** The BC trenches were surface stabilized as a unit. The backfilled trenches have been covered with clean soil and posted as Underground Radioactive Material. Concrete AC 540 markers outline the area where the trenches are located, but do not identify specific trench locations. The trench is within the posted Radiologically Controlled Area known as the BC Controlled Area (UPR-200-E-83). The trench was divided into 7.6-meter (25-foot) sections by 1.2-meter (4-foot) high earthen dams. Each section had a wooden cover. A 1.22-meter (48-inch) diameter pipe was placed along the bottom. The pipe was corrugated with five 10.16-centimeter (4-inch) diameter holes around the bottom half.  
**Location:** The trench is located south of the 200 East Area (across Route 4S) in the BC Crib Area.  
**Related Sites/Structures:** The trench is associated with 300 Area laboratory facilities and the 340 facility.  
**Process Description:** Liquid waste from the 300 Area laboratory facilities was sent to the 340 facility via the process sewer. Waste that was above the release limits for the 300 Area Process Ponds was sent by tanker truck to the 200 Area for disposal. The trench was covered with 8 wooden cover frames, 5.5 meter (18 feet) wide by 8.5 meter (28 feet) long a 7.62-centimeter (3-inch) schedule 40, carbon steel pipe, approximately 7 meters (23 feet) long placed along a side of the structure.  
**Waste Type:** Process Effluent  
**Waste Description:** The site received Battelle Northwest laboratory (BNWL) waste from the 300 Area. The waste is low in salt and is neutral to basic.

---

**Code:** 200-E-14  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 200-E-14; 216-B-201; 216-BC-201 Siphon Tank; IMUST; Inactive Miscellaneous Underground Storage Tank  
**Type:** Storage Tank  
**Status:** Inactive  
**Start Date:** 1/1/1956  
**End Date:** 1/1/1957  
**Description:** The 216-B-14, 216-B-15, 216-B-16, 216-B-17, 216-B-18 and 216-B-19 cribs and the 216-BC-201 siphon tank were surface stabilized as a single area. All the surface structures (risers and vents) have been removed. There are concrete AC 540 markers to identify the site. The vents were visible until 1981 when the area was surface stabilized. The vent risers were removed at ground level and the area was covered with at least 0.6 meters (2 feet) of additional top soil. The area is posted as Underground Radioactive Material.  
**Location:** The siphon tank is located south of Route 4S, south of the 200 East Area. The tank is north of and adjacent to the 216-B-14 through 216-B-19 Cribs. The tank is 18 meters (60 feet) north of the center line between the 216-B-14 and 216-B-15 Cribs.  
**Related Sites/Structures:** The tank is associated with the 2805-E-3 and 2805-E-4, 200-E-222-PL pipelines, the 216-B-14, 216-B-15, 216-B-16, 216-B-17, 216-B-18 and 216-B-19 cribs, 241-BY Tank Farm and 221-U.  
**Process Description:** The 216-BC-201 siphon tank was used to discharge waste to the 216-B-14, 216-B-15, 216-B-16, 216-B-17, 216-B-18 and 216-B-19 cribs. The siphon tank would receive and hold the
waste until the tank level reached 1.6 meters (5.5 feet). When this level was reached, the
siphon action would begin and the tank contents would discharge to the designated crib. The
siphon action would stop when the tank level reached 0.07 meters (6 inches). The siphon
action was intended to flood the crib area with a significant amount of liquid, resulting in a
uniform spread of contaminants throughout the crib, instead of a large amount of contaminants
concentrating near the discharge point.

**Waste Type:** Process Effluent

**Waste Description:** Most of the liquid waste dispersed through this tank originated from the Uranium Recovery
Process in 221-U (U-Plant). The process reclaimed the uranium metal from the tank farm waste
derived from the bismuth phosphate fuel processing activities. Curren (1972) states that 216-B-
17 and 216-B-19 also received scavenged tank farm waste. The waste includes ferrocyanide,
phosphate, cesium, strontium, uranium, cobalt and ruthenium. The total effluent to the six cribs
that passed through the 216-BC-201 Siphon Tank was 3.896E+07 liters (1.032E+07 gallons).
At the time of discharge (1956), the total radionuclide activity for all six cribs equaled 26 curies
of cobalt-60, 1,840 curies of cesium-137, 1,850 curies of strontium-90, 70 grams of plutonium
and 1,410 kilograms (640 pounds) of uranium.

<td></td>
</tr>
<tr>
<td>Process Description</td>
<td>Many documents state the unit operated from August 1947 to June 1976. In June 1976, the stack drainage was rerouted to a cell drainage sample tank. The french drain is constructed of two 1.22 meter (4 feet) diameter by 1.53 meter (5 feet) long tile pipes, stacked vertically and filled with crushed limestone. The unit has a plywood cover, located 2.44 meters (8 feet) below grade. Two and a half tons (2,270 kilograms) of limestone were used as a base and to fill the tile pipes. The bottom of the drain is 5.5 meters (18 feet) below ground surface. However, an Atlantic Richfield Hanford Company memo, created on October 3, 1974, states the drain line to the french drain was cut and capped in June 1974.</td>

<tr>
<td>Waste Description</td>
<td>The site received the 291-B-1 Stack drainage. In 6/76, the stack drainage was rerouted to a catch tank, jetted to the wind tunnel, drained to a sump, and then pumped to a cell drainage sample tank. The waste is low in salt and is neutral to basic.</td>
<td></td>
</tr>
</tbody>
</table>
The crib is not visible because the 225-B Building was built on top of the crib site in 1975. There is a sign posted on the south wall of the 225-B building indicating where the 216-B-60 crib is located.

The crib is located at the west end of the 221-B Building. The southeast portion of the 225-B Encapsulation Facility was built over the crib site.

The crib is associated with the 221-B facility operations.

The 216-B-60 crib was a single use, specific retention crib. The crib was constructed of two steel caissons positioned side by side (standing on end) that were 2.4 meters (8 feet) in diameter and 4.2 meters (14 feet) tall. The two caissons were installed in November 1967 to receive waste from the cleanout of the 0.6 meter (24 inch) 221-B cell drain header. The cleanout process was completed in December 1967. The first caisson received 18, 499 liters (4887 gallons) of sludge solids and was capped with concrete. The second caisson received a small volume of flush water. The 0.6 meter (24 inch) line was plugged after cleanout and the caissons were backfilled to grade.

The site received the cell cleanout solid and liquid waste from the 61 centimeter (24 inch) 221-B Building cell cleanout drain line. The waste was low in salt and was neutral to basic. Composite sample results indicated 715.5 kilograms of uranium, 0.08 grams of plutonium, 777 curies of Ce-144, 8 curies of Cs-137 and 5 curies of Eu-154.

The B Plant facility is one of the original Hanford chemical processing buildings. The 221-B Process Canyon is a large, reinforced concrete building. It consists of twenty sections (two cells per section) with expansion joints between each section. The building is divided lengthwise into the gallery side and the canyon chemical processing side by a thick, concrete shielding wall running the full length of the building.

The facility is located inside 200 East Area, on Atlanta Ave.

The site received the cell cleanout solid and liquid waste from the 61 centimeter (24 inch) 221-B Building cell cleanout drain line. The waste was low in salt and was neutral to basic. Composite sample results indicated 715.5 kilograms of uranium, 0.08 grams of plutonium, 777 curies of Ce-144, 8 curies of Cs-137 and 5 curies of Eu-154.
Description: The septic tank is surrounded by chain with four steel posts painted yellow. The tank is posted with a septic tank sign. The tank has two 10 centimeter (4-inch) PVC pipes which protrude vertically from the ground. The sanitary tile field is surrounded with a steel post and chain barricade and is posted with Caution Underground Radioactive Material signs.

Location: The site is located just east of the 221-B Building and south of the inactive 2607-E4 septic tank.

Process Description: The septic system received waste from the 221-B Building.

Waste Type: Process Effluent

Waste Description: The site received sewage from lavatory facilities within the 221-B Building.

---

**Code:** 200-E-55  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 200-E-55; Effluent Drain East of 291-B Sand Filter; Miscellaneous Stream #322

**Type:** French Drain  
**Start Date:** 1/1/1948  
**End Date:** 1/1/1997

**Description:** There are no visual surface features for this drain. It has been marked with a single steel post. The drain is below grade and east of the B-Plant Sand Filter. The french drain consists of a hole 1.83 meters (6 feet) in diameter, 0.9 meters (3 feet) deep backfilled with gravel.

**Location:** The french drain is located 3.6 meters (12 feet) east of the east end of the 291-B Sand Filter (WIDS Site Code 200-E-30).

**Related Sites/Structures:** The drain is associated with the 291-B Sand Filter (200-E-30). The pipeline to this french drain is sitecode 200-E-214-PL.

**Process Description:** Sand Filters were added to the B Plant exhaust system in 1948. Condensate from the sand filter drained to a pipe in the bottom of the east end of the sand filter that dispersed the effluent to a gravel filled hole adjacent to the sand filter.

**Waste Type:** Steam Condensate

**Waste Description:** The drain received condensate from the B-Plant canyon sand filter and rain water that leaked through the sand filter roof. An auger drill sample of the sand filter french drain was collected in September 1994. A spilt spoon sample was collected at 4.8 meters (16 feet) below ground surface. Maximum contamination levels in the soil read 20,000 disintegrations per minute beta/gamma and 2100 disintegrations per minute alpha with hand held instruments. The sample was shipped to a mobile laboratory for analysis.

---

**Code:** 2607-E4  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 2607-E4; 2607-E4 Septic Tank and Tile Field

**Type:** Septic Tank  
**Start Date:** 1/1/1963  
**End Date:** 1/1/1998

**Status:** Inactive

**Description:** The septic tank and tile field are marked with a Sanitary Sewer/Drain Field sign and lie with a posted Underground Radioactive Material area. The 2607-E4 Septic Tank is constructed of reinforced concrete that drains to an adjacent tile field.

**Location:** The 2607-E4 Septic Tank is located northeast of the 221-B Building. The tile field is northeast
The 2607-E4 Septic Tank and associated tile field were designed to accept and treat sanitary sewer effluent from B-Plant facilities.

This septic tank received sanitary wastewater and sewage from B Plant facilities at an estimated rate of 0.24 cubic meters (8.5 cubic feet) per day. The tank was abandoned in 1998. No information was provided related to sampling.

The unplanned release is not separately marked or posted. The contamination was assumed to have migrated from the source, which was a pipeline leak that occurred four months earlier.

The release occurred on the south side of the 221-B Building.

Soil contamination was detected approximately 24.4 meters (80 feet) from the location of a waste line rupture location that was identified on June 17, 1946. The additional contamination was assumed to be migration from the first line failure. Following the discovery of the additional contamination, test holes were dug to determine the extent of the contamination.

This unplanned release is associated with UPR-200-E-80 and 200-E-226-PL.

The original line break (metal waste line) had dose rates up to 400 rad per hour.

A document written on 11/18/1947 states radioactive particulate matter was found within a 305 meters (1,000 feet) radius around the B Plant and T Plant stacks. A study of the ground contamination found that mist-like particles were released over a larger area and that the particulate matter had magnetic properties.

Hanford Site Waste Management Units Report
February 2015
Waste Description: Spotty ground contamination around the B Plant stack. Most stack releases consisted of ruthenium.

Code: UPR-200-E-44  Classification: Accepted
Names: UPR-200-E-44; BCS Waste Line Leak South of 221-B; UN-200-E-44  Reclassification: None
Type: Unplanned Release  Start Date: 1/1/1972
Status: Inactive  End Date:
Description: The release site is not separately marked or posted. There is no visual evidence of the area that caved in.
Location: The unplanned release occurred south of 221-B, near the R-17 Change House. north of 7th Street. The Change House no longer exists.
Release Description: A small cave-in was discovered south of the R-17 change house next, to the black-top road (7th Street). There was no radiological reading identified in the cave-in at the time of discovery. An excavation was done after lunch that identified a leak in the 15 centimeter (6 inch) BCS crib line. Soil removed from the excavation was contaminated from 10,000 to 20,000 counts per minute. The dose rate on the pipe was 20 millirad per hour. There was no contamination spread from the excavation.
Related Sites/Structures: This site is associated with B Plant and UPR-200-E-103.

Waste Type: Steam Condensate
Waste Description: The leaking effluent from the BCS crib line caused the ground to cave in. The dirt was contaminated with readings of 10,000 to 20,000 counts per minute. The pipe was contaminated with readings up to 20 millirem per hour.

Code: UPR-200-E-52  Classification: Accepted
Names: UPR-200-E-52; Contamination Spread Outside the North Side of 221-B; UN-200-E-52  Reclassification: None
Type: Unplanned Release  Start Date: 1/1/1975
Status: Inactive  End Date:
Description: In 2008, an area approximately 4 meters (13 feet) wide by 9 meters (30 feet) was posted with a WIDS sign and Underground Radioactive Material Area signs (see photos).
Location: The unplanned release occurred on the north side of 221-B, near the steps that cross the railroad tunnel. Soil contamination occurred under the drain of the steam pressure relief pipe discharge from the E-5-2 Strontium Concentrator.
Release Description: On August 1, 1975, soil contamination ranging to 20,000 counts per minute was detected under the drain of the steam pressure relief pipe discharge from the E-5-2 Strontium Concentrator, and an area about 0.91 meters (3 feet) wide and 2.74 meters (9 feet) high on the north side of the 221-B Building was contaminated to 100,000 counts per minute outdoors. Soil on the western berm adjacent to the railroad cut was also contaminated. The apparent cause was that contamination migrated from the leaking tube bundle of the recently replaced E-5-2 strontium concentrator to the pipe gallery piping. It was then forced outside by operation of the relief valve when the operating steam pressure was increased to 35 pounds per square inch while the relief valve setting remained at 32 pounds per square inch.
Waste Type: Stormwater Runoff
Waste Description: Beta/gamma with readings up to 20,000 counts per minute were found in the soil under the steam pressure relief discharge pipe from the E-5-2 Strontium Concentrator. Another area on the north side of 221-B was contaminated up to 100,000 counts per minute.

Code: UPR-200-E-54
Names: UPR-200-E-54; Contamination Outside 225-B Doorway; UN-200-E-54
Type: Unplanned Release
Status: Inactive
Classification: Accepted
Reclassification: None
Start Date: 1/1/1977
End Date:

Description: There is a sign posted on the south wall of 225-B, next to Door 130, that reads UPR-200-E-54. There is no radiological posting around the doorway or in the soil adjacent to the concrete door pad.

Location: The site is located adjacent to exit door #130 on the south side of the 225-B Building.

Release Description: On July 20, 1977, water used for decontaminating a manipulator seeped under an exit door of the 225-B Building spreading low-level contamination onto the concrete door pad and adjacent soil. Radiation readings on the pad were 25 millirads per hour direct and 20,000 counts per minute smearable. While decontaminating the manipulator, the water spray wand was accidentally directed toward the corridor door by the operator. Water was forced under the door into the corridor. The water trickled down the corridor to a drain in the Service Gallery. As water passed the exit door about 1.89 liters (0.5 gallons) seeped under the unsealed threshold onto the pad and soil.

Waste Type: Steam Condensate
Waste Description: Water seeping under an exit door caused beta/gamma with readings of 25 millirads/hour direct and 20,000 counts per minute smearable on the concrete pad outside the door at 225-B. Contamination readings in the soil were 10,000 counts per minute. The contaminated liquid was from a manipulator decontamination activity.

Code: UPR-200-E-55
Names: UPR-200-E-55; Contamination Spread South of B Plant; UN-200-E-55
Type: Unplanned Release
Status: Inactive
Classification: Accepted
Reclassification: None
Start Date: 1/1/1979
End Date:

Description: A single post with a sign that reads UPR-200-E-55 is currently located under an aboveground line. The area is not radiologically posted. It marks the approximate location of the release.

Location: The release occurred on the south side of B-Plant, at the 212-B Building. Smearable contamination was found around the K-3 filter area, that is located on the roof of the 212-B Building, on the roadway southwest of the K-3 filter area, and the gravel area southwest of the 212-B Building.

Release Description: On April 27, 1979, wind spread contamination from a plastic sheeting in a radiation zone near the 212-B Building to an adjacent area. The incident occurred after the K-3 east filter was changed out. During the changeout plastic was laid down for contamination control within a radiation zone. The wind whipped the contamination plastic as it was being packaged for burial. The general area was surveyed and spots of contamination ranging from 5,000 counts per minute to 30,000 counts per minute were found outside the radiation zone.
Waste Type: Stormwater Runoff
Waste Description: While changing the K-3 filter, wind blew beta/gamma contamination (particles), with readings of 5,000 to 30,000 counts per minute, outside the radiation zone.

Code: UPR-200-E-80
Names: UPR-200-E-80; 221-B R-3 Line Break; R-3 Radiation Zone; UN-200-E-80; UN-216-E-8
Type: Unplanned Release
Status: Inactive
Start Date: 1/1/1946
End Date: 1/1/1946
Classification: Accepted
Reclassification: None
Description: The unplanned release is not separately marked or posted.
Location: The release occurred in an underground pipeline, located on the south side of the 221-B Canyon Building, near the R-3 stairwell. The leak resulted in a contaminated area measuring 30 meters (100 feet) wide by 152 meters (500 feet) in length, along the south side of the 221-B building.
Release Description: On June 17, 1946, an underground metal waste line failure was detected near section R-3 on the south side of the 221-B building. ARH-780 says the dose rate at ground surface level was 400 rad per hour. The leak was confirmed by hydrostatic testing. A 1946 letter report states the dose rate at the cave-in location was greater than 4000 R/hr. (4000 Rep/hr with a Victoreen probe). Operations were halted for six days to change the waste routing and cover the area with several feet of gravel. A portion of the area had caved in to a depth of approximately 1 meter (3 feet). The excavated contaminated soil was taken to the Dry Waste Burial Ground. The excavation was backfilled. After covering the contamination, the dose rate was reduced to 100 millirad per hour.
Related Sites/Structures: UPR-200-E-80 is associated with an underground metal waste line from the 221-B Canyon Building and UPR-200-E-1. It is likely associated with 200-E-226-PL pipeline (line V743).
Waste Type: Sanitary Sewage
Waste Description: The release consisted of approximately 10 curies of fission products from the "metal waste" pipe line.

Code: UPR-200-E-85
Names: UPR-200-E-85; Line Leak at 221-B Stairwell R-13; UN-200-E-41; UN-200-E-85; UN-216-E-13; UPR-200-E-41
Type: Unplanned Release
Status: Inactive
Start Date: 1/1/1972
End Date: 1/1/1972
Classification: Accepted
Reclassification: None
Description: The R-13 Utility Pit is covered with a steel lid. The site was stabilized in 1984 and posted with Underground Radioactive Material signs.
Location: UPR-200-E-85 occurred south of the center of the 221-B Building, near the R-13 Utility Pit.
Release Description: During a routine survey, it was discovered that an unencased transfer line leading from the ion exchange tank 18-1 in the 221-B building to the 241-BX-154 Diversion Box had leaked process waste near the R-13 Utility Pit. The contaminated waste apparently seeped through a wall joint and ran into the electric utility pit. Radiation measurements were taken near the bottom of the pit. The measurements read 15 rad per hour at a distance of 5 centimeters (2 inches) from the...
Related Sites/Structures: UPR-200-E-85 is associated with the 18-1 Tank in the 221-B Building, the 241-BX-154 Diversion Box and the R-13 Utility Pit. This occurrence was also given the number UPR-200-E-41.

Waste Type: Water
Waste Description: The waste line contained ion exchange waste from tank 18-1, located inside the B Plant canyon. Soil samples collected in 1972 found the release was predominantly cesium-137. Approximately 30 curies of cesium was released, but half of the release was removed with the soil excavated to expose the line leak.

<tr>
<td>Waste Type:</td>
<td>Sanitary Sewage</td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>Approximately 75 grams (3 ounces) of plutonium-239 may have leaked into the soil at 224-B, based on an actual excavation that found contaminated soil at 224-T in 200 West Area.</td>
<td></td>
</tr>
</tbody>
</table>
contaminated dirt was taken to the burial ground. The line was found to have several openings in it. The leaking section of pipe was removed and replaced. There was no spread of contamination or personnel contamination noted during the line repair.

**Related Sites/Structures:**
- UPR-200-E-103 was associated with the 221-B Building, the BCS transfer line south of the R-17 Change House, and UPR-200-E-44. It may be associated with pipelines 200-E-161-PL or 200-E-162-PL.

**Waste Type:** Stormwater Runoff

**Waste Description:** The release consisted of contaminated liquid from the BCS crib line, with radiation levels up to 1,500 counts per minute at the surface of the depression and 100,000 counts per minute inside the excavation.
**200-CP-1**

<td></td>
</tr>
</tbody>
</table>
| Location: | The site is located at the center of the south side of the 202-A Building, approximately 23
meters (75 feet) from the building.

**Related Sites/Structures:**
The site is associated with PUREX Trap #3 and pipeline 200-E-267-PL.

**Process Description:**
A sump in the bottom of Trap Pit #3 collected steam condensate, rain water and equipment leakage and drained it to 216-A-12.

**Waste Type:**
Misc. Trash and Debris

**Waste Description:**
The site received the Steam Trap Pit #3 drainage from the 202-A Building. The waste was low in salt and was neutral to basic. The site contains less than 50 curies total beta activity. It is possible that more than one Trap Pit drained to this french drain.

**Code:** 216-A-13  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 216-A-13; 216-A-13 French Drain; Miscellaneous Stream #460

**Type:** French Drain  
**Start Date:** 1/1/1956  
**End Date:** 1/1/1962

**Location:** The site is located approximately 6 meters (20 feet) west and 6 meters (20 feet) south of the southwest corner of the 202-A Building.

**Related Sites/Structures:**
The site is associated with PUREX, the 216-A-35 French Drain and pipeline 200-E-273-PL.

**Process Description:**
The site received the seal water from the air sampler vacuum pumps in the 202-A Building.

**Waste Type:** Equipment

**Waste Description:**
The site received the seal water from the air sampler vacuum pumps in the 202-A Building. The waste is low in salt, neutral to basic, and contains less than 1 curie total beta activity. The 1993 PUREX AAMS Report lists the total volume released as 100,000 liters (30,000 gallons), but does not give the reference for this discrepancy from the original Stenner report. It is assumed that the original number is correct, and the AAMS report added an extra "0" in error.

**Code:** 216-A-14  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 216-A-14; French Drain - Vacuum Cleaner Filter Pit; Miscellaneous Stream #462

**Type:** French Drain  
**Start Date:** 1/1/1956  
**End Date:** 1/1/1972

**Location:** The drain is not marked or posted. There are no visible surface features for this french drain. The Vacuum Cleaner Filter Pit is a concrete box with approximately 0.6 meters (2 feet) above grade. The sump is inside the pit and drains through an underground pipe to the buried french drain. The drain is composed of two reinforced concrete pipes placed vertically end to end.
The excavation is 3.0 meters (10 feet) in diameter and extends to a depth of 1.5 meters (5 feet) below the bottom. Both the drain and the excavation are filled with 8-centimeter (3-inch) rock to the top and backfilled over. The filter pit access is labeled Contamination Area, Radiation Area, Airborne Contamination and Confined Space. A 10 centimeter (4 inch) M23b-UD inlet pipe, approximately 1.5 meters (5 feet) long, extends horizontally into the unit, 7.9 meters (26 feet) below grade. The site has a 1.3 centimeter (0.5 inch) thick steel cover.

**Location:** The site is located south of the center of the 202-A Building, 5.5 meters (18 feet) east of the Filter Pit.

**Related Sites/Structures:** The site is associated with the Vacuum Cleaner Filter Pit and pipeline 200-E-268-PL.

**Process Description:** A sump in the bottom of Filter Pit collected steam condensate, stormwater and equipment leakage that drained to 216-A-14.

**Waste Type:** Water

**Waste Description:** The site received the vacuum cleaner filter and blower pit drainage from the 202-A Building. The waste was low in salt, neutral to basic, and contains less than 1 curie total beta activity.

---

**Code:** 216-A-32 **Classification:** Accepted

**Names:** 216-A-32; 216-A-32 Crib

**Type:** Crib **Start Date:** 1/1/1959

**Status:** Inactive **End Date:** 1/1/1972

**Description:** The site is currently surrounded with cement posts with Underground Radioactive Material signs. There had been an inner area marked with steel posts, chains and Surface Contamination signs. The area was surface stabilized in 2001 and is now covered with clean gravel.

**Location:** The crib is located northeast of 202-A, inside the PUREX exclusion fence.

**Related Sites/Structures:** The site is associated with 202-A and the 200-E-107 stabilized area. The pipeline associated with this crib is sitecode 200-E-194-PL.

**Process Description:** Perforated vitrified clay pipe was placed horizontally on the fill 1.5 meters (5 feet) above the bottom of the excavation. Two layers of sisalkraft paper separate the crib gravel from the overlying earthen backfill.

**Waste Type:** Soil

**Waste Description:** The site received the 202-A canyon crane maintenance facility floor, sink, and shower drainage. The site contains less than 1 curie total beta activity. In a letter (Walsar 1966), Isochem Corporation indicates the intent to dispose of 24,600 liters (6,500 gallons) of approximately 50% Soltrol (a brand of purified kerosene) diluent in this crib. BHI-00178 (1995) reports that investigators were unable to verify if the proposed disposal took place.

---

**Code:** 216-A-35 **Classification:** Accepted

**Type:** French Drain **Start Date:** 1/1/1963

**Status:** Inactive **End Date:** 1/1/1966

**Description:** The drain is a raised cement structure, painted yellow and surrounded with Underground
Radioactive Material signs. The top cover is marked Confined Space.

Location: The site is located approximately 9 meters (30 feet) south of the west end of the 202-A PUREX Building, south of the 216-A-13 French Drain.

Related Sites/Structures: The site is associated with PUREX, the 216-A-13 French Drain and pipeline 200-E-272-PL.

Process Description: The site is a french drain that was a replacement for the 216-A-13 French Drain. The inlet pipe enters the french drain 3.2 meters (10.5 feet) below grade. Disposal to the site was terminated when the effluent flow rate exceeded the infiltration capacity of the soil. The site was deactivated by capping the effluent pipeline to the unit and rerouting the effluent to the 216-A-29 Ditch via the 202-A Chemical Sewer.

Waste Type: Sanitary Sewage

Waste Description: The site received the seal cooling water from the air sampler vacuum pumps in the 202-A Building. The waste is low in salt, neutral to basic, and contains less than 1 curie of total beta activity.

---

Code: 241-A-151
Names: 241-A-151; 241-A-151 Diversion Box
Type: Diversion Box
Status: Inactive

Description: The site is a reinforced concrete structure with cover blocks. Most of the structure is below grade. It is marked and radiologically posted.

Location: The diversion box is located south of the east end of the 202-A Building.

Release Description: Multiple documented Unplanned Releases are associated with this diversion box.

Waste Type: Stormwater Runoff

Waste Description: The unit transferred process effluents from the PUREX facility to the tank farms. Lead shielding may also be contained inside the diversion box.

---

Code: 241-A-302A
Type: Catch Tank
Status: Inactive

Description: The unit is an underground, cylindrical vessel made of carbon steel. It sits inside a pump pit.
with a riser extending to the surface. It is surrounded with posts and chain and marked with radiological signs.

**Location:** The catch tank is located south of the east end of the 202-A building and west of the 241-A-151 Diversion Box. It is located inside the PUREX security fence.

**Related Sites/Structures:** The site is associated with the 241-A-151 Diversion Box. The drain line to this catch tank is V028.

**Process Description:** The tank received excess process effluent and leaks from the 241-A-151 Diversion Box.

**Waste Type:** Stormwater Runoff

**Waste Description:** This unit I collected drainage from the 241-A-151 diversion box. Volumes varied according to specific plant operation. Prior to being pumped out in 1992, the tank contained 13,626 liters (3,605 gallons) of waste. In 1994, it was reported to contain 5984 liters (1583 gallons) of effluent. The 1996 report said it contained 6418 liters (1698 gallons) of waste.

**Description:** The site is a 1.2 meter (4 foot) diameter concrete drain with a metal plate cover. It is flush with the ground surface. On October 15, 1998, the inside of the drain was dry.

**Location:** The site is located on the southeast corner of 202-A, east of railroad tunnel #1 (218-E-14). It is located inside posted boundaries sitecode 200-E-107, that has been recently stabilized and downposted to an Underground Radioactive Material area.

**Related Sites/Structures:** The site is associated with the PUREX facility and 200-E-107.

**Process Description:** Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.

**Waste Type:** Water

**Waste Description:** The site received non-contaminated steam condensate. However, the drain is located within an area that had been posted as a Radiological Contamination Area (see sitecode 200-E-107). A radiation survey done in October 1998 did not detect any contamination.

<td>End Date: 1/1/1997</td>
</tr>
<tr>
<td>Description: The site is a 0.9 meter (3 foot) diameter concrete drain under a steam line with a metal cover. There is a rusty pipe going into the drain. On October 15, 1998, the inside of the drain was dry. It was inside a posted Contamination Area.</td>
<td></td>
</tr>
<tr>
<td>Location: The site is located on the southeast corner of the PUREX Railroad Cut. It is inside a posted radiologically posted area known as 200-E-107.</td>
<td></td>
</tr>
<tr>
<td>Process Description: Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.</td>
<td></td>
</tr>
</tbody>
</table>
Waste Type: Chemicals
Description: Although the drain received non-contaminated steam condensate, it is located inside and area that had been a posted Contamination Area (200-E-107).

Code: 200-E-84
Names: 200-E-84; 202A Building Steam Condensate; Injection Well (C); Miscellaneous Stream #58
Type: Injection/Reverse Well
Status: Inactive
Description: The site is a 0.9 meter (3 foot) diameter, gravel filled french drain that received steam condensate. The drain is flush with the surrounding gravel surface except for a small lip on one side. A steel drain pipe extends over the french drain.
Location: The drain is located on the west end of 202-A, under the filter banks. It is located inside a Radiological Buffer Area.
Process Description: Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion. The silver pipe above this drain is a pressure relief valve associated with PUREX the building steam system.

Waste Type: Water
Description: The drain was installed to receive steam condensate. The Inventory of Miscellaneous Streams Report states the steam source has been eliminated and that it is a gravel filled french drain with no cover, that has a potential to receive stormwater runoff. A site walkdown in 1998 determined the pipe above the drain is a pressure relief valve associated with the PUREX building steam system. The walkdown team believes the drain is not physically located in a location that would collect stormwater run off.

Code: 200-E-107
Names: 200-E-107; Contamination Area East of PUREX; PUREX E Field
Type: Unplanned Release
Status: Inactive
Description: The site was a large, irregularly shaped, posted Contamination Area. The posted contamination east of the tunnels (218-E-14 and 218-E-15) extended into the double security fence. The area east of the Railroad Cut included the 216-A-32 Crib and the 2607-EE Sanitary Septic Tank and Tile Field, but ended at the inner security fence. In May 2000, a narrow corridor was considered a Radiological Buffer Area and separated the northern portion of the Contamination Area from the southern portion. Both sections are considered to be one waste site. The entire area was stabilized and reposted an Underground Radioactive Material Area in 2001.
Location: The site was the posted Contamination Areas located on the east side of the PUREX tunnels and east of the RR Cut, inside the PUREX facility fence. The area was stabilized and reposted as an Underground Radioactive Material area.
Residual surface contamination exists from years of PUREX facility operations. It is not attributed to a single contamination event.

The ground around the PUREX facility was contaminated from various sources during years of operation activities.

The site is a septic tank with a drain field extending northeast of the septic tank. The area is surrounded with light duty posts and chain. One riser pipe is visible.

The unit received sanitary wastewater and sewage from the PUREX facility. The source area is in a potentially contaminated zone; therefore, the waste has the potential of being contaminated.

This release occurred in the eastern half of the PUREX exclusion area. The exclusion area is posted as a Contamination Area. The release can not be individually distinguished within the zone.

Contamination spread to the eastern half of the PUREX exclusion area.

On November 30, 1961, a general spread of low-level contamination to the eastern half of the PUREX exclusion area occurred. Fission products escaped from a trap pit because of failures in a process vessel steam coil and in the trap pit piping.

The surface contaminated areas inside the PUREX facility fence were surface stabilized in 1999 and 2001. See WIDS sitecodes 200-E-103 and 200-E-107.

Fission product specks were released from a PUREX trap pit due to process vessel steam coil failures.
### Code: UPR-200-E-39
#### Classification: Accepted

#### Names:
- UPR-200-E-39; Release from 216-A-36B Crib Sampler (295-A); UN-200-E-39

- **Type:** Unplanned Release

- **Status:** Inactive

#### Description:
The release site is not separately marked or posted. It is located inside a large surface stabilized area known as 200-E-103 that is posted as an Underground Radioactive Material area.

#### Location:
The site release occurred on the ground and blacktop area outside the 216-A-36B Crib Sampler Shack (#295-A). The sample shack is located inside the PUREX Exclusion fence, south of 202-A, adjacent to the west side of the PUREX Storage Tunnel.

#### Release Description:
On February 6, 1968, pressurized ammonia scrubber liquid was found to be spewing from the vent filter at the 216-A-36B Crib Sampling Shack (295-A). The contaminated ammonia scrubber water erupted through the vent and filter and onto the ground around the outside of the sample shack. Approximately 60.4 square meters (650 square feet) of ground and blacktop was affected. Contamination levels ranged from 20 to 450 millirad/hour. The cause was determined to be that the export pressure was too high, resulting in back-pressure through the vent.

#### Related Sites/Structures:
The site is associated with 216-A-36 Crib, the 295-A Sample Shack and 200-E-103.

#### Waste Type:
Equipment

- **Waste Description:**
The site received pressurized PUREX ammonia scrubber waste containing fission products. The readings were 20 to 450 millirad/hour.

---

### Code: UPR-200-E-96
#### Classification: Accepted

#### Names:
- UPR-200-E-96; Ground Contamination SE of PUREX; UN-200-E-96; UN-216-E-24

- **Type:** Unplanned Release

- **Status:** Inactive

#### Description:
The site was described in 1980 as an area measuring approximately 1.0 hectare (2.5 acres) located adjacent to the east and south sides of 202-A (PUREX). These areas are now covered with gravel and posted as Underground Radioactive Material areas.

#### Location:
The release site include contaminated areas on the south and east sides of PUREX.

#### Release Description:
From a conversation with Harold Maxfield on October 8, 1981, it was determined the area had became contaminated by residual specks from the operation of the 291-A Stack and work activities in the 241-A-151 diversion box during the operational years of the PUREX Plant.

#### Related Sites/Structures:
The release site is associated with 200-E-103, 200-E-107, the 291-A Stack and the 241-A-151 Diversion Box.

#### Waste Type:
Stormwater Runoff

- **Waste Description:**
The release consisted of low-level radioactive particles resulting from PUREX operations, most likely fall out from the 291-A stack and diversion box activities.

**Description:**
The 202-S Building is one of the five canyon buildings. The inactive waste management unit is a large reinforced concrete structure. The canyon's processing areas and equipment are contained in small rooms called cells. The nine cells are arranged in rows that are spanned by a large crane. Each cell is topped by a thick, concrete cover. This cover is removed by the crane, allowing access to the underlying cells. The gallery above the cell cover is the same height as the cell, allowing process equipment to be manipulated during maintenance and operations.

**Location:**
The 202-S Building is located in the southern portion of the 200 West area just north of the 222-S Laboratory.

**Related Sites/Structures:**
- Structures associated with this facility include the 200 West Tank Farms, 202-S process equipment, 211-S Tank Farms, the S-Plant Cribs, Ditches, and Trenches, and waste transfer lines (200-W-152-PL).
- The Reduction Oxidation (REDOX) Facility was used to extract plutonium and uranium from fuel rods irradiated at the Hanford Site reactors. The REDOX process employed an organic solvent extraction process that used methyl isobutyl ketone to separate uranium and plutonium from each other and the fission products in the fuel rod.

**Waste Type:**
- Process Effluent

**Description:**
The unit contains solid radioactive waste.

<td>Names</td>
<td>202-S:1; 211-S Tank Farm</td>
</tr>
</tbody>
</table>

**Description:**
The 211-S Tank Farm is located west of the 202-S canyon building. It was a liquid chemical storage area. The tank farm consists of eight above ground steel storage tanks ranging from 16,430 liters (4300 gallons) to 186,200 liters (49,000 gallons). The tanks held nitric nonahydrate, nitric acid, sodium dichromate and sodium hydroxide. All of the tanks, pumps and piping were flushed and emptied when the REDOX facility was deactivated. The area had been posted as a Contamination Area due to migration of contamination from nearby contaminated processes and Surface Contamination Areas. The 211-S Tank Farm was covered with a minimum of 15.24 centimeters of clean gravel in November 2002. The area was downposted as an Underground Radioactive Material Area.

Names: UPR-200-W-57; 233-S Fire; UN-200-W-57; UPR-200-E-120 (error in area number assignment)  
Reclassification: None  
Type: Unplanned Release  
Status: Inactive  
Start Date: 1/1/1963  
End Date: 
Description: A fire, which started in the 233-S Building, spread plutonium contamination throughout the building and to a small degree outside of the building. The release site is not physically marked or posted.

Location: The 233-S building had been located in 200 West Area, north of the 202-S building. The building was demolished in 2004.

Release Description: On November 6, 1963, a fire started in the 233-S Building. The underlying cause of the incident was not positively identified. Plutonium contamination was spread within and outside the building by smoke and firefighting operations. It took about 1.5 hours to put out the fire with dry chemical extinguishers (sodium bicarbonate). Alpha radiation levels after the fire were greater than 5 million disintegrations per minute from plutonium-contaminated materials in the soot, ashes, and in the air.

Waste Type: Process Effluent  
Waste Description: Alpha radiation levels in plutonium-contaminated materials in the soot, ashes, and in the air greater than 5 million disintegrations per minute.

Code: UPR-200-W-61  
Classification: Accepted  
Names: UPR-200-W-61; REDOX Ground Contamination; UN-200-W-61  
Reclassification: None  
Type: Unplanned Release  
Start Date: 1/1/1966  
End Date: 
Description: The area is not currently marked or posted.

Location: The incident occurred outside of the REDOX Building near the southwest corner.

Release Description: On April 24, 1966, a fire hose ruptured while flushing the H-10 to 241-SX transfer line. Backflow from the transfer line contaminated an outside ground area. Readings were from 4,000 to 100,000 counts per minute over an area of about 19 square meters (200 square feet).

Waste Type: Equipment  
Waste Description: Beta/gamma with readings from 4,000 to 100,000 counts/minute was measured at the site.

Code: UPR-200-W-96  
Classification: Accepted  
Names: UPR-200-W-96; 233-S Floor Overflow; 233-SA Floor Overflow; UN-216-W-4  
Reclassification: None  
Type: Unplanned Release  
Start Date: 1/1/1969  
End Date: 1/1/1969  
Description: The release effected the floor of the 233-SA Filter Exhaust Building, the concrete pad outside the north door of the filter exhaust building, the electric motor pad, and the ground surface on the north side of the 233-SA filter exhaust building. The 233-S facility was demolished in 2003.
and 2004. The release site is not specifically marked or posted.

**Location:** UPR-200-W-96 occurred adjacent to and directly north of the 233-S Filter House (233-SA Filter Exhaust Building).

**Release Description:** On January 9, 1969, plutonium-contaminated water backed up in the 233-SA Filter House drain and overflowed to a low spot on the ground directly north of the 233-S Building. Because the ground was frozen, the water could not percolate, so a pool formed. The area affected was reported as 150 square yards, which equals 125.42 square meters.

**Related Sites/Structures:** UPR-200-W-96 was associated with the 233-SA Filter Exhaust Building.

**Waste Type:** Storage Tank

**Waste Description:** The release consisted of water from the filter house drain line that contained 0.1 grams (0.004 ounces) of plutonium-239. Smear samples taken of the water and surfaces involved were as follows: 1) water on the floor of the 233-SA Filter Exhaust Building was greater than 40,000 disintegrations per minute; 2) smears of the concrete pad outside the door of the filter building were 10,000 disintegrations per minute; 3) smears of the electric motor pad were 10,000 disintegrations per minute; and 4) water in the overflow pool was 600 disintegrations per minute.

<td>Description</td>
<td>The 221-U Process Canyon is a large, reinforced concrete building. It consists of twenty sections (two cells per section) with expansion joints between each section. The building is divided lengthwise into the gallery side and the canyon chemical processing side by a thick, concrete shielding wall running the full length of the building. The building contains processing equipment and tanks that supported the uranium recovery process. The canyon deck currently is used to store radioactively contaminated surplus/spare equipment. The 221-U facility is accessed through the 271-U annex, which is attached to the west side of the 221-U building. From 2009 through 2011, the facility was prepared for decommissioning. The interior of the facility was emptied. The canyon cells were filled with grout. Ancillary equipment and structures were removed. The Interim Completion Report (DOE/RL-2011-80) provides project details.</td>
</tr>
<tr>
<td>Location</td>

</tr>
<tr>
<td>Process Description:</td>
<td>221-U was used for the Uranium Recovery Process. This process extracted relatively pure uranium from the liquid waste from the bismuth phosphate plutonium separation process that was stored in the tank farm tanks. The Uranium Recover process transformed the recovered uranium into uranium trioxide powder. The bismuth phosphate process, used in T Plant and B Plant, isolated only the plutonium from the dissolved, irradiated fuel rods. The bismuth phosphate &quot;Metal Waste&quot; stream, containing uranium and associated the fission products, was transferred to the underground storage tanks in the tank farms. The metal waste stream contained approximately 0.5 pounds of uranium per gallon of liquid waste. The uranium bearing waste in the tank farms was recovered from the underground tanks by sluicing and transferred to 221-U for processing. Tributyl Phosphate (TBP) solvent was used to extract and decontaminate the recovered uranium from the fission products and residual plutonium. The Uranium Trioxide Plant (224-U) was used to the purified uranyl nitrate solutions and calcine into uranium trioxide powder. The operation in 224-U continued after the completion of the Uranium Recovery process ended in 1958. Different chemical separation processes were used in REDOX and PUREX that separated the uranium from the waste stream, in the form of Uranyl Nitrate, before the waste was sent to the tank farms. The Uranyl Nitrate stream from the Redox facility was sufficiently decontaminated from the fission products to permit a direct feed to the 224-U calcination facility via an aboveground pipeline. Uranyl Nitrate from PUREX was delivered to 224-U via tanker trucks. After the Uranium Recovery process ended in 1958, the U Plant canyon was used to decontaminate large pieces of process equipment. This activity was transferred to 221-T in 1961.</td>

#### Code: 221-U:1

- **Names:** 221-U:1; Chemical Storage Tanks; 211-U Tank Farm
- **Type:** Process Unit/Plant
- **Status:** Inactive

**Description:**
The aboveground features of the 211-U Tank Farm were removed in 2009. It was a bulk liquid storage area, consisting of nine aboveground storage tanks. The tanks were located on the west side of the 221-U building. Six tanks were horizontal tanks, 2.7 meter diameter, 11 meters long (9 foot diameter, 36 feet long). Three of the horizontal tanks were sodium hydroxide storage tanks, one was a demineralized water storage tank and two were considered spare tanks. Three tanks were vertical tanks, 3 meter diameter, 4.2 meters high (10 foot diameter, 14 feet high). One was a demineralized water storage tank and two were chemical make-up tanks. The bulk liquid was transferred to the 211-U tanks from rail cars or trucks. The remaining posted Underground Material Area is sitecode 200-W-239.

In 2002, only four horizontal tanks and one vertical tank remained. The area had been posted with Radiological Buffer Area/Radioactive Material Area signs. The area around the tanks was covered with clean gravel and reposted with Underground Radioactive Material signs. The remaining posted Underground Radioactive Material Area is sitecode 200-W-239.

**Related Sites/Structures:**
The remaining posted Underground Radioactive Material Area is sitecode 200-W-239.

#### Code: 221-U:2

- **Names:** 221-U:2; Chemical Storage Tanks; 211-AU Tank Farm; 211-UA
- **Type:** Process Unit/Plant
- **Status:** Inactive

**Description:**
The aboveground features of the 211-UA (alias 211-AU) Tank Farm were removed in 2009. It consisted of sixteen aboveground storage tanks. Thirteen tanks had a capacity of 380,000 liters (100,000 gallons) each. The tanks were located on the west side of the 221-U building. Nine of these tanks were nitric acid storage tanks and four were sodium hydroxide storage tanks. Three smaller tanks 2.7 meters in diameter and 2.7 meters tall (9 feet diameter, 9 feet tall) were nitric acid sample tanks. The bulk liquid was transported to the tanks in railcars or trucks. The remaining posted Underground Radioactive Material Area is sitecode 200-W-239.
The Uranium Recovery Process at 224-U received uranyl nitrate from REDOX and PUREX. After the uranium was removed, the "reclaimed" nitric acid was stored in the 211-UA tanks. It was transferred from 224-U to 211-UA via overhead lines. The slightly radioactive nitric acid was recycled back to REDOX and PUREX. In the 1960's and 1970's it was returned to the separations facilities in railcars. It was pumped out of the 211-UA tanks into the railcars via underground lined and a pump pit. Some leakage was associated with the pumping process and caused low level radioactive contamination around the area.

The reclaimed nitric acid storage was moved from 211-UA to a holding tank within the 224-U facility in the 1980's and the railcar unloading platform was abandoned. Some residual acid and waste water, contaminated above crib release limits, continued to be stored in the 211-UA tanks. All the acid and waste water was removed from the tanks prior to being transitioned to the new Environmental Restoration Contractor in 1994. Although the tanks were emptied, the acid pump pit and underground lines had not been flushed. Leaking valves and seals and residual contamination in the pump pit caused low level radioactive contamination to spread around the tanks and railcar unloading platform. The area was posted as a Contamination Area again in the early 1990's. The lines and pump pit were flushed in 1998 and the surface contamination was covered with gravel. The area was changed to an Underground Radioactive Material Area.

In 2002, only ten tanks remained. They had been posted with Contamination Area signs. The area surrounding the tanks was covered with clean gravel and reposted with Underground Radioactive Material signs.

Related Sites/Structures: The remaining posted Underground Radioactive Material Area is sitecode 200-W-239.

The SubSite is Part Of: 200-W-239

The Codes: 221-U

Names: 221-U; 221-U Building; 221-U Canyon Building; 276-U; U Plant

The SubSite is Part Of: 996

The Codes: 221-U:3

Names: 221-U:3; 276-U Tank Farm; Solvent Storage Tanks

Type: Process Unit/Plant

Status: Inactive

Classification: Accepted

Reclassification: None

Start Date: End Date:

Description: The 276-U Solvent storage area consists of six tanks mounted inside a cement basin, located on the south end of the 221-U building. Tank leakage was collected in a sump that could be returned to the tanks, sent to a drum out facility of discharged to cribs. The 276-U tanks are connected to the 221-U building by the hot pipe trench in the 221-U pipe gallery. Organic make-up solutions of tributyl phosphate and dilutent were stored and treated and routed to the 221-U vessels via the pipe gallery. The dilutent storage tank has a (29,000 gallon) capacity. The tributyl phosphate storage tank has a (6,000 gallon) capacity. The organic receiver storage tank has a (10,000 gallon) capacity. The organic treatment storage tank has a (10,000 gallon) capacity. The organic treatment sample storage tank has a (1,300 gallon) capacity. The RAX feed storage tank has a (10,000 gallon) capacity.

Related Sites/Structures: This area was also documented in Sitecode 276-U. 276-U is considered a duplicate of 221-U:3.
### Building 271-U Office Building

**Code:** 271-U  
**Names:** 271-U; 271-U Office Building  
**Type:** Office  
**Status:** Inactive  
**Start Date:** 1/1/1952  
**End Date:**  
**Classification:** Accepted  
**Reclassification:** None  

**Description:** The 271-U Office Building was the office/service building constructed of a reinforced concrete foundation, floors, and pillars with pumice block walls. The four story structure (including the basement) is physically attached to the gallery side of the 221-U Canyon.

**Location:** The building is attached to the northern gallery side of 221-U.

**Related Sites/Structures:** Structures associated with 271-U include the 221-U Canyon, other U Plant Facilities, and the shops, maintenance, and ventilation equipment in the 271-U basement.

**Process Description:** The building has been used primarily for office space. Previously, the building has been used for storing contaminated equipment, craft services, process support functions and training. The third floor of the building was used for preparing chemicals and plutonium storage.

### Building 291-U Fan Control House

**Code:** 291-U  
**Names:** 291-U; 291-U Fan Control House  
**Type:** Process Unit/Plant  
**Status:** Inactive  
**Start Date:** 1/1/1945  
**End Date:**  
**Classification:** Accepted  
**Reclassification:** None  

**Description:** The building is constructed of reinforced concrete foundation and floor, concrete and block walls, and a concrete slab roof covered with asphalt and gravel, trimmed in wood. It is a one-story, one-room building with wooden doors containing the ventilation system instrumentation. Two electric fans are located outside, adjacent to the building. The fan control house is located within a larger, posted Underground Radioactive Material area, although the 291-U building and exhaust fans remain posted as Contamination Areas.

**Location:** The building is located east of 221-U.

**Related Sites/Structures:** The 291-U-1 Stack, 291-U Stack Sand Filter (200-W-44), and 221-U Vessel Vent Pit (216-U-7) are associated with the exhaust system.

**Process Description:** The 291-U Complex was originally built in 1944-1945 to provide exhaust ventilation for the 221-U Canyon Building. The 221-U Building is retired, but the 291-U exhaust ventilation system still serves its original purpose and is planned to remain in operation until the 221-U Building is decommissioned.

### Building 291-U-1 Stack

**Code:** 291-U-1  
**Names:** 291-U-1; 291-U-1 Stack, 291-U Stack  
**Type:** Stack  
**Status:** Inactive  
**Start Date:** 1/1/1945  
**End Date:**  
**Classification:** Accepted  
**Reclassification:** None  

**Description:** The unit consists of a reinforced concrete stack, lined with acid-resistant brick resting on an
The stack is 61 meters (200 feet) high and 4.3 meters (14 feet) in diameter at the base. The stack is located within a larger Underground Radioactive Material area, although the 291-U building and exhaust fans remain posted as Contamination Areas.

**Location:** The stack is located east of 221-U.

**Process Description:** The ventilation system for U-Plant was taken off line on September 15, 2011. The system was completely deactivated and final effluent samples were obtained.

The 291-U Complex was originally built in 1944-1945 to provide exhaust ventilation for the 221-U Canyon Building. The 221-U Building is retired, but the 291-U exhaust ventilation system still serves its original purpose and is planned to remain in operation until the 221-U Building is decommissioned. In April 2005, the drainage valve from the 291-U-1 stack to the 241-UX-302A catch tank was closed.

200-CW-1

Code: 216-A-25  
Classification: Accepted

Names: 216-A-25; 216-A-25 Swamp; Gable Mountain Pond; Gable Mountain Swamp; Gable Pond
Reclassification: None

Type: Pond  
Start Date: 1/1/1957

Status: Inactive  
End Date: 1/1/1987

Description: The site was a large, water-filled pond that received cooling water from the Plutonium Uranium Extraction (PUREX) and B-Plant operations. The pond had a total surface area of 32 hectares (82 acres), 28 hectares (71 acres) in the main pond and a 4.4-hectare (11-acre) overflow pond. The average depth of the unit was 1.5 meters (5 feet), with a maximum depth of 3 meters (9 feet). The pond has been backfilled and surface stabilized. The backfilled pond is delineated with concrete markers and posted as Underground Radioactive Material. An additional area of soil contamination was identified in 1996, north of the west end of the overflow pond. This area was given the Waste Information Data System (WIDS) Site Code number 600-118. In 1997, the area was surface stabilized and reposted as Underground Radioactive Material, adding 3.3 hectares (8.2 acres) to the total radiologically posted area.

Location: The site is located south of Gable Mountain, north of Route 11A.

Release Description: Radiation surveys done following the F-15 Tank coil leak in June 1964 found up to 22 rads/hour at 5 centimeters (2 inches) over the inlet, and 500 millirem per hour at 5 centimeters (2 inches) along the shoreline.

Water samples ranged from 48,000 picocuries per cubic centimeter (collected in June 1964) to 12 picocuries per cubic centimeter (collected in October 1964). A task force was formed consisting of operations management personnel, process engineers, a chemist, a geologist/hydrologist, a biologist, a health physicist and a waste disposal engineer. A follow up report written in 1965 (Radiation Control of Accidentally Contaminated Seepage Ponds, RL-SA-15) determined that of the 10,000 curies of fission products released, the highest percentage of significant contaminants was niobium-95, zirconium-95, yttrium-91, strontium-89, cerium-144 and praseodymium-144. Water fowl were periodically harvested following the incident to determine the amount of external and internal contamination. External contamination on waterfowl collected at Gable Pond ranged from 100 millirem per hour (collected on June 22, 1964) to 500 counts per minute (collected on November 3, 1964). The internal strontium and cesium concentration ranged from 180,000 picocuries per gram of cesium-137 and 370 picocuries per gram of strontium (analyzed in June 1964) to 1 picocuries per gram of cesium-137 and less than detectable strontium (analyzed in November 1964).

Copper sulfate was added on two occasions to Gable Pond to eliminate algae and invertebrates following the 1964 incident in order to eliminate water fowl food sources. Three parts per billion of copper sulfate was the desired concentration.

Most of the contamination was absorbed into the pond bottom sediments. An effort was made to coat the pond bottom with bentonite clay to reduce the percolation rate and raise the liquid level of the pond one foot. Applying a uniform layer of clay was a problem. After adding six and a half tons of clay non uniformly by various methods, other solutions were sought.

In 1964, ground water samples in the vicinity (north/northeast) of Gable Pond were sampled. Analysis ranged from 49 picocuries per cubic centimeter in August 1964 to 11 picocuries per gram in October 1964. The contaminants were mostly ruthenium-103, ruthenium-106 and zirconium-niobium-95. Down gradient wells were at background levels. It was determined that groundwater contamination was not a significant problem. However, groundwater samples
An outfall structure was located at the southeast corner of the unit (see H-2-3332). The pond is also associated with an overflow area known as 600-118.

**Waste Type:** Misc. Trash and Debris

**Waste Description:**

Until May 1958, the unit received the process cooling water from 202-A Building (Plutonium Uranium Extraction [PUREX] Plant). From May 1958 to 1960, the unit received the above plus cooling water from the contact condenser in the 241-A-431 Building. In 1960, the unit received the above plus the surface condensator cooling water in the 241-A-401 Building (A Tank Farm). From November 1967 to January 1968, the unit received the above plus the wastewater from the 284-E Powerhouse. From January 1968 to March 1969, the unit received the above plus the cooling water and steam condensate from the 244-AR Vault. In March 1969, the pipeline to the contact condenser cooling system from the 241-A-431 Building Vault was valved out. After March 1977, the unit received the above plus the 242-A Evaporator steam condensate cooling water. RHO-CD-798 shows a valve at the east end of the 216-B-2-3 Ditch connecting to PUREX Cooling Water Line to Gable Pond. The graphic is labeled "Effluent Pipelines and Transfer Capabilities for Gable Mountain and B Ponds". The B-Plant Aggregate Area Management Study Report [AAMSR] does not list B-Plant as a contributor to the Gable Pond inventory. However, WHC-SD-DD-TI-036 states that Gable Pond later served B-Plant.

---

**Code:** 216-B-3 **Classification:** Accepted

**Names:** 216-B-3; 216-B-3 Main Pond; 216-B-3 Swamp; B Plant Swamp; B Pond; B Swamp; B-3 Pond; West Side Overflow Pond

**Reclassification:** None

**Start Date:** 1/1/1945 **End Date:** 1/1/1994

**Description:** The 216-B-3 Pond has been backfilled and surface stabilized. It is marked and posted with Underground Radioactive Material Area signs and Danger - Do Not Enter signs. The main pond was roughly rectangular, with a surface area of 14 hectares (35 acres). The pond was expanded to include three additional lobes, 216-B-3A, 216-B-3B, and 216-B-3C, with areas of 4 hectares (10 acres), 4 hectares (10 acres), and 17 hectares (41 acres), respectively. The three expansion lobes are considered three separate waste sites. The expansion ponds were separate RCRA treatment, storage and disposal (TSD) units.

**Location:** The pond is located east of the 200 East Area perimeter fence, northeast of the 202-A Building.

**Release Description:** In addition to routine flows, the following process upsets have added to the inventory of the pond: UPR-200-E-32: In November 1963, a coil leak developed in the 221-B Building 6-1 Tank; UPR-200-E-34: In June 1964, a cooling coil leak developed in the F-15 process waste tank in the Plutonium Uranium Extraction (PUREX) facility; UPR-200-E-51: On 5-18-77 fifteen kilograms of cadmium was released to B Pond via the ditches; UPR-200-E-138: In March 1970, a leaking manometer sensing line from the 221-B Building 8-1 Tank.

**Related Sites/Structures:** The site is associated with B Plant and PUREX operations, the 216-B-3 ditches, the 216-A-29 Ditch, 216-B-3A, 216-B-3B, 216-B-3C and the 200-E-126-PL pipeline system.

**Process Description:** The site received waste between April 1945 and May 1994. Prior to the construction of the 216-B-3A and 216-B-3B Expansion Ponds in 1983, an area directly west of the Main Pond served as an overflow area. The 216-B-3A and 216-B-3B Expansion Ponds were constructed to receive the increased effluent discharge from the restart of the PUREX Facility. The 216-B-3C Expansion Lobe was constructed to received the increased effluent due to the closure of Gable

**Hanford Site Waste Management Units Report**

February 2015
Mountain Pond.

Waste Type: Process Effluent

Waste Description: Waste streams flowed from the 216-A-29 and 216-B-3-3 Ditches into the 216-B-3 Pond. Discharges to 216-B-3 via 216-B-3-3 included: 221-B Building steam condensate and process cooling water; 284-E Powerhouse water; 244-CR Vault cooling water; 244-AR Vault and 242-A Evaporator cooling water; 202-A process cooling water, condenser cooling water, and air sampler vacuum pumps seal cooling water; 241-BY Tank Farm condenser cooling water; and Waste Encapsulation Storage Facility cooling water. Discharges to 216-B-3 via 216-A-29 included 202-A chemical sewer and acid fractionator condensate. The main pond received corrosive and toxic dangerous waste from two primary sources: the regeneration of the Plutonium Uranium Extraction (PUREX) plant demineralizer columns and from spills of dangerous or mixed waste from PUREX. The spills included hydrazine, cadmium nitrate, and ammonium fluoride/ammonium nitrate. The backwash from the regeneration of the demineralizer columns included nitric acid, sulphuric acid, sodium hydroxide, and potassium hydroxide.

Code: 216-B-3A RAD

Names: 216-B-3A RAD; West Expansion Lobe; 216-B-3 1st Overflow Pond; 216-B-3A Expansion Lobe

Type: Pond

Status: Inactive

Classification: Accepted

Reclassification: None

Description: This site is the residual radioactive contamination that remains in the 216-B-3A Pond. The site was closed out as a RCRA Treatment, Storage and Disposal Unit following cleanup of chemical contamination. The unit is roughly rectangular with approximately 4.5 hectares (11 acres) of surface area. It is inactive and dry. It was sampled and released from radiological controls with the exception of the percolation trench that is posted as a Soil Contamination Area. The pond was approximately 5.5 meters (18 feet) lower than the 216-B-3 Main Pond elevation. 8-millimeter (0.3-inch) plastic was placed along the slope of the pond banks and covered with gravel.

Location: The pond is located east of 200 East Area, east of the 216-B-3 Main Pond.

Release Description: In 1958, the dike on the east side of the 216-B-3 Pond broke and flooded into a ravine on the east side of the pond. The area was released from radiological controls in 1970. The area where the release occurred was later used to create the 216-B-3A Lobe of B Pond. Later, in 1984, a break in the barrier between 216-B-3A and 216-B-3B (West and East Expansion Lobes) was noted.

Related Sites/Structures: The overflow pond is associated with UPR-200-E-14, 216-B-3, 216-B-3B and 216-B-351 Spillway.

Process Description: The 216-B-3A was constructed to receive overflow from the 216-B-3 Main Pond due to increased effluent discharge from the restart of the Plutonium Uranium Extraction (PUREX) plant. The 216-B-3A Overflow Pond was connected to the 216-B-3 Main Pond by the 216-B-351 Spillway. The spillway was designed with a manually operated slide gate in the headwall. The water flowed from the main pond, through the culvert, down a 0.61-meter (2-foot) wide, concrete-lined ditch, to a fiberglass reinforced 0.3-meter (1-foot) flume, to the overflow pond. The pond operated from October 1983 to January 1984, when the dike between the 216-B-3A and 216-B-3B ponds failed (Occurrence Report #84-02). Prior to the dike failure, the 216-B-3B Pond had never been used. All the discharge from the failed dike was contained in the 216-B-3B Pond. In response to the incident, the 216-B-3A and 216-B-3B Ponds were isolated.
Effluent flow to the 216-B-3 Main Pond was reduced. A trench was dug in the 216-B-3A Pond to increase its infiltration rate. The trench measured 182 meters (600 feet) by 9 meters (30 feet) and was 2 meters (6 feet) deep. The debris from the dike failure was removed from the 216-B-3B Pond and a series of trenches were dug to increase its infiltration rate. Both 216-B-3A and 216-B-3B Ponds were fully operational by June 1984.

Waste Type: Equipment

Waste Description: 216-B-3A received overflow from the 216-B-3 Main Pond. Potential sources include 221-B steam condensate and process cooling water, 284-E Powerhouse water, 244-CR, 244-AR and 242-A cooling water, 202-A process, condenser, and air sampler vacuum pump cooling water, 202-A chemical sewer, fractionator condensate, and WESF cooling water.

Code: 216-B-3B RAD

Names: 216-B-3B RAD; East Expansion Lobe; 216-B-3B Expansion Lobe Residual Radioactive Waste

Type: Pond

Status: Inactive

Classification: Accepted

Reclassification: None

Start Date: 1/1/1984

End Date: 1/1/1985

Description: The unit is roughly rectangular with approximately 4.4 hectares (11 acres) of surface area. It is dry with a small radiologically posted area (Surface Contamination) in the northwest corner of the pond. The 216-3A, 3B and 3C Expansion ponds make up a separate RCRA TSD Unit.

Location: The pond is located east of the 200 East Area perimeter fence and east of the 216-B-3 Main Pond.

Release Description: In January 1984, the dike between 216-B-3A and 216-B-3B was found to be breached in the vicinity of the overflow channel. (Unusual Occurrence Report 84-02). The channel and the supporting area were washed away. There was no effluent released beyond the pond boundaries. At the time of the release, radiological surveys of the area found it to be clean and the area was released for the repair crews. There is currently (July 1999) a small Surface Contamination Area posted in the northwest corner of the pond at a rip rap inlet. This inlet may be the "overflow channel" mentioned in the 1984 Unusual Occurrence Report, but no sketch of the release area was included with the occurrence report.

Related Sites/Structures: The overflow pond is associated with 216-B-3, 216-B-3A and the 216-B-351 Spillway.

Process Description: The 216-B-3A and 216-B-3B were constructed to receive overflow from the 216-B-3 Main Pond due to the increased effluent discharge from the restart of the Plutonium Uranium Extraction (PUREX) plant. In January 1984, the dike between the 216-B-3A and 216-B-3B ponds failed. Prior to the dike failure, the 216-B-3B Pond had never been used. All the discharge from the failed dike was contained in the 216-B-3B Pond. In response to the incident, the 216-B-3A and 216-B-3B Ponds were isolated. Effluent flow to the 216-B-3 Main Pond was reduced. A trench was dug in the 216-B-3A Pond to increase its infiltration rate. The trench measured 182 meters (600 feet) by 9 meters (30 feet) and was 2 meters (6 feet) deep. The debris from the dike failure was removed from the 216-B-3B Pond and a series of trenches were dug to increase its infiltration rate. Both 216-B-3A and 216-B-3B Ponds were declared fully operational by June 1984. Although 216-B-3B was considered an active pond, it never received any effluent with the exception of the 216-B-3A dike failure incident. The spillway between 216-B-3A and 216-B-3b is know as 216-B-351. It consists of a 1 meter (36 inch) diameter corrugated steel culvert.

Waste Type: Storage Tank
Waste Description: With the exception of the 216-B-3A dike failure incident, the 216-B-3B Pond Lobe was never used. In 1991, a characterization borehole was drilled through the 216-B-3B Pond (well # 699-42-41B). It was drilled to a depth of 124 feet with a cable tool rig and split tube sampling. The casing was later pulled and the well was abandoned. Twenty six samples were analyzed for radionuclides (Sample numbers B00GV6 - B00GV9, B00GW0 -B00GW9, B00GX2 -B00GX8, B00GY0- B00GY2, B00GY9, B00GZ2-B00GZ8). No radioactive field readings were noted. Aliquots submitted to the onsite laboratory found no evidence of radioactive contamination. Samples were taken at intervals from depths of 1.5 to 37 meters (5 to 122 feet).

Code: 216-B-3C RAD  Classification: Accepted

Names: 216-B-3C RAD; 216-B-3C Expansion Lobe  Reclassification: None

Type: Pond  Start Date: 1/1/1985

Status: Active  End Date: 1/1/1997

Description: The unit is rectangular pond with approximately 17 hectares (41 acres) of surface area. It was excavated into a very coarse gravel layer with a very high percolation rate. The pond was constructed with eight parallel north-south trenches and one east-west trench at the spillway.

Location: The site is located east of the 200 East Area Perimeter fence and southeast of the 216-B-3 Main Pond.

Related Sites/Structures: The site is associated with the PUREX facility, 216-B-3 Main Pond and the 200 East Powerhouse Ditch.

Process Description: The 216-B-3C Pond was constructed in 1985 to accommodate the increased effluent flow that resulted from the decommissioning of Gable Mountain Pond. In 1994, when the 216-B-3-3 Ditch and the 216-B-3 Main Pond sites were decommissioned, effluent was routed directly to the 216-B-3C Pond via a pipeline. A spillway (216-B-354) consisting of two 0.76-meter (30-inch) corrugated metal pipes was designed for a maximum flow of 74,000 liters (20,000 gallons) per minute. Later, the pond was considered a contingency pond for the Treated Effluent Disposal Facility (TEDF) effluent could be diverted to 216-B-3C in the event that Pump Station 3 fails.

Waste Type: Storage Tank

Waste Description: The 216-B-3C received effluent from the 216-B-3A Overflow Pond from 1985 to 1994. In 1994, the effluent from the 216-B-3-3 Ditch was routed directly to the 216-B-3C. Effluent included water from the 200 East Powerhouse Ditch. The flow to 216-B-3C was permanently isolated on August 18, 1997.

Code: 216-S-16P  Classification: Accepted

Names: 216-S-16P; REDOX Pond #2; 202-S Swamp #1; 202-S Swamp and Ditch  Reclassification: None

Type: Pond  Start Date: 1/1/1957

Status: Inactive  End Date: 1/1/1975

Description: The pond has been backfilled and surface stabilized. It is surrounded by concrete markers and posted with Underground Radioactive Material signs. The pond consisted of four lobes separated by dikes and a leach trench that extended east from Lobe #2 toward the 216-S-17 Pond.

Location: The unit is located outside the southwest corner of the 200 West Area perimeter fence.
Process Description:
The pond received cooling water and steam condensate discharge from the REDOX facility via the 216-S-16 Ditch and also overflow from the 216-U-10 Pond via the 216-U-9 Ditch. The 216-S-16 Pond was constructed to replace the 216-S-17 Pond and the 216-S-5 Crib.

Waste Type: Process Effluent

Waste Description:
The site received process cooling water and steam condensate from the 202-S Building until June 1967. Only lobe #1 received REDOX process effluent. The 202-S Building process (REDOX) was put on standby in July 1967. After July 1967, the site received condenser and vessel cooling water from concentrator boil-down operations in the 202-S Building via the 216-S-16 Ditch and overflow from the 216-U-10 Pond via the 216-U-9 Ditch.

Release Description:
UPR-200-W-47 and UPR-200-W-59 are associated with the 216-S-16 Pond.

Related Sites/Structures:
The site is associated with the 216-S-16 Ditch, the 216-U-10 Pond, 216-U-9 Ditch, UPR-200-W-47 and UPR-200-W-59.

Process Description:
The site received process cooling water and steam condensate discharge from the REDOX facility via the 216-S-16 Ditch and also overflow from the 216-U-10 Pond via the 216-U-9 Ditch.

Location:
This site is southwest of the 202-S Building and west of the 216-S-10 Pond.

Description:
This site consists of a 6.9 to 8.5 hectare (17 to 21 acre) pond. The site was interim stabilized in 1984 and posted as "Underground Radioactive Material". The original pond site was formed by creating an earthen dike approximately one meter (3.3 feet) high on the north and west sides of the site. The designated use area was approximately 23 hectares (57 acres), but photographs indicated that only 8 hectares (20 acres) were inundated at any time. The pond averaged about 0.3 meters (1 foot) deep with a maximum depth of 0.6 meters (2 feet).

Release Description:
The pond was contaminated with multiple unplanned releases of fission product contaminants from the 202-S operation. A radiological survey map (hand drawn on 10/7/52) indicated dose rates around the pond perimeter ranging from 10 to 470 millirem per hour. High dose rates were observed in the vegetation growing in the pond. In December 1952, wild water fowl were observed feeding in the grossly contaminated swamp. A duck was killed and found to have a dose rate of 100 millirem per hour. Balloons and noise makers were placed around the pond to keep the birds off the pond. In 1953, naphtha and copper sulfate were added to the pond to kill the vegetation. By February 1954, dose rates at the edge of the pond were as high as 1500 millirem per hour. CAUTIONARY NOTE: Historical radiation survey data indicates that the radioactive inventory data in this site may be larger than the estimated inventories. Do not base safety limits for any intrusive or soil-disturbing activities on estimated inventories without confirmation from site sampling or current survey readings.

Related Sites/Structures:
The associated structures are the 202-S Building and the 207-S Retention Basin. The pipeline associated with the 216-S-17 pond is sitecode 200-W-152-PL.

Process Description:
The site provided ground disposal of process effluent from the 202-S facility via the 207-S Retention Basin and overflow from the 216-U-10 Pond via the 216-U-9 Ditch.

Waste Type: Storage Tank
Waste Description: Until January 1953, the site received process cooling water and steam condensate from the 202-S Building. After January 1953, the site received the 202-S Building effluent and the overflow from the 216-U-10 Pond via the 216-U-9 Ditch. During April and May of 1953, solvent naphtha was utilized to kill the vegetation, but it did not work. During July 1953, copper sulfate, 2-4-D, and sodium chlorate were also used to kill vegetation. In October 1952, a steam coil failure (UPR-200-W-15) in the REDOX D-12 Waste Concentrator caused gross contamination of process cooling water, the 207-S Retention Basin and the 216-S-17 Swamp. During November 1952, another unplanned release (UPR-200-W-13) caused further contamination at the 207-S Retention Basin and the 216-S-17 Swamp. The major potential radiological contaminants of concern are cesium-137, strontium-90, and uranium-238.

<td>Description:</td>
<td>This site is a 12 hectare (30 acre), backfilled, surface stabilized pond. It is posted with Underground Radioactive Material signs.</td>
</tr>
</tbody>
</table>
Location: This site is located south of 16th Street and east of Dayton Avenue. It is west of the 241-S Tank Farm.

Process Description: The site received effluents from various facilities at various times. It received steam condensate from 231-Z, 234-5Z Buildings and 231-Z Laboratory wastes via 216-Z-1, 216-Z-11 and 216-Z-19 Ditches. It received 284-W Powerhouse process cooling water, waste water from 2723-W Original Laundry/Mask Cleaning Station and the 2724-W (new) Laundry, chemical sewer wastes from 221-U Building, cooling water from 224-U Building, 241-U-110 Tank condenser and 242-S Evaporator steam condensate water via 216-U-14 Ditch. At first, the pond received effluents only from the 284-W Powerhouse and the original Laundry/Mask Cleaning facility (2723-W). No elevated levels of radioactivity were recorded during this time. When 234-5 (Plutonium Finishing Plant) began adding effluent to the pond in 1949, elevated levels of radioactivity in the pond were noted. In 1966, ARCHO reported an estimated 8 kilograms of plutonium had been released through the Z ditches, but that only an estimated 1.5 kilograms of the plutonium may have reached the 216-U-10 Pond. U Plant began to operate the Uranium Metal Recovery program in 1952. Process waste from U Plant was released to the pond through the 216-U-14 ditch. Several significant releases of cesium and strontium are known to have been released via this route during 1956 and 1957. The Uranium Oxide Facility (224-U) also began adding cooling water to the effluent in the 216-U-14 ditch. An estimated 1,500 kilograms of depleted uranium were released from this facility over 21 years of operation. Small amounts of cesium and strontium was added to the 216-U-14 ditch from the 241-SX farm condenser cooling water effluent.

Waste Type: Not Specified

Waste Description: The large volumes of low-level wastewater and occasional isolated releases of considerably higher level, non-routine discharges have resulted in the accumulation of transuranic, fission product and activation product inventories. It is estimated that 90% of the plutonium introduced to the waste stream from Z Plant was retained in the ditches (216-Z-1, 216-Z-11 and 216-Z-19).

Code: 216-U-11
Names: 216-U-11; 216-U-11 (New Ditch); 216-U-11 (Old Ditch); 216-U-11 Ditch; 216-U-11 Trench; 216-U-12; U Swamp Extension Ditch
Type: Ditch
Status: Inactive
Description: This site consists of a backfilled, interim stabilized ditch that is posted with "Underground Radioactive Material" signs.
Location: This site is located on the west side of 216-U-10 Pond outside the west perimeter fence of 200 West Area.
Related Sites/Structures: The associated trench is the 216-U-10 Pond. The pipeline between the pond and trench is sitecode 200-W-169-PL.

Hanford Site Waste Management Units Report
February 2015
This site received overflow from the 216-U-10 Pond via a metal culvert under Dayton Ave. The original ditch was between 573 and 597 meters (1,880 and 1,960 feet) long with a 1.5-meter (5-foot) wide bottom and operated from 1944 to 1955. The ditch was expanded in August 1955. The expansion was a total of 1,048 meters (3,440 feet) long and included 247 meters (810 feet) of the original ditch. The new ditch was roughly U-shaped (in plan view). A pond sometimes formed in the center of the U when significant amounts of water overflowed from the 216-U-10 Pond. The unit received the 216-U-10 Pond overflow until it was retired in 1957.

Waste Type: Not Specified

The ditch received overflow from the 216-U-10 Pond. A limited field investigation of high-priority waste units was conducted from August 1993 through August 1994. This investigation included the 216-U-11 Ditch. A special surface radiation survey was done with the MSCM II tractor and two surface soil samples were collected near the two outlet lines. Approximately 6% of the ditch surveyed with the tractor showed readings elevated above background. However, a recheck of these areas with hand-held instruments did not show elevated readings, so it is assumed the elevated readings were due to sub-surface contamination. The surface soil sample results were insignificant.

Code: UPR-200-W-124
Names: UPR-200-W-124; Dike Break at the REDOX Pond; UN-200-W-124
Type: Unplanned Release
Status: Inactive

Description:
The historical documentation for this release is vague. It most likely occurred at the 216-S-17 Pond. The Sketch G in HW-60807 points to 216-S-17 but the location description text in HW-60807 could also indicate the 216-S-19 Pond.

Location:
PNL-6464 states UPR-200-W-124 occurred in a southwest direction from the REDOX Pond. This description is vague because there is more than one pond associated with REDOX. The Sketch (G) in HW-60807 points to 216-S-17 Pond as the release location.

Release Description:
A dike break caused the contamination of an area extending southwest of the REDOX Pond.

Related Sites/Structures:
UPR-200-W-124 was associated with the REDOX Pond.

Waste Type: Storage Tank

Description:
The waste was contaminated cooling water from the process tanks at the 202-S Building.
# 200-CW-3

**Code:** 200-N-3  
**Classification:** Accepted  
**Names:** 200-N-3; Ballast Pits  
**Reclassification:** Interim No Action (3/17/2010)  
**Type:** Depression/Pit (nonspecific)  
**Status:** Inactive  
**Start Date:**  
**End Date:**

### Description:
The remedial action chosen for this waste site is No Action. Several open pits are located southwest of the (demolished) 212-P building. Each pit is approximately 12 meters across. The soil contains large amounts of gravel sized rock. Debris in the form of metal pipes, wood, electrical insulators, metal cans and rusted drums were noted inside the pit during a site visit in May 2004.

### Location:
The pits are located southwest of the (demolished) 212-P building. They are northwest of the intersection of two gravel roads, Deer Street and Delridge Avenue.

### Waste Type:
Process Effluent

### Waste Description:
A 1992 site visit indicated electrical conduit and mechanical parts were visible in the bottom of the pits. A 1996 site visit found only a small amount of metallic debris in the bottom of one pit. In 2004, metal piping, electrical insulators, wood, rusted 5 gallon cans and small rusted drums were identified in the pit. It is possible there were less tumbleweeds in the pit during this visits that may have obscured some of the debris during other site visits.

### Closure Info:
In July 2009, focused and discrete confirmatory soil samples were collected from the 200-N-3 waste site. The analytical results were compared to the Deep and Shallow Zone Look Up Values to determine whether further remediation was required. The analytical results from the soil samples are below the applicable Look Up Values.

The sampling approach included using Radiological field screening surveys of the ground surface as a guide for focused sampling. Test pit sampling or other comparable techniques were used to sample to a depth of 15 feet. A radiological field survey was performed in each test pit (sample location) or direct push at every foot in depth. Cesium-137 or Strontium-90 was used (as appropriate) as an indicator for each sample. Based on the sampling design, the combination of the radiological surveys and samples taken from the most likely candidate locations for contamination, the characteristics of the 200-N-3 are consistent with a surface-level non-radiological debris dump site. No source of contamination or contributor exists or remains in the surrounding media. The findings from these sampling activities are considered representative of the waste site and are adequate to conclusively support a decision of no action.

Soil cleanup levels were established in the Remaining Sites ROD (EPA 1999) based on a limited ecological risk assessment. These soil cleanup levels are referred to as Look Up Values. A baseline risk assessment for the outer area will include a more complete quantitative ecological risk assessment. When complete, this risk assessment will be used to support a future final closeout decision for the 200-N-3 waste site as part of final closure of the outer area.

---

_Hanford Site Waste Management Units Report_

February 2015
**Description:** The waste site has been remediated and Interim Closed Out. A portion of the north end of this pond was excavated during remediation. No chains or barriers delineated the boundaries of this site. All radiological postings were removed in 2010, following remediation of the pond. A single permanent concrete monument had marked the north end of the pond site. The concrete marker had one Underground Radioactive Material sign on it.

**Location:** The site is located approximately 274 meters (900 feet) south, southeast of the demolished 212-N Building.

**Related Sites/Structures:** The site is associated with 212-N. The pipeline that fed the pond is sitecode 600-285-PL.

**Process Description:** The pond received basin overflow cooling water from the 212-N Fuel Storage Facility via an underground 46-centimeter (18-inch) diameter vitrified clay pipe (see sitecode 600-285-PL). The pond consisted of a natural depression in the natural terrain and the discharged water was dispersed by evaporation and percolation into the ground.

**Waste Type:** Process Effluent

**Waste Description:** The site received the basin overflow from the 212-N Building. The waste type is low level radioactivity.

**Closure Info:** The selected remedy of Remove Treat and Dispose (RTD) commenced at 216-N-1 waste site on November 5, 2009 and was completed on December 29, 2009. RTD activities involved the removal and disposal of contaminated soil from the 216-N-1 waste site at the Environmental Restoration Disposal Facility (ERDF). The excavation activity was planned to occur in stages with the area of highest contaminant concentration in the center being removed first with the vertical excavation depth set at 3.1 meters (10 ft) below ground surface. Soil removal, followed by verification sampling, was planned to be performed repeatedly until the analytical data showed residual contaminant concentrations in the excavated area were below RAGs; thereby demonstrating that RAOs were attained. With the investigative sample results showing the extent of the contaminated area bounded at sample locations 2, 7 and 8, a maximum of two iterations was anticipated to be required. Ultimately, RAOs were met after only one phase of excavation followed by verification sampling. The final excavation area was 460 square meters (4,740 square feet), measured at ground surface with a slope of 1.5 to 1, to a depth of 3.1 meters (10 feet).

Radiological field screening was performed over the entire surface of the remediated area. Radiological field screening of the remediated surface and the samples collected indicated no detectable dose rates above background. Once the waste site has been backfilled and/or contoured, native plant species will be seeded in the area, as applicable.

**Code:** 216-N-2

**Classification:** Accepted

**Reclassification:** Interim No Action (7/30/2007)

**Names:** 216-N-2; 216-N-2 Trench; 212-N #1 Trench; 212-N Storage Basin Crib #1; 216-N-1 Trench

**Type:** Trench

**Start Date:** 1/1/1947

**End Date:** 1/1/1947

**Description:** The site has been evaluated and reclassified to "No Action". The site was surrounded by a light weight chain barrier and concrete markers. It was posted with "Underground Radioactive Material" warning signs. A single chain enclosed both the 216-N-2 and 216-N-3 Waste Sites.

**Location:** The site was located approximately 15 to 30 meters (50 to 100 feet) northwest of the 212-N Building. The trench was adjacent and parallel to the 216-N-3 Trench.
Related Sites/Structures: The site was associated with the 216-N-3 and 212-N facility.

Process Description: The 216-N-2 Trench was constructed in 1947 to accommodate water from the fuel basin when it was drained for undefined "special testing." Per documentation, in 1952 when activities in 200-N facilities ceased, the trench was taken out of service, the overground pipeline was placed into the trench, then backfilled with clean soil.

Waste Type: Water

Waste Description: The site received the basin water and sludge from the 212-N Fuel Storage Basin when it was drained for special tests. The site was deactivated by removing the overground piping and backfilling the unit with 1.8 meters (6 feet) of clean soil. Typically practice was to place the aboveground piping in the trench prior to backfilling. The waste type is low activity.

Closure Info: Due to the rocky backfill material that had previously been placed in the trench, focused, discrete samples were collected from four test pits on March 7, 2007. The samples were collected from four specific test pits [2 samples at 3 meters (10 feet) depths and 2 samples at 4.6 meters (15 feet) depths].

The site was investigated through field observations, radiological screening, and focused sampling and analysis for the purpose of determining if hazardous or radiological contaminants were present. To confirm the conceptual model of removal, treatment and disposal or No Action, an investigation of the site was performed.

During the excavation and sampling of the test pits, radiological field surveys were conducted on each excavator bucket of soil utilizing a cesium 137 tracer (i.e., indicator) to determine the presence of radiological contamination. The contaminants of concern (COCs) for the site were identified based on existing information for the site and the COCs listed in the Remaining Sites ROD. The COC list included: americium 241, cobalt 60, cesium 137, europium 152, europium 154, europium 155, tritium, strontium 90, plutonium 238, plutonium 239/240, nickel 63, thorium 232, technetium 99, uranium 233/234, uranium 235, uranium 238, hexavalent chromium, mercury, lead, barium, trivalent chromium, cadmium, antimony, arsenic, manganese, zinc, and polychlorinated biphenyls.

The analytical results from the test pit soil sampling were shown to be below the Look Up Values, the RAGs and the RAOs and met the cleanup objectives for direct exposure, groundwater protection, and river protection. The RSVP does not discuss the status of the pipeline that was thought to have been disposed in the trench. All analytical data were found acceptable for decision making purposes and were stored in the Hanford Environmental Information System. The data was also summarized in Appendix E of the RSVP.

These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future use of shallow zone soil [i.e., surface to 4.6 meters (15 feet)] and that contaminant levels remaining in the soil were protective of groundwater and the Columbia River. There was no deep zone for the site therefore, no institutional controls were required.

In accordance with this evaluation, the sampling results support a reclassification of the site to "No Action", as recorded on Waste Site Reclassification Form 2007-016. According to the RSVP the site will be revegetated with native grasses and regraded in accordance with the RD/RAWP.

Code: 216-N-3 Classification: Accepted
Reclassification: Interim No Action (7/30/2007)

Names: 216-N-3; 216-N-3 Trench; 212-N #2 Grave; 212-N #2 Trench; 212-N Storage Basin Crib #2; 212-N-2 Trench

Type: Trench
Status: Inactive
Start Date: 1/1/1952
End Date: 1/1/1952

Description: The site has been evaluated and reclassified to "No Action". The site was surrounded by a lightweight chain barrier and concrete markers. It was posted with Underground Radioactive Material signs. Both the 216-N-2 and 216-N-3 trenches were located within the chained barrier.

Location: The site was located approximately 15 to 30 meters (50 to 100 feet) northwest of the 212-N Building. The trench was adjacent and parallel to the 216-N-2 Trench. A single lightweight chain barrier enclosed both trenches.

Process Description: In 1952 when activities in the 200-N facilities ceased, the fuel storage basins of each of the 212 Buildings were rinsed clean to remove sludge and residual water. About 7.6 x 106 Liters of sludge/water was pumped into the 216-N-3, 216-N-5, and 216-N-7 Trenches located northwest of each facility via temporary pipelines. The trenches were 3 to 6 meters (10 to 20 feet) wide and 15 to 24 meters (50 to 80 feet) long. When the trenches were taken out of service, the overground pipelines were placed into the trench and the units were backfilled with clean soil. Each building has been used since for storage of contaminated waste or materials, but no additional liquid wastes have been discharged. A limited radiological characterization of the Annual surface radiological surveys have not detected any surface contamination. Four trenches (216-N-2, 216-N-3, 216-N-5, and 216-N-7) were reported to have received equally minute quantities of cesium-137 and strontium-90 but no plutonium or uranium. No inventory of organic or inorganic compounds is available for these sites. HW-28471 states that the fuel storage basin at 212-N was drained in 1947 to prepare the facility for special tests that were to be conducted in the basin. There is no documentation that describes the type of special tests done at this site.

Waste Type: Process Effluent
Waste Description: The site received fuel storage basin water and sludge from the 212-N Building when the facility was shut down in 1952. The site was deactivated by removing the overground piping and backfilling the unit with 1.8 meters (6 feet) of clean soil. Typically, the above ground pipe was placed into the trench prior to backfilling. The waste type is low activity.

Closure Info: Due to the rocky backfill material that had previously been placed in the trench, focused, discrete samples were collected from four test pits on March 1, 2007. The samples were collected from four specific test pits [2 samples at 3 meters (10 feet) depths and 2 samples at 4.6 meters (15 feet) depths]. An additional sample was collected at the less than 3 meter (10 foot) level that represented an elevated radiological reading (527 counts per minute with a 350 counts per minute background). No hose or piping was found during the test pit excavations.

The current site conditions as documented in the Remaining Sites Verification Package (RSVP) for the site have achieved the Remedial Action Objectives (RAOs) and the corresponding Remedial Action Goals (RAGs) as established in the Remedial Design/Remedial Action Work Plan for Select 200 North Area Waste Sites (216-N-2, -3, -5, & -7) in the 200-CW-3 Operable Unit (RD/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD).

In accordance with this evaluation, the sampling results support a reclassification of the site.
"No Action", as recorded on Waste Site Reclassification Form 2007-017. According to the RSVP the site will be re-vegetated with native grasses and re-graded in accordance with the RD/RAWP.

</tbody>
</table>

**Description:** The waste site has been remediated and Interim Closed Out. The site had been marked by "Underground Radioactive Material" warning signs attached to concrete AC-540 marker posts that surround the site. The radiological postings were removed in September 2010.

**Location:** The site was located approximately 274 meters (900 feet) south-southeast of the demolished 212-P Building.

**Related Sites/Structures:** The pond received basin overflow cooling water from the 212-P Storage Facility via an underground 46 centimeter (18-inch) diameter vitrified clay pipe (sitecode 600-286-PL).

**Process Description:** The pond consisted of a natural depression in the terrain and the discharged water was dispersed by evaporation and percolation into the ground. Except for an occasional berm, no excavation or other effort was made to define or enhance the pond formation.

**Waste Type:** Process Effluent

**Waste Description:** The site received the basin overflow waste from the 212-P Building. The waste is low activity.

**Closure Info:** Investigative sampling was performed May 22 through June 2, 2009. Twenty sample locations were identified. Sample locations 1, 2, 3, 9, 12, 15, and 20 were targeted because they are located in the influent stream portion of the pond (lowest elevation) to define the extent of downgradient contamination from the point source. Sample locations 4 through 8, 10, 11, 17, and 19 were targeted to define the lateral extent of contamination from the influent stream area. Radiological indicators (dose rate readings above background) were found at seven locations: sample locations 1, 3, 2, 9, 12, 15, and 20. Contaminants at all other sample locations were below Look-Up Values. The results from the first phase of investigative sampling effectively identified and bounded the extent of the contaminated area to be subject to Remove, Treat, Dispose (RTD). This reduced the excavation area to an area of 8,011 square meters (86,229.68 square feet). RTD commenced at 216-N-4 waste site in December 2009 and was completed in July 2010. RTD activities involved the removal of contaminated soil from the 216-N-4 waste site and disposal at the Environmental Restoration Disposal Facility (ERDF). The final excavation footprint was 7,430 square meters (79,975.85 square feet) measured at ground surface with a slope of 1.5 to 1.0.

**Description:** The site has been remediated and "Interim Closed Out". Prior to remediation the site was surrounded by a light weight chain barrier and concrete markers. It was posted with
"Underground Radioactive Material" warning signs.

**Location:** The site was located approximately 30 meters (100 feet) northwest of the 212-P Building.

**Related Sites/Structures:** The site was associated with the 216-N-2 Trench, 216-N-3 Trench and 212-N facility.

**Process Description:** In 1952 when activities in the 200-N facilities ceased, the fuel storage basins of each of the 212 Buildings were rinsed clean to remove sludge and residual water. About 7.6 x 106 Liters of sludge/water was pumped into the 216-N-3, 216-N-5, and 216-N-7 Trenches located northwest of each facility via temporary pipelines. The trench was 3 to 6 meters (10 to 20 feet) wide and 15 to 24 meters (50 to 80 feet) long. When the trench was taken out of service, the overground pipeline was placed into the trench and the units were backfilled with clean soil. Each building has been used since for storage of contaminated waste or materials, but no additional liquid wastes have been discharged. A limited radiological characterization of the Annual surface radiological surveys have not detected any surface contamination. Four trenches (216-N-2, 216-N-3, 216-N-5, and 216-N-7) were reported to have received equally minute quantities of cesium-137 and strontium-90 but no plutonium or uranium. No inventory of organic or inorganic compounds was available for these sites. The HW-28471 document states that the fuel storage basin at 212-N was drained in 1947 to prepare the facility for special tests that were to be conducted in the basin. There was no documentation that described the type of special tests done at this site.

**Waste Type:** Process Effluent

**Waste Description:** The site received the basin water and sludge cleanout from the 212-P Basin during shutdown of the area. Typically, the above ground piping was placed in the trench prior to backfilling. The waste type is low activity.

**Closure Info:** The site was investigated through field observations, radiological screening, and focused sampling and analysis for the purpose of determining if hazardous or radiological contaminants were present. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels was made for the site contaminants of concern. Screening levels were not exceeded for the site constituents. A baseline risk assessment for the river corridor portion of Hanford began in 2004, which included a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support a future final closeout decision for the site.

Geophysical survey data indicated a northwest southeast trending feature that had the characteristics typically associated with soil that has been disturbed by excavation or trenching. The disturbed area was roughly six meters (20 feet) wide, 22 meters (72 feet) long, and two meters deep. The northwest end of the area was not distinct but appeared to be slightly outside of the monuments surrounding the trench. There were no concentrations of buried debris or piping identified in the disturbed area. A very large boulder that could not be moved or broken up was identified as the only notable anomaly within the trench boundaries. While awaiting the analytical results, all soil was placed back into the excavated trench, and the area was stabilized.

Remediation of the site began on April 30, 2007 and was completed on May 11, 2007. A total of approximately 1,288 metric tons (1,420 tons) of contaminated material was excavated and disposed at the Environmental Remediation Disposal Facility. The excavation was approximately 316 square meters (3,360 square feet) in area at the top of the excavation with a 1.5 to 1 slope down to 4.6 meters (15 feet).

For the sampling effort, field screening was used to establish site radiological contamination levels. In addition, field screening for radiological contamination (cesium-137) was used as a "tracer" (i.e., indicator) to locate areas of chemical contamination. When field screening results indicated the presence of radiological contamination, the areas were further characterized with
laboratory analytical samples. The post remediation sampling and analysis results indicated achievement of compliance with the RAOs and the RAGs identified in the Remaining Sites ROD and the RD/RAWP. After remediation the waste site was radiologically screened and sampled on May 16, 2007. Laboratory analysis was performed to verify that remediation was complete.

**Code:** 216-N-6  
**Classification:** Accepted

**Names:** 216-N-6; 216-N-6 Swamp; 212-R Swamp  
**Reclassification:** Interim Closed Out (6/3/2011)

**Type:** Pond  
**Start Date:** 1/1/1944

**Status:** Inactive  
**End Date:** 1/1/1952

**Description:** The waste site has been remediated and Interim Closed Out. The site had been marked with "Underground Radioactive Material" warning signs attached to concrete AC-540 marker posts. The postings were removed after remedial activities were completed.

**Location:** The site was located in the 200 North Area, north of Route 11A. It was approximately 274 meters (900 feet) southeast of the 212-R Building.

**Related Sites/Structures:** The site is associated with the 212-R building and its connecting underground pipeline (sitecode 600-287).

**Process Description:** The site received contaminated fuel basin overflow cooling water from the 212-R Storage Facility via an underground 46-centimeter (18-inch) diameter vitrified clay pipe. The pond consisted of a natural depression in the terrain. Water discharged from the 212-R building was dispersed by evaporation and percolation into the ground. Except for an occasional berm, no excavation or other effort was made to define or enhance the pond formation. A report issued in 1953 documents contamination with a maximum dose rate of 50 mr/hr was observed in this swamp prior to being backfilled.

**Waste Type:** Process Effluent

**Waste Description:** The site received the normal overflow from the 212-R Fuel Storage Basin. The waste is low activity.

**Closure Info:** The selected remedy of Remove, Treat, Dispose (RTD) commenced at 216-N-6 Waste Site in July 2010 and was completed in August 2011. RTD activities involved the removal of contaminated soil from the 216-N-6 Waste Site and disposal at the Environmental Restoration Disposal Facility (ERDF). The final excavation area was 2,584 square meters (26,625.8 square feet) measured at ground surface. Additionally, the excavation was finished with a slope of 1.5 to 1.0, to a range of depths with the base (floor) of the excavation varying from roughly 1.21 meters (4 feet) to 2.43 meters (8 feet).

Radiological field screening was performed over the entire surface of the remediated area. Due to process knowledge of comingled radiological and chemical constituents, field screening for radiological contamination was used as an indicator to locate areas of chemical contamination. The survey was performed using standard radiological survey instruments in accordance with approved practices and procedures to obtain dose and contamination measurements with sufficient sensitivity to meet cleanup levels. Radiological screening was also performed on the samples themselves during the collection of verification samples. Radiological field screening of the remediated surface and the samples collected indicated no detectable dose rates above background.

**Code:** 216-N-7  
**Classification:** Accepted

<tr>
<td>Waste Description: The site received the water and sludge from 212-R Fuel Storage Basin clean out. The site was retired when 212-R was shut down. The waste type is low activity.</td>
<td></td>
</tr>
<tr>
<td>Closure Info: The 216-N-7 Waste Site was initially investigated through field observations and focused sampling and analysis for the purpose of determining if hazardous or radiological contaminants were present. The results of the focused sampling of test pits identified levels of contaminants of concern above the Remedial Action Goals (RAGs). Consequently, the trench was excavated to a depth of 4.6 meters (15 feet) to remove contaminated soil and debris for remediation of the waste site. No aboveground piping was found during the remediation activity. Remediation began on May 21, 2007 and was completed on June 21, 2007. The excavation was approximately 713 square meters (7,680 square feet) in area at the top of the excavation with a 1.5 to 1 slope down to 4.6 meters (15 feet). Approximately 2,631 metric tons (2,900 tons) of material from the site were disposed at ERDF. Once the excavation and disposal of the contaminated soil and debris was completed, radiological field surveys were conducted utilizing a cesium-137 tracer (i.e., indicator) to confirm the removal of detectable contamination, and waste site sampling and analysis were conducted using a multi-incremental sampling design. Multi-incremental sampling was implemented on June 26, 2007. The sample results indicated that the site achieved compliance with the RAOs and the RAGs. A summary of the cleanup evaluation for the soil results against the applicable criteria was presented in Table 1 of RSVP. Soil cleanup levels were established in the Remaining Sites ROD based on a limited ecological risk assessment. These soil cleanup levels are referred to as Look-Up Values. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels has been made for the site contaminants of concern. Screening levels were not exceeded for the site constituents. A baseline risk assessment for the river corridor portion of Hanford began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support a future final closeout decision for the site.</td>

**Reclassification:** Rejected (3/17/2010)
Tile Field

Type: Septic Tank
Status: Inactive
Start Date: 1/1/1944
End Date: 1/1/1952

Description: The site has been evaluated and reclassified to Rejected per form 2010-018. It is a septic tank and drain field. The tank is a rectangular, open-topped, concrete tank buried to grade level. A field surveillance done in 1998 found the tank to be mostly filled in with soil.

Location: The unit is located south of the 2743-R Guard House foundation and south of the 212-R Building. The drain field lies south of the septic tank.

Related Sites/Structures: The 2743-R Guard House was serviced by the 2607-R Septic Tank. Only the building foundation remains.

Process Description: The 2607-N septic tank is constructed of reinforced concrete. The tank is 1.2 meters (4 feet) long, 0.6 meters (2 feet) wide and 2.5 meters (8.25 feet) deep (inner dimensions). The tank had a design capacity of 795 liters (210 gallons) based on a user capacity of 6 persons, a flow of 132 liters (35 gallons) of sewage per capita per day, and an average detention time of 1 day. The top of the tank is at the ground surface and the tank is accessible through a 0.9-meter (3-foot) manhole.

Waste Type: Storage Tank
Waste Description: The site received sanitary waste from the 2607-R Guard House. The 910-liter (240-gallon) septic tank appears to have been filled with soil. An associated drain field exists.

Code: 600-285-PL
Classification: Accepted
Reclassification: Interim No Action (10/27/2009)

Type: Radioactive Process Sewer
Status: Inactive
Start Date: 1/1/1945
End Date: 1/1/1952

Description: The waste site is an underground, 46 centimeter (18 inch) diameter, vitrified clay pipe that fed the 216-N-1 pond. A site visit in July 2010 observed the pipeline was posted with Underground Radioactive Material Pipeline signs. The Confirmatory Sampling/No Action remediation alternative was selected for this pipeline. Only a small portion of the clay pipeline was removed and pulverized for sampling. The remainder of the pipeline was left in place and the radiological postings were removed in November 2010.

Location: The pipeline is located in the 200 North Area. It extends south from the 212-N building to the 216-N-1 Pond.

Related Sites/Structures: The pipeline is associated with the 212-N building and the 216-N-1 Pond.

Process Description: The pond received basin overflow cooling water from the 212-N Fuel Storage Facility via an underground 46-centimeter (18-inch) diameter vitrified clay pipe.

Waste Type: Chemicals
Waste Description: The contaminants of potential concern (COPCs) for the 600-285-PL, 600-286-PL and 600-287-PL waste sites were identified based on existing information for the site and the COPCs listed in the Remaining Sites ROD. The COPC list identified in the Sampling and Analysis Plan for Remediation of 200 North Area Waste Sites located in the 200-CW-3 Operable Unit (SAP) (DOE/RL-2007-54) includes americium-241, cobalt-60, cesium-137, europium-152, europium-

Closure Info: On June 3 and 9, 2009, focused, discrete samples were collected from 600-285-PL, 600-286-PL and 600-287-PL waste site outfalls. The clay pipe samples were pulverized and divided into two samples (duplicate samples). As described in the SAP, radiological screening was performed prior to and during sampling. Surveys were performed near the origins of the pipelines located at the building each pipeline serviced via a manhole and at the discharge point of the pipelines into the ponds. The culvert and pipelines radiological survey readings did not exceed background. A portion of each pipeline was removed and pulverized before analysis.

The results of the focused sampling performed per DOE/RL-2007-54, Sampling and Analysis Plan for Remediation of 200 North Area Waste Sites Located in the 200-CW-3 Operable Unit, identified no contaminants above the Remedial Action Goals (RAGs) and are in compliance with the Remedial Action Objectives (RAOs). The waste site confirmatory sampling results, reported in DOE/RL-2009-84, support a reclassification of this site to No Action. The waste site confirmatory sampling results indicate current site conditions are in compliance with the RAOs and RAGs for pipeline 600-285-PL. It was left in place. Although the Confirmatory Sampling/No Action remediation alternative was selected for pipelines in 2009 for 600-286-PL and 600-287-PL, these two clay pipelines were removed in 2010. The 600-285-PL clay pipe was not removed.

Code: 600-286-PL  Classification: Accepted

**Description:**
The remediation alternative selected for this site was Confirmatory Sampling/No Action. In
2009, the only postings at UPR-200-N-1 were Contamination Area and Radiation Area postings
immediately around the rail cars that remain on the rail spur.

In 1992, the railroad track was delineated with light weight chain and posted with Surface
Contamination signs and measured 91 meters (300 feet) in length. UPR-200-N-1 was the
portion of the railroad track extending south from the demolished 212-R building.

**Location:**
The site is located in 200 North Area, northwest of the intersection of Route 4 North and Route
11A. The site is adjacent to the 212-R building.

**Process Description:**
From 1944 to 1952, irradiated fuel rods were transported to 212-R from the 100 Area reactors
by train in water filled cask cars. The fuel rods were transferred from the rail cars to water filled
storage basins inside the building. The short lived radionuclides were allowed to decay before
transporting the fuel rods to the 200 Areas for processing. From 1982 to 1986, the 212-R
facility was used as a maintenance facility for radiologically contaminated rail cars in need of
brake and wheel maintenance. Over time, movement and repair of contaminated rail cars
caused the track to become contaminated. In 1998, two locomotives and five cask cars were
being stored at this location within the Surface Contamination Area.

**Waste Type:** Storage Tank

**Waste Description:**
Contaminated rail cars are stored on this railroad spur.

**Closure Info:**
In July 2009, the UPR-200-N-1 waste site was investigated using field observations and
focused sampling and analysis for the purpose of determining if hazardous or radiological
contaminants were present. This investigative activity was performed in accordance with
Sampling and Analysis Plan (DOE/RL-2007-54) and Remedial Design/Remedial Action Work
Plan for 200 North Area Waste Sites located in the 200-CW-3 Operable Unit (DOE/RL 2007-
When the current sampling evolution began, the only postings within or near UPR-200-N-1 were Contamination Area and Radiation Area postings immediately around the rail cars that remain on the rail spur. In July 2009, the UPR-200-N-1 waste site was investigated using field observations and focused sampling and analysis for the purpose of determining if hazardous or radiological contaminants were present. This investigative activity was performed in accordance with Sampling and Analysis Plan (DOE/RL-2007-54) and Remedial Design/Remedial Action Work Plan for 200 North Area Waste Sites located in the 200-CW-3 Operable Unit (DOE/RL 2007-55). When the current sampling evolution began, the only postings within or near UPR-200-N-1 were Contamination Area and Radiation Area postings immediately around the rail cars that remain on the rail spur.

In July 2009, focused and discrete samples were collected from the UPR-200-N-1 waste site from three boreholes. The decision logic associated with judgment/focused methodology includes identifying discrete sample locations based on radiological surveys of the area. Radiological surveys in accordance with COPCs identified for this site, is an indicator of the potential presence of COPCs. Radiological surveys of greater than 90% of the surface area of the waste site (including the tracks beneath the rail cars) showed no radiation levels above background and no detectable contamination. Visual inspection showed discoloration in one location, on the east side of the rail road tracks, approximately mid way down the length of the waste site. Based on the radiological surveys, process knowledge and the visual inspection of the site, three discrete borehole samples were collected. One was collected at the north end of the waste site closest to 21 2-R, the location with the most potential for the presence contamination based on process knowledge. One was collected in roughly the middle on the east side, where discolored soil was identified and one was collected at the south end of the waste site, bounding the furthest extent of the waste site to ensure that the waste site.

Radiological surveys were conducted on the borehole contents after removal from the sample equipment to determine potential locations for obtaining discrete samples. The survey results indicated that the soil sample was below radiological background levels and based upon visual inspections, no evidence existed to support the identification of discrete sample locations. As a result, discrete samples were obtained at each borehole at the approximate midpoint (5 to 7 feet below surface) and at the 15-foot depth in accordance with the SAP.

<td>Description: The remedial alternative selected for this waste site was Confirmatory Sampling/No Action. The waste site was a 6.1 by 6.1-meter (20 by 20-foot) area surrounded by a lightweight chain barrier and Underground Radioactive Material warning signs. There were two open, wood lined holes with valves inside the posted area. They measured approximately 1 meter square and were approximately 1 meter deep. A site visit in July 2010 observed the area adjacent to the pump house foundation posted with chain and Underground Radioactive Material (URMA) signs. Another area nearby contained debris and was posted with Soil Contamination Area (SCA) signs. In March 2011 the surface debris inside the Soil Contamination Area was removed. A Walking Stick radiological survey was done on both posted areas and found to be free of contamination. The 2009 sample results were reviewed. All the post, chains and radiological postings were removed on March 7, 2011.</td>

Hanford Site Waste Management Units Report
February 2015 1021
### Location:
The site is adjacent to the northern Well Pump House (Well House No. 2) foundation located east of the demolished 212-R Building. The well house building was demolished in September 2004.

### Release Description:
There is no information available to explain the nature or cause of the contamination.

### Related Sites/Structures:
The two valve boxes are associated with the well water supply system located within the barrier.

### Process Description:
The valve boxes appear to have been related to the pump house operation.

### Waste Type:
Equipment

### Waste Description:
The contaminants of potential concern (COPCs) for the UPR-200-N-2 waste site were identified based on existing information for the site. COPCs are listed in the Remaining Sites ROD and carried forward to the Sampling and Analysis Plan for Remediation of 200 North Area Waste Sites located in the 200 CW 3 Operable Unit (SAP) (DOE/RL 2007-54) and include americium 241, cobalt 60, cesium 137, europium 152, europium 154, europium 155, tritium, strontium 90, plutonium 238, plutonium 239/240, nickel 63, thorium 232, technetium 99, uranium 233/234, uranium 235, uranium 238, hexavalent chromium, mercury, lead, barium, trivalent chromium, cadmium, antimony, arsenic, manganese, zinc, and polychlorinated biphenyls.

### Closure Info:
In June 2009, soil samples were collected and radiological surveys were performed on soil removed with a backhoe to a depth of 15 feet. Radiological survey readings did not exceed background levels.

The analytical results from the soil samples meet the remedial action objectives for direct exposure, groundwater protection, and river protection as specified in the Remaining Sites Record of Decision. In accordance with this evaluation, the sampling results support a reclassification of the UPR-200-N-2 waste site to No Action status, as recorded on the Waste Site Reclassification Form included with this report. Per TPA MP-14, No Action status indicates that a waste site does not require any further remedial action under RCRA Corrective Action, CERCLA, or other cleanup standards based on an assessment of quantitative data collected for the waste site as evaluated under this interim Record of Decision. This waste site and the data obtained from the subject sampling evolution will be included in the risk assessment and remedial investigation and feasibility study for final closure of this area.

### Release Description:
There is no information available to explain the nature or cause of the contamination. However, on a site walkdown, done in April 2000, a Radiological Control Technician used her instrumentation to do an informal survey of the posted area. No contamination was evident on the surface of the posted area.
200-CW-5

Code: 216-Z-1D
Names: 216-Z-1D; Drainage Ditch to U Swamp; Z Plant Ditch; 216-Z-1
Type: Ditch
Status: Inactive
Classification: Accepted
Reclassification: None
Start Date: 1/1/1944
End Date: 1/1/1959

Description: The 216-Z-1D Ditch is a backfilled, surface stabilized ditch that runs from a point east of the 231-Z Building, curving southward to the 216-U-10 Pond. In 1949, the northern portion of the ditch was backfilled. The backfilled portion of the ditch was replaced with an underground pipeline (see sitecode 200-W-125-PL) to transport 231-Z effluent. The southern portion of the ditch is co-located within a large Underground Radioactive Material area that also includes the 216-Z-11 and 216-Z-19 ditches.

Location: The unit is east of 231-Z Building and runs south to the 216-U-10 Pond. The northern portion of the ditch, which had been converted to a pipeline, was shifted to the east of the original ditch.

Release Description: When the 216-Z-19 Ditch was being excavated in 1971, approximately 130 meters (425 feet) of the backfilled 216-Z-1 Ditch near the pipeline outfall was accidently exhumed (UPR-200-W-110).

Process Description: The 216-Z-1D Ditch was used to transfer liquid waste from 231-Z, 234-5Z, and 291-Z Buildings to the 216-U-10 Pond.

The 216-Z-1D Ditch operated from 1944 to 1959. It was 1,295 meters (4,249 ft) long and 0.6 meters (2 ft) deep, with a bottom width of 1.2 meters (4 ft). The side slopes were 2.5:1. Originally, the ditch flowed from a headwall located approximately 60 meters (196 ft) east of Building 231-Z before turning south to connect to the 216-U-10 pond.

In 1949, after approximately 4 years of operations and as part of Building 234-5Z (Z Plant) construction, the north 526 meters (1,725 ft) section of this ditch was abandoned, backfilled, and replaced with process sewer piping (see WIDS 200-W-125-PL) that was routed around 234-5Z facility security fencing. A new headwall was constructed approximately 457 meters (1,500 ft) downstream where the new pipeline emptied into the remaining south portion of the ditch.

The Record of Decision - Hanford 200 Area Superfund Site 200-CW-5 and 200-PW-1, 200-PW-3 and 200-PW-6 Operable Units (ROD) states the north portion of the 216-Z-1D Ditch did not contain significant contamination when it was abandoned in 1949. The early plutonium purification process in the 231-Z Plutonium Isolation Plant that produced the 216-Z-1D Ditch waste stream was a tightly controlled process due to the high value of the concentrated plutonium product being processed. At that time, process waste streams were segregated with regard to their potential to contain plutonium. Waste streams containing a significant amount of plutonium were recycled directly back to the 224-T Concentration Facility. All other secondary waste streams having a potential to contain plutonium were sent to the 231-W-151 Sump where they were analyzed, neutralized, and either recycled back to the 224-T Concentration Facility for reprocessing. If the plutonium was not considered recoverable, it was disposed to the 216-Z-4 Trench, 216-Z-5 Crib, 216-Z-6 Crib, and/or 216-Z-10 Injection/Reverse Well. Waste containing plutonium was not expected to have been disposed to the 216-Z-1D Ditch before 1949.

The coil failures that were the major source of cooling water waste stream contamination...
occurred after 1949. No reports of process-upset discharges to the 216-Z-1D (prior to 1949) have been identified. According to sample data gathered in 1981, the north portion of 216-Z-1D is significantly less contaminated than the south portion of the 216-Z-1D Ditch. Samples collected at the north end of the 216-Z-1D Ditch identified a maximum plutonium concentration of less than 70 pCi/g.

The south portion of 216-Z-1D continued to operate until 1959. It had the potential to receive cooling water waste containing constituents associated with the additional processes that occurred at the 231-Z Plutonium Isolation Plant after 1949. Open ditches were routinely surveyed for radiological contamination to control the potential spread of windblown contamination. The cooling water waste streams were not recognized as having a potential to contain plutonium.

---

**216-Z-11**

**Classification:** Accepted

**Reclassification:** None

**Type:** Ditch

**Status:** Inactive

**Start Date:** 1/1/1959

**End Date:** 1/1/1971

**Description:** The 216-Z-11 ditch is a backfilled, surface stabilized ditch that ran from the east side of the 234-5Z facility southward to the 216-U-10 Pond. The ditch is currently co-located within a large, posted Underground Radioactive Material area that also includes the 216-Z-1D and 216-Z-19 ditches. When active, the unit was a long narrow ditch with 2.5:1 sloped sides and a 0.05% grade.

**Location:** The ditch began at a point southeast of the 241-Z tanks and ran south to the 216-U-10 Pond. The first 37 meters (120 feet) of the ditch and last 203 meters (665 feet) of the ditch reused portions of the 216-Z-1D Ditch.

**Related Sites/Structures:** Structures associated with this unit include the remnants of the 216-Z-1D and 216-Z-19 Ditches, UPR-200-W-110, the 216-U-10 Pond, and the culvert beneath Sixteenth street. The pipeline from 231-Z to the ditches is sitecode 200-W-125-PL. The pipeline from 234-5Z to the ditch is sitecode 200-W-207-PL.

**Process Description:** The 216-Z-11 Ditch was installed to replace the 216-Z-1D ditch. The 216-Z-11 ditch received liquid waste from Plutonium Finishing Plant process sewer, 291-Z and 231-Z until it was deactivated in 1971. The 216-Z-11 was replaced by the 216-Z-19 Ditch. During the 1960's, a special Space Nuclear Auxiliary Power program was operating in Z-Plant. The program isolated plutonium-238 and released an unknown amount of plutonium 239/240 to the 216-Z-11 ditch as waste.

---

**216-Z-19**

**Classification:** Accepted

**Reclassification:** None

**Type:** Ditch

**Status:** Inactive

**Start Date:** 1/1/1971

**End Date:** 1/1/1981

**Description:** The 216-Z-19 Ditch is a backfilled, surface stabilized site. The ditch is currently co-located within a large Underground Radioactive Material area that also includes the 216-Z-1D and 216-Z-11 ditches.

**Location:** The ditch is an irregular site positioned in a north-south configuration. The head end is located east of the 216-Z-1A Tile Field and extends southward to the 216-U-10 Pond.
Process Description:
The 216-Z-19 Ditch operated as a waste disposal/transfer line for various Plutonium Finishing Plant facilities. The ditch received effluent from the 234-5Z, the 291-Z stack, and the 231-Z Buildings. The ditch was fed by three underground process sewer pipelines that entered the head end of the ditch. The ditch was deactivated and backfilled when discharges transferred to the 216-Z-20 Crib.

Related Sites/Structures:
Structures associated with this site include the remnants of the 216-Z-1D and the 216-Z-11 Ditches, the 216-U-10 Pond, the stormwater and process sewer outfalls from the Plutonium Finishing Plant, and the pipeline from 231-Z. The pipeline from 231-Z is sitecode 200-W-125-PL. The pipeline from 234-5Z to the ditch is sitecode 200-W-207-PL.

Release Description:
In March of 1976, an estimated 30 to 60 grams of plutonium was accidentally released to the 216-Z-19 ditch. Soil samples collected from the ditch in March and April 1976 identified large amounts of plutonium and americium. In an effort to keep the contamination contained within the ditch, three earth dams were constructed across the ditch at intervals to impound the water and allow the contaminants to settle to the bottom. A sprinkler system was installed to keep the downstream portions of the ditch from drying and allowing contamination to spread in the wind. The dams were removed in June 1978.

Reclassification:
216-Z-20; Z-19 Ditch Replacement Tile Field
Crib
Inactive

Names:
Type: Crib
Status: Inactive
Start Date: 9/24/1981
End Date: 7/19/1995
Description: The site is marked and posted as an Underground Radioactive Material area. The site was permanently isolated by filling the manhole at the head end of the crib with concrete on 6/1/95.
Location: The site is located northwest of the 241-U Tank Farm. It is west of and parallel to the backfilled 216-Z-19 Ditch.
Related Sites/Structures: The crib is associated with the 234-5 and 236 facilities. The pipeline from 234-5Z to 216-Z-20 is sitecode 200-W-207-PL. Effluent from pipeline 200-W-125-PL was also diverted to 216-Z-20.
Process Description: The crib was build to receive effluent from the Plutonium Finishing Plant facilities and the 231-Z building. It was built to replace the 216-Z-19 ditch. Although drawing H-2-92061 indicates the crib structure has varied depths of 2.7 to 8.8 meters (9 to 29 feet) below ground surface, a recent engineering review determined this to be an error. Note 10 on this drawing states there was a soil mound at this station and other areas. Backfill soil was to be leveled to maintain uniform elevation after 216-Z-20 was constructed. The crib structure varied depths are now assumed to be 2.47 to 3.87 meters (8.09 to 12.69 feet) below ground surface. Three 6 inch (15 centimeter) perforated PVC distribution pipes run the length the crib to the south end, where the pipes are capped. A set of risers (three in a row across the width of the unit) rose to a height of 0.46 meters (1.5 feet) above grade at 4 locations along the length of the unit. The unit was filled with gravel and backfilled over with soil with a side slope of 1:2.

Code: UPR-200-W-110
Names: UPR-200-W-110; Contaminated Soil from 216-Z-1; UN-216-W-20 Spoil Trench
Type: Trench
Status: Inactive
Start Date: 1/1/1971
End Date: 1/1/1971

Hanford Site Waste Management Units Report
February 2015
Description: The site is a one-time use waste disposal trench. The trench is the location where backfill material from the north end of the 216-Z-1 Ditch was placed following excavation for a new ditch. During construction for the 216-Z-19 Replacement Ditch, workers placed the excavated material on a spoils pile. Later that material was found to be contaminated and it was moved to the disposal trench.

The ditches and the trench have been backfilled and are co-located within an "Underground Radioactive Material" (URM) zone. This area was surface stabilized in 1982. The area is marked with concrete posts and an intermittent light chain.

The site is vegetated with crested wheatgrass and Indian rice grass over very sandy soil. There is evidence of rodent burrowing on and adjacent to the URM area. An air monitor is on the site at the north end.

Location: The site is east of and parallel to the north end of the 216-Z-19 and 216-Z-11 ditches in the 200 West Area.

Release Description: On April 14, 1971, Plant Forces mistakenly dug into the contaminated backfill of the abandoned 216-Z-1 Ditch while excavating a new ditch. Approximately 130 meters (425 feet) of the abandoned ditch was uncovered before the error was discovered. An inch-thick decayed vegetation matting from the bottom of the old ditch was found to contain alpha contamination to a maximum of 100,000 disintegrations per minute. The matting was broken up during the excavation and scattered through the "spoil pile" of the new ditch. Only a trace of contamination was detected in the excavation. Work was discontinued until surveys could be completed for a proper routing of the new ditch. A sprinkler system was installed to prevent the wind from spreading contamination from the spoil pile. The new ditch (216-Z-19) was dug approximately 10.7 (35 feet) west of the original buried ditch. The 216-Z-19 was ready for water diversion as soon as the 16th Street culvert was cleaned of sludge and weeds. A 4.6 meter (15 foot) deep burial trench was dug east of and adjacent to the 216-Z-11 ditch. A 2.1 meter (7 foot) layer of spoils material was placed in the trench and covered with 2.4 meters (8 feet) of clean soil overburden.

Related Sites/Structures: UPR-200-W-110 was associated with the 216-Z-1 Ditch and the 216-Z-19 Ditch. The trench (UPR-200-W-110) is within a larger Underground Radioactive Material (URM) area.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: Decayed vegetation matting from the bottom of the 216-Z-1 Ditch was found to contain alpha contamination to a maximum of 100,000 disintegrations per minute. The 216-Z-1 Ditch was contaminated with americium and plutonium originating from process leaks contaminating the Z Plant cooling water discharge system. The contamination subsequently settled out of the water or was absorbed by aquatic plant life growing on the sides and bottom of the ditch. Radioactivity computed from soil samples taken from the spoil pile showed an alpha concentration of 0.34 nanocuries per gram of soil. This was 30 times less than the minimum 10 nanocuries per gram standard that required "packaging for recovery" plutonium burials.

</tr>
<tr>
<td>Process Description</td>
<td>The 216-B-5 reverse well is the deepest Hanford reverse well and the only one to discharge waste directly to the water table. The reverse well received approximately 30,600,000 liters (8,008,000 gallons) of B Plant and 224-B waste solutions. The waste overflowed into the reverse well from the 241-B-361 settling tank, which removed the particulates. A total of 4.7 kilograms (10.3 pounds) of plutonium was discharged to the settling tank and reverse well. Half of the plutonium was retained in the settling tank. An estimated 2.15 kilograms (4.7 pounds) of plutonium overflowed into the reverse well. A water sample collected from well 299-E33-18 in September 1947 revealed alpha contamination in the groundwater (&lt;20 x 10-7 micro curies/liter). Eleven additional wells were drilled in 1947 and 1948 to evaluate the contamination plume. The zone of groundwater contamination extended laterally 600 meters (2000 feet) from the reverse well. The reverse well was characterized again in 1980.</td>

Description: 144 stabilization. The contaminated soil from the unplanned release area and the cribs were covered with clean backfill and posted with Underground Radioactive Material signs. The crib locations are identified with light post and chain with Cave-in Potential signs.

Location: The site is located north of 241-B Tank Farm and east of Baltimore Avenue. The cribs are approximately 8.6 meters (28.2 feet) apart. 216-B-7B is the northwest crib, and 216-B-7A is the southeast crib.

Related Sites/Structures: The cribs are associated with 221-B, 224-B, the 241-B Tank Farm, tanks 241-B-201 through 241-B-204, and UPR-200-E-144. The pipeline that fed the cribs is sitecode 200-E-281-PL.

Process Description: The 216-B-7A and 216-B-7B site consists of two wooden cribs, placed side by side, connected by underground piping. They were originally known as the 241-B-1 and 2 cribs. Effluent drained into 216-B-7A and 216-B-7B simultaneously through a T-fitting in the pipeline from the 201-B settling tanks (241-B-201, 241-B-202, 241-B-203 and 241-B-204) located inside the 241-B Tank Farm. Process effluent from 221-B and 224-B was routed to the settling tanks from 1946 through 1967 and dispersed to the cribs. In 1951, cell drainage from 221-B was diverted to the 216-B-9 Crib. In 1954, the 224-B waste stream was diverted to the 216-B-8 Crib when the cribs exceeded their infiltration capacity. The cribs were reactivated and used intermittently from December 1954 through May 1967 when it was determined that they had reached their radionuclide capacity.

A letter written by G.L. Hanson in September 1967 states that the cribs received approximately 49 million liters (13 million gallons) of process waste from 221-B and 224-B from 1946 through 1958. These wastes contained 4300 grams of plutonium and 5400 curies of beta/gamma emitters. After 1958, the cribs received an additional 752,000 liters (198,000 gallons) of B Plant waste containing 2100 curies of beta/gamma emitters that included 14 curies of Cesium-137 and 2080 curies of Strontium-90. Cesium, cobalt, tritium and alpha contamination was detected in groundwater samples taken from well 299-E33-18 in 1967, which monitors these cribs.

Waste Type: Process Effluent

Waste Description: The site received the liquid waste from 221-B and 224-B via overflow of 201-B Settling Tanks. From September 1946 through October 1947, the cribs received waste from 224-B. From October 1947 to August 1948, the site received the 224-B waste stream plus cell drainage (tank 5-6) and other liquid waste from 221-B. From August 1948 to July 1951, the site received liquid waste from 224-B. The tank 5-6 waste was diverted to the 216-B-9 Crib. From July 1951 through December 1954, the cribs continued to receive waste from 224-B. In December 1954 the cribs exceeded their infiltration capacity and the waste was diverted to the 216-B-8 Crib. From December 1954 to October 1961, the site received Cell 5-6 drainage and equipment cleanout waste from 224-B. From October 1961 to May 1967, the site received decontamination and construction waste from 221-B. In May 1967 it was determined that the cribs has reached their radionuclide capacity and were terminated. The B Plant effluent was rerouted to the 216-B-12 Crib. The waste is low in salt, neutral to basic, and contains transuranic (TRU) fission products.

Cave-In Potential signs. The surface is covered with gravel.

**Location:**
The site is located north of the 241-B Tank Farm, east of Baltimore Avenue. It is north of 216-B-7A and 216-B-7B Cribs.

**Related Sites/Structures:**
The site is associated with 221-B, 224-B, 241-B, 200-E-45 (Health Instrument Shaft) and UPR-200-E-144. The pipeline associated with this crib is sitecode 200-E-178-PL.

**Process Description:**
B Plant operated from April 1945 through October 1952, separating plutonium from irradiated fuel rods using the bismuth phosphate process. The first separation step removed the metal coating from the fuel rods. Next the uranium was dissolved and the plutonium was extracted. The waste from this step was called Metal Waste. This waste stream contained all of the uranium and 90% of the fission products and was stored in the single shell tanks. The extracted plutonium went through two decontamination cycles to further purify it. The first cycle waste was combined with the coating waste. It contained 10% of the fission products and 1% of plutonium. The second decontamination cycle waste contained less than 0.1% of the fission products. The first and second cycle waste were originally discharged to the single shell tanks. In 1948, due to the lack of waste storage space in the tank farms, second cycle waste stored in the tank farms began to be released to cribs. The 216-B-8 Crib received second cycle waste from B Plant via the 241-B-110, 241-B-111 and 241-B-112 cascading tanks, located in the 241-B Tank Farm.

**Waste Type:** Process Effluent

**Waste Description:**
From February 1948 through July 1951, the site received second-cycle waste supernatant from 221-B Building. In August 1948, sludge from the 241-B-104 tank was inadvertently released to the crib and the crib became plugged. The sludge contained roughly 1000 times the amount of plutonium and 5000 times the fission products as would be found in the supernate usually discharged to cribs. Acid was added to the crib in an attempt to unplug the crib. The acid did not significantly improve the crib blockage so the tile field was added to receive crib overflow. From July 1951 to December 1951, the site received the second cycle waste plus cell drainage stored in Tank 5-6 and other liquid waste from in 221-B Building. From December 1951 to December 1952, the site received decontamination and cleanup waste generated during the shutdown of 221-B and 224-B. Some documents state the pipeline to the 216-B-8 Crib was blanked and the effluent routed to 216-B-7A in December 1954. However, H-2-2928 shows the effluent was rerouted to 216-B-11 A&B. The waste is high in salt, is neutral to basic, and contains transuranic (TRU) waste and fission products.

Hanford Site Waste Management Units Report
February 2015
Process Description: The 216-B-9 Crib and Tile Field were built to replace the 241-B-361 Settling Tank and the 216-B-5 Reverse well. The drainage waste from the B Plant 5-6W cells was rerouted directly to this crib, by-passing the 241-B-361 settling tank. The 216-B-9 crib carries an alias of 241-B-361 crib, even though the 241-B-361 tank was by-passed. A total of 18,400,000 liters of waste was discharged to the crib between August 1948 and January 1950. The waste contained approximately 95 grams (3.3 ounces) of plutonium and 2050 curies of fission products. Sludge in the waste plugged the crib and decreased its capacity. Acid was added to the crib to keep it in operation. The crib eventually became sealed with sludge and overflow into the tile field began in November 1948. Test holes were placed in the tile field to inspect its drainage. In April 1949, 7 inches of liquid was found in Test Hole #2. A sample of the liquid was analyzed and revealed 11.5 micro curies/liter of fission products and 9,000 disintegrations per minute per liter of alpha contamination. Test Hole #2 was found to be dry in October 1949. Sediment samples taken at that time revealed 152 micro curies per kilogram of fission products and 943,000 disintegrations per minute per kilogram of alpha contamination.  

The crib is associated with 221-B and UPR-200-E-7. The pipeline associated with this crib is 200-E-195-PL and 200-E-199-PL.

Related Sites/Structures: The crib is associated with 221-B and UPR-200-E-7. The pipeline associated with this crib is 200-E-195-PL and 200-E-199-PL.

Process Description: The 216-B-9 Crib and Tile Field were built to replace the 241-B-361 Settling Tank and the 216-B-5 Reverse well. The drainage waste from the B Plant 5-6W cells was rerouted directly to this crib, by-passing the 241-B-361 settling tank. The 216-B-9 crib carries an alias of 241-B-361 crib, even though the 241-B-361 tank was by-passed. A total of 18,400,000 liters of waste was discharged to the crib between August 1948 and January 1950. The waste contained approximately 95 grams (3.3 ounces) of plutonium and 2050 curies of fission products. Sludge in the waste plugged the crib and decreased its capacity. Acid was added to the crib to keep it in operation. The crib eventually became sealed with sludge and overflow into the tile field began in November 1948. Test holes were placed in the tile field to inspect its drainage. In April 1949, 7 inches of liquid was found in Test Hole #2. A sample of the liquid was analyzed and revealed 11.5 micro curies/liter of fission products and 9,000 disintegrations per minute per liter of alpha contamination. Test Hole #2 was found to be dry in October 1949. Sediment samples taken at that time revealed 152 micro curies per kilogram of fission products and 943,000 disintegrations per minute per kilogram of alpha contamination.  

The unit is a wooden structure, 4.3 by 4.3 meters (14 by 14 feet) (bottom surface) by 2.4 meters (8 feet) high, located in an excavation. The timbers are 15.2 by 15.2 centimeters (6 by 6 inches). The tile field, 55.0 by 25.6 meters (180 by 84 feet), is 165 meters (540 linear feet) of 15.2-centimeter (6-inch) clay tile pipe, with each leg in a trench 1.2 meters (4 feet) wide at the bottom. Pipes are buried 3.7 meters (12 feet) deep at head and 1.8 meters (6 feet) at the other end. Above and below the pipes are 45.7 centimeters (18 inches) of gravel. Roofing felt covers the top side of the pipes. Three legs branch from each side of clay pipe, leaving at 45 degrees to the trunk. The side slope is 1:1.5.

Waste Type: Storage Tank

Waste Description: The site received cell drainage and other liquid waste via Tank 5-6 in 221-B Building. The waste is low in salt, neutral to basic, and contains transuranic (TRU) and fission products. A sample of the sediments collected in 1949 through a well casing revealed 1830 microcuries per kilogram of fission products and 14,800,000 disintegrations per minute per kilogram of alpha contamination.

Code: 216-B-11A&B
Names: 216-B-11A&B; 216-B-11B; 242-B-1 Crib; 216-B-11 Crib; 216-B-11A & B
Type: French Drain
Status: Inactive
Start Date: 1/1/1951
End Date: 1/1/1954
Classification: Accepted
Reclassification: None

Description: The cribs are located beneath a larger area of scraped contaminated soil from the UPR-200-E-144 stabilization, completed in 1992. The consolidated contaminated soil was covered with clean backfill and reposted as Underground Radioactive Material. The crib locations are identified with light post and chain with Cave-in Potential signs. The cribs consists of two corrugated metal culverts that are buried vertically. The metal culverts are perforated with holes that begin 15.24 centimeters (6 inches) from the bottom of the culverts. The culverts are 9.15 meters (30 feet) long and 2.44 meters (8 feet) in diameter. They are filled with 32.13 cubic meters (42 cubic yards) of rock. The culverts are placed 18 meters (60 feet) apart and are connected with a 7.6 centimeter (3 inch) steel pipe.

Location: The cribs are located north of 241-B Tank Farm, and east of Baltimore Avenue, adjacent to the 216-B-7A&B Cribs. The 216-B-11A is the southern crib; 216-B-11B is the northern crib. The
cribs are 16 meters (52.5 feet) apart.

**Related Sites/Structures:** There are two pipelines associated with these cribs. See sitecodes 200-E-176-PL and 200-E-177-PL.

**Process Description:** The site originally received condensate waste from the 242-B Evaporator. Drawing H-2-2928 shows 216-B-8 crib waste being rerouted to 216-B-11 A&B in 1954.

**Waste Type:** Storage Tank

**Description:** The 216-B-35 through 216-B-42 trenches were surface stabilized as a unit. The area is marked with concrete AC-540 posts and Underground Radioactive Material signs. The surface has been planted with wheat grass.

**Location:** The trench is located north of B Plant and west of the 241-BX Tank Farm.

**Related Sites/Structures:** The trench is associated with 221-B and the 241-BX Tank Farm.

**Process Description:** In order to provide the tank space needed to support the fuel separations operations in 200 East and West Areas, first cycle supernate stored in the single shell tanks was intentionally discharged to specific retention trenches during 1953 and 1954. Specific retention disposal utilized the moisture retention capacity of the relatively dry soils above the regional ground water table. The volume of liquid disposed to each trench was limited to ten percent of the soil volume between the bottom of the trench and the groundwater table. B Plant and T Plant used the bismuth phosphate process to separate plutonium from irradiated fuel from 1944 through 1956. The first step in the process was to dissolve the metal coating from the fuel rods. The next step dissolved the uranium and extracted the plutonium. The uranium waste was known as the metal waste stream. It contained the bulk of the uranium and 90% of the cesium-137 and strontium-90. The plutonium stream went through two additional decontamination cycles to purify it, producing the first and second cycle waste streams. The first cycle waste stream contained approximately 10% of the long lived fission products and 1% of the plutonium. The coating waste was combined with the first cycle waste. The liquid waste from these processes was initially stored in the single shell tanks in tank farms. By 1948, limited space in the tank farms resulted in the decision to discharge the second cycle waste to cribs. In 1951, the 242-B and 242-T Evaporators began to concentrate the first cycle waste to reduce the volume of waste stored in the tank farms. By 1953, the need for tank space resulted in the first cycle waste that was being stored in the single shell tanks, to be discharged via overground pipelines to specific retention trenches. Some specific retention trenches received the waste from the bottoms of the 242-B and 242-T Evaporator tank or tri-butyl phosphate waste from the Uranium Recovery process.

**Waste Type:** Storage Tank
Waste Description: The site received first-cycle supernatant waste from 221-B Building. The waste is high in salt and is neutral to basic.

*Hanford Site Waste Management Units Report*

February 2015
Description: The 216-B-35 through 216-B-42 trenches were surface stabilized as a unit. The area is marked with concrete AC-540 posts and Underground Radioactive Material signs. The surface has been planted with wheat grass.

Location: The trench is located north of B Plant and west of the 241-BX Tank Farm.

Related Sites/Structures: This trench is associated with the Uranium Recovery operation done at the 221-U facility.

Process Description: In order to provide the tank space needed to support the fuel separations operations in 200 East and West Areas, first cycle supernate stored in the single shell tanks was intentionally discharged to specific retention trenches during 1953 and 1954. Specific retention disposal utilized the moisture retention capacity of the relatively dry soils above the regional groundwater table. The volume of liquid disposed to each trench was limited to ten percent of the soil volume between the bottom of the trench and the groundwater table. B Plant and T Plant used the bismuth phosphate process to separate plutonium from irradiated fuel from 1944 through 1956. The first step in the process was to dissolve the metal coating from the fuel rods. The next step dissolved the uranium and extracted the plutonium. The uranium waste was known as the metal waste stream. It was combined with the coating waste to form the waste stream known as first cycle waste. It contained the bulk of the uranium and 90% of the cesium-137 and strontium-90. The plutonium stream went through additional decontamination cycles to purify it, producing the second cycle waste stream. The liquid waste from these processes were initially stored in the single shell tanks in tank farms. By 1948, limited space in the tank farms resulted in the decision to discharge the second cycle waste to cribs. In 1951, the 242-B and 242-T Evaporators began to concentrate the first cycle waste to reduce the volume of waste stored in the tank farms. By 1953, the need for tank space resulted in the first cycle waste that was being stored in the single shell tanks, to be discharged via overground pipelines to specific retention trenches. Some specific retention trenches received the waste from the bottoms of the 242-B and 242-T Evaporator tanks or tri-butyl phosphate waste from the Uranium Recovery process.

Waste Type: Process Effluent

Waste Description: The site received the scavenged tributyl phosphate (TBP) supernatant waste from the 221-U Building via the 241-BY tank farm. The waste is high in salt and is neutral to basic.

Names: 216-B-43; 216-BY-1 Cavern; 216-BY-1 Crib

Type: Crib

Status: Inactive

Location: The unit is located north of 241-BY Tank Farm and west of Baltimore Avenue in a common area with 216-B-44 through 216-B-50.

Release Description: See UPR-200-E-9 and UPR-200-E-89

Related Sites/Structures: The crib is associated with the 221-U Uranium Recovery process. The pipeline that fed the BY cribs is discussed in sitecode 200-E-219-PL.

Process Description: From 1952 through 1958, Bismuth Phosphate process waste stored in 241-T, TX, 241-B, BX, BY, 241-C and 241-U tank farms was transferred to 221-U to recover the uranium from the
waste after the tank sludge had been thinned with nitric acid. The uranium was extracted from the tank waste using Tri-butyl Phosphate (TPB) in a normal paraffin dilutent. The waste from the uranium recovery process was neutralized and transferred to the 241-BY tank farm. The TBP process waste was treated with potassium ferrocyanide to precipitate most of the cesium and strontium. The supernate was decanted first to the 216-B-43 through 49 cribs and later to the BC Cribs and trenches. Crib 216-B-50 was not used for TBP waste. Each of the eight cribs (216-B-43 through 216-B-50) were constructed of four 1.22-meter (4-foot) diameter by 1.22-meter (4 foot) long concrete culverts buried vertically, 2.14 meters (7 feet) below grade, on a 1.53-meter (5-foot) bed of 7.62-centimeter (3-inch) gravel (291 cubic meters [380 cubic yards]). The culverts are arranged in a square with the centers spaced 4.58 meters (15 feet) apart in a 9.15 by 9.15 by 4.58-meter (30 by 30 by 15-foot) deep excavation. Each culvert is fed by an 20.32-centimeter (8-inch) steel pipe coming from a main and forming a chevron pattern. Each culvert has a concrete cover.

**Waste Type:** Steam Condensate

**Waste Description:** The site received the scavenged tributyl phosphate (TBP) supernatant waste from 221-U Building. The waste is high in salt and is neutral to basic. It included inorganic compounds such as ferrocyanide, nitrate and phosphate. (active in November 1954)

Waste Type: Storage Tank
Waste Description: The site received scavenged tributyl phosphate (TBP) supernatant waste from 221-U Building. The waste is high in salt and is neutral to basic. It included inorganic compounds such as ferrocyanide, nitrate and phosphate. (Active September 1955)
**Reclassification:** 216-B-48; 216-BY-6 Cavern; 216-BY-6 Crib

**Names:**
- 216-B-48
- 216-BY-6 Cavern
- 216-BY-6 Crib

**Type:** Crib

**Status:** Inactive

**Start Date:** 1/1/1955

**End Date:** 1/1/1955

**Description:**
The 216-B-43 through 216-B-50 cribs were stabilized as a unit with gravel. The group of cribs are surrounded with light chain and posted Underground Radioactive Material.

**Location:**
The unit is located north of 241-BY Tank Farm and west of Baltimore Avenue in a common area with the 216-B-43 through 216-B-50 cribs.

**Process Description:**
From 1952 through 1958, Bismuth Phosphate process waste stored in 241-T, TX, 241-B, BX, BY, 241-C and 241-U tank farms was transferred to 221-U to recover the uranium from the waste after the tank sludge had been thinned with nitric acid. The uranium was extracted from the tank waste using Tri-butyl Phosphate (TPB) in a normal paraffin diluent. The waste from the uranium recovery process was neutralized and transferred to the 241-BY tank farm. The TBP process waste was treated with potassium ferrocyanide to precipitate most of the cesium and strontium. The supernate was decanted first to the 216-B-43 through 49 cribs and later to the BC Cribs and trenches. Crib 216-B-50 was not used for TBP waste. The crib was constructed of four 1.22-meter (4-foot) diameter by 1.22-meter (4 foot) long concrete culverts placed vertically, 2.14 meters (7 feet) below grade, on a 1.53-meter (5-foot) bed of 7.62-centimeter (3-inch) gravel (291 cubic meters [380 cubic yards]). Pipes are arranged in a square with the centers spaced 4.58 meters (15 feet) apart in a 9.15 by 9.15 by 4.58-meter (30 by 30 by 15-foot) deep excavation. Each culvert was fed by an 20.32-centimeter (8-inch) steel pipe coming from a main and forming a chevron pattern. Each culvert has a concrete cover.

**Waste Type:** Storage Tank

**Waste Description:** The site received scavenged tributyl phosphate (TBP) supernatant waste from 221-U Building. The waste is high in salt and is neutral to basic. It included inorganic compounds such as ferrocyanide, nitrate and phosphate. The pipeline to the unit was valved out when specific retention capacity was reached. Crib service duration discrepancies appear in historical documentation. ARH-947, HW-55176 and HW-83718 show November 1955 to February 1957 as the service duration. RHO-CD-673 shows November 1955 to July 1957 as the service duration. ARH-2806 shows November 1955 to November 1955 as the service duration. The start and end dates for adjacent cribs was 1955. In 1956 when a nearby groundwater monitoring well found elevated levels of cobalt-60 and cesium 137, effluent release in this area was discontinued. So the 1957 end date is questionable.

Related Sites/Structures:
The crib is associated with the 221-U Uranium Recovery process. The pipeline that fed the BY cribs is discussed in sitecode 200-E-219-PL.

Process Description:
The 216-B-50 crib received condensate from the 241-BY tank farm In-Tank Solidification system. The crib was originally constructed along with seven others in the same location (216-B-43 through 49) to receive scavenged tributyl phosphate (TBP) waste. The other seven were used for this purpose, but taken out of service when a cobalt-60 and cesium-137 breakthrough to groundwater occurred in 1956. The decision to use the 216-B-50 crib for ITS condensate was made about 8 or 9 years later when monitoring showed that the groundwater radioactivity levels were definitely decreasing. The crib was constructed of four 1.22-meter (4-foot) diameter by 1.22-meter (4 foot) long concrete culverts placed vertically, 2.14 meters (7 feet) below grade, on a 1.53-meter (5-foot) bed of 7.62-centimeter (3-inch) gravel (291 cubic meters [380 cubic yards]). Pipes are arranged in a square with the centers spaced 4.58 meters (15 feet) apart in a 9.15 by 9.15 by 4.58-meter (30 by 30 by 15-foot) deep excavation. Each culvert was fed by an 20.32-centimeter (8-inch) steel pipe coming from a main and forming a chevron pattern. Each culvert has a concrete cover.

Waste Type: Process Effluent
The site received the waste storage tank intermediate level process condensate from the In Tank Solidification (ITS) #1 unit in the 241-BY Tank Farm. Since startup of the #1 ITS in March, 1965, approximately five and one-half million gallons of condensate containing about 120 beta curies of activity, including about 70 curies of cesium-137, have been routed to the 216-B-50 crib (as of April 1968). The crib was originally constructed along with seven others in the same location to receive scavenged tributyl phosphate (TBP) waste. The other seven were used for this purpose, but the crib site was taken out of service when a cobalt-60 and cesium-137 breakthrough occurred. The decision to use the 216-B-50 crib for ITS condensate was made about 8 or 9 years later when it was known that the groundwater activity levels were definitely decreasing. It was recognized that the crib had limited use. 216-B-50 crib has a bottom area of 83.6 square meters (900 square feet), and its capacity had been adequate for the 5-6 gallons per minute flow of condensate. Now that the capacity of #1 ITS has been doubled (Project ICE-618), it is doubtful that the crib will have sufficient capacity without a significant rise in the level of water in the crib. This increase of water level could drive the condensate through the highly contaminated zone under the other seven cribs (216-B-43 through 49) that are located 15 to 76 meters (50 to 250 feet) from the 216-B-50 crib. Flow data obtained from the monitoring wells showed that condensate sent to the 216-B-50 crib tended to migrate under the highly contaminated cribs. To avoid potential flooding of 216-B-50, 216-B-61 crib was proposed. The #2 ITS Unit, also located in the 241-BY Tank Farm used crib 216-B-57, which was designed for receiving only the condensate flow from the #2 Unit. The 216-B-50 crib needed to be taken out of service because of its size limitations and because of the close proximity of the highly contaminated cribs (216-B-43 through 216-B-49) that had been used for scavenged TBP wastes. These seven cribs received over 400,000 curies of beta activity including about 13,000 and 4,000 curies of long lived strontium and cesium, respectively. The groundwater under these cribs still contains detectable concentrations of cesium-137 and cobalt-60 (April...
Names: 200-E-45; Contaminated Pump Run-in Caisson; Health Instrument Shaft; HI Shaft

Reclassification: None

Type: Silo

Start Date: 1/1/1948

End Date: 1/1/1973

Status: Inactive

Description: The site is a concrete shaft, 16.6 meters (55 feet) deep. It is constructed of prefabricated concrete sections, 2.4 meters (8 feet) in diameter and 1.9 meters (6 feet 2 inches) high. Steel pipes were installed laterally through holes in the side of the shaft at 3 meters (10 feet) and 6 meters (20 feet) from the surface toward the 216-B-8 Crib. The pipes were 15 centimeters (6 inches) in diameter, and 6.6 meters (22 feet) long. The site is topped with a large circular cover with a smaller manhole, a hatch and a vent pipe. The shaft lid is now covered with clean gravel, surrounded by light duty posts and chain and is posted as an Underground Radioactive Material Area.

Location: The shaft is located north of 241-B Tank Farm and west of the of the 216-B-8 Crib.

Related Sites/Structures: The HI Shaft is associated with the 216-B-8 Crib.

Process Description: The Health Instrument Shaft was originally installed to allow Health Instrument technicians to descend a ladder and collect liquid and soil samples from a depth of approximately 3 meters (10 feet) and 6 meters (20 feet) below the bottom of the 216-B-8 Crib through openings in the shaft. Perforated lateral pipes extending beneath the crib allowed liquid waste from the crib to enter the pipes and collect in sample cups. Other holes were made in the side of the shaft facing the crib to collect sediment samples. Samples were collected for several years and ended on December 31, 1949. The shaft structure was later filled with water and used to test contaminated tank farm pumps. The last known pump test was done in 1973. In 1949, radiological readings up to 4 rad/hour were recorded at the bottom of the shaft. As of December 1949, 105 liquid samples, 4 sludge samples and 7 sediment samples had been collected and analyzed to characterize the operation of the 216-B-8 Crib. Liquid samples collected at the 3 meter (10 foot) level and the 6 meter (20 foot) level both contained an average of 0.5 microcuries per liter. In August 1948, sludge from the 104-B tank was inadvertently jetted to the 216-B-8 Crib. A sudden decrease in the crib capacity led to the discovery of approximately 37.5 centimeters (15 inches) of sludge in the crib. Some sludge washed to at least 6.1 meters (20 feet) below the crib bottom and was collected in the HI Shaft sample cups. The plutonium activity in the sludge samples was 900 microcuries per kilogram of sludge. This is 1000 times higher than the plutonium content of the supernate liquid usually discharged to cribs. The fission product activity in the sludge samples was 9,000 microcuries per kilogram of sludge. This is roughly 5,000 times greater than the fission product activity in supernate liquid. Liquid sample collected in the HI Shaft prior to the sludge discharge contained less than 1000 disintegrations per minute per liter of alpha contamination. Liquid samples collected after the sludge release contained an average of 17,500 disintegrations per minute per liter of alpha contamination. Sediment samples collected from approximately 5.5 meters (18 feet) below the crib through the HI Shaft prior to the sludge release contained beta-gamma activity of 0.13 microcuries per kilogram. After the sludge release the activity increased to 0.33 microcuries per kilogram. No alpha contamination was found in the sediment samples.

Waste Type: Steam Condensate

Waste Description: The shaft was used to obtain samples from the 216-B-8 Crib. The bottom of the shaft occasionally collected a significant amount of crib seepage that was pumped out of the shaft and back to the crib. Later the shaft was intermittently filled with water and used as a contaminated pump testing pit.
### Code: 216-S-9
- **Classification:** Accepted
- **Names:** 216-S-9; 216-S-9 Crib
- **Reclassification:** None
- **Type:** Crib
- **Start Date:** 1/1/1965
- **End Date:** 1/1/1969

**Description:** The unit is a gravel structure with a side slope of 1:1.5. Waste flowed into the unit through the distribution system, which consists of 177 meters (581 feet) of 15-centimeter (6-inch) Vitrified Clay Tile (VCT) perforated pipe in a U-shape, 4.6 meters (15 feet) by 89.9 meters (295 feet), and connected by 7.3 meters (24 feet) of 4.6-centimeter (3-inch) Schedule 10 pipe in a Y-shape. The entire distribution system is 6.4 meters (21 feet) below grade.

**Location:** The crib is located east of 241-S, SX, SY Tank Farms.

**Related Sites/Structures:** The crib is associated with the 216-S-7 crib, 216-S-23 crib and the 200-W-138-PL and 200-W-139-PL pipelines.

**Process Description:** The following are related to the unit: two 20-centimeter (8-inch) diameter, 8.5-meter (28-foot) long V.C.T. gage wells, with the bottom 0.9 meters (3 feet) perforated; two 0.6-meter (2-foot) by 0.6-meter (2-foot) by 0.3-meter (1-foot) concrete pads for gage wells; one 30-centimeter (12-inch) diameter, 7.3-meter (24-foot) long, V.C.T. vent with filter; one 0.6-meter (2-foot) by 0.6-meter (2-foot) by 1.2-meter (4-foot) concrete pad for the vent; approximately 1,767 cubic meters (62,400 cubic feet) of gravel fill and 960.3 square meters (10,336 square feet) of plastic barrier; 12,690 cubic meters (448,000 cubic feet) of gravel backfill.

**Waste Type:** Storage Tank

**Waste Description:** The site received process condensate from the D-2 Receiver Tank in the 202-S Building. The waste is acidic.

### Code: 216-S-13
- **Classification:** Accepted
- **Names:** 216-S-13; 216-S-6; 276-S Crib
- **Reclassification:** None
- **Type:** Crib
- **Start Date:** 1/1/1952
- **End Date:** 1/1/1972

**Description:** The crib is surrounded with steel posts and chain. It is posted with Underground Radioactive Material and Cave-In Potential signs. The unit is a square wooden crib box, with open bottom enclosed on four sides with sheathing. The crib box sits in a partially backfilled hole. The unit was then backfilled to grade. The crib box has a riser vent, and one inlet pipe near the top of the box.

**Location:** The crib is located northwest of the 202-S Building and south of the 216-S-7 crib.

**Related Sites/Structures:** The site is associated with the 203-S Decontaminated Storage Facility, 204-S Uranium Nitrate Hexahydrate Lag Storage Facility, and the 276-S Organic-Solvent Make-up Facility. The pipelines associated with 216-S-13 crib are discussed in sitecode 200-W-150-PL.

**Process Description:** From January 1952 to June 1967 the unit received liquid waste from the 203-S Decontaminated Metal Storage Facility, the 203-S Uranium Nitrate Hexahydrate (tank farm), 204-S; 204-S Tank Farm & Pumphouse, 205-S Process Vault & Chemical Makeup Building and the 276-S Organic-Solvent Make-up Facility. From June 1967 to July 1972 the unit received occasional sump waste from the 204-S Facility.

**Waste Type:** Process Effluent
Waste Description: The site received mixed, organic waste containing nitrate, methyl isobutyl ketone, and sodium dichromate. Radionuclides include cobalt-60, strontium-90 and cesium-137. The waste was low in salt and is neutral to basic. A 1966 internal memo suggests that 25,000 gallons of hexone from the 276-S tanks 141 and 142 were discharged to the 216-S-13 crib over a three month time period.

Code: 216-S-21
Names: 216-S-21; 216-SX-1; 216-SX-1 Cavern or Crib
Type: Crib
Status: Inactive
Classification: Accepted
Reclassification: None
Start Date: 1/1/1954
End Date: 1/1/1970
Description: The site was interim stabilized in 1991 and is posted "Underground Radioactive Material." The site consists of one wooden crib box with two vent risers and one test well going through the center of the box. This crib box sits in a gravel layer in the bottom of a square pit. The rest of the pit is backfilled.

Location: This site is west of the 241-S Tank Farm and north of 216-S-25.
Related Sites/Structures: The crib is associated with the 241-SX-401 Condenser Facility. The pipeline associated with this crib is sitecode 200-W-160-PL.
Process Description: This site provided subsurface liquid disposal for the 241-SX-401 Condenser Facility.
Waste Type: Chemicals
Waste Description: The site received 241-SX condensate from the condensers in the 401-SX Condenser Facility via the 241-SX-206 Tank. The waste is low in salt and is neutral to basic. The waste contained sodium and ammonium nitrate.

Code: 216-T-3
Names: 216-T-3; 241-T-361-A Reverse Well; 361-T Reverse Well
Type: Injection/Reverse Well
Status: Inactive
Classification: Accepted
Reclassification: None
Start Date: 6/1/1945
End Date: 8/1/1946
Description: The 216-T-3 identified with concrete AC-540 makers and Underground Radioactive Material signs. The reverse well is constructed of steel pipe extending deep into the ground. There are two wells inside the posted area. The one on the north side of the posted area has a cap with the remnants of a gauge. The one near the southwest side of the area has a plain well cap.

Location: This site is located northwest of the 241-T-361 Settling Tank and northeast of the 216-T-6 Crib.
Related Sites/Structures: The associated structures are the 221-T Building and the 241-T-361 Settling Tank. The pipeline from 224-T that fed the reverse well is sitecode 200-W-226-PL.
Process Description: This reverse well received liquid disposal from the 221-T and the 224-T facilities via the 241-T-361 Settling Tank. Discharge to the reverse well was discontinued in 1946 and the effluent was routed to the 216-T-6 crib. Some 224-T waste was diverted to the 241-T-252 Diversion box (per H-2-951).
Waste Type: Process Effluent
**Waste Description:** The reverse well received 221-T and 224-T liquid waste via the 241-T-361 settling tank. The waste included cell drainage from tank 5-6 in 221-T and 224-T waste. The chemical inventory includes nitrate, potassium, sodium, ammonium nitrate, sodium oxalate, fluoride, sulfate and phosphate. The radionuclide inventory includes 3350 grams of plutonium and 2800 curies of fission products.

**Code:** 216-T-5  
**Classification:** Accepted  
**Names:** 216-T-5; 216-T-5 Grave; 216-T-5 Trench; 241-T-5 Trench; 216-T-12  
**Reclassification:** None  
**Type:** Trench  
**Start Date:** 1/1/1955  
**End Date:** 1/1/1955  
**Description:** The 216-T-5 trench is marked and posted with Underground Radioactive Material signs.  
**Location:** This site is located west of the 241-T Tank Farm and northwest of the 216-T-32 Crib.  
**Related Sites/Structures:** The trench is associated with the 221-T Building and the 241-T Tank Farm.  
**Process Description:** This trench received 221-T second cycle supernatant that had been stored in the 241-T-112 tank via an overground pipeline. The trench was active in May 1955. Due to the lack of waste storage space in the tank farms, second cycle waste from the bismuth phosphate fuel separation operations, which had been stored in the tank farms, began to be released to cribs and specific retention trenches in 1948. The extracted plutonium went through two decontamination cycles to further purify it. The first cycle waste was combined with the coating waste. It contained 10% of the fission products and 1% of plutonium. The second decontamination cycle waste contained less than 0.1% of the fission products.  
**Waste Type:** Process Effluent  
**Waste Description:** The site received second cycle supernate waste that contained nitrate, sodium silicate, sodium, ammonium nitrate, fluoride, sulfate, and phosphate. Second cycle waste contained less than 0.1% fission products.

**Code:** 216-T-6  
**Classification:** Accepted  
**Names:** 216-T-6; 216-T-361 (1&2 Cribs); 361-T-1&2 Cribs; 216-T-5  
**Reclassification:** None  
**Type:** Crib  
**Start Date:** 1/1/1946  
**End Date:** 1/1/1951  
**Description:** The 216-T-6 Cribs are delineated with light post and chain and Cave-in Potential signs. The area is surrounded with concrete AC-540 markers and Underground Radioactive Material signs.  
**Location:** The 216-T-6 Cribs are located north of 23rd Street, southwest of the 221-T Building. They are adjacent to the 216-T-3 Reverse Well and the 241-T-361 Tank.  
**Related Sites/Structures:** The associated structures are the 221-T and 224-T Facilities and the 241-T-361 Tank. The pipeline that fed the cribs is sitecode 200-W-227-PL.  
**Process Description:** The cribs received liquid waste from the 221-T and 224-T Facilities via the 241-T-361 Settling Tank. The cribs were built to replace the 216-T-3 Reverse Well when it was abandoned in August 1946. From August 1946 to October 1946, the cribs received cell drainage from Tank 5-6 in the 221-T Building and waste from the 224-T Building via the overflow from 241-T-361
Settling Tank. From October 1946 to June 1951, the site received cell drainage from Tank 5-6 in the 221-T Building. In June 1951, the 241-T-361 Settling Tank was deactivated, and the 224-T Building effluent was rerouted to 216-T-32 Crib. In June 1951 the site was deactivated to evaluate the radionuclide disposal characteristics of the crib. The crib pipeline was blanked south of the 241-T-361 Settling Tank. The 221-T waste was rerouted to the 216-T-7 Crib.

**Waste Type:** Process Effluent  
**Waste Description:** The cribs received waste from 221-T and 224-T that was low in salt, neutral to basic and contained nitrate, sodium, ammonium nitrate, sodium oxalate, fluoride, sulfate, and phosphate.

**Code:** 216-T-7  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 216-T-7; 216-T-7 Tile Field; 216-T-7TF; 241-T-3 Tile Field  
**Type:** Drain/Tile Field  
**Start Date:** 1/1/1948  
**End Date:** 1/1/1955  
**Description:** The 216-T-7 Tile Field is delineated with concrete AC-540 markers and posted with Underground Radioactive Material signs.  
**Location:** The 216-T-7 Tile Field is located adjacent to the west side of the 241-T Farm fence and north of 23rd Street. A portion of the tile field extends inside the tank farm fence.  
**Related Sites/Structures:** The 216-T-7 Tile Field is associated with the 216-T-7 Crib (site code 200-W-52), the 241-T-112, and the 221-T and 224-T facilities.  
**Process Description:** The 216-T-7 crib (site code 200-W-52) received second cycle supernate from 221-T, 224-T waste and tank 5-6 waste after it cascaded through the 241-T-110, 241-T-111 and 241-T-112 tanks. The 216-T-7 Tile Field received overflow from the crib.

**Waste Type:** Process Effluent  
**Waste Description:** The site received second-cycle supernatant waste from the 221-T Building until June 1951 via the 241-T-110, 241-T-111 and 241-T-112 tanks. From June 1951 to June 1952, the site received the 221-T Building effluent plus cell drainage from Tank 5-6 in the 221-T Building. From June 1952 to November 1955, the site received the 221-T Building effluent plus waste from the 224-T Building. The waste is high in salt and is neutral to basic and contains nitrate, potassium, sodium, ammonium nitrate, sodium oxalate, fluoride, sulfate, and phosphate.

**Code:** 216-T-14  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 216-T-14; 241-T-1 Trench; 216-T-1 Grave; 216-T-13  
**Type:** Trench  
**Start Date:** 1/1/1954  
**End Date:** 1/1/1954  
**Description:** The 216-T-14, 216-T-15, 216-T-16 and 216-T-17 trenches were surface stabilized as a unit. The area is identified with concrete AC-540 markers and are posted with Underground Radioactive Material signs. The surface has been planted with wheat grass.  
**Location:** The trench is located north of 23rd Street and northeast of the 241-T Tank Farm.  
**Related Sites/Structures:** The trench is associated with 221-T, the 241-T Tank Farm and UPR-200-W-166.
**Process Description:** In order to provide the tank space needed to support the fuel separations operations in 200 East and West Areas, first cycle supernate stored in the single shell tanks was intentionally discharged to specific retention trenches during 1953 and 1954. Specific retention disposal utilized the moisture retention capacity of the relatively dry soils above the regional ground water table. The volume of liquid disposed to each trench was limited to ten percent of the soil volume between the bottom of the trench and the groundwater table. B Plant and T Plant used the bismuth phosphate process to separate plutonium from irradiated fuel from 1944 through 1956. The first step in the process was to dissolve the metal coating from the fuel rods. The next step dissolved the uranium and extracted the plutonium. The uranium waste was known as the metal waste stream. It contained the bulk of the uranium and 90% of the cesium-137 and strontium-90. The plutonium stream went through two additional decontamination cycles to purify it, producing the first and second cycle waste streams. The first cycle waste stream contained approximately 10% of the long lived fission products and 1% of the plutonium. The coating waste was combined with the first cycle waste. The liquid waste from these processes was initially stored in the single shell tanks in tank farms. By 1948, limited space in the tank farms resulted in the decision to discharge the second cycle waste to cribs. In 1951, the 242-B and 242-T Evaporators began to concentrate the first cycle waste to reduce the volume of waste stored in the tank farms. By 1953, the need for tank space resulted in the first cycle waste, that was being stored in the single shell tanks, to be discharged via overground pipelines to specific retention trenches.

**Waste Type:** Process Effluent

**Waste Description:** The site received the first-cycle supernatant waste from the 221-T Building via the 241-T-104, 241-T-105 and 241-T-106 Tanks in the 241-T Tank Farm. The waste is high in salt and is neutral to basic.

Waste Type: Process Effluent

Waste Description: The site received the first-cycle supernatant waste from the 221-T Building via the 241-T-104, 241-T-105 and 241-T-106 Tanks in the 241-T Tank Farm. The waste is high in salt and is neutral to basic.

Code: 216-T-18

Names: 216-T-18; 216-T-17 Crib; Scavenged TBP Waste; Test Crib for 221-U Building; 216-T-17

Type: Crib

Status: Inactive

Start Date: 1/1/1953

End Date: 1/1/1953

Description: The site is marked with concrete AC-540 markers. The site is posted as an "Underground Radioactive Material" area. The surface is covered with gravel.

Hanford Site Waste Management Units Report
February 2015
Location: This site is located northeast of 241-TY Farm and north of the 216-T-26 Crib.

Related Sites/Structures: The site is associated with the uranium recovery process done at 221-U.

Process Description: Although many references state the crib received scavenged tri-butyl phosphate waste from 221-T (T Plant), it is believed that the reference to T Plant was a typographical error that was carried into subsequent documentation. It should have said 241-T Tank Farm. Document WHC-MR-0227, Tank Wastes Discharged Directly to the Soil at Hanford states that the ferrocyanide (TBP) scavenging process was tested in U Plant in October 1953. HW-33591 states the scavenged waste was pumped from the 241-T-101 tank to a hole in the ground located north of the 241-T-17 monitoring well. Ferrocyanide and nickel were added to the uranium recovery waste to remove cesium-137 from the waste stream so it could be discharged to the ground instead of requiring tank storage. The treated test waste was pumped to a single shell tank for settling (241-T-101) in October 1953. Because of poor pH control during the test, only half of the resultant scavenged waste was discharged to the 216-T-18 crib in December 1953. The other half remained stored in the single shell tank.

Waste Type: Process Effluent

Waste Description: There is a discrepancy in the historical documentation of the waste disposed to this crib. Some references state the site received a test batch of ferrocyanide scavenged tri-butyl phosphate waste from 221-U in December 1953. The waste was high in salt, neutral to basic, and contained nitrate, sodium silicate, sodium, sodium hydroxide, sodium aluminate, fluoride, sulfate, phosphate and nitrite. HW-33591 states that 256,000 gallons of waste was pumped from tank 241-T-101 to a hole in the ground located north of the 241-T-17 monitoring well. Maxfield (1979) states the crib received a million liters of first cycle waste from 221-T that included 1800 grams of plutonium.

Code: 216-T-19
Names: 216-T-19; 216-T-19TF; 216-TX-1; 241-TX-153 Crib and Tile Field; 241-TX-3
Type: Crib
Status: Inactive
Start Date: 1/1/1951
End Date: 1/1/1980
Classification: Accepted
Reclassification: None

Description: The crib and tile field are enclosed within a chain barricade. The crib is enclosed within a second chain barricade that is posted with Cave-In Potential signs. The outer chain is posted with "Underground Radioactive Material" signs. The site construction is wooden crib box with a riser, set into a square bottom pit with sloping sides. The crib has an inlet and outlet pipe. The outlet pipe connects to a tile field. The tile field consists of a central pipe running the length of a rectangular trench with sloping sides. Pipes branch off the main pipe over the length of the trench. After construction, the crib and tile field were backfilled to grade.

Location: This site is located southwest of the 241-TX Tank Farm and east of the 216-Z-7 Crib.

Related Sites/Structures: The crib and tile field are associated with the 242-T Building, 221-T Building, the 224-T Building and the 241-TX-153 Diversion Box. The pipeline to the crib is 200-W-213-PL.

Process Description: The site provided subsurface liquid disposal for process condensate from the waste evaporator in 242-T, cell drainage from Tank 5-6, second-cycle supernatant waste from 221-T, and waste from the 224-T Building.

Waste Type: Process Effluent
### Waste Description:
The site received waste containing nitrate, sodium, ammonium nitrate, sulfate, and phosphate.

**Waste Type:** Water

**Waste Description:**
The trench received first cycle supernate from 221-T that was high in salt, neutral to basic, and contained fluoride, nitrate, nitrite, phosphate, sodium, sodium aluminate, sodium hydroxide, sodium silicate, and sulfate.
Process Description: In order to provide the tank space needed to support the fuel separations operations in 200 East and West Areas, first cycle supernate stored in the single shell tanks was intentionally discharged to specific retention trenches during 1953 and 1954. Specific retention disposal utilized the moisture retention capacity of the relatively dry soils above the regional groundwater table. The volume of liquid disposed to each trench was limited to ten percent of the soil volume between the bottom of the trench and the groundwater table. This site was used for subsurface liquid disposal of first-cycle supernatant waste from 221-T via the 241-TX-109, 241-TX-110, and 241-TX-111 Tanks. The trench was active in July and August 1954. The trench was deactivated when the specific retention capacity was reached by removing the overground piping and backfilling the trench.

Waste Type: Process Effluent

</table>
Waste Type: Steam Condensate
Waste Description: The trench received evaporator bottom waste consisting of sludge from condensing first cycle waste in the 242-T Evaporator. It was high in salt, neutral to basic, and contained fluoride, nitrate, nitrite, phosphate, sodium, sodium aluminate, sodium hydroxide, sodium silicate, and sulfate.

Code: 216-T-26   Classification: Accepted
Names: 216-T-26; 216-TX-1 Crib; 216-TY-1 Cavern; 216-TY-1 Crib; 241-TX-1 Cavern   Reclassification: None
Type: Crib   Start Date: 1/1/1955
Status: Inactive   End Date: 1/1/1956
Description: The 216-T-26, 216-T-27 and 216-T-28 cribs are enclosed within a common steel post and chain barricade that is posted "Underground Radioactive Material". The 216-TY-201 flush tank is located in the northeast corner of the area. Two small concrete pads are located east of the crib area.
Location: This site is located inside 200 West Area, south of 23rd Street and east of Camden Ave.
Related Sites/Structures: The associated structures are the 221-T Building, the 241-TY-101, 241-TY-103, and 241-TY-104 tanks and 241-T-112, the 216-TY-201 flush tank. The pipelines associated with this crib are 200-W-175-PL and 200-W-188-PL.
Process Description: The site provided subsurface liquid disposal for first-cycle scavenged supernatant waste from 221-T via an underground pipeline and the 216-TY-201 Flush Tank after cascading through the 241-TY-101, 241-TY-103, and 241-TY-104 tanks and later from 241-T-112 tank.
In 1955, in order to provide enough tank space in the tank farms required to continue to support fuel separation operations and plutonium production, T Plant began to scavenge newly generated first cycle waste before sending it to the tank farms. By adding ferrocyanide to the waste stream, the cesium-137 was precipitated, significantly reducing the quantity of long-lived radionuclides. This process allowed the first cycle waste to be discharged to the ground instead of to single shell tanks.
The unit consists of a steel inlet pipe reducing to a steel pipe, below grade. This pipe branches to four steel pipes, each one extending to a concrete open-end sewer pipe. These structures lie in an excavation with a side slope of 1:1.5. A gravel fill is covered by earth backfill.

Waste Type: Process Effluent
Waste Description: The site received first-cycle scavenged supernatant waste from T Plant containing ferrocyanide, fluoride, nitrate, nitrite, phosphate, sodium, sodium aluminate, sodium hydroxide, sodium silicate and sulfate.

Code: 216-T-32   Classification: Accepted
Names: 216-T-32; 216-T-6; 241-T #1 & 2 Cribs   Reclassification: None
Type: Crib   Start Date: 1/1/1946
Status: Inactive   End Date: 1/1/1952
Description: The crib is located inside the 241-T Tank Farm fence. The fence is posted with Radiological Buffer Area/Underground Radioactive Material signs. The tank farm has a gravel surface. The crib is not separately identified.

</tbody>
</table>
**200-EA-1**

**Code:** 207-A-NORTH  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 207-A-NORTH; 207-A-NORTH Retention Basin; 207-A; 207-A North; 207-A Retention Basin

**Type:** Retention Basin  
**Start Date:** 1/1/1977  
**End Date:** 1/1/1999

**Status:** Inactive

**Description:** The 207-A North basins consist of three Hypalon lined, concrete basins. The basins are surrounded with posts and chain. There is no radiological posting on the north basins.

**Location:** The 207-A-NORTH basins are located east of 242-A Evaporator building, adjacent to the 207-A-SOUTH basin.

**Related Sites/Structures:** The basins are associated with the 242-A Evaporator facility, 216-A-25 Pond and 216-B-3 Pond. The pipelines from 242-A Evaporator to the 207-A basins are sitecode 200-E-234-PL. The basin distribution lines are sitecode 200-E-235-PL.

**Process Description:** The basins were alternately filled, sampled, and emptied when meeting specifications. The basins discharged via pipeline to the 216-B-3C pond. Discharge to the 216-B-3C pond was discontinued in early 1997 and the basin effluent was diverted to the 200 Area Treated Effluent Disposal Facility (TEDF). The basin was physically isolated in 1999. The isolation is documented in ECN-653675 and Work Package EL-98-00091.

A 4-in (10 cm) fill line enters each basin, approximately 2 ft (0.6 m) long (inside basin structure) and a 3-in (7.6 cm) drain line exits.

**Waste Type:** Water

**Waste Description:** The basins have been receiving steam condensate from the 242-A Evaporator since 1977. Effluent was originally sent to the 216-A-25 (Gable Pond) and later to the B Pond system. When the B-Ponds became inactive, effluent was diverted to TEDF.

**Code:** 216-A-1  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 216-A-1; 216-A-1 Cavern; 216-A-1 Trench

**Type:** Crib  
**Start Date:** 1/1/1955  
**End Date:** 1/1/1955

**Status:** Inactive

**Description:** The 216-A-1 and 216-A-7 cribs are located within the same radiologically posted area. They are marked and posted with Underground Radioactive Material signs.

**Location:** The site is located inside the 200 East Area perimeter fence extension, east of the 241-A Tank Farm, along Canton Avenue.

**Related Sites/Structures:** The site is associated with the 202-A sample pit #3 and the 200-E-158-PL pipeline.

**Process Description:** The site received start up waste from PUREX during November and December 1955 via an overground pipeline. When the specific retention capacity was reached, the site was deactivated by removing the overground piping and backfilling. The site is composed of 15-centimeter (6-inch) perforated Vitrified Clay Pipe (VCP), 9.1 meters (30 feet) long, running horizontally at 2.7 meters (9 feet) below grade, with two 9.1 meter (30-foot) lengths of 15-
centimeter (6-inch) perforated VCP placed perpendicularly to the first length of pipe, forming an H pattern. There is approximately 1.8 meters (6 feet) or 310 cubic meters (11,000 cubic feet) of coarse rock in the excavation bottom. The side slope, surface to 2.1 meters (7 feet) deep, is 1:1.5, 2.1 meters (7 feet) to site bottom is 1:2.

**Waste Type:** Water

**Waste Description:** The site received the depleted uranium waste from the cold startup run in the 202-A Building. Some cesium-137, cobalt-60 and strontium-90 is also present.

---

**Code:** 216-A-2

**Classification:** Accepted

**Names:** 216-A-2; 216-A-2 Cavern; 216-A-2 Crib

**Reclassification:** None

**Type:** Crib

**Start Date:** 1/1/1956

**End Date:** 1/1/1963

**Description:** The crib is covered with gravel and marked with concrete AC-540 posts. The crib is located within a larger URM, known as 200-E-103. The unit consists of 15-centimeter (6-inch) perforated vitrified clay pipe lines. Two 6.1-meter (20-foot) lengths form a cross pattern horizontally, 6.4 meters (21 feet) below grade. It has approximately 1.8 meters (6 feet) of coarse rock with a volume of 140 cubic meters (5,000 cubic feet) and is backfilled over. The side slope from grade to 6.4 meters (21 feet) is 1:1.5 and from 6.4 meters (21 feet) to 8.2 meters (27 feet) is 1:2.

**Location:** The 216-A-2 site is located south of the 202-A Building (PUREX), inside the facility exclusion area fence.

**Related Sites/Structures:** The site is associated with the 202-A Building, the 241-A-151 Diversion Box and 200-E-103. The pipelines associated with the crib are sitecode 200-E-183-PL and 200-E-184-PL.

**Process Description:** The site received organic waste from the 202-A building via two 10 centimeter (4 inch) diameter vitrified clay pipes (see sitecode 200-E-184-PL).

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The site received organic wastes from the 202-A Building. The waste is low in salt and is neutral to basic.

---

**Code:** 216-A-3

**Classification:** Accepted

**Names:** 216-A-3; 216-A-3 Cavern; 216-A-3 Crib

**Reclassification:** None

**Type:** Crib

**Start Date:** 1/1/1956

**End Date:** 4/1/1981

**Description:** The crib is marked and posted with Underground Radioactive Material signs.

**Location:** The unit is located directly south of the 275-EA Building, west of Canton Avenue and north of the 202-A Building.

**Related Sites/Structures:** The crib is associated with 203-A. The 216-A-3 pipeline is sitecode 200-E-168-PL.

**Process Description:** From 1956 to 1967, the site received silica-gel regeneration waste and pump house drainage from 203-A and drainage from the UNH storage pit. The silica gel discharge was discontinued in 1967. The site was taken out of service in April 1981. The waste was rerouted so that any
low level radioactive waste was sent to the 216-A-29 Ditch. The unit contains a 10-centimeter (4-inch) Schedule 10 perforated 304 stainless steel pipe placed horizontally 2.4 meters (8 feet) below grade and two 6.1-meter (20-foot) lengths of this pipe placed perpendicularly to the first pipe, forming an H pattern. The site has approximately 2.4 meters (8 feet) of gravel fill with a volume of 280 cubic meters (10,000 cubic feet) and has been backfilled. The side slope surface to 2.1 meters (7 feet) deep is 1.5:1 and from 2.1 meters (7 feet) to the site bottom is 2:1.

Waste Type: Barrels/Drums/Buckets/Cans
Waste Description: Until November 1967, the site received wastes from the silica-gel regeneration in the 203-A Building, the uranyl nitrate hexahydrate (UNH) storage pit drainage, and the liquid waste from the 203-A Pump House. After November 1967, the site received UNH Storage Pit drainage, liquid drainage, liquid waste from the 203-A Building enclosure sumps, and the heating coil condensate from the P1 through P4 UNH tanks. Between 1967 and 1970, the site discontinued receiving discharge from silica-gel regeneration wastes. The above wastes are reworked through the uranium cycle and any resulting waste with low radioactivity are sent to 216-A-29. The waste included uranium, cesium-137, strontium-90 and ruthenium-106.

<td>Status</td>
<td>Inactive</td>
</tr>
<tr>
<td>Description</td>
<td>The site is located within a large gravel area, known as the PUREX Stabilized Area (sitecode 200-E-103). A large green vent riser extends above the surface.</td>
</tr>
<tr>
<td>Location</td>
<td>The site is located south of the 202-A Building and east of 216-A-2, inside the PUREX Exclusion Fence.</td>
</tr>
<tr>
<td>Release</td>
<td>UPR-200-E-15 documents the event that occurred in 1958, when the 216-A-4 Crib plugged and caused contaminated liquid to flood the ground surface. The contaminated soil was placed into a trench near the south border of the crib (see sitecode 200-E-102) and covered with 0.3 meters (1 foot) of soil.</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The 216-A-4 crib is associated with 216-A-2 Crib, 241-A-151, the PUREX laboratories, UPR-200-E-15 and 200-E-103. The site has also been identified as receiving drainage from the 291-A Stack (see Site Comment section). The pipelines associated with this site are 200-E-183-PL, 200-E-185-PL and 200-E-196-PL.</td>
</tr>
<tr>
<td>Process</td>
<td>The crib received laboratory cell drainage from the 202-A building, and possibly drainage from the 291-A stack. The unit consists of two 6.1-meter (20-foot) lengths of 15-centimeter (6-inch) perforated vitrified clay pipe, forming a cross pattern horizontally, 5.5 meters (18 feet) below grade. The excavation has 2.4 meters (8 feet) of coarse rock fill with a volume of 280 cubic meters (10,000 cubic feet) and has been backfilled. The side slope surface to 5.5 meters (18 feet) deep is 1:1.5 and from 5.5 meters (18 feet) to the site bottom, 1:2.</td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Asbestos (friable)</td>
</tr>
<tr>
<td>Waste Description:</td>
<td>The site received the laboratory cell drainage from the 202-A Building (the site was reported to have also received 291-A-1 Stack drainage, see the Site Comments section under the Summary tab). The waste is low in salt and is neutral to basic. The 216-A-4 Crib also received waste solution from the 216-A-2 waste collection tank, the U Cell U-3 and U-4 laboratory waste receiver tanks (located in the acid storage vault), the dissolver off-gas scrubbers and the 241-A-151 Diversion Box Catch Tank. 216-A-4 was intended to receive a maximum of (75 gallons per minute) low level radioactive liquid waste. Waste volume from the laboratory waste and cell drain was 52,990 liters (14,000 gallons).</td>
</tr>

</table>
**Code:** 216-A-5  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 216-A-5; 216-A-5 Cavern  
**Type:** Crib  
**Start Date:** 1/1/1955  
**End Date:** 1/1/1966  
**Status:** Inactive  

**Description:** The crib is marked and posted with Underground Radioactive Material signs.  

**Location:** The crib is located south of the 202-A Building between the inner and outer PUREX exclusion area fences.  

**Related Sites/Structures:** The site is associated with the PUREX process, 200-E-58 and the 216-A-10 crib. The 216-A-5 crib pipeline is sitecode 200-E-239-PL.  

**Process Description:** The crib received acidic process condensate from 202-A from December 1955 through November 1961. After 1961, the crib was used as a backup waste site for the 216-A-10 crib. It received additional waste in October 1966. The unit consists of a 20-centimeter (8-inch) vitrified clay pipe (VCP) placed horizontally, 7.3 meters (24 feet) below grade and two 10.7-meter (35-foot) lengths of 20-centimeter (8-inch) VCP placed perpendicular to the first pipe, forming an H pattern. The site is backfilled with approximately 2.4 meters (8 feet) of coarse rock fill with a volume of 595 cubic meters (21,000 cubic feet). The side slope from the surface to 7.3 meters (24 feet) deep is 1:1.5 and from 7.3 meters (24 feet) to the bottom, 2:1.  

**Waste Type:** Barrels/Drums/Buckets/Cans  

**Waste Description:** Until November 1961, the site received process condensate from the 202-A Building. From November 1961 to October 1966, the site was active but received no waste (backup for the 216-A-10 Crib). In October 1966, the site received process condensate from the 202-A Building. The waste is acidic.

**Reclassification:** None  
**Names:** 216-A-6; 216-A-6 Cavern; 216-A-6 Crib  
**Type:** Crib  
**Start Date:** 11/1/1955  
**End Date:** 1/1/1970  
**Status:** Inactive  

**Description:** The site is marked with AC-540 markers and posted with Underground Radioactive Material signs. The unit was constructed with a 38-centimeter (15-inch) Vitrified Clay Pipe (VCP) placed horizontally 3.7 meters (12 feet) below grade the length of the unit. Five 31-meter (100-foot) lengths of perforated 15-centimeter (6-inch) VCP are placed perpendicularly to the first pipe at 6.1-meter (20-foot) intervals. The site contains approximately 2,580 cubic meters (91,000 cubic feet) of coarse gravel fill, backfilled over. The side slope from the surface to 2.1 meters (7 feet) is 1:1 and from 2.1 meters (7 feet) to the site bottom, 2:1.  

**Location:** The site is located outside the 200 East Area perimeter fence, east of the Plutonium Uranium Extraction (PUREX) facility and south of 241-AP Tank Farm.  

**Release Description:** UPR-200-E-19, UPR-200-E-21, UPR-200-E-29 are associated with 216-A-6.  

**Related Sites/Structures:** The crib is associated with the 216-A-30 crib and 200-E-113-PL.  

**Waste Type:** Misc. Trash and Debris
Waste Description: Until January 1961, the site received the steam condensate, the equipment disposal tunnel floor drainage, the water-filled door drainage and the slug storage basin overflow waste from the 202-A Building. From January 1961 to March 1966, the site was inactive. After March 1966, the site received the previously mentioned effluents again. The waste is low in salt and is neutral to basic.

Code: 216-A-9 Classification: Accepted
Names: 216-A-9; 216-A-9 Crib Reclassification: None
Type: Crib Start Date: 3/1/1956
Status: Inactive End Date: 8/1/1969

Description: The crib is a surface stabilized area, marked with light post and chain. It is posted as an Underground Radioactive Material area.

Location: 216-A-9 Crib is located inside 200 East Area, north of 4th Street. The site is located 150 meters (500 feet) west of the 241-A Tank Farm and 275 meters (900 feet) north of 275-EA Building along Fourth Street.

Related Sites/Structures: The site is associated with PUREX processes and N Reactor liquid waste. The pipeline associated with this crib is sitecode 200-E-238-PL.

Process Description: The site contains a 25 centimeter (10-inch) Schedule 30 steel perforated pipe, placed horizontally, 2.7 meters (9 feet) below grade. The site has 1,840 cubic meters (65,000 cubic feet) of gravel fill and has been backfilled. The side slope is 2:1. The crib was used for disposal of PUREX acid fractionator condensate and cooling water. The crib surpassed its capacity in 1958 and was taken out of service. In April 1966, the crib was approved for disposal of liquid N Reactor decontamination waste, that was to that was transported to the crib in tanker trucks. The waste was discharged into the Truck Unloading Station adjacent to the crib. This process continued until October 1966. The crib was inactive until August 1969, when PUREX acid fractionator waste was again sent to the 216-A-9 crib.

Waste Type: Oil

Waste Description: Until February 1958, the site received the acid fractionator condensate and the condenser cooling water from the 202-A Building. From February 1958 to April 1966, the site was inactive. From April 1966 to October 1966, the site received N Reactor decontamination waste via a manhole at the truck unloading station. From October 1966 to August 1969, the site was inactive. In August 1969, the site received the acid fractionator condensate from the 202-A Building. The waste is acidic.

Code: 216-A-10 Classification: Accepted
Names: 216-A-10; 216-A-10 Crib Reclassification: None
Type: Crib Start Date: 1/1/1956
Status: Inactive End Date: 1/1/1987

Description: The site is covered with gravel with no vegetation growing on it. It is surrounded with light posts and chain and posted as Underground Radioactive Material.

Location: The site is located south of the 202-A Building.

Although the crib was built in 1956, it did not receive contaminated waste until 1961. Early discharge reports list effluent volumes for the 216-A-10 crib that did not contain any plutonium or beta/gamma values. A 1980 telephone conference documentation sheet explained that the crib received water testing effluent in 1956. The crib was active until 1978. The crib was inactive until October 1981, when it again received acidic process condensate from 202-A. The crib was deactivated in March 1987.

The unit consists of a 20-centimeter (8-inch) SST pipe placed horizontally 9.1 meters (30 feet) below grade, 8.2 meters (27 feet) east of the centerline. The site has a wedge-shaped cross section and a side slope of 1:1.5. The excavation has 4.6 meters (15 feet) of rock fill with a volume of 11,700 cubic meters (414,000 cubic feet) of rock fill and has been backfilled over.

During 1956, the site was used only for testing purposes using nonradioactive water. From 1956 to November 1961, the site was inactive. From November 1961 to January 1978, the site received process condensate from the 202-A Building. From January 1978 to October 1981, the site was again inactive. From October 1981 to 1986, the site received the process condensate from the 202-A Building. The crib received Process Distillate Discharge (PDD), a corrosive/mixed waste, at an average flow rate of 227 liters/minute (60 gallon/minute). The discharge was an acidic waste stream generated from two product concentrators in the Plutonium Uranium Extraction (PUREX) process. The pH of this waste ranged from 1.0 to 2.5 standard units which makes it a corrosive mixed waste. Approximately 62.6 million kilograms (138 million pounds) of waste were disposed of in the crib in 1986. Characterization holes placed through the crib in 2003 found cesium-137 at depths ranging from 48 to 84 feet below ground surface and europium-154 at approximated 84 feet below ground surface.

The unit is composed of two, 1.2 meter (4 foot) diameter, 1.2 meter (4 foot) long bell-end, reinforced concrete sewer pipes placed vertically end to end. It is filled with 1.8 meters (6 feet) of stone. Approximately 11 meters (35 feet) of vent pipe extends from the grade surface to the concrete drain structure. 1.6 meters (5.5 feet) of vent pipe extends above grade.

The site is located approximately 82 meters (270 feet) south of the center of the 202-A Building and east of the Sampler Pit #4.

The site is associated with PUREX, the 216-A-10 crib and the 216-A-5 crib. The pipeline to this French drain is 200-E-242-PL.

The drain received condensate and storm water that collected in the drain at the bottom of the Process Condensate Sample Pit #4. A leak in one of the fittings may have allowed radioactive liquid to be released to the french drain. A manhole cove on the top of the sample pit may have allowed stormwater to enter the pit.

The site received the drainage from the 216-A-10 Process Condensate Sampler Pit #4. The waste is acidic. The site contains less than 50 curies total beta activity.

**Code:** 216-A-15

**Type:** French Drain

**Status:** Inactive

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The site received the drainage from the 216-A-10 Process Condensate Sampler Pit #4. The waste is acidic. The site contains less than 50 curies total beta activity.
### Site 1: 216-A-18 Trench

**Start Date:** 11/1/1955  
**End Date:** 1/1/1956  
**Status:** Inactive  
**Description:** The site is marked and posted with Underground Radioactive Material signs.  
**Location:** The site is located outside of the 200 East Area perimeter fence, east of the 241-AX Tank Farm, along Canton Avenue.  
**Related Sites/Structures:** The site is associated with the 202-A facility.  
**Process Description:** The trench received start up waste from PUREX via an aboveground pipeline. The site was an excavation with a side slope of 1:2. No crib structure was ever built.  
**Waste Type:** Misc. Trash and Debris  
**Waste Description:** The site received the depleted uranium waste from the cold start-up run at 202-A Building.

### Site 2: 216-A-19 Trench

**Start Date:** 11/1/1955  
**End Date:** 1/1/1956  
**Status:** Inactive  
**Description:** The site is marked and posted with Underground Radioactive Material signs. In February 2001, a narrow area posted with Soil Contamination Area signs extended between the 216-A-19 southern site boundary and northern boundary of 216-A-34.  
**Location:** The site is located east of the 200 East Area perimeter fence, north of the 216-A-8 Crib.  
**Process Description:** The site received PUREX start up waste during November and December 1955. Several references state it also received condenser cooling water from the 241-A-431 building via the 216-A-34 Ditch. However, drawings do not show the 216-A-34 Ditch connecting to the 216-A-19 Grave. HW-40763 states that in December 1955, the ditch received PUREX waste from "C-203 and C-204 tanks". The ditch was also used for disposing of depleted uranium from the cold start up of PUREX.  
**Waste Type:** Storage Tank  
**Waste Description:** The site received the 241-A-431 Building contact condenser cooling water via the 216-A-34 Ditch and the depleted uranium waste from the cold start-up run at the 202-A Building. HW-40763 states that in December 1955, the ditch received PUREX waste from "C-203 and C-204 tanks".

### Site 3: 216-A-20 Trench

**Start Date:** 11/1/1955  
**End Date:** 1/1/1956  
**Status:** Inactive  
**Description:** The site is marked and posted with Underground Radioactive Material signs.  
**Location:** The site is located east of the 200 East Area perimeter fence, north of the 216-A-8 Crib.  
**Process Description:** The site received PUREX start up waste during November and December 1955. Several references state it also received condenser cooling water from the 241-A-431 building via the 216-A-34 Ditch. However, drawings do not show the 216-A-34 Ditch connecting to the 216-A-19 Grave. HW-40763 states that in December 1955, the ditch received PUREX waste from "C-203 and C-204 tanks". The ditch was also used for disposing of depleted uranium from the cold start up of PUREX.  
**Waste Type:** Storage Tank  
**Waste Description:** The site received the 241-A-431 Building contact condenser cooling water via the 216-A-34 Ditch and the depleted uranium waste from the cold start-up run at the 202-A Building. HW-40763 states that in December 1955, the ditch received PUREX waste from "C-203 and C-204 tanks".
Type: Trench  
Start Date: 11/1/1955
Status: Inactive  
End Date: 12/1/1955
Description: The site is marked and posted with Underground Radioactive Material signs.
Location: The site is located east of the 200 East Area perimeter fence, north of the 216-A-8 Crib.
Release Description: HW-60807 includes a comment note, stating that 216-A-20 overflowed. The overflow covered an area measuring approximately 30 meters (100 feet) north and 60 meters (200 feet) east of the crib site. The overflow area was hand drawn onto H-2-56521.
Process Description: 216-A-20 was originally a test hole excavated with a drag line and used for PUREX start-up waste. The site also received cooling water from the 241-A-431 building contact condenser via the 216-A-34 Ditch. The site was backfilled when the specific retention capacity was reached.
Waste Type: Process Effluent
Waste Description: The site received the 241-A-431 Building contact condenser cooling water via the 216-A-34 Ditch and the depleted uranium waste from the cold start-up run at the 202-A Building.

Code: 216-A-21  
Classification: Accepted
Reclassification: None
Name: 216-A-21 Crib
Type: Crib  
Start Date: 10/1/1957
Status: Inactive  
End Date: 6/1/1965
Description: The crib is covered with gravel. It is marked and posted with Underground Radioactive Material signs. A 10-centimeter (4-inch) stainless steel distribution line runs horizontally through the length of the site, 2.1 meters (7 feet) below grade. Branching horizontally from this distribution line are four 1.2-meter (4-foot) sections of 10-centimeter (4-inch) tubing. Branching vertically at the same locations are four 2.4-meter (8-foot) sections of 10-centimeter (4-inch) schedule 40 perforated pipe running to the bottom of the site. The excavation is V-shaped in cross-section with a side slope of 1:1.5. The excavation has approximately 1.8 meters (6 feet) of gravel fill and is backfilled over.
Location: The site is located south of the 202-A Building inside the PUREX Exclusion Fence.
Related Sites/Structures: The site is associated with the 202-A facility, 293-A, 291-A, 293-A and 200-E-103. The VCP pipeline associated with this crib is sitecode 200-E-193-PL. The stainless steel line is sitecode 200-E-196-PL.
Waste Type: Soil
Waste Description: Until June 1958, the site received sump waste from 293-A Building. From June 1958 to December 1958, the site was inactive. From December 1958 to June 1965, the site received the above effluent, laboratory cell drainage from the 202-A Building, and the 291-A-1 Stack drainage. The waste is low in salt and is neutral to basic.

Code: 216-A-22  
Classification: Accepted
Reclassification: None
Type: Crib  
Start Date: 11/1/1955
The crib is marked with a single cement AC-540 marker and Underground Radioactive Material signs.

The site is located along the north wall of the 203-A Building, north of PUREX.

UPR-200-E-17 is described as yellow, uranium contaminated soil on the 216-A-22 Crib. No date is provided for this event, but it was documented in a 1959 report. Another release occurred on April 20, 1961. A UNH tank truck overflowed on the loading apron at 203-A. One thousand three hundred and thirty five pounds of depleted uranium was lost to the ground. The solution drained through an open plug valve in the sump and then went into the 216-A-22 French Drain. No WIDS sitecode is associated with this event.

The site is associated with the 203-A facility and UPR-200-E-17. The pipeline associated with this drain is sitecode 200-E-159-PL.

The 203-A tank farm was used for storage and shipping of uranyl nitrate hexahydrate (UNH) product and concentration of UNH waste. It consisted of 460,000 liter (100,000 gallon) stainless steel tanks for UNH storage and three smaller nitric acid tanks. Two 10-centimeter (4-inch) effluent pipes are associated with the french drain. One pipe entered the crib 0.5 meters (1.5 feet) above original grade. This pipe is no longer visible as it was covered over to stabilize contamination. The pipe from the truck loadout apron enters the site horizontally, 2.4 meters (8 feet) below grade. The excavation is 4.9 meters (16 feet) in diameter at grade and 1.8 meters (6 feet) in diameter at the bottom, with a side slope of 3:1 (V:H). Approximately 3 meters (10 feet) of gravel fills the excavation bottom, and the site is backfilled.

The site received the drainage from the 203-A Building truck loadout apron, the sump waste from the 203-A Building enclosure, and the heating coil condensate from the P-1 through P-4 uranyl nitrate hexahydrate (UNH) tanks. The waste is low in salt, neutral to basic, and contains less than 1 curie total beta activity. The site received some uranium from the discharges. In 1961, a release from a UNH truck spilled 1335 pounds of uranium on the truck apron. Some of this drained into the 216-A-22 crib.

There are no visible surface features for this drain. The unit is composed of three clay pipe (each 5 feet long) segments buried vertically. Some references state the clay pipe diameter is 3 feet and some state the diameter is 4 feet.

The site is located inside the PUREX security fence, south of the 291-A Control House and approximately 4.57 meters (15 feet) south of 216-A-26A French Drain.

This site is associated with the 291-A Fan Control Building, the 216-A-26A french drain and pipeline 200-E-270-PL.

This french drain was installed to replace the 216-A-26A french drain. Both drains received effluent from floor drains inside the 291-A Fan House. 216-A-26 was removed from service in 1991.

Chemicals
**Waste Description:** The site received the floor drainage from the 291-A Fan Control House. The waste was low in salt, neutral to basic, and contains less than 1 curie of total beta activity. The quantity of discharge is unknown.

**Code:** 216-A-26A  
**Classification:** Accepted  
**Reclassification:** None

**Type:** French Drain  
**Start Date:** 1/1/1959  
**End Date:** 1/1/1965

**Status:** Inactive  
**Description:** There are no surface features for this drain. The unit is composed of three sections of clay pipe each 1.5 meters (5 feet) long, placed vertically end to end below grade. Some references state the pipe diameter was 0.9 meters (3 feet) and other references state the diameter as 1.2 meters (4 feet).

**Location:** The french drain is located inside the PUREX security fence, south of the 291-A Building.

**Related Sites/Structures:** The site is associated with the 291-A stack, fan house, the 216-A-26 French Drain and pipeline 200-E-270-PL.

**Waste Type:**Misc. Trash and Debris

**Waste Description:** The site received the floor drainage from the 291-A Fan Control Room. The waste is low in salt, neutral to basic, and contains less than 1 curie total beta activity.

**Waste Description:** The site received the floor drainage from the 291-A Fan Control House. The waste was low in salt, neutral to basic, and contains less than 1 curie of total beta activity. The quantity of discharge is unknown.
Type: Crib  
Start Date: 1/1/1958

Status: Inactive  
End Date: 1/1/1967

Description: The site is not currently marked or posted.

Location: The site was located near the northwest corner of the 203-A Building, north of PUREX.

Process Description: The 203-A tank farm was used for storage and shipping of uranyl nitrate hexahydrate (UNH) product and concentration of UNH waste. It consisted of 460,000 liter (100,000 gallon) stainless steel tanks for UNH storage and three smaller nitric acid tanks. The french drain received liquid waste from the 203-A sumps and heating coil condensate from the uranyl nitrate tanks. The effluent piping to the site was blanked off in November 1976 when the flow rate exceeded the infiltration capacity. The excavation had a 6-meter (20-foot) diameter at grade and a 3-meter (10-foot) bottom diameter, with a truncated cone shape. The excavation contained approximately 2.7 meters (9 feet) of gravel fill and was backfilled to grade. The unit contained a 10-centimeter (4-inch) stainless steel 304 perforated pipe, 5.2 meters (17 feet) long, extending horizontally 1.2 meters (4 feet) below grade and a 5-centimeter (2-inch) diameter, schedule 40, perforated stainless steel liquid level riser pipe, 4 meters (13 feet) long.

Waste Type: Water

Waste Description: The site received the liquid waste from the 203-A Building enclosure sumps and the heating coil condensate from the P1 through P4 uranyl nitrate hexahydrate (UNH) tanks. The waste is low in salt and is neutral to basic. Uranium may have been discharged to the waste site.

Code: 216-A-29

Classification: Accepted

Reclassification: None

Names: 216-A-29; 216-A-29 Ditch; A-29 Ditch; Snow's Canyon

Type: Ditch  
Start Date: 1/1/1955

Status: Inactive  
End Date: 1/1/1991

Description: The ditch was backfilled and surface stabilized in 1991. It is posted as an Underground Radioactive Material area.

Location: The ditch originated southeast of the 241-A Tank Farm (east of 241-AP tank farm) outside of the 200 East Area perimeter fence. The ditch emptied into 216-B-3-3 Ditch which terminated at 216-B-3 Pond.

Related Sites/Structures: The chemical sewer line that fed the ditch is sitecode 200-E-187-PL. The ditch had two earth dams with wooden gates structures to regulated water flow. They were located at N41150, W45500 and N41550, W45200. The ditch is also associated with the 216-B-3 Pond, the 216-B-3 ditches, 200-E-286 swamp (A Swamp) and UPR-200-E-51.

Process Description: From 1946 through 1953, a shallow depression, known as the Powerhouse Swamp and also the "A Swamp" (See sitecode 200-E-286) was located at W46600/N40400. This swamp area was located approximately in the same location as the head end of the 216-A-29 ditch. The head end of the 216-A-29 ditch was modified several times. The final relocation of the head end occurred 1983, during the construction of the 241-AP tank farm. From 1955 through 1991, the 216-A-29 ditch followed a natural depression, known as Snow's Canyon, toward the 216-B-3 ditch and pond area. The ditch received waste from the PUREX facility between November 1955 and September 1991.
**Waste Type:** Soil

**Waste Description:** The unit received waste from 202-A Chemical Sewer, acid fractionator condensate and condenser cooling water that flow to 216-B-3 Pond. Until December 1957, the site received process cooling water and chemical sewer waste from 202-A. From December 1957 to February 1958, the site received all of the above, but the process cooling water was rerouted to 216-A-25 Pond. From February 1958 to December 1962, the ditch received the above plus acid fractionator condensate from 202-A. From December 1962 to December 1963, the ditch also received seal cooling water from air sampler vacuum pumps in 202-A. From December 1963 to January 1966 the vacuum pump cooling water was rerouted to 216-A-35 French Drain.

**Type:** Crib

**Status:** Inactive

**Description:** The crib is surrounded with concrete AC-540 markers and posted with Underground Radioactive Material signs.

**Location:** The crib is located outside the 200 East Area perimeter fence, east of the 202-A Building.

**Related Sites/Structures:** The crib is associated with PUREX operations. Two 8-inch (20 cm) carbon steel gage wells extending from the bottom to 3 ft (0.9 m) above grade. A 15-inch (38 cm) diameter vent riser extending from the distribution pipe to 3 ft (0.9 m) above grade. Two 16-in (41 cm) by 16-inch (41 cm) by 8-inch (20 cm) concrete pads supporting the gage wells. 47,720 square feet (4430 square meters) of polyethylene sheets were added. The site is associated with the 216-A-6 Crib. The pipeline from PUREX associated with this crib is sitecode 200-E-113-PL and 200-E-260-PL. The pipeline from the 216-A-37-1 distribution box to the 216-A-30 crib distribution box is sitecode 200-E-232-PL. The pipeline from 216-A-30 to the 216-A-37-2 Distribution Box is 200-E-233-PL.

**Process Description:** The unit includes two distribution pipes: one 38 cm (15 inch) corrugated perforated pipe running approximately 1.2 meters (4 ft) below grade to the center of the unit, the other a 41 cm (16 inch) steel pipe running parallel to the other, 1.2 meters (4 ft) below grade to the center of the unit, then angling 45 degrees and changing to a 38 cm (15 inch) corrugated, perforated pipe running 2.1 to 2.4 meters (7 to 8 ft) below grade to the end of the unit. It is filled with 1.5 meters (5 ft) or a total of 3,480 cubic meters (123,000 cu ft) of gravel, and the site has been backfilled. The side slope is 1.5:1.

**Waste Type:** Soil

**Waste Description:** Until 11/65, the site received the steam condensate, equipment disposal tunnel floor and water-filled door drainage, and the slug storage basin overflow waste from 202-A Building. From 11/65 to 1/70, the 216-A-6 Crib was restored to service to receive some of the above effluents because the effluent flow rate had exceeded the infiltration capacity of this unit. From 1/70 to 6/92, the site received the above effluent because the 216-A-6 Crib was deactivated. The waste was low in salt and is neutral to basic. TPA Milestone M-17-22A required that PUREX steam condensate discharge to 216-A-30 Crib be discontinued by June 1992. The fourth amendment to the TPA (89-10 Rev 3) documents that the steam condensate stream was shut down in June 1992 and that all discharges to this crib were discontinued. The unit was permanently isolated in 1995.

**Names:** 216-A-33; 216-A-33 Dry Well; 216-A-26B  
**Reclassification:** None

**Type:** French Drain  
**Start Date:** 1/1/1955

**Status:** Inactive  
**End Date:** 1/1/1964

**Description:** The 291-AE Filter Building has been built over the site where this drain was located. The stainless steel (M21-UD) inlet pipe entered the unit 1.5 meters (5 feet) below grade. The french drain had a carbon steel cover.

**Location:** The site is located inside the PUREX security fence, south of 202-A, and southwest of the 291-A stack.

**Related Sites/Structures:** The french drain is associated with the 291-A Fan House and pipeline 200-E-269-PL.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The site received the bearing coolant waste from the 291-A-1 Stack electrical exhaust fans. The waste is low in salt, neutral to basic, and contains less than 1 curie of total beta activity.

---

**Names:** 216-A-34; 216-A-34 Crib; 216-A-34 Ditch  
**Reclassification:** None

**Type:** Ditch  
**Start Date:** 11/1/1955

**Status:** Inactive  
**End Date:** 12/1/1957

**Description:** The site is marked and posted with Underground Radioactive Material signs. It has a small amount of bunch grass vegetation growing on it. In February 2001, a posted Soil Contamination Area extended northward from the edge of 216-A-34 to 216-A-19.

**Location:** The site is located east of the 200 East Area perimeter fence. It is north of the 216-A-8 crib.

**Process Description:** The site received cooling water from the contact condenser in the 241-A-431 building. Drawings indicate a 38 centimeter (15 inch) diameter clay pipe fed 216-A-34 and was connected to the headwall. Ditch effluent was routed to the 216-A-19 and 216-A-20 trenches. Maxfield (1979) describes the site as two ditches; one ditch measuring 85 meters (280 feet) long and 9 meters (30 feet) wide and a second ditch measuring 39.6 meters (130 feet) long and 9 meters (30 feet wide). However, it is not clear if there were two ditches or actually a headwall structure and a ditch. The Maxfield ditch dimensions are similar to the headwall structure dimensions. Drawings show the headwall width was 3 meters (10 feet) wide at the west end fanning out to 12 meters (40 feet) wide at the east end. The headwall structure had 1:2 side slopes. The headwall structure was 39.6 meters long (130 feet). It tapered off into an open ditch. The ditch terminated in the 216-A-20 Grave. No documentation has been located to describe how the effluent was directed to the 216-A-19 Grave.

**Waste Type:** Soil

**Waste Description:** The site received the cooling water from the contact condenser in the 241-A-431 Building in route to the 216-A-19 and 216-A-20 Trenches. The site contains less than 1 curie total beta activity.
### Description:
The 216-A-36A and 216-A-36B cribs are located inside a common light post and chain area. The 216-A-36A is the at the north end of the chained area. The large chained area is posted with Underground Radioactive Material signs. The risers near the center of the cribs had been posted with Soil Contamination signs, but were surface stabilized in May 2010.

### Location:
The crib is located south of the 202-A Building and west of Canton Avenue, outside the security fence.

### Related Sites/Structures:
The pipeline associated with this crib is 200-E-253-PL.

### Process Description:
The 216-A-36A portion of the crib was activated in September 1965 to receive ammonia scrubber waste from PUREX. A new annular dissolver was installed in A cell in October 1965. Shortly after the start up of the new dissolver system, it was noted that significant quantities of fission products were being flushed to the 216-A-36A Crib. Monthly discharge records estimated that approximately 135,000 curies of fission products, that included 610 curies of cesium-137 and 625 curies of strontium-90, had been release to the crib from October 1965 through January 1966. In December 1965, a test well was drilled into the crib to determine the extent of the fission products in the ground and to determine if the crib should continue to be used. On December 29, 1965, a soil sample was collected from the boring that read between 300 and 500 R/hour. Work was stopped and special procedures, including use of long handled tongs and exposure time monitoring, were required for handling and disposing of the excavated material. It was calculated that approximately 400,000 curies of contaminants had been discharged to the crib that included 1600 curies of cesium-137. The 216-A-36A portion of the crib was terminated in March 1966. The existing pipeline was extended to the 216-A-36B portion of the crib. A 29 meter (95 foot) concrete dam was placed between the 216-A-36A and 216-A-36B crib sections. The original excavation is 183 meters (600 feet) long by 3.4 meters (11 feet) wide by 6.7 meters (22 feet) deep with a 1:1.5 backslope. The excavation has 0.9 meters (3 feet) of gravel fill and a 15-centimeter (6-inch) M-8 (stainless steel) perforated pipe is placed horizontally. A plastic barrier separates the gravel from the overlying backfill and the site has been backfilled to original grade. The northernmost 30.5 meters (100 feet), now called 216-A-36A, was isolated and deactivated. The remaining 152 meters (500 feet) of the crib was renamed 216-A-36B and remained active during the majority of PUREX operation.

### Waste Type:
Misc. Trash and Debris

### Waste Description:
The site received the ammonia scrubber waste from the 202-A Building. The waste is low in salt and is neutral to basic. The site was deactivated because of a large discharge of fission products. In December 1965, it was calculated (from bore hole soil samples) that approximately 400,000 curies of contaminants had been discharged to the crib that included 1600 curies of cesium-137.

---

### Hanford Site Waste Management Units Report
February 2015 1071
216-A-36A Crib. The 216-A-36B is the southern end of the chained area. The large chained area is posted with Underground Radioactive Material signs. The risers near the center of the cribs had been posted with Soil Contamination Area signs, but were surface stabilized in May 2010. The 216-A-36B portion of the chained area is considerably larger than the 216-A-36A portion.

Location: The crib is located south of the 202-A Building and west of Canton Avenue, outside the security fence.

Release Description: During the week of May 21 to May 28, 1970, an abnormally large quantity of radionuclides was discharged to the A36-B crib. A letter from C. W. Malody reports that the volume was 1.6 million liters (420,000 gallons), and the sample analysis showed 9.3 kilograms (20.5 pounds) of uranium; 82.3 grams (2.9 ounces) of plutonium; 15,900 Curies of total beta; 9,050 Curies of 95-zirconium; 4,390 Curies of 106-ruthenium; and 5,800 Curies of 144-cerium were released to the crib during those dates. For 1969, the 12 month total of waste to the crib was 10 kilograms (22 pounds) of uranium; 7.2 grams (2.5 ounces) of plutonium; 1790.8 Curies of beta; 6.6 Curies of cobalt-60; 99.1 Curies of strontium-90, 110.2 Curies of cesium-137, and 454.0 Curies of ruthenium-106 in 17.8 million liters (4.695 gallons) volume of liquid.

Related Sites/Structures: The site is associated with 202-A facility and 216-A-36A Crib. The pipeline associated with this crib is 200-E-253-PL.

Process Description: The 216-A-36B Crib was built to replace the 216-A-36A Crib, that had been terminated due to the large amounts of fission products discharged to it. The 216-A-36B Crib was constructed by extending the pipeline from the 216-A-36A Crib in March of 1966. A concrete dam was placed between the two portions of the crib. The 216-A-36B crib received ammonia scrubber waste from the PUREX process. Fuel rods from the 100-N reactor were clad in zirconium. Removal of the zirconium cladding required using ammonium fluoride and ammonium nitrate solutions (AFAN). The dissolving process produced a large amount of ammonia offgasses. The offgases was scrubbed with water to reduce the amount of water released to the air. Spent ammonia scrubber waste was transferred to a concentrator where the waste was distilled. The crib received discharge condensate from the waste stream concentrator. The unit is a gravel structure with a 15-centimeter (6-inch) M-8 perforated pipe placed horizontally, 7 meters (23 feet) below grade. The excavation has 620 cubic meters (22,000 cubic feet) of gravel fill, and the site has been backfilled. The side slope is 1:1.5.

Waste Type: Soil

Waste Description: Until October 1972, the site received the ammonia scrubber waste from the 202-A Building (Plutonium Uranium Extraction [PUREX]). The site was retired in October 1972 when the PUREX plant shut down. In November 1982, the site was reactivated to receive the above wastes when PUREX operations resumed. The waste is low in salt and is neutral to basic. The concentrations of ammonium hydroxide discharged to the crib resulted in the waste stream being classified as a dangerous waste. During the week of May 21 to May 28, 1970, an abnormally large quantity of radionuclides was discharged to the A36-B crib. A letter from C. W. Malody reports that the volume was 1.6 million liters (420,000 gallons). The sample analysis showed 9.3 kilograms (20.5 pounds) of uranium; 82.3 grams (2.9 ounces) of plutonium; 15,900 Curies of total beta; 9,050 Curies of 95-zirconium; 4,390 Curies of 106-ruthenium; and 5,800 Curies of 144-cerium were released to the crib during those dates. For 1969, the 12 month total of waste to the crib was 10 kilograms (22 pounds) of uranium; 7.2 grams (2.5 ounces) of plutonium; 1790.8 Curies of beta; 6.6 Curies of cobalt-60; 99.1 Curies of strontium-90, 110.2 Curies of cesium-137, and 454.0 Curies of ruthenium-106 in 17.8 million liters (4.695 gallons) volume of liquid.
### Crib Description:

The crib is marked and surrounded with concrete AC-540 markers and Underground Radioactive Material signs.

### Location:

The unit is located outside of the 200 East Area perimeter fence, east of the 202-A Building.

### Related Sites/Structures:

The site is associated with the 242-A Evaporator. The pipeline from 207-A to 216-A-37-1 is sitecode 200-E-232-PL.

### Process Description:

The crib received process condensate waste from the 242-A Evaporator facility. The unit is a gravel structure with a 25-centimeter (10-inch) corrugated, galvanized, perforated pipe located horizontally, 2.1 meters (7 feet) below grade. The excavation contains 1.5 meters (5 feet) of gravel fill with a volume of 150 cubic meters (5,300 cubic feet) and has been backfilled over. The side slope is 1:1.

### Waste Type:

Process Effluent

### Waste Description:

The site received process condensate from the 242-A Evaporator. The process condensate had been determined to be regulated as a mixed waste due to the presence of spent halogenated and nonhalogenated solvents and for the toxicity of ammonia. The estimated annual quantity of dangerous waste was 4.912E+07 kilograms (1.083E+08 pounds), representing the maximum annual output of evaporator process condensate during operating campaigns.

### Related Sites/Structures:

### Waste Type:

Process Effluent

### Waste Description:

The crib is surrounded by light posts and a chain. It is posted with Underground Radioactive Material signs. There are no concrete AC-540 markers or signs to label the site.

The crib is located southwest of 202-A Building north of 1st Street. It is located south of the PUREX security fence.

The site is associated with the 216-A-10 crib. The pipeline to the 216-A-38-1 crib is sitecode 200-E-240-PL. There are two radiological test wells (one at each end of the crib).

The crib was built to replace the 216-A-10 crib, but had not been activated when plans for modifying the PUREX head end process were begun. The planned building addition would have been constructed immediately adjacent to the crib. For this reason, the crib was activated. The site is identified in the project proposal (Project IAP-606) as the PUREX Process Condensate Crib - 216-A-38. It was intended to receive the PUREX process condensate waste that was being discharged to the 216-A-10 Crib. The 216-A-10 was showing signs of strontium-90 saturation. The replacement crib was required for continued disposal for the disposal of large volumes [1,040,000 to 1,230,000 liters (275,000 to 325,000 gallons per day)] of condensate waste. There was a potential for this process condensate to become grossly contaminated as a result of reduced vapor phase deentrainment or foaming in the concentrator. The location for the 216-A-38-1 Crib was chosen to shorten piping runs and take advantage of the high percolation rate [76 to 95 liters (20-25 gallons)] per day per square foot. The existing 216-A-10 crib could not be depended upon for continued disposal of process condensate. It had been in operation since June 1961 (five years), and had received about 1,800 million liters (475 million gallons) of condensate which contained about 115,000 curies of beta activity (as of June 1966). Strontium-90 had been verified to be in the groundwater under the crib. There is a 15-centimeter (6-inch) perforated stainless steel distribution pipe (from PUREX and running the length of the crib) reducing to 10-centimeter (4-inch) perforated pipe placed at 10 meters (33 feet) below grade. This pipe was isolated with the installation of a blind flange in 1989. There is 1.5 meters (5 feet) of gravel in the excavation with a membrane barrier between the gravel and the backfill. The excavation was backfilled with excavated material. The side slopes of the excavation were cut at 1:1.

Although the crib was built to receive PUREX effluent, it was never used.
Process Description: The 216-A-40 Basin was built to retain diverted contaminated water from 244-AR Vault. The basin was originally an open, rubber lined trench that was divided into 3 sections. A 0.3 meter (12 inch) diameter schedule 40 distribution pipe ran horizontally through the south end of the unit, 3.7 meters (12 feet) below grade. Collapsible rubber bladders (200,00 gallon capacity) were utilized to contain the contaminated cooling water and steam condensate. Contaminated cooling water and steam condensate from the 244-AR Vault were diverted to the 216-A-40 Retention Basin when the effluent was above standard release limits for the water to be sent to the 216-B-3 or 216-A-25 Ponds. The retention basin bladders failed in 1979 and the unit was removed from service. Although it was not being used, it remained an open basin until 1994. Contamination from inside the open basin affected the surrounding area via wind and animal related contamination migration.

The diverter was a two-compartment concrete structure with a motor driven diverter valve. Each bladder was equipped with a concrete sump and a 3 inch pipeline connected to the pump caisson (lines 321, 322 and 324). The pump caisson was connected to a pipeline (line 323 aka 216-E-274-PL) that routed contaminated water into the tank farm system, via the 244-A lift station.

Waste Type: Soil
Waste Description: The site received and stored in rubber bladders, the diverted cooling water and steam condensate from the 244-AR Vault.

Code: 216-A-41
Type: Crib
Status: Inactive
Start Date: 1/1/1968
End Date: 1/1/1974
Description: The site is a small crib that is no longer marked or posted. The area where the crib is assumed to be located is covered with gravel.
Location: The crib is located northwest of the 296-A-13 stack, west of Buffalo Ave. and north of the 244-AR Vault facility.
Related Sites/Structures: The crib is associated with the 296-A-13 Stack (291-AR Filter Building Stack) (WIDS Site 296-A-13) and the 291-AR Filter Building. The Filter Building is related to the 244-AR Vault Canyon. The pipeline to the crib is 200-E-276-PL.
Process Description: The crib received drainage from the 296-A-13 Stack (WIDS Site 296-A-13). The stack is connected to the 291-AR Filter Building. The bottom of the crib (elevation: 207 meters [678.5 feet]) is filled with 0.5 meters (1.5 feet) of 3.8 to 25.4-centimeter (1.5 to 10-inch) rock, then 20.3 centimeters (8 inches) of 1.9 to 3.8-centimeter (0.75 to 1.5-inch) gravel, and several centimeters of 1.9-centimeter (0.75-inch) gravel. This material is covered by a layer of 20 millimeter polyethylene and 10.2 centimeters (4 inches) of sand (elevation: 208 meters [681.0 feet]). The site was then backfilled with soil to a ground elevation of 209 meters (684.0 feet) (with the crown at 212 meters [696.0 feet]). The side slope is 1:1. A 10.2-centimeter (4-inch) vitrified clay pipe enters the crib (from the 296-A-13 Stack) at elevation 208 meters (681.0 feet) and connects to the crib dispersion structure, constructed of 20.3 by 20.3 by 40.6-centimeter (8 by 8 by 16-inch) bond beam concrete blocks placed end-to-end. The pipeline from the stack (296-A-13) to the crib is approximately (15 feet) long and extends northwest (30 degrees west of true north) from the stack. The site is not marked in the field. The mapped center point
The location of the site is based on drawing coordinates from H-2-61975, "216-A-41 Crib, Plan and Profile". Drawing H-2-44501, "Area Map-200 East, A Plant Facilities", shows the crib at the same location.

**Waste Type:** Soil

**Waste Description:** The site received the 296-A-13 Stack condensate drainage. According to RHO-CD-673, the waste was potentially slightly acidic and contained less than 1 curie total beta activity. Potential contaminants of concern (Stenner) may be tritium, cobalt-60, strontium-90, and cesium-137.

### Code: 216-A-42

**Classification:** Accepted

**Type:** Retention Basin

**Start Date:** 1/1/1978

**End Date:** 1/1/1997

**Description:** The site is surrounded with steel posts and chain. It is posted with Underground Radioactive Material signs. Concrete cover blocks are visible on the top of the basin. The chain link fence has been removed. The site consists of a rubber-lined trench divided into three holding basins by two internal berms. One end of the trench features the inlet structure for the 91-centimeter (36-inch) diameter cooling water line while the other end has the inlet structure for the 20.3-centimeter (8-inch) diameter steam condensate pipeline. Both lines enter at 2.9 meters (9.5 feet) below grade. Outlet drains are located at the low-points in each basin and connect to the 216-A-42A Pump Station. The capacity of the three basins is in excess of 6.1E+06 liters (1.6E+06 gallon). The trench is equipped with a float. Concrete cover blocks were installed over the basins in 1984.

**Location:** The retention basin is located outside the eastern 200 East Area security fence. It is east of the 202-A Building, directly east of the 216-A-6 Crib.

**Process Description:** The 216-A-42 Retention Basin was built to hold cooling water or steam condensate that was contaminated above standard release limits and prevent its disposal to the Gable and B Pond systems or to cribs. After the retained effluent contents were analyzed, a built-in recovery system provided the capability of pumping solutions back into the PUREX facility for reprocessing (see sitecode 200-E-261-PL) or to cribs for disposal. Prior to the construction of the 241-AP Tank Farm (1983), the basin was connected to the 0.9 meter (36 inch) diameter corrugated metal pipeline (200-E-127-PL) that flowed to the Gable and B Ponds. A 0.3 meter (1 foot) diameter chemical sewer line (200-E-187-PL) tied the basin to the 216-A-29 ditch. Portions of the chemical sewer line and the corrugated metal pipe were removed during the 241-AP Tank Farm construction.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** The unit received chemically or radioactively contaminated diversions from the PUREX chemical sewer line, cooling water line, and steam condensate lines. Depending upon the treatment required for the contaminant, the waste was released from the unit to the 216-A-30, 216-A-37-1 and 216-A-37-2 Cribs, to PUREX process piping, or to the Tank Farms.

### Code: 216-A-45

**Classification:** Accepted

**Names:** 216-A-45; 216-A-45 Crib

**Reclassification:** None

---

*Hanford Site Waste Management Units Report*

February 2015 1076
### Type: Crib

**Start Date:** 3/4/1987  
**End Date:** 9/1/1991

**Description:** The crib is surrounded with light post and chain. It is posted as an Underground Radioactive Material area. There is a considerable amount of vegetation growing on the crib surface.

**Location:** The 216-A-45 Crib is located south of the PUREX facility, southwest of the 216-A-10 Crib.

**Release Description:** On April 2, 1987, more than 5 pounds of pure nitric acid in 6200 pounds of water was discharged to the 216-A-45 crib. The pH was greater than 2.0. The release was neutralized by adding additional carbonate to the A5 neutralization tank (sitecode 200-E-58).

**Related Sites/Structures:** The crib is associated with the 202-A facility. The pipeline that fed this crib is sitecode 200-E-231-PL.

**Process Description:** The unit has an associated drain field consisting of five 10-centimeter (4 inch) diameter perforated, fiberglass-reinforced pipes evenly spaced across the width. At the bottom is 1.7 meters (5.5 feet) of clean rock, 8 to 13 centimeters (3 to 5 inches) in diameter. A layered cover consisting of a 15 centimeters (6 inches) layer of 8 to 13 centimeters (3 to 5-inch) diameter clean rock, a 15 centimeters (6-inch) layer of 1.9-centimeter (3/4-inch) gravel, a sheet of 10-mil polyethylene, and a 10-centimeter (4-inch) layer of sand are placed over the unit.

**Waste Type:** Steam Condensate  
**Waste Description:** The unit received process condensate from the 202-A Building (PUREX). Discharge to this crib was discontinued in mid-1989 and the waste stream was routed to storage tanks (WHC-EP-0367). TPA milestone M-17-20A required all discharge to the 216-A-45 Crib be ceased by September 1991. The Fourth Amendment to the TPA confirms that this milestone was met.

---

### Type: Retention Basin

**Start Date:** 1/1/1945  
**End Date:** 1/1/1997

**Description:** The unit is a concrete-lined basin, divided into two equal sized sections. The basin is surrounded by a 2.4 meter (8 foot) chain link fence and posted with Contamination Area signs.

**Location:** The site is located inside 200 East Area, northeast of the 221-B Building and south of the 241-B Tank Farm. It is on the east side of Baltimore Ave..

**Related Sites/Structures:** The basin has an inlet structure on the west and an outlet structure on the east side. There are two 0.9 square meter (3 square foot) sumps, one for each basin section. The basin is also associated with UPR-200-E-32. The 200-E-112-PL pipeline connects to the west side of the retention basin. The valve box on the east side of the retention basin tied into the pipeline that fed the 216-B-63 Ditch (sitecode 216-E-191-PL). The B Plant Chemical Sewer pipeline (200-E-188-PL), the pipeline to the 216-B-2-1 and 216-B-2-2 ditches (200-E-204-PL) and the pipeline to the 216-B-2-3 ditch (200-E-205-PL) are connected to the valve pit located east of the valve box. The pipeline from 242-B to the basin is sitecode 200-E-264-PL. The cooling water pipeline from 241-BY tank farm to the basin is 200-E-265-PL. In 1987, the entire 216-B-2 ditch system was replaced with a single pipeline (200-E-126-PL) that connected the 207-B retention basin to the 216-B-3 ditch and pond system.

**Process Description:** The retention basins served as settling basins, receiving B Plant process sewer effluent through an underground pipeline prior to being discharged to the 216-B-2-1, 216-B-2-2, 216-B-2-3 ditches. It was possible to divert effluent to the 216-B-63 ditch. The 216-B-2-1, 216-B-2-2 and
216-B-2-3 ditches were connected to the 216-B-3 ditches and ponds. The 242-B Evaporator also discharged to the 207-B Retention Basin.

Waste Type: Chemicals

Waste Description: The unit received process cooling water from process equipment jackets in the 221-B Building. Normally, activity levels were low, and the water was discharged to the 216-B-3 Pond via the 216-B-2-1, 216-B-2-2, 216-B-2-3 and 216-B-3-1, 216-B-3-2 and 216-B-3-3 ditches. The valve box on the east side of the retention basin tied into the pipeline that fed the 216-B-63 Ditch (sitecode 216-E-191-PL). The B Plant Chemical Sewer pipeline, a pipeline from 242-B Evaporator building and a cooling water pipeline from 241-BX tank farm also fed the retention basin.

Code: 216-B-2-1
Names: 216-B-2-1; 216-B-2W; B Ditch; B Swamp Ditch; 216-B-1; 216-B-2
Type: Ditch
Status: Inactive

ditch has been backfilled and surface stabilized. It is located within a larger Underground Radioactive Material area that includes the 216-B-2-1, 216-B-2-2 and 216-B-2-3 stabilized ditches.

Location: The ditch is located in the northeast quadrant of 200 East Area. The head end of the unit is located near the east side of the 207-B Retention Basin. The ditch ran in an east-west direction until it connected to a section of underground pipeline near the northeast corner of 218-E-12A Burial Ground.

Release Description: The first 305 meters (1000 feet) became grossly contaminated in 1963 (See UPR-200-E-32).

Related Sites/Structures: The ditch is associated with B-Plant, 207-B, 216-B-3-1, 216-B-3 and UPR-200-E-32. The pipelines associated with the ditch are WIDS sitecodes 200-E-112-PL, 200-E-188-PL and 200-E-204-PL.

Process Description: Process effluent from B-Plant was routed to the 207-B Retention Basin. Effluent was released from the 207-B Retention Basin to the 216-B-2-1 ditch that connected to the 216-B-3-1 ditch and terminated in the 216-B-3 Pond. The 216-B-2-1 ditch was closed after it was grossly contaminated by a coil leak effluent release from B-Plant in 1963 (UPR-200-E-32). It was replaced by the 216-B-2-2 ditch.

Waste Type: Chemicals

Waste Description: Until March 1952, the site transported steam condensate, process cooling water, and chemical sewer from 221-B waste. After March 1952, the site transported the streams identified above in addition to the 241-CR Vault cooling water.

Code: 216-B-2-2
Names: 216-B-2-2; 216-B-2-2W; 216-B-1 Ditch
Type: Ditch
Status: Inactive

Description: The ditch has been backfilled and surface stabilized. It is located within a large Underground Radioactive Material area that includes the 216-B-2-1, 216-B-2-2 and 216-B-2-3 backfilled...
ditches. The individual ditches are not marked. The head end of the ditch is located near the 207-B Retention Basin. The lower end terminated near the northeast corner of the 218-E-12A Burial Ground.

**Location:**
The ditch is located northwest of the 207-B Retention Basin.

**Release Description:**
In March 1970, approximately 1000 curies of strontium-90 was released to the ditch via the Chemical Sewer (see UPR-200-E-138).

**Related Sites/Structures:**
The following are related to the site: 207-B, 216-B-2-1, 216-B-2-3, 216-B-3-1, 216-B-3-2, and the 216-B-3 Pond. The pipelines associated with the ditch are WIDS sitecodes 200-E-112-PL, 200-E-188-PL, 200-E-203-PL and 200-E-204-PL.

**Process Description:**
The site received chemical process sewer effluent from B Plant and its support facilities. The construction of the 216-B-2-2 ditch reused 762 meters (2500 feet) of the 216-B-2-1 ditch. Approximately 330 meters (1100 feet) of new ditch was dug. When active, the open ditch was 4.6 meters (15 feet) wide at the top with a side slope of 2.5:1.

**Waste Type:**
Chemicals

**Waste Description:**
Until January 1965, the ditch transported and percolated 241-CR Vault cooling water, 221-B cooling water and steam condensate (replacing 216-B-2-1), and chemical sewer toward 216-B-3 Pond. From January 1965 to November 1967, the same effluents as those listed above in addition to 241-BY Tank Farm In Tank Solidification (ITS) Unit 1 cooling water were transported and percolated by the ditch. From November 1967 to February 1968, the same effluents as those listed above minus 284-E Powerhouse waste and steam condensate were released to the ditch. From February 1968 to April 1970, the same effluents as those listed above plus the 241-BY Tank Farm ITS Unit 2 were released to the ditch. An Unplanned Release on March 22, 1970 released approximately 1000 curies of strontium-90. After April 1970, the site received cleanup waste from 207-B Retention Basin.

**Code:** 216-B-2-3
**Classification:** Accepted

**Names:** 216-B-2-3; 216-B-2-3W; B Pond Ditch; B Swamp Ditch

**Type:** Ditch
**Start Date:** 1/1/1970

**Status:** Inactive
**End Date:** 1/1/1987

**Description:** The ditch is currently backfilled and surface stabilized. It is located inside a large Underground Radioactive Material area that includes the 216-B-2-1, 216-B-2-2 and 216-B-2-3 ditches.

**Location:**
The head end of the ditch was located 180 meters (600 feet) southeast of 241-B Tank Farm. The ditch ran southeast and connected to an underground pipe near the northeast corner of 218-E-12A Burial Ground.

**Related Sites/Structures:**
The ditch is associated with the 207-B Retention Basin. The pipelines associated with the ditch are WIDS sitecodes 200-E-188-PL and 200-E-205-PL.

**Process Description:**
The ditch was used to transport liquid waste from B-Plant to 216-B-3 Pond. It was built to replace the contaminated of 216-B-2-2 Ditch in 1970. The side slope is 2.5:1. The radionuclide inventory for the ditch is included with the 216-B-3 Pond.

**Waste Type:** Equipment

**Waste Description:** From April 1970 to July 1973, the site transported and percolated the 241-CR Vault cooling water, 221-B Plant cooling water, and condenser cooling water from 241-BY Tank Farm ITS (In Tank Solidification) Units 1 and 2. The waste flowed into the 216-B-3 Pond. After July 1973, the ditch received the above-listed effluents except from 241-BY Tank Farm ITS Units 1...

**Description:** A concrete AC-540 post marks the location of this site and is labeled as an Underground Radioactive Material site. The reverse well is a 15.25-centimeter (6-inch) diameter pipe extending 48 meters (160 feet) below ground surface. The lower 7.6 meters (25 feet) of casing is perforated. The vent pipe was cut below grade.

**Location:** The reverse well is located 3.6 meters (12 feet) west and 0.9 meters (3 feet) north of the 222-B Building.

**Related Sites/Structures:** This reverse well is associated with the 222-B Laboratory.

**Process Description:** The reverse wells at 222-T and 222-B were installed to provide disposal for the laboratory hot sink and sample table. During the bismuth phosphate fuel separation process, batch samples were analyzed in the 222-T and 222-B laboratories. HW-4850, written in 1945, states that the 222-T laboratory was discharging approximately 2.6 curies of fission products and 600 milligrams of plutonium to the dry well per month. Since similar work was done at the 222-B Laboratory, similar waste inventory can be assumed.

**Waste Type:** Process Effluent

**Description:** The unit is a 3.7 by 3.7 by 1.1 meters (12 by 12 by 3.5 feet) wooden structure in an excavation. The side slope is 1:1. The bottom of the excavation is 6.1 meters (20 feet) below grade. The structure is not gravel-filled and has cave-in potential. The surface of the unit has subsided about 0.9 meters (3 feet) in the center, possibly indicating deterioration of the lumber. The site is marked and posted with Underground Radioactive Material and Cave-In-Potential signs.

**Location:** The unit is located south of the west end of 222-B Building.

**Related Sites/Structures:** The pipelines associated with this crib are WIDS sitecodes 200-E-174-PL and 200-E-175-PL.

**Waste Type:** Process Effluent
Waste Description: Until December 1951, the site received the decontamination sink and sample slurper waste from 222-B Building and floor drainage from 292-B Building. After December 1951, the site received the same as above minus the 222-B Building waste. The waste is acidic and contains transuranics and fission products.

Code: 216-B-10B
Names: 216-B-10B; 222-B-2 Crib; 216-B-10 Crib
Type: Crib
Status: Inactive
Description: The unit is a 3.7 by 3.7 by 1.1-meter (12 by 12 by 3.5-foot) wooden structure in an excavation. The side slope is 1:1. The bottom of the excavation is 6.1 meters (20 feet) below grade. The structure is not gravel-filled and has cave-in potential. The earth has subsided about 0.9 meters (3 feet) over the top of the unit. No site marker post is present.
Location: The unit is located south of the west end of 222-B Building.
Related Sites/Structures: The pipeline associated with this crib is WIDS sitecode 200-E-174-PL.
Waste Type: Process Effluent
Waste Description: From December 1949 to December 1951 the site received the decontamination sink and sample slurper waste from the 222-B Building and the floor drainage from the 292-B Building. From December 1951 to May 1969 the site received only the floor drainage from the 292-B Building. From May 1969 to October 1973 the site received only the decontamination sink and shower waste from the 221-BC Building.

Code: 216-B-12
Names: 216-B-12; 216-ER Crib; 216-ER-1,2,3 Cribs
Type: Crib
Status: Inactive
Description: The crib is marked and posted with Underground Radioactive Material and Cave-in Potential signs.
Location: The unit is located northwest of the 221-B Building and north of 7th Street.
Related Sites/Structures: The crib is associated with the 270-E-1 neutralization pit, 216-B-62 crib and the 200-E-160-PL and 200-E-162-PL pipelines.
Process Description: The crib originally received 221-U and 224-U condensate waste, transported from 200 West Area via the Cross Site Transfer Line (line V219). The crib also received condensate waste from 221-B Plant via pipeline 200-E-160-PL and later via 200-E-162-PL. A lateral pipe extends to 216-B-12, crib #2, from the 200-E-162-PL pipeline, that also fed the 216-B-62 crib.
The unit consists of a series of 3 cascading, 4.9 by 4.9 by 3.0-meter (16 by 16 by 10-foot) high wooden boxes in an excavation. A 1.3-centimeter (0.5-inch) rock backfill lies in the bottom 3.7 meters (12 feet) of the excavation and beneath each box is approximately 1.2 meters (4 feet) of this rock. The lumber is primarily 15.2 by 20.3-centimeter (6 by 8-inch) Douglas fir. The site contains 2,900 cubic meters (3,800 cubic yards) of 1.3-centimeter (0.5-inch) gravel. The side slope is 1:1.
Waste Type: Process Effluent

Waste Description: From November 1952 to December 1957, the site received the process condensate waste from the tributyl phosphate uranium recovery processes at the 221-U and 224-U Buildings as well as B Plant condensate. From December 1957 to May 1967, the site was inactive. From May 1967 to November 1967, the site received construction waste from 221-B Building. After November 1967, the site received process condensate from 221-B Building. The waste is low in salt and is neutral to basic.

Code: 216-B-51

Names: 216-B-51; 216-BY-9 Crib

Type: French Drain

Status: Inactive

Description: The site is a small Underground Radioactive Material area measuring approximately 3 meters by 3 meters (10 feet by 10 feet). The concrete drain structure extends approximately 0.3 meters (1 foot) above the ground surface. The structure is approximately 1.5 meters (5 feet) in diameter with a wooden lid. The structure is also posted with Fixed Contamination Area signs.

Location: The french drain is south of 12 Street and east of Baltimore Ave. It is north of the 241-B Tank Farm and northeast of the 216-B-8 Crib and Tile Field.

Release Description: See UPR-200-E-144

Related Sites/Structures: The french drain is associated with 200-E-114-PL, 200-E-221-PL and UPR-200-E-144.

Process Description: The french drain received drainage from the pipeline that transferred tri-butyl phosphate waste from the 241-BY Tank Farm to the BC Crib and Trenches. The drain was active from January 1956 to January 1958. The unit is constructed of sections of 1.5 meter (5 foot) diameter concrete pipe stacked vertically extending 30 centimeters (1 foot) above ground and 4.3 meters (14 feet) below ground. The pipe is filled with 4 meters (13 feet) of gravel. The french drain has a wood cover with vent holes.

Waste Type: Equipment

Waste Description: The site received drainage from the BC Crib pipeline. The pipeline carried high salt, neutral to basic scavenged tributyl phosphate waste via 241-BY tank farm to the BC Crib area. The site contains less than 10 curies total beta.
feet of membrane barrier.

Location: The site is located west of 225-B, and north of 7th Street.

Related Sites/Structures: The site is associated with the 221-B facility. The pipeline to the 216-B-55 crib is discussed in sitecode 200-E-161-PL.

Process Description: The site has received steam condensate from 221-B Building. The waste was low in salt and neutral to basic pH. The steam condensate was sent to the 216-B-55 Crib from 1967 to 1990. (DOE/RL-89-28) TPA milestone M-17-25 required all discharge to the crib to be ceased by Sept. 1991.

Waste Type: Equipment

Waste Description: The site has received steam condensate from 221-B Building. The waste is low in salt and is neutral to basic. The steam condensate was sent to the 216-B-55 Crib from 1967 to 1990. (DOE/RL-89-28) TPA milestone M-17-25 required all discharge to the crib to be ceased by Sept. 1991.

---

Code: 216-B-59 Classification: Accepted
Names: 216-B-59; 216-B-58 Ditch; 216-B-58 Trench Reclassification: None
Type: Trench Start Date: 1/1/1967
Status: Inactive End Date: 1/1/1974

Description: The original 216-B-59 was an unlined trench. The site was upgraded to a retention basin in 1974 (see 216-B-59B). The lined retention basin was constructed over top of the unlined 216-B-59 trench. There are currently no visual features remaining of the unlined trench. The concrete-lined basin is enclosed by a 2 meter (6 foot) chain link fence.

Location: The site is located northeast of 221-B. It is on the east side of Baltimore Ave. and north of 7th Street.

Related Sites/Structures: This site is associated with 216-B-59B and the 221-B facility. The pipeline that fed the site is 200-E-277-PL.

Process Description: The original trench (216-B-59) was designed as an emergency cooling water diversion for 221-B cooling water with radionuclide concentrations above those allowed for the existing ponds. The site was activated in 1967 and received only a single discharge of approximately 477,000 liters (126,000 gal) of waste in March 1968. The trench was upgraded in 1974 to a retention basin by adding a hypalon liner and changing its identification number to 216-B-59B. It held diverted cooling water for subsequent reprocessing. It was later upgraded again (in 1983) by replacing the hypalon liner with a concrete liner and cover.

Waste Type: Process Effluent

Waste Description: The unlined trench received diverted cooling water from the 221-B Building. Only one diversion occurred (3/68) before the unit was lined and renamed the 216-B-59B Retention Basin.

---

Code: 216-B-59B Classification: Accepted
Names: 216-B-59B; 216-B-59 Retention Basin Reclassification: None
Type: Retention Basin Start Date: 1/1/1974
Status: Inactive End Date: 1/1/1997
Description: The site is a concrete structure enclosed by a six foot (2 meter) chain link fence.

Location: The site is located inside 200 East Area, approximately 700 feet northeast of the 221-B Building. It is on the east side of Baltimore Ave. and north of 7th Street. The concrete basin structure and haplon liner were placed on top of the area previously known as the 216-B-59 trench.

Related Sites/Structures: The 216-B-59B Retention Basin is associated with the 216-B-59 trench and the 221-B facility. The pipeline that fed the site is 200-E-277-PL.

Process Description: The 216-B-59B retention basin was designed to receive diverted 221-B Building cooling water that contained radionuclide concentrations above the limits allowed for disposal in the B Pond system. The diverted waste was pumped back into 221-B to be reprocessed. In 1974, the 216-B-59 unlined trench was upgraded to a Retention Basin by adding a hypalon liner and changing its identification number to 216-B-59B. The haplon liner was replaced, in 1983, with a concrete liner and cover.

Waste Type: Process Effluent

Waste Description: This unit received contaminated cooling water from the 221-B Building. The diverted effluent was pumped back into 221-B for reprocessing.

Code: 216-B-62

Names: 216-B-62; 216-B-62 Crib; 216-B-62 Enclosed Trench

Type: Crib

Status: Inactive

Start Date: 11/1/1973

End Date: 9/1/1991

Description: The crib is surrounded with cement AC-540 markers and posted with Underground Radioactive Material signs.

Location: The crib is located northwest of the 221-B building, west of Atlanta Ave.

Related Sites/Structures: The pipeline to the 216-B-62 crib is discussed in sitecode 200-E-162-PL.

Process Description: The crib was constructed in 1969 and put on standby, to serve as the eventual replacement crib for the 216-B-12 crib. 216-B-62 was activated in 1973. The site received process condensate from the 221-B building. The crib has 4 feet (1.2 meters) of gravel fill on the bottom. A perforated, 6 inch (15 cm) diameter fiberglass, reinforced epoxy pipe runs the length of the unit, 3 feet (0.9 meters) above the bottom.

Waste Type: Chemicals

Waste Description: The site has received process condensate from the 221-B Building Separations Facilities. TPA milestone M-17-26 required all discharge to the Crib to be ceased by Sept. 1991.

Code: 216-B-63

Names: 216-B-63; 216-B-63 Ditch; 216-B-63 Trench; B Plant Chemical Sewer Ditch

Type: Ditch

Status: Inactive

Start Date: 1/1/1970

End Date: 1/1/1992

Description: The site has received process condensate from the 221-B Building Separations Facilities. TPA milestone M-17-26 required all discharge to the Crib to be ceased by Sept. 1991.
Description: The site is a ditch that has been backfilled and surface stabilized. It is posted as an Underground Radioactive Material area and has Danger - Keep Out signs. Prior to stabilization, the ditch had an earth shielding berm and a side slope of 1.5:1.

Location: The site is located inside the 200 East Area, east of the 241-B Tank Farm and northeast of the 207-B Retention Basin.

Related Sites/Structures: The ditch was associated with 221-B, 225-B, and 271-B. The pipeline associated with the ditch is 200-E-191-PL. The B Plant chemical sewer pipeline is sitecode 200-E-188-PL. The chemical sewer and the pipeline to the ditch are connected to a valve pit east of the 207-B Retention Basin.

Process Description: From March 1970 to May 1970, the 216-B-63 ditch received ITS-2 cooling water. The 216-B-63 ditch began to receive B Plant chemical sewer waste in May 1970 and continued through February 1992. The ditch received chemical sewer effluent from 221-B, 225-B and 271-B. The ditch was not connected to the B Pond system. The ditch terminated south of the 218-E-12B Burial Ground. 216-B-63 was designed to also receive diverted contaminated cooling water from 207-B and prevent it from reaching the 216-B-3 Pond, but no cooling water was actually ever diverted to the 216-B-63 ditch (see DOE/RL-92-05). In August 1970, the bottom of the ditch was dredged. The dredged material was contaminated with beta/gamma levels up to 3000 counts per minute. In February 1992, Project W-003 rerouted and replaced the VCP pipeline south of 211-BA, thereby eliminating the use of the 216-B-63 ditch. The chemical sewer effluent was combined with the B Plant cooling water effluent and discharged directly to the 216-B-3 Pond.

Waste Type: Soil

Waste Description: From March 1970 to May 1970, the 216-B-63 ditch received 241-BY tank farm In-Tank Solidification (ITS-2) cooling water. The site has received effluent from the 221-B, 225-B, and 271-B Building floor drains and chemical sewer wastes. Waste included corrosive (acidic and caustic) dangerous waste from the regeneration of demineralizer columns at B Plant. Radiological discharges were considered to be relatively low, with at total of approximately 8.7 curies of beta and 7.6 kilograms (16.7 pounds) of uranium. The unit has not received dangerous waste since September 1985. In 1987, two incidental acid releases occurred. In February 1992, the chemical sewer discharge to the 216-B-63 ditch was eliminated. Effluent was rerouted to 216-B-3 Ponds via underground pipelines. TPA milestone M-17-04B required the elimination of B-Plant Chemical Sewer effluent to the 216-B-63 Ditch by February 1992.

Code: 216-B-64

Classification: Accepted

Names: 216-B-64; 216-B-64 Crib; 216-B-64 Retention Basin; 216-B-64 Trench

Type: Retention Basin

Start Date: 1/1/1974

End Date: 1/1/1997

Description: The waste site has been evaluated and determined to require No Action. The chain link fence that once surrounded the basin has been removed. It was surrounded with light post and chain and posted as an Underground Radioactive Material Area. The basin contains a rubber bladder with a 190,000 liter (50,000 gallon) capacity. The unit is divided into two 6.1 meter (20 feet) by 19.8 meter (65 feet) sections. A concrete roof covers the basin.

Location: The retention basin is located west of the 225-B building.

Related Sites/Structures: The basin is associated with 221-B operations and UPR-200-E-64. The pipelines to the basin are discussed in sitecode 200-E-163-PL.
The basin was built to serve as an emergency diversion basin for steam condensate that exceeded crib release limits. Under normal conditions, the steam condensate stream flowed through the BCS diverter station located at the south end of the basin and was discharged to the 216-B-55 crib. Under emergency conditions, the effluent stream could be diverted to the 216-B-64 basin. The water collected in the basin could be routed through the pump pit, located on the east side of the basin, and pumped back to 221-B or routed to the 216-B-55 crib.

The unit was intended to receive steam condensate from the 221-B Building that exceeded release limits. A facility test was conducted, but the basin was never used.

No remediation was performed at this site. The No Action classification is documented on form 2004-111. The basin was built, but never received any waste.

The site is delineated with light post and chain. It is posted with Underground Radioactive Material and Inactive Miscellaneous Underground Storage Tank signs. The surface is covered with coarse rock.

The tank operated from April 1945 to September 1947, acting as a settling tank for waste originating in B Plant cells 5 and 6 and also low level concentrator condensate from the 224-B facility. The waste was routed first to the 241-B-154 Diversion Box before being transferred to the settling tank. After settling, the supernate from the tank was discharged to the 216-B-5 reverse well. During its period of service, 120 million gallons of waste passed through the tank. The waste contained approximately 4.3 kilograms of plutonium. It is estimated that half of the plutonium overflowed into the reverse well, leaving an estimated 2.4 kilograms of plutonium in the 241-B-361 tank. An estimated two million curies of strontium also remains in the tank. The tank sludge was sampled and analyzed in 1979. The sludge composition was consistent with the bismuth phosphate process. The 241-B-361 tank is constructed of 15-centimeter (6-inch) reinforced, prestressed concrete. The top of the unit is 1.8 meters (6 feet) below grade. Eleven risers are visible above grade. One is equipped with a manual tape, a second contains two dip tubes, a third vents the unit, and the eight remaining are blanked off.

The unit received low salt, alkaline radioactive liquid wastes from cell washings collected in the 5-6W Cells in 221-B and low level concentrator condensate from the 224-B facility. Although some reports estimate the quantity of waste in the tank as 121,000 liters (32,000 gallons), the unit is now estimated to contain 83,000 liters (22,000 gallons) of sludge containing 2.46 kilograms (5.42 pounds) of plutonium and 1,060 curies beta/gamma. The tank solids are primarily bismuth phosphate residue described as black in color with a pudding like consistency. The current volume is unknown and not monitored. The tank contents was sampled in 1979. The sludge contained 3.4 microcuries/gram of Pu-239, 1.4 microcuries/gram.
of Cs-137, and 23 microcuries/gram of SR-90. The liquid contained 6.1E-7 microcuries/ml of Pu-239, 2.5E-3 microcuries/ml of Cs-137, and 3.1E-5 microcuries/ml of Sr-90.

</tbody>
</table>
Location: The site is located in 200 East Area, south of 7th Street. It is east of the 209-E Facility and southwest of where the 201-C building once stood.

Related Sites/Structures: The site is associated with 201-C, 241-CX-71, 200-E-156-PL pipeline and 200-E-41.

Process Description: The crib received cold run waste and process condensate from the 201-C (Hot Semiworks) test facility. The 201-C building went through three operational modes. It was originally built in 1949 as a pilot plant for the Reduction Oxidation (REDOX) Process. In 1954, the building was used as a pilot plant for the Plutonium Uranium Extraction (PUREX) Process. The plant was converted to recover strontium from process wastes in 1961. Waste neutralized in the 241-CX-71 tank was discharged to this crib. The structure is 7.0 by 2.4 by 1.7 meters (23 by 8 by 5.5 feet), constructed of 2.4-meter by 20-centimeter by 20-centimeter (8-foot by 8-inch by 8-inch) concrete ties, 2.4-meter by 20-centimeter by 10-centimeter (8-foot by 8-inch by 4-inch) spacer blocks, and 1.1-meter by 2.4-meter by 15-centimeter (3.7-foot by 8-foot by 6-inch) roof slabs. The unit has 1.5 meters (5 feet) or 120 cubic meters (4,200 cubic feet) of gravel fill backfilled over with 0.6 meters (2 feet) of soil, leaving 1.5 meters (5 feet) of the excavation unfilled. The distance from the release point to the site bottom is 1.2 meters (4 feet). The side slope is 1:2.

Waste Type: Process Effluent

Waste Description: From January 1953 until September 1955, the site received high salt waste (HSW), cold-run waste, and the process condensate from the 201-C Building. From September 1955 to June 1957, the site received the HSW cold-run waste from the 201-C Building. Waste neutralized in the 241-CX-71 tank was discharged to this crib. The waste is high in salt and is neutral to basic.

---

Code: 216-C-2  Classification: Accepted
Names: 216-C-2; 216-C-2 Dry Well; 216-C-2 Reverse Well; 291-C Dry Well  Reclassification: None
Type: Injection/Reverse Well  Start Date: 1/1/1953
Status: Inactive  End Date: 5/16/1988

Description: The reverse well is no longer visible. It is not separately marked or posted from the surrounding stabilized area (200-E-41) that is posted as Underground Radioactive Material.

Location: The unit is located inside the 200-E-41 Stabilized Area, south of 7th Street in 200 East Area. It is southeast of the former 291-C-1 Stack location, in the Hot Semiworks area.

Related Sites/Structures: The dry well is related to the 291-C-1 Stack and the 291-C-1 Stank Ventilation Filter. The pipelines associated with 216-C-2 are sitecodes 200-E-251-PL and 200-E-252-PL.

Process Description: The dry well was a 30.5-centimeter (12-inch) diameter pipe that extended 0.3 meters (1 foot) above grade to 12 meters (40 feet) below the surface. The bottom 7.6 meters (25 feet) of the pipe was perforated. The drain is surrounded by a concrete collar at grade. A 10-centimeter (4-inch) stainless steel saran-lined inlet pipe connected the unit to the 291-C-1 Stack. A second inlet line constructed of 5.1-centimeter (2-inch) stainless steel pipe connected to the 291-C-1 Stack Ventilation Filter.

Waste Type: Water

Waste Description: The site received 291-C Stack drainage and the seal water drainage from the stack ventilation filters. The volume discharged to the unit is unknown. The waste is low in salt and is neutral to basic. The site contains less than 1 curie total beta activity.

</table>

**Description:**

The crib is marked with concrete AC-540 markers and Underground Radioactive Material signs. It is located within the larger, surface stabilized area known as 200-E-41.

**Location:**

The crib is located south of 7th Street, within the Hot Semiworks stabilized area (200-E-41).

**Related Sites/Structures:**

The crib is associated with the 201-C facility, 241-CX-71 and 200-E-41. The pipeline associated with this crib is sitecode 200-E-173-PL.

**Process Description:**

The crib received 201-C "high salt waste" cold run waste via a 15-centimeter (6-inch) diameter galvanized, corrugated, perforated piping placed horizontally at 3.4 meters (11 feet) below grade. Two 6.1-meter (20-foot) lengths are placed perpendicularly to the inlet pipe, forming an H pattern. The side slope is 1:1. The site contains approximately 1.8 meters (6 feet) or 74 cubic meters (2,600 cubic feet) of gravel fill and has been backfilled. The waste release point is 1.5 meters (5 feet) from the site bottom.

**Waste Type:**

Process Effluent

**Waste Description:**

The site received the high salt waste (HSW) cold run waste from the 201-C Building. It received some waste that had passed through the 241-CX-71 Neutralization Tank.

**Description:**

The crib is marked with concrete AC-540 markers and Underground Radioactive Material signs. It is located within the larger, surface stabilized area known as 200-E-41.

**Location:**

The crib is located south of 7th Street, within the Hot Semiworks stabilized area (200-E-41).

**Related Sites/Structures:**

The crib is associated with the 201-C facility, 241-CX-71 and 200-E-41. The pipeline associated with this crib is sitecode 200-E-173-PL.

**Process Description:**

The unit is constructed of 15-centimeter (6-inch) diameter galvanized, corrugated, perforated piping placed horizontally at 3.4 meters (11 feet) below grade. Two 6.1-meter (20-foot) lengths are placed perpendicularly to the inlet pipe, forming an H pattern. The side slope is 1:1. The site contains approximately 1.8 meters (6 feet) or 74 cubic meters (2,600 cubic feet) of gravel fill and has been backfilled. The waste release point is 1.5 meters (5 feet) from the site bottom.

**Waste Type:**

Process Effluent

**Waste Description:**

The site received the process condensate from the 201-C Building and the 241-CX Vault floor drainage in the 241-CX area. The waste is acidic.
| Description | The site is surrounded by steel post and chain. It is posted with Underground Radioactive Material signs. |
| Location | The site is located southwest of the 209-E Building, inside the 209-E exclusion area fence. |
| Related Sites/Structures | The crib is associated with 209-E-WS-3. The pipeline associated with this crib is sitecode 200-E-172-PL. |
| Process Description | The crib received radioactive liquid waste from the 209-E Critical Mass Laboratory via 5 centimeter (2 inch) diameter steel pipeline that connected to a 0.15 meter (6 inch) diameter, perforated vitrified clay distribution pipe, placed horizontally 3 meters (9 feet) below grade. Two lengths of clay pipe are placed perpendicularly to the first, forming an H pattern. The site contains 123 cubic meters (4,100 cubic feet) of gravel fill and has been backfilled. |
| Waste Type | Process Effluent |
| Waste Description | The 216-C-7 crib received liquid waste from the 209-E Building Critical Mass Laboratory. Small tanks held reflector water that contained nitric acid, plutonium, uranium and neutron poisons such as boron, cadmium and gadolinium. The crib was placed on standby in 1983. |

| Code | 216-C-10 | Classification | Accepted |
| Names | 216-C-10; 216-C-10 Crib | Reclassification | None |
| Type | Crib | Start Date | 11/1/1964 |
| Status | Inactive | End Date | 10/1/1969 |
| Description | The site is marked with concrete AC-540 markers and Underground Radioactive Material signs. The surface is covered with gravel. |
| Location | The site is located south of 7th Street and southeast of the 201-C Building core. |
| Related Sites/Structures | The site is associated with the 201-C facility and the 200-E-157-PL pipeline. |
| Process Description | The crib received process condensate from 201-C via a 7.6-centimeter (3-inch) diameter stainless steel pipe, located horizontally, 1.2 meters (4 feet) below grade. The site slope is 1:1.5. The site contains 48 cubic meters (1,700 cubic feet) of gravel fill and has been backfilled with dirt. |
| Waste Type | Water |
| Waste Description | The site received process condensate and liquid waste from the 201-C Building. The waste was acidic. |

| Code | 291-C-1 | Classification | Accepted |
| Names | 291-C-1; 291-C-1 Stack; 291-C Stack Burial Trench | Reclassification | None |
| Type | Burial Ground | Start Date | 1/1/1949 |
| Status | Inactive | End Date | 1/1/1987 |
| Description | The 291-C Stack was a double-shell structure made of reinforced concrete, acid-resistant brick and mortar. The stack was demolished in 1988 and now lies in a trench south of where it
stood. The area has been surface stabilized with an ash cover (sitecode 200-E-41). The stack burial trench is not marked and cannot be separately distinguished from the rest of the surface stabilized area.

**Location:** The stack was located east of the 201-C facility, south of 7th Street in 200 East Area.

**Related Sites/Structures:** The site is associated with 201-C and the 200-E-41 surface stabilized area.

**Process Description:** The stack provided exhaust air ventilation for the 201-C cells and process vessels. Forty fiber glass filters were located in an underground concrete cell. An array of HEPA filters was contained in another below-grade enclosure.

**Waste Type:** Water

**Waste Description:** The radioactively contaminated stack now lies in a trench south of where it stood. It was estimated to contain 100 curies of plutonium and 600 curies of beta contamination.

---

**Code:** 2704-C-WS-1

**Names:** 2704-C-WS-1; Gatehouse French Drain; 2704-C French Drain

**Type:** French Drain

**Status:** Inactive

**Classification:** Accepted

**Reclassification:** None

**Start Date:** 1/1/1949

**End Date:** 1/1/1998

**Description:** The 2704-C Building was demolished in 1998. The area where the french drain was located is now within a larger gravel area that is posted Underground Radioactive Material (URM). The drain is no longer visible at the location described. The drain could be covered with gravel or by the two dumpsters located in the area. There is a possibility that this site is the same site as that identified in HW-22955 as a quench tank. The description follows. Steam condensate drained to a quench tank at the southwest corner of the building (2704C). Sanitary waste drains through a 10.2 centimeter (4 inch) cast iron line running beneath the floor slab from the toilet room to a point 1.5 meters (5 feet) west of the building where it connects to a 10.2 centimeter (4 inch) tile drain. The overflow from the quench tank also flows into this tile drain which runs to the sanitary waste disposal field. The sanitary waste disposal field is part of the 2607-E7 Septic System. (Drawings H-2-4033, H-2-4012, and H-2-4013 identify a quench tank. Drawing H-2-77665 identifies a french drain).

**Location:** This site is located in 200 East. It is located at the southwest corner of the 2704-C Building.

**Related Sites/Structures:** The site was related to the 2704-C, Office and Gate House. The pipeline associated with this french drain is sitecode 200-E-250-PL. The Hot Semiworks surface stabilized area is known as 200-E-41. The demolished 2704-C building and drain are adjacent to the Hot Semiworks stabilized area.

**Process Description:** The 2704-C building was originally built in 1949 to support the Hot Semiworks operations. It was a one story wooden structure, on a cement slab foundation, that contained the security office (Gate House), a lunch room and a toilet. Building steam condensate drained to a quench tank located at the southwest corner of the building. During the 1980s, 2704C housed the 200 East Tank Farms Health Physics (HPT) Offices. Prior to demolition by Bechtel Hanford Inc. (BHI), the building was designated a contaminated facility.

**Waste Type:** Water

**Waste Description:** Although the drain received building steam condensate, periodically the drain was labeled with radioactive postings.
Reclassification: 200-E BP; 200-E Burning Pit; 200 East Burn Pit

Burn Pit

Inactive

Start Date: 1/1/1950

End Date: 1/1/1970

Description: The burn pit is a large depression. There is limited growing vegetation. The surface is mostly rock and gravel. In 2010, most of the burn pit was posted as a Soil Contamination Area, due to contaminated tumbleweed fragments accumulating within the pit.

Location: The burn pit is located in the northeast corner of 200 East Area, south of 12th Street and west of Canton Ave. It is a large excavation located east of the 218-E-8 Burial Ground.

Related Sites/Structures: The site is associated with WIDS sitecode 200-E-8 BPDS, 200-E-109 and UPR-200-E-106.

Process Description: Burn pits were typically used for disposal of non radioactive construction and office wastes. Sometimes paint, solvents and chemicals were dumped there. The pit was also used to burn tumbleweed that were collected off the 200 East Area perimeter fences. In the late 1990's, miscellaneous, non-radioactive material began to be stored inside the burn pit. Many damaged load luggers and large Basin Disposal, Inc. trash containers accumulated in the pit. Some containers were empty, but some containers had material in them. In the spring of 2010, MSA began to remove the containers from the burn pit. The containers were radiological surveyed and released. The released containers were sent off site to Basin Disposal, Inc. One large roll off container may be sent to the Environmental Restoration Disposal Facility (ERDF).

Waste Type: Process Effluent

Waste Description: A site visit in 1991 noted an area within the pit posted with asbestos warning signs.

Waste Type: Process Effluent

Waste Description: This site received construction and office waste 1,500 cubic meters (1,960 cubic yards), paint wastes, and chemical solvents 1,000 cubic meters (1,300 cubic yards).

Reclassification: 200-E PD; 200-E Powerhouse Ditch; 200 East Powerhouse Pond

Active

Start Date: 1/1/1945

End Date: 

Description: The site currently consists of an open ditch, measuring approximately 580 meters, running east to west. The eastern portion of the original ditch was backfilled in 1996, due to a contamination spread. This portion is currently posted with Underground Radioactive signs.

Location: The ditch is located north of 4th Street and south of the Hot Semi-Works area.

Related Sites/Structures: The ditch is associated with the 284-E Powerhouse, 283-E, 282-E, 200-E-286 swamp, UPR-200-E-100 and UPR-200-E-143. The pipeline associated with the ditch is sitecode 200-E-237-PL.

Process Description: The ditch is fed from a 42 inch diameter underground pipeline connected to the 282-E, 283-E and 284-E facilities. The original, horse shoe shaped ditch emptied into a shallow depression east of the 200 East Area fence known as the Powerhouse Pond (see 200-E-286) from 1946.
through 1953. In 1954, the powerhouse ditch effluent was redirected in a northeast direction, to connect to 216-B-3 Pond. The water was discharged from the ditch to a 24 inch diameter pipeline that led to the 216-B-3C Pond. In 1997, when discharges to the 216-B-3C Pond were discontinued, the effluent from the Powerhouse Ditch was diverted to the 200 Area Treated Effluent Disposal Facility (TEDF). The 284-E powerhouse was completely shut down in 1998. After the powerhouse was shutdown, a small amount of effluent continued to be discharged to the ditch from the 282-E and 283-E water treatment facility and reservoir. During 1997 and 1998, blowdown/boiler condensate from the Johnson Controls facility also discharged to the ditch. A very small amount of effluent continues to be discharged to the pipeline (200-E-237-PL) that feeds the ditch.

**Waste Type:** Equipment

**Waste Description:** The ditch received cooling water, boiler blowdown, floor drain discharge, softener regeneration effluents, filter backwash, and sedimentation basin cleanout from 282-E, 283-E and 284-E. During 1997 and 1998, a small amount of water from the Johnson Controls package boiler was discharged to the ditch. The volume of discharge has varied of the life of the ditch. Only a very small amount of water is currently discharged to the pipeline and ditch.

---

**Code:** 200-E-4

**Classification:** Accepted

**Names:** 200-E-4; 209-E North Dry Well; Critical Mass Laboratory Dry Well North; Miscellaneous Stream #730

**Reclassification:** None

**Type:** French Drain

**Start Date:** 1/1/1958

**End Date:** 1/1/1959

**Description:** The site is a 1.2 meter (4 foot) diameter dry well, covered with a yellow metal cover. In 2011, amended water was sprayed during the 209E building demolition activities. Post-demolition, three to six inches of surface material was removed from all areas affected by the amended water and prior to applying a gravel cap. The final gravel cap was expanded to cover all affected areas. The posted URMA was expanded to include the entire gravel cap. The gravel cap now covers several WIDS sites. The additional WIDS sites under the 209E gravel cap are 200-E-4, 200-E-35, 209-E-WS-1, 209-E-WS-2, 2718-E-WS-1 and 200-E-293 (2718E footprint). The 209-E-WS-3 (Tank 111), adjacent to the south side of the foundation, is within the URMA but was not covered or backfilled.

**Location:** The site is located approximately 7.6 meters (25 feet) north of the northwest corner of the 209-E Critical Mass Laboratory Service Building.

**Related Sites/Structures:** The site is connected to 209-E Critical Mass Lab via underground piping (see sitecode 200-E-249-PL) and the 209E gravel cap (200-E-294).

**Waste Type:** Water

**Waste Description:** The waste was steam condensate from the steam trap in the valve pit plus steam condensate from the equipment room.

---

**Code:** 200-E-13

**Classification:** Accepted

**Names:** 200-E-13; Rubble Piles from RCRA General Inspection #200EFY95 Item #7

**Reclassification:** None

**Type:** Dumping Area

**Start Date:**

**End Date:**
Description: A 1995 site inspection identified this site and described it as numerous rubble piles. These piles contained inert construction debris, such as wood, asphalt, dirt, pipe and concrete. Another site visit occurred in February 1997. The following debris was identified: asphalt paving, concrete, steel pipe, rebar and PVC pipe. During a GPS survey on August 26, 1998, it was observed that debris was concentrated in piles south of an old borrow area. However, there were also isolated piles/berms of debris beyond this concentration, primarily to the west. Some scattered debris and half-buried towels or rags were observed in the borrow area. A site visit on July 26, 1999, confirmed the previous site conditions.

Location: The site is located inside 200 East Area, south of the PUREX facility. The site is north of First Street, off a dirt road approximately 220 meters (722 feet) west of the intersection of First Street and Canton Avenue.

Waste Type: Process Effluent
Waste Description: The waste contains inert construction debris that includes wood, asphalt, dirt, pipe, and concrete.

compressors, and other heavy equipment. As of October 2001, the site no longer shows visual evidence of oil contaminating the soil. In 1996, the soil had an odor like diesel fuel, but this was not reported in 2001. The contamination noted in 1996 appeared to be spotty. An electrical receptacle marks each end of the site.

**Location:** The site is located in the 200 East area, south of B Plant, within the former ICF Kaiser Construction Complex.

**Release Description:** Heavy equipment was stored in this area for several years. The contaminated soil is most probably due to equipment leakage.

**Waste Type:** Steam Condensate

**Waste Description:** The soil at the site is contaminated with oil and diesel fuel.

---

**Code:** 200-E-29  
**Names:** 200-E-29; Unplanned Release from 241-ER-152 Diversion Box  
**Type:** Unplanned Release  
**Status:** Inactive  
**Classification:** Accepted  
**Reclassification:** None

**Description:** The site is a large, irregular shaped, posted Underground Radioactive Material (URM) area. A smaller triangular shaped URM area is located adjacent to the east shoulder of Atlanta Ave., northwest of the larger, stabilized 200-E-29 area. Another small URM area is located adjacent to a row of conex boxes, east of the larger stabilized area.

**Location:** The site is located south of 221-B, south of 7th Street and east of Atlanta Ave. It surrounds the 241-ER-152 Diversion Box.

**Related Sites/Structures:** The site is associated with the 241-ER-152 Diversion Box.

**Waste Type:** Steam Condensate

**Waste Description:**

---

**Code:** 200-E-43  
**Names:** 200-E-43; Regulated Equipment Storage Area; Tank Car Storage Area; TC-4 Spur Tank Car Storage Area  
**Type:** Storage  
**Status:** Inactive  
**Classification:** Accepted  
**Reclassification:** None

**Description:** This site consists of a chain link fenced portion of the TC-4 Spur located northwest of the PUREX facility. The site was used to store railroad tank cars containing liquid radioactive material that require controls due to radiological dose rate conditions. The fence gate is locked. The area had been posted as a Radioactive Material Area (RMA) and an Underground Radioactive Material area (URM). However, in January 1999, it was only posted as an Underground Radioactive Material area. It is also posted with "Danger - Unauthorized Personnel Keep Out" signs. The ties between the rails are covered with gravel.
The site is located inside 200 East Area, north of 4th Street.

On December 17, 2010, approximately 576,000 gallons of potable water discharged to the ground during a construction water line tie in activity. The water flowed south, from the line break and flooded a portion of the TC-4 Spur Railcar Storage Area and the UPR-200-E-88 stabilized railroad track. Although no railcars are being stored here, the area is still fenced and radiologically posted.

The site is associated with the TC-4 Railroad Spur and UPR-200-E-88.

The fenced area was used to stage railroad tank cars that transported liquid waste to the 204-AR waste unloading facility.

The waste site is an irregular shaped area in the bottom of a soil depression. Rockwell document RHO-CD-1048 and photographic documentation from 1982 indicate this area was used to store contaminated equipment. The size, shape and type of posting has varied over the years.

The site is located adjacent to and east of 218-E-12B Burial Ground and adjacent to and south of 218-E-8 Burial Ground inside 200 East Area.

This site is associated with 200-E-109, UPR-200-E-50 and UPR-200-E-62.

Misc. Trash and Debris

Contaminated soil specks, vegetation and animal feces have been identified in this area.

The area adjacent to the 201-C Building has been surface stabilized with flyash. The stabilized area has been given the WIDS Site code 200-E-41 and is posted as an Underground Radioactive Material area. The release site is not separately marked or posted, and may be combined with 200-E-41.

The waste line leak was adjacent to the east side of the 201-C Building.

HW-52860 states that teflon flange gaskets on the stainless steel underground waste line from 201-C to 241-C Tank Farm developed leaks. The leaks caused the underground area next to the east side of the 201-C Building and an underground area near the east facility fence to become
Contaminated (see 200-E-57). Radiation readings in 1957 were greater than 100 rad per hour at a depth of 3.66 meters (12 feet) adjacent to the 201-C Building and near the fence. The underground waste line was abandoned and by pass sections installed. New sections of pipeline were installed south of the leaking sections.

**Related Sites/Structures:**
The site is associated with 200-E-57, surface stabilized area 200-E-41 and pipelines 200-E-149-PL and 200-E-257-PL.

**Process Description:**
The Hot Semiworks Facility was constructed in 1949. The facility was a pilot plant for the testing of the REDOX and PUREX plutonium separation processes from 1952 through 1957. The facility pilot tests used irradiated fuels. The facility was placed in standby status in 1957. In 1961 the plant was converted for the strontium recovery process of waste stored in tank farms. The Hot Semiworks facility permanently shut down in 1967. Decommissioning began in 1983 and was completed in 1987.

**Waste Type:** Steam Condensate

**Waste Description:** A leaking underground waste line caused the soil beneath the line to become contaminated. The pipeline carried waste from the 201-C Building to the 241-C Tank Farm. Maximum contamination levels in 1957 were greater than 100 rad per hour.

**Code:** 200-E-57  **Classification:** Accepted

**Names:** 200-E-57; 241-C Waste Line Leak East of 201-C; Waste Line Leak #2  **Reclassification:** None

**Type:** Unplanned Release  **Start Date:**

**Status:** Inactive  **End Date:**

**Description:** The area around the Hot Semiworks Facility has been surface stabilized with flyash. The stabilized area is known as 200-E-41 and is posted with Underground Radioactive Material signs. This release site is separately not marked or posted, and may be combined with 200-E-41.

**Location:** This release occurred at an underground waste line, located east of the 201-C Building, adjacent to the east Semiworks fence. The fence no longer exists.

**Release Description:** HW-52680 states that teflon flanges on the 5-centimeter (2-inch) stainless steel underground waste line from 201-C to the 241-C Tank Farm leaked and caused the soil beneath the line to become contaminated. One leaking flange was located near the Semiworks fence. The attached sketch indicates an underground contaminated area measuring 9 meters (30 feet) long. Radiological readings in 1957 ranged from 6 rad per hour at a depth of 0.3 meters (1 foot) to greater than 100 rad per hour at a depth of 4.5 meters (15 feet) at this location. The document states the line also leaked in an area adjacent to the east side of the 201-C Building (see 200-E-56). The underground waste line was abandoned and by pass sections installed. New sections of pipeline were installed south of the leaking sections.

**Related Sites/Structures:** The site is associated with 200-E-41 and 200-E-56.

**Process Description:** The Hot Semiworks Facility was constructed in 1949. The facility was a pilot plant for the testing of the REDOX and PUREX plutonium separation processes from 1952 through 1957. The facility pilot tests used irradiated fuels. The facility was placed in standby status in 1957. In 1961 the plant was converted for the strontium recovery process of waste stored in tank farms. The Hot Semiworks facility permanently shut down in 1967. Decommissioning began in 1983 and was completed in 1987.

**Waste Type:** Steam Condensate
### Waste Description:

A leaking underground waste line caused the soil beneath the line to become contaminated. The pipeline carried waste from the 201-C Building to the 241-C Tank Farm. Maximum contamination levels in 1957 were greater than 100 rad per hour.

### Code: 200-E-58

### Classification: Accepted

### Names: 200-E-58; 216-A-5 Neutralization Tank; 216-A-5 NU; 270A; IMUST; Inactive Miscellaneous Underground Storage Tank; Tank A5

### Reclassification: None

### Type: Neutralization Tank

### Start Date: 1/1/1955

### End Date: 1/1/1987

### Description:

The site is an underground tank used to neutralize acidic waste prior to disposal. A 101-centimeter (40-inch) riser is visible at the surface. The cylindrical tank sits vertically on a concrete pad. The tank is constructed of welded stainless steel and has a capacity of approximately 28,400 liters (7,500 gallons). A 20-centimeter (8-inch) inlet pipe enters from the north near the base of the tank. The inlet connects into distribution piping constructed of 20-centimeter (8-inch) stainless steel pipe welded into a cross with 1.9-centimeter (3/4-inch) holes drilled at 23-centimeter (9-inch) intervals. A 20-centimeter (8-inch) outlet pipe exits to the south near the top of the tank. A 101-centimeter (40-inch) riser extends 30 centimeters (12 inches) above the surface. The "charging riser" is for adding limestone to the tank to act as a neutralizing agent.

### Location:

The tank is located south of PUREX, inside the security fence. It is located south of the 295-AB building, north of the 216-A-5 Crib and northwest of the 216-A-10 Crib.

### Related Sites/Structures:

The site is related to the 202-A Building (PUREX Canyon), the 216-A-5 Crib, and the 216-A-10 Crib. The pipelines from PUREX to the neutralization tank and from the neutralization tank to the 216-A-5 Sample Pit #4 are described in 200-E-241-PL.

### Process Description:

Acidic liquid waste entered the tank from the bottom and was forced upward through a bed of limestone. Interaction with the limestone neutralized the waste prior to overflow through the outlet pipe. The neutralized waste was discharged to a crib.

### Waste Type: Steam Condensate

### Waste Description:

The tank was used to neutralize acid waste from PUREX prior to ground disposal. From 1955 to 1961, the neutralized waste was discharged to the 216-A-5 Crib. From 1961 to 1987 the neutralized waste was discharged to the 216-A-10 Crib.

### Code: 200-E-68

### Classification: Accepted

### Names: 200-E-68; 291A Control House Steam Condensate; Injection Well (L); Miscellaneous Stream #59

### Reclassification: None

### Type: Injection/Reverse Well

### Start Date: 

### End Date: 

### Status: Inactive

### Description:

The site is a 1.2 meter (4 foot) diameter drain with a metal cover. Several disconnected, asbestos covered steam lines hang above it.

### Location:

The site is located south of PUREX, between the 291-A stack exhaust fans and the 292-AB stack building. It is on the southeast corner of 291-A building. It is located inside a Contaminated Area, which surrounds the 291-A building and stack structures.
**Process Description:** Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.

**Waste Type:** Ash

**Waste Description:** The site received non-contaminated steam condensate, but is located inside a posted Contamination Area.

**Description:** 200-E-109 is areas of contaminated tumbleweed accumulation located mostly in the northeast portion of 200 East Area. The contaminated vegetation is carried by the wind. When the site was originally added to the WIDS database, it consisted of numerous radiologically posted areas along 12th Street and Canton Avenue inside the 200 East Area as well as inside and around the Liquid Effluent Retention Facility, east of 200 East Area. Some areas were posted Contamination Area with a Radiological Buffer Area and others were posted High Contamination Area with a Radiological Buffer Area. The original posted areas were eventually
cleaned up and the posting was removed. However, additional areas of accumulated tumbleweed fragments continue to be discovered and posted over the years. The number of posted areas, their size and shape vary with additional radiological surveys.

**Location:** The site includes numerous radiologically posted areas, located in the northeast portion of the 200 East Area and beyond the 200 East Area perimeter fence. Contaminated vegetation is often identified on the northern 200 East Area fence line along 12th Street, the eastern fence along Canton Avenue, near Gate 810 and outside the 200 East Area fence in and around the Liquid Effluent Retention Facility. The posted areas size and shape varies often, with additional radiological surveys.

**Related Sites/Structures:** UPR-200-E-92 and UPR-200-E-93 reported contaminated tumbleweed fragments along the east perimeter fence of 200 East area in 1980. The tumbleweeds reported in both UPR-200-E-92 and UPR-200-E-93 were removed from the fenceline in 1981. It is also associated with burial ground 218-E-12b, which has been considered a major source of the contaminated waste.

**Waste Type:** Steam Condensate

**Waste Description:** Most of the contamination identified is tumbleweed and tumbleweed fragments.

Type: Unplanned Release
Status: Inactive

Description: The area where the contamination is located is marked with two Underground Radioactive Material signs, on steel posts. The posts are located on the north and south sides of the road. The contamination is located between the signs, under the surface of the gravel road.

Location: The site is located on an unnamed gravel road east of the 207-B Retention Basin and south of the 216-B-2-3 Ditches.

Process Description: The roads inside 200 East and West Areas are routinely surveyed by a truck mounted with radiation detectors. The detectors are equipped with an alarm that makes an audible sound to
alert the driver if radiation above a predetermined limit is detected.

**Waste Type:** Process Effluent

Code: 209-E-WS-2
Names: 209-E-WS-2; Critical Mass Lab French Drain
Type: French Drain
Status: Inactive
Description: The drain was a 1.2 meter (4 foot) diameter drain in a gravel area southeast of the building. It was painted with yellow paint and has a metal cover. In 2011, amended water was sprayed during the 209E building demolition activities. Post-demolition, three to six inches of surface material was removed from all areas affected by the amended water and prior to applying a gravel cap. The final gravel cap was expanded to cover all affected areas. The posted URMA was expanded to include the entire gravel cap. The gravel cap now covers several WIDS sites. The additional WIDS sites under the 209E gravel cap are 200-E-4, 200-E-35, 209-E-WS-1, 209-E-WS-2, 2718-E-WS-1 and 200-E-293 (2718E footprint). The 209-E-WS-3 (Tank 111), adjacent to the south side of the foundation, is within the URMA but was not covered or backfilled.

Location: The unit is located at the southeast corner of the Critical Mass Laboratory (laboratory wing).
Related Sites/Structures: The site is associated with the 209-E Critical Mass Laboratory and 200-E-294. The pipelines to the french drain are described in sitecode 200-E-247-PL.
Process Description: The unit is a french drain that received condensate from the Critical Mass Lab HEPA filters and heat exchange system.
Waste Type: Chemicals
Waste Description: The waste at the unit includes steam condensate through a collapsed rusted pipe from the Heat Exchanger located in Room 11 of 209-E and a stainless steel pipe from the clean side of the HEPA filters.

Code: 209-E-WS-3
Names: 209-E-WS-3; Critical Mass Laboratory Valve Pit and Hold Up Tank (209-E-TK-111); IMUST; Inactive Miscellaneous Underground Storage Tank
Type: Valve Pit
Status: Inactive
Description: The Valve Pit has a steel lid and posted with Radioactive Material, Internally Contaminated Systems Located Within, and Confined Space, Dome Loading, Ignition Control and IMUST warning signs. In December 2011, the 209-E facility was demolished. On 10/10/2011 the task of disconnecting, cutting and plugging five lines in the 209-E Valve Pit (209-E-WS-3) that isolated Tank-111 was completed. The Valve Pit metal lid will be placed back on it. The 209E facility slab is sitecode 200-E-294. The pit will not be covered or back-filled with gravel, because there are other lines still in the valve pit associated with the tank farms and not part of the facility demolition work scope.
In 2011, amended water was sprayed during the 209E building demolition activities. Post-demolition, three to six inches of surface material was removed from all areas affected by the amended water and prior to applying a gravel cap. The final gravel cap was expanded to cover all affected areas. The posted URMA was expanded to include the entire gravel cap. The gravel cap now covers several WIDS sites. The additional WIDS sites under the 209E gravel cap are 200-E-4, 200-E-35, 209-E-WS-1, 209-E-WS-2, 2718-E-WS-1 and 200-E-293 (2718E footprint). The 209-E-WS-3 (Tank 111), adjacent to the south side of the foundation, is within the URMA (200-E-294) but was not covered or backfilled.

Location: The tank is located underground, near the south end of the 209-E Facility. The north edge of the tank is about 3 ft (0.9 m) south of the south wall of the 209-E Building's Critical Assembly Room and abuts the east side of the exhaust equipment pad.

Related Sites/Structures: There is a thin, cadmium-lined Hold-Up Tank, 209-E-TK-111, associated with and under the Valve Pit. The pipelines to the valve pit are described in sitecode 200-E-248-PL. The 209E posted area is 200-E-294.

Process Description: A 189 liter (50 gallon) holding tank (209-E-TK-111) is located under the valve pit. The tank was used as a drain tank. The tank held the condensate prior to being released to the cribs. The tank was routinely sampled for plutonium content to determine that the contents were below crib discharge levels. Present contents of the tank are estimated to consist of residual water from condensate collection, containing only low levels of plutonium. After sampling, the contents was discharged to the 216-C-7 crib. The 216-C-7 crib was placed on standby in 1983.

Waste Type: Soil

Waste Description: The Semi-Works Source Aggregate Area Management Study Report states that no wastes are present in the Critical Mass Laboratory Valve Pit. However, radioactive contamination is present in the valve pit sump, although no specific waste inventories for this unit were found. The Hold Up tank was routinely sampled to verify plutonium levels were below limits prior to discharging the contents to the crib.

This Site has the Following SubSites:

Code: 209-E-WS-3:1
Names: 209-E-WS-3:1; 209-E-TK-111 Hold Up Tank

Code: 209-E-WS-3:1
Classification: Accepted
Names: 209-E-WS-3:1; 209-E-TK-111 Hold Up Tank
Reclassification: None
Type: Valve Pit
Status: Inactive
Start Date:
End Date:
Description: The 209-E-TK-111 tank is inactive. It is a passively ventilated drain tank. A recent vapor sample did not identify any flammable gas within the vessel. In December 2011, the 209-E facility was demolished. On 10/10/2011 the task of disconnecting, cutting and plugging five lines in the 209-E Valve Pit (209-E-WS-3) that isolated Tank-111 was completed. The tank was used to hold condensate from the facility. It was routinely sampled to determine that plutonium levels were below limits prior to discharging the contents to the crib. Therefore, it is estimated to consist of residual water from condensate collection and low levels of plutonium. This tank meets the definition of an IMUST tank. It is a 189 liter (50 gallon) capacity tank lined with cadmium. It is located underground, adjacent to the Criticality Assembly Room (CAR) at the south end of the 209-E building. It is covered by a steel pit cover and posted with Radioactive Material, Contamination Area and Confined Space Entry signs.

In 2011, amended water was sprayed during the 209E building demolition activities. Post-demolition, three to six inches of surface material was removed from all areas affected by the
amended water and prior to applying a gravel cap. The final gravel cap was expanded to cover all affected areas. The posted URMA was expanded to include the entire gravel cap. The gravel cap now covers several WIDS sites. The additional WIDS sites under the 209E gravel cap are 200-E-4, 200-E-35, 209-E-WS-1, 209-E-WS-2, 2718-E-WS-1 and 200-E-293 (2718E footprint). The 209-E-WS-3 (Tank 111), adjacent to the south side of the foundation, is within the URMA (200-E-294) but was not covered or backfilled.

The SubSite is Part Of:

Code: 209-E-WS-3
Names: 209-E-WS-3; Critical Mass Laboratory Valve Pit and Hold Up Tank (209-E-TK-111); IMUST; Inactive Miscellaneous Underground Storage Tank

<td>It is associated with 270-E, the 221-B, 224-B Buildings, 200-E-160-PL and the 216-B-12 Crib. UPR-200-E-64 documents that ants brought contamination to the surface in the vicinity of the 270-E Tank and caused contamination to spread.</td>
</tr>
<tr>
<td>Process</td>
<td>The tank was used to neutralize acidic process condensate from the 221-B and the 224-B facilities, via the 241-ER-151 Diversion Box (lines V219, V225, 9719, 9653, 9808).</td>
</tr>
</tbody>
</table>
Condensate entered the tank at the bottom and flowed upward through the limestone to an outlet pipe located 2.4 meters (8 feet) above the tank bottom. The tank contained a limestone bed through which the condensate percolated, reacted, and then overflowed to the 216-B-12 Crib. The tank had a 100 centimeter (40 inch) diameter chute and a 15 centimeter (6 inch) diameter riser extending to the surface from the stainless steel below grade tank.

Waste Type: Storage Tank
Waste Description: A 1974 report indicated the surface of the sludge was located at 2.27 meters (7.58 feet). No liquid was visible at this time. Sludge volume was estimated to be 14,440 liters (3,800 gallons). Radiation readings were less than 100 counts per minute direct and smearable, and less than 0.5 millirad/hour at the risers. Waste in this tank should include: limestone, process condensate precipitates, salts and residual process condensates. The process condensate that passed through this tank contained an average of 0.015 grams per gallon of uranium, 2.6 E-7 grams per gallon of plutonium and 1.8 E-6 curies per gallon of beta emitters.

Code: 299-E24-111  Classification: Accepted
Names: 299-E24-111; Experimental Test Well Site; Lysimeter Test Site; Miscellaneous Stream #803  Reclassification: None
Type: Injection/Reverse Well  Start Date: 9/22/1980
Status: Active  End Date: 1/1/2000
Description: The site is an injection well surrounded by 32 observation wells. The 299-E24-111 injection well head is located inside a small posted Underground Radioactive Material area. There is a small Soil Contamination Area (SCA) located southwest of the well. The SCA is where the 5,700 liter (1500 gallon) above ground solution tank (connected to the well) had been located.
Location: The site is located southwest of the PUREX facility and west of the 216-A-38-1 Crib.
Related Sites/Structures: The injection well was connected to a 5,700-liter (1,500-gallon) above ground mixing tank. The injection well is surrounded by eight concentric rings of observation wells. There are a total of 32 observation wells. The observation wells are each 15-centimeter (6-inch) diameter steel casings, 19.8 meters (65 feet) long. These observation wells are identified as 299-E24-76 through 299-E24-107. The injection well is constructed of a 4.6-meter (15-foot) long, 2.5-centimeter (1-inch) diameter pipe inside a 4.6-meter (15-foot) casing that is welded together at the lower end. This assembly is cemented inside a 4.6-meter (15-foot), 15-centimeter (6-inch) diameter Schedule 40 steel well.
Process Description: In 1980, uniform solutions of calcium chloride, calcium nitrate, and selected tracers were placed into the above ground mixing tank on a weekly basis and injected into the well. The 32 observation wells monitored the injected material. The tracers included sorbing and nonsorbing ions. Calcium was added at a concentration of 0.01 normal as 0.005 normal calcium nitrate plus 0.005 normal calcium chloride to reduce permeability changes of the sediments during injection, and to provide the nonsorbing ions nitrate and chloride. Cesium-134 is a gamma emitter and undergoes strong sorption by the sediments. Strontium-85 was chosen because it is a gamma emitter and is moderately sorbed by sediments. Each injection consisted of filling the holding tank, adding the tracers, mixing the water and tracers, and then injecting the solution. Water for each of the 10 weekly injections was transported to the site from a nearby safety shower in 1900 liter (500 gallon) vinyl bags. From the bags, 3800 liters (1000 gallons) of water was metered into a 5700 liter (1500 gallon) tank. Calcium salts and additional sorbing tracers, barium and rubidium, were dissolved in two 50 liter (13 gallon) carboys at the injection site. The carboys were rinsed and the rinsate was added to the tank. The radiological tracers strontium-85 and cesium-134 were delivered for each weekly injection as a 20 milliliter solution. The glass vial containing the tracers arrived at the site in a lead container called a pig.
The pig was placed in the tank on a rack before opening and removing the vial. The vial was handled with modified tongs. The cap was unscrewed from the vial, the vial contents poured into the calcium solution in tank, and the vial and cap rinsed using a polyethylene wash bottle. Washing continued until less than 300 counts per minute were observable with a handheld GM probe in contact with the vial and cap. For the first three tanks of solutions, the contents were circulated in tank until the solution was uniform, as evidenced by constant gamma activity at all points on the tank exterior. It was found that a uniform count rate was obtainable within 5 minutes after starting circulation, but mixing was continued for 2 hours. For the remaining injections, the tracer and calcium solutions were added after 1900 liters (500 gallons) of water was metered into the tank. Adding the final 1900 liters (500 gallons) induced enough mixing to obtain a uniform count rate at the tank surface. Both the circulation and partial filling method appeared to provide adequate mixing. In May and June 2000, a new injection well was placed near the original injection well, but outside the posted Underground Radioactive Material area. The new well was injected five times. The third injection contained a potassium bromide tracer. Four soil cores were collected around the new injection well. Each core sample was 18 meters (59 feet) deep.

Waste Type: Process Effluent

Waste Description: Eleven 3,780-liter (1,000-gallon) injections of uniform solutions of calcium chloride, calcium nitrate were made into the injection well. Eight injections contained selected radioactive tracers (cesium-134 and strontium-85). Three injections did not contain tracers. In 1995 the injection well was surveyed with a Radiologic Logging System (RLS) down-hole logging probe. No Strontium-85 was identified. Residual cesium-134 peaks were identified at depths between 4.9 and 5 meters (16 and 16.5 feet). The fact that cesium-134 was detected 15 years after injection is an indication of the tracer's high sorption potential. The maximum activity was 0.04 picocuries per gram (pCi/g) at 5 to 5.2 meters (16.5 to 17 feet) below grade level. PNNL scheduled an additional injection experiment at this site in 2000 that added another injection well (10 meters [30 feet] deep) near the center of the cluster, injected a potassium bromide tracer and collected soil cores. Each of the five injections was equal to 4000 liters. Data were obtained by lowering sensors to the desired depth in observation wells. Sensors used included neutron-neutron moisture probes, geiger-Muller (GM) probes, gamma energy analysis (GEA) probes, and gamma-gamma probes.

Code: 2607-E3
Names: 2607-E3; 2607-E3 Septic System; 2607-E3 Septic Tank and Drainfield; TFS of 218-E-4; Tile Field South of 218-E-4
Type: Septic Tank
Status: Inactive
Start Date: 1/1/1948
End Date: 1/1/1997

Description: The site is a septic tank and drainfield. It is surrounded with a chain and marked with a sign that reads Sanitary Sewer/Drain Field. The septic tank is constructed of reinforced concrete. The tank is 8.7 meters (28 feet 8 inches) long, 2.7 meters (9 feet) wide, and 3.8 meters (12 feet 6 inches) deep (interior dimensions). The tank had a design capacity of 38,680 liters (10,220 gallons) based on a user capacity of 292 persons, a flow of 132 liters (35 gallons) of sewage per capita per day, and an average detention time of 1 day. The top of the tank is at the ground surface. The tank was accessed through three 0.9 meter (3 foot) manholes. The drainfield is comprised of at least 712 meters (2,336 feet) of vitrified clay pipe or drain tile (at least 2.4 meters [8 feet] per capita). The laterals are open jointed and are spaced 2.4 meters (8 feet) apart.

Location: This unit is located approximately 100 meters (400 feet) north of the 221-B Building. The drainfield is located north of the septic tank and south of the 218-E-4 Burial Ground.
The 2607-E3 Septic Tank and Drainfield were designed to accept, treat, and dispose of sanitary sewer effluent from the buildings in the B Plant complex.

This site received sanitary wastewater and sewage from B Plant facilities at an estimated rate of 509 cubic feet (14.4 cubic meters) per day. The septic tank was abandoned in 1997. No information was provided related to sampling of the tank contents. DOE/RL-92-05 states that the septic tank and tile field are not known to contain radioactive or hazardous waste.

In July 2011, the septic tank was properly abandoned per WAC 246-272A-0300. This system included a single compartment tank with a dosing system and a leaching trench. An abandoned tile field, which was replaced by the sanitary leaching trench, is also included with this site. This septic system received sanitary wastewater and sewage from the Critical Mass facilities near 209-E.

WHC-SD-LL-SP-001 indicated the 2607-E5 Septic Tank and associated leaching trench received sanitary sewer effluent from the 209-E, the 2704-C, and the 2718-E Buildings. WHC-SD-LL-SP-001 indicated the 2607-E5 Septic Tank and associated leaching trench received sanitary sewer effluent from the 209-E, the 2704-C, and the 2718-E Buildings. It states that a construction design was approved in 1995 to add more facilities to the 2607-E5 system, but the project was cancelled. Other documentation and field investigations dispute the accuracy of the document, related to the facilities served by 2607-E5. Drawing M-2904-E, Sheet 27 does not show enough detail to make a determination. H-2-4033 shows that 276-C had no sanitary waste. All liquid waste from this facility went to the 216-C-3 crib. Revision 7 of H-2-4033 (1963) revised the drawing to include the abandoned tile field and the two small inline septic tanks (2607-E7 and 2607-E). (The WIDS numbers for these two tanks are 2607-E7A and 2607-E7B). The two smaller tanks were probably added when 209-E (Critical Mass Laboratory) was tied into the system.

WHC-SD-LL-SP-001 states this system received sanitary wastewater and sewage from the 209-E, the 2704-C, and the 2718-E Buildings at an estimated rate of 78 cubic feet (2.21 cubic meters) per day. Originally, the 2607-E5 tank serviced the 2707-C Change House. The change
house had both a toilet and shower used by personnel working within the Hot Semiworks facilities. There may be a potential for radiological contamination within the 2607-E5, 2607-E7 (WIDS 2607-E7A), 2607-E (WIDS 2607-E7B), Sanitary Leaching Trench, or the Abandoned Tile Field. A 2010 drawing review and facility walkdown found no drains, sinks or toilet facilities in the 2718E building.

### Code: 2607-E6
**Classification:** Accepted

***Names:*** 2607-E6; 2607-E6 Septic Tank and Tile Field

***Type:*** Septic Tank

***Start Date:*** 1/1/1953

***End Date:*** 1/1/1997

***Location:*** The site is a septic tank and drainfield. The drain field is surrounded by a wooden fence. The surface is vegetated with brush.

***Process Description:*** The unit received sanitary waste from MO405 and the PUREX facility.

### Code: 2607-E7A
**Classification:** Accepted

***Names:*** 2607-E7A; 2607-E7

***Type:*** Septic Tank

***Start Date:*** 1/1/1963

***End Date:***

***Location:*** This system lies north of the 209-E Building and west of the 2607-E5 Septic Tank.

***Process Description:*** In July 2011, the septic tank was properly abandoned per WAC 246-272A-0300. The septic tank received sanitary wastewater and sewage. This tank is a 1.7 meters (66 inches) by 2.7 meters (105 inches) precast concrete septic tank with a single 61 centimeters (24 inch) diameter cover. The tank is inline with the 2607-E5 septic tank and the 2607-E (WIDS 2607-E7B). The septic tank drained to the sanitary leaching trench.

***Related Sites/Structures:*** The 2607-E7A Septic System is associated with the 209-E, 2704-C, 2718-E, MO-337 (moved) and the MO-543 (moved) Buildings. This system is in series with the 2607-E5, 2607-E7B septic tanks and a leaching trench.

***Process Description:*** The 2607-E7A Septic System and the associated leaching trench were designed to accept and treat sanitary sewer effluent from the 209-E, 2704-C, 2718-C, MO-337 (moved to another location), and MO-543 (moved to another location).

### Code: 2607-E7B
**Classification:** Accepted

***Waste Description:*** The 2607-E7A Septic System receives sanitary wastewater and sewage at an estimated rate of 58 cubic feet (1.64 cubic meters) per day.
Names: 2607-E7B; 2607-E7B Septic System; 2607-E7

Names: 2607-E9; 2607-E9 Septic System; 242B/BL Septic Tank and Drain Field  
Type: Septic Tank  
Status: Inactive  
Description: This 1,900-liter (500-gallon) septic tank received sanitary wastewater and sewage from the 242-B and the 242-BL Buildings. This system has an associated drain field. It was abandoned and the tank filled with sand. The site is in a contamination area. A brief visit was made to the site in February 2000 to find the drainfield and to try to improve the mapping of the site. A "Drainfield" sign was found on the ground on the eastern side of the contamination area that surrounds the site. The former extent of the drainfield can be approximated using fence posts inside the contamination area (some of which still have chain attached), fallen chain on the ground plus the fence posts making up the eastern boundary of the contamination area. No access ports, lids or risers associated with the septic tank were visible. Evidence of the septic tank may have been obscured by tumbleweeds growing in the center of the contamination area near the drainfield.  
Location: This unit lies north of the 207-B Retention Basin and east of the 242-B Building.  
Related Sites/Structures: The 2607-E9 Septic Tank is associated with a drain field and the 242-B and the 242-BL Buildings.  
Process Description: The 2607-E9 Septic Tank and associated drain field were designed to accept sanitary sewer effluent from the 242-B and the 242-BL Buildings.  
Waste Type: Process Effluent  
Waste Description: The 2607-E9 Septic Tank received sanitary wastewater and sewage at an estimated rate of 0.71 cubic feet (0.02 cubic meters) per day.
### Code: 2607-E12  
### Classification: Accepted  
### Reclassification: None  
### Type: Septic Tank  
### Status: Active  

**Description:** The septic system consists of the original 242-A septic tank and seepage pit (see subsite 1), two newer septic tanks and two drain fields (see subsite 2) that service multiple buildings. The 5,000 gallon (18,927 liters) tank was converted to a dosing chamber when the new 10,000 gallon (37,854 liters) septic tank was installed approximately 45 feet (13.7 meters) to the south. The first drain field is located west of the 207-A Retention Basins. It was replaced with a trench-like drainfield located approximately 400 feet (122 meters) east of the septic tanks and east of the 207-A Retention Basins.

**Location:** The original 242-A septic tank and seepage pit is located on the 242-A building parking lot. Two newer septic tanks and two drainfields are located east of Canton Avenue, north of 4th Street. The first drainfield is located west of the 207-A South retention basins. The second drainfield is located east of the retention basins and has a barricade marker fence around the large depression.

**Related Sites/Structures:** Buildings serviced by this system are: 272-AW, MO-266, MO-268, MO-267, MO-393, MO-996, 241-A Tank Farm, 241-AP, and 242-A.

**Process Description:** The settling chamber (the larger southern most tank) receives the effluent first. The effluent then goes to the dosing chamber (smaller northern tank) which is connected by underground pipeline to the trench-like drainfield.

**Waste Type:** Storage Tank

**Waste Description:** Characteristics of the sanitary waste water from the 200 Areas are considered to be similar to residential sanitary waste. There are no known process or radioactive waste streams entering the sanitary waste system.

### This Site has the Following SubSites:

### Code: 2607-E12:1  
### Names: 2607-E12:1; Original Septic Tank and Seepage Pit  

**Code: 2607-E12:2  
### Names: 2607-E12:2; 2607-E12 Septic System**

**Description:** The original Septic Tank and Seepage Pit for the 242-A evaporator building is located beneath the building parking lot, east of 242-A. It is surrounded by yellow protective concrete posts. This portion is inactive.

<td></td>
<td></td>
</tr>
</tbody>
</table>
**Process Description:** The 216-BY-201 flush tank received tri-butyl phosphate waste via the 241-BY tank farm and then released it to the 216-B-43 through 49 cribs. The 216-B-50 crib did not receive tri-butyl phosphate waste.

**Related Sites/Structures:** UPR-200-E-9 is associated with 216-BY-201 and the 216-B-43 through 50 cribs.

**Waste Type:** Steam Condensate

**Waste Description:**

**Release Description:** On September 15, 1955 approximately 41,600 liters (11,000 gallons) of tri-butyl phosphate (TBP) supernate waste overflowed from the 216-BY-201 flush tank and ran over the ground toward the 216-B-43 crib. Most of the contamination was pushed into a shallow area southeast of the 216-B-43 crib and covered with 0.6 meters (2 feet) of clean dirt. The contamination left near the flush tank was covered with 3 meters (10 feet) of clean soil.

**Type:** Unplanned Release

**Start Date:** 1/1/1957

**Status:** Inactive

**Description:** A contamination spread occurred along the railroad tracks while transporting tube bundles from PUREX to the burial ground. The release is not separately marked or posted.

**Location:** The site is along the PUREX railroad right-of-way, both inside and outside the PUREX exclusion fence. The contamination inside the fence is considered part of the Railroad Cut (WIDS site code 200-E-44).

**Release Description:** In September 1957, contamination ranging from 5 to 20 rads/hour was spread in the craneway, canyon, railroad tunnel, and on the remote crane and railroad right-of-way during transport of two failed waste concentrator tube bundles.

**Related Sites/Structures:** The site is associated with 200-E-44 (PUREX Railroad Cut).

**Waste Type:** Steam Condensate

**Waste Description:** Loose contamination from concentrator tube bundles spread from the PUREX crane, into the tunnel and onto the railroad right-of-way.

**Code:** UPR-200-E-12

**Classification:** Accepted

**Names:** UPR-200-E-12; Contaminated Purex Railroad Spur; UN-200-E-12

**Reclassification:** None

**Type:** Unplanned Release

**Start Date:** 1/1/1957

**Status:** Inactive

**End Date:**

**Description:** This unplanned release is no longer marked or posted. Portions of the TC-4 Spur (a.k.a. UPR-200-E-88) and a section of track south of the 218-E-5 Burial Ground (UPR-200-E-95) have been covered with dirt and posted with Underground Radioactive Material signs.

**Location:** The unplanned release effected the railroad track extending from the PUREX tunnel to an
unnamed Burial Ground.

**Release Description:**
On November 15, 1957, a burial box containing failed process jumpers dripped contaminated liquid while in transit to the burial ground. This resulted in spotty contamination of 40 to 1,700 millirads/hour to the railroad roadbed. Contamination also spread to the canyon deck, tunnel, and tunnel cut.

**Related Sites/Structures:**
This site is associated with UPR-200-E-11, UPR-200-E-88, 200-E-43 and 200-E-44.

**Process Description:**
Some burial casks were shielded with water that was removed before placing the material into the burial ground. Sometimes railcars were washed down to remove loose contamination before transporting the load to the burial ground.

**Waste Type:** Steam Condensate

**Waste Description:** Contaminated liquid with readings ranging from 40 to 1,700 millirads/hour dripped on the railroad track during transport of a burial box containing failed process jumpers. The dose rate on the burial box was 450 millirads/hour at 45.8 meters (150 feet).

---

**Code:** UPR-200-E-17

**Classification:** Accepted

**Names:** UPR-200-E-17; Overflow at 216-A-22; UN-200-E-17

**Type:** Unplanned Release

**Start Date:** 1/1/1958

**Status:** Inactive

**Description:** The 216-A-22 crib is marked with a single cement post and posted with Underground Radioactive Material signs. The unplanned release is not separately marked or posted. The release cannot be visually identified.

**Location:** The release effected the ground on top of the 216-A-22 Crib, located north of PUREX, north of the 203-A facility, near the 216-A-28 French Drain.

**Release Description:** Sufficient splashing occurred when the 216-A-22 Crib inlet failed, causing the ground on top of the crib to become yellow with uranium. No specific occurrence date is mentioned. HW-60807 was issued in July 1959, so it occurred prior to that date. The 216-A-22 french drain was active from 1955 through 1958.

**Related Sites/Structures:** The site is associated with 216-A-22 and 203-A.

**Process Description:** The 203-A tank farm was used for storage and shipping of uranyl nitrate hexahydrate (UNH) product and concentration of UNH waste. It consisted of 460,000 liter (100,000 gallon) stain less steel tanks for UNH storage and three smaller nitric acid tanks.

**Waste Type:** Water

**Waste Description:** The release consisted of uranium (from UNH storage) contamination on the ground surface from the failed 216-A-22 Crib inlet.

---

**Code:** UPR-200-E-19

**Classification:** Accepted

**Names:** UPR-200-E-19; Contamination Release at 216-A-6 Sampler Pit; UN-200-E-19

**Type:** Unplanned Release

**Start Date:** 1/1/1959

**Status:** Inactive

**End Date:**
**Description:** The Unplanned Release is not visually obvious, but a single T-Post with a WIDS number is placed near the 220A structure. The 220A area is posted Fixed Contamination/Underground Radioactive Material Area.

**Location:** The release occurred adjacent to the 220A structure. 220A is synonymous with the A-6 Proportional Sampler. It is located east of the 202-A Building.

**Release Description:** HW-60807 refers to the A-6 Proportional Sampler Pit on page 17. The report states that low-level fission product seeped into the ground around the edges of the concrete pad. The contamination was caused by moisture dripping from the vent pipe bonnet.

**Related Sites/Structures:** The site is associated with the 216-A-6 Crib and 200-E-113-PL and structure 220A.

**Process Description:** Pipeline 200-E-113-PL passed through the Proportional Sampler before terminating in the 216-A-6 crib.

**Waste Type:** Steam Condensate

**Waste Description:** The site received low-level fission products that dripped onto the ground from the vent pipe bonnet.

### Code: UPR-200-E-20
### Classification: Accepted
### Reclassification: None
### Names: UPR-200-E-20; Contaminated Purex Railroad Spur; UN-200-E-20
### Type: Unplanned Release
### Start Date: 1/1/1959
### Status: Inactive
### End Date: 

**Description:** The site is located at the PUREX railroad right-of-way. The release is not separately marked or posted.

**Location:** Contamination occurred on the PUREX railroad bed and right-of-way to the Burial Ground, both inside and outside the PUREX exclusion fence. The contamination inside the fence is considered part of the PUREX Railroad Cut (Waste Information Data System [WIDS] site code 200-E-44).

**Release Description:** On November 20, 1959, PUREX tube bundles in transit for burial provided some spotty ground contamination.

**Waste Type:** Stormwater Runoff

**Waste Description:** While transporting PUREX tube bundles to the burial ground via railcar, spotty contamination was found on the railroad track.

### Code: UPR-200-E-21
### Classification: Accepted
### Reclassification: None
### Names: UPR-200-E-21; 216-A-6 Overflow; UN-200-E-21
### Type: Unplanned Release
### Start Date: 2/1/1959
### Status: Inactive
### End Date: 

**Description:** The unplanned release is not separately marked or posted. The 216-A-6 Crib area has been surface stabilized and is posted as "Underground Radioactive Material."

**Location:** Contamination occurred adjacent to the 216-A-6 Crib. The crib is located east of the PUREX facility, outside the 200 East Area perimeter fence.
Release Description: In February 1959, the 216-A-6 Crib overflowed and contaminated the adjacent area to 500 millirads/hour.
Related Sites/Structures: The release is associated with the 216-A-6 crib.
Waste Type: Construction Debris
Waste Description: The release contaminated the crib surface with beta/gamma with readings to 500 millirads/hour.

Code: UPR-200-E-29  
Names: UPR-200-E-29; 216-A-6 Overflow; UN-200-E-29  
Type: Unplanned Release  
Status: Inactive  
Description: The 216-A-6 Crib area has been surface stabilized and is posted as "Underground Radioactive Material."
Location: The release location is in the area of the 216-A-6 Crib.
Release Description: HW-67985, issued on January 20, 1961, reported the 216-A-6 Crib overflowed.
Related Sites/Structures: The site is associated with 216-A-6 Crib.
Waste Type: Sanitary Sewage
Waste Description: The release contaminated the crib surface with beta/gamma with readings to 30 rads/hour at a distance of 1.2 meters (4 feet).

Code: UPR-200-E-33  
Names: UPR-200-E-33; Contaminated Purex Railroad Tracks; UN-200-E-33  
Type: Unplanned Release  
Status: Inactive  
Description: A contamination spread occurred on the PUREX railroad bed and right-of-way to the burial ground. The contamination was located both inside and outside the PUREX exclusion fence. The contamination inside the fence is considered part of the PUREX Railroad Cut (Waste Information Data System [WIDS] site code 200-E-44).
Location: The release site is located at the railroad right-of-way from PUREX to the 200 East Burial Ground, adjacent to the 216-A-9 crib.
Release Description: On March 20, 1964, a leaking tube bundle burial box in transit to the burial ground contaminated a portion of the railroad right-of-way and area adjacent to the 216-A-9 Crib. The contamination spread occurred in February 1964. The February Monthly Report for 1964 (HW-81078) was issued on 3-20-64. This report states that decontamination was successful, but does not give any details of the decontamination activity.
Waste Type: Stormwater Runoff
Waste Description: A description of the waste is not available from documents. Contamination resulted from a leaking tube bundle in a burial box on a railcar.

Code: UPR-200-E-35  Classification: Accepted
Names: UPR-200-E-35; 218-E-13; Buried Contaminated Pipe; UN-218-E-1  Reclassification: None
Type: Unplanned Release  Start Date: 1/1/1966
Status: Inactive  End Date: 1/1/1966
Description: The site is the location of a (1966) contaminated concrete pipe repair. The site is no longer marked or posted. It is inside the PUREX exclusion fence.
Location: The site is located west of the PUREX Patrol Gate House south of 4th Street.
Release Description: The release is from an underground concrete line repair in August 1966. This site received broken pieces of contaminated concrete from the pipe trench, which were left in the excavation hole and buried following repair to the piping at that location. The site contains less than 1 curie fission products. It was estimated to be located 107 meters (350 feet) west of the PUREX badge house.
Waste Type: Stormwater Runoff
Waste Description: This site received broken pieces of contaminated concrete from the pipe trench, which were left in the excavation hole and buried following repair to the piping at that location. The site contains less than 1 curie fission products.

Code: UPR-200-E-37  Classification: Accepted
Names: UPR-200-E-37; Contamination East of Hot Semi-Works; UN-200-E-37; UN-216-E-37; UN-216-E-39  Reclassification: None
Type: Unplanned Release  Start Date: 1/1/1967
Status: Inactive  End Date: 1/1/1989
Description: There is currently no physical evidence of the unplanned release site. It is no longer marked or posted.
Location: The release occurred east of the Hot Semi-Works facility, south of 7th Street.
Release Description: On July 31, 1967, a release from the Strontium Semi-Works (SSW) facility was documented on a Radiation Occurrence Report. At the time of the occurrence, a fence surrounded the facility. The original occurrence description stated that the contamination was confined to the east side of the Strontium Semi-Works, extending a length of 183 meters (200 yards) and also to a dirt road outside the facility fence. The area was roped off, roads were blocked and sprinklers were set up in the contaminated areas. The blacktop roads were cleaned.
Waste Type: Stormwater Runoff
Waste Description: A contamination spread (particulate) was caused by the removal of two Semiworks A cell pumps, with a maximum beta/gamma reading of 200 millirad/hour.

Code: UPR-200-E-43  Classification: Accepted
Names: UPR-200-E-43; Road Contamination Near 241-  Reclassification: None

BY Tank Farm; UN-200-E-43

Type: Unplanned Release  Start Date: 1/1/1972
Status: Inactive  End Date:

Description: The location of this release is not marked or posted.

Location: The release occurred on a section of the roadway between the 241-BY Tank Farm and the burial ground. The exact location cannot be determined with existing documentation.

Release Description: On January 10, 1972, while in transit for burial, the 102-BY Pump contaminated a section of the road from the 241-BY Tank Farm to the burial ground. Contamination readings ranged from 1,000 to 100,000 counts per minute.

Waste Type: Steam Condensate
Waste Description: The road contaminated with beta/gamma with readings of 1,000 to 100,000 counts per minute while transporting a pump from 241-BY-102 to the burial ground.

Code: UPR-200-E-50  Classification: Accepted
Names: UPR-200-E-50; Soil Contamination at the Overground Equipment Storage Yard; UN-200-E-50  Reclassification: None

Type: Unplanned Release  Start Date: 1/1/1974
Status: Inactive  End Date:

Description: In 1974, an area of ground contamination was identified that measured from 15 to 30 meters (50 to 100 feet) wide and 137 meters (450 feet) long south southeast of the Overground Storage Area. The release is not currently marked or posted.

Location: The release location was southeast of the Overground Radioactive Equipment Storage Yard and north of 241-C Tank Farm.

Release Description: On September 24, 1974, ground contamination was identified outside the radiation zone at the Overground Radioactive Equipment Storage Yard, north of 241-C Tank Farm. A resulting swath of ground contamination was identified (approximately 75 feet wide and 450 feet long) extending southeast of the Overground Storage Yard with particle contamination ranging from 100,000 counts per minute to 3000 counts per minute, decreasing in intensity and frequency with distance from the source.

Follow-up surveys of the Overground Storage Area identified a possible source to be a 6 meter by 9 meter (20 foot by 30 foot) area of contaminated soil inside the radiation zone. Highly contaminated pumps (250 rad per hour) had been stored in that area with readings of 300 millirem per hour under the where pumps had been sitting. The pumps were moved to the burial ground on April 26, 1974. Due to climatic conditions when the pumps were moved, the soil beneath the pumps was not completely decontaminated. The contaminated ground beneath the pumps was covered with plastic and secured with dirt. On September 26, 1974, high winds blew the plastic cover loose, causing contamination to spread downwind (southeast) of the Overground Storage Yard. An additional survey in the Overground Storage Yard identified two empty capsules with smearable contamination of 30,000 counts per minute and more soil contamination beneath the capsules reading 1.5 rad per hour. A resulting contamination spread, measuring approximately 75 feet wide and 450 feet long was identified extending southeast of the Overground Storage Yard. Levels of contamination ranged from 100,000 counts per minute near the storage area and decreased to 3000 counts per minute. The capsules were taken to the burial ground to avoid further contamination spreads.
This release is associated with 200-E-53.

Stormwater Runoff

Wind blew specks of contamination out of the Overground Storage Yard posted radiation zone. The source was from contaminated equipment being stored at the Overground Radioactive Equipment Storage Yard. Maximum beta/gamma readings of 3,000 to 100,000 counts/minute were found on a swath of ground south southeast of the storage area. The intensity of the radiological readings decreased with greater distance away from the source.

The 1982 release site was an area approximately 5 centimeters (2 inches) wide and 30 meters (100 feet) long on a hill near the 200 East Overground Storage Area. The release was cleaned up within 3 days. The site is no longer marked or posted.

The release occurred at the 200 East Burning Ground (also known as the 200 East Burn Pit), located south of 12th Street and west of Canton Ave.

Radioactive liquid was spilled from a pressure test assembly while in transit. The release occurred on March 19, 1982. The ground contamination was picked up, placed in barrels, and removed to the burial ground. The release was cleaned up to background levels and was released from area posting on March 22, 1982.

The release is associated with the Overground Storage Area, sitecode 200-E-53.

The site is a large area posted with chain and Underground Radioactive Material Area signs. The size and shape of the posted area has changed periodically as a result of annual radiological surveys and clean up efforts.

The site is inside 200 East Area, north of 7th Street, adjacent to the west side of the 216-B-64 Basin.

The original unplanned release documentation states ants burrowed into contaminated soil that was caused by leakage from the 270-E-1 Tank and brought the contamination to the surface. Later documentation suggests the contamination source was the small diameter vertical pipe (swab riser) located west of 216-B-64 basin.
Waste Type: Steam Condensate
Waste Description: The contamination found in the soil and ant hills consisted predominantly of cesium-137 and strontium-90, with readings to 60,000 counts per minute. Several sources of contamination have been suggested. A swab riser on an underground pipeline appears to be the source.

Code: UPR-200-E-66
Type: Unplanned Release
Status: Inactive
Description: The release is not separately marked or posted. The 216-A-42 Basin had been surrounded by a wire fence and posted with Soil Contamination signs. In 2001, the fence was removed and the area was surface stabilized. It was covered with clean backfill and down posted to Underground Radioactive Material (URM). The release site is located within the URM area.
Location: The release site was located adjacent to the 216-A-42 Retention Basin, which is located outside of the eastern 200 East Area perimeter fence.
Release Description: A November 7, 1984, a radiation survey identified contamination both inside and outside of the area posted as a radiation zone around the perimeter of the 216-A-42 Basin. Contaminated liquid in the basin had evaporated allowing dried contamination specks to be spread by wind. At the time of this release, contamination levels were 40,000 counts per minute on the ground within the retention basin fence. Smears of the walls and bottom of the basin ranged from 200 to 100,000 counts per minute. The area outside the retention basin fence revealed specks with a maximum level of 3,000 counts per minute located between the road and the fence.
Related Sites/Structures: The release is associated with the 216-A-42 Basin.

Code: UPR-200-E-69
Names: UPR-200-E-69; Railroad Car Flush Water Radioactive Spill; UN-200-E-69; UN-216-E-69
Type: Unplanned Release
Status: Inactive
Description: The railroad tunnel area has a 1.2 meter (4 foot) high fence along the side of the tracks. The area was posted with Radiologically Controlled Area signs. In 1998, the track from the tunnel door to Atlanta Ave. was covered with gravel and reposted as Underground Radioactive Material.
Location: The release effected the 221-B railroad cut, tunnel, and track.
Release Description: On 6-19-84, a concrete burial box (K-3 filter type) was removed from the 221-B railroad tunnel containing waste drums from 225-B and 221-B canyon waste. After loading, the burial string was bumped by the locomotive several times to remove the flush water from the lid of the burial box. No water was seen on the lid of the box or the deck of the flat car when the car left the tunnel. When the train stopped with the burial box about 180 meters (600 feet) from the tunnel door, contamination was noted on and near the west rail of the track. Contamination levels were 20,000 counts per minute with 4000 counts per minute smearable on the track. The water was not noted before the box was moved because high dose rates coming from the burial box (400 millirem/hour at a distance of 100 feet) prevented personnel from getting close enough to identify any liquid. After the contamination was identified, the train could not move back into the tunnel without contaminating the locomotive.

Waste Type: Misc. Trash and Debris
Waste Description: Water dripped from a burial box containing waste was from 225-B and the 221-B canyon. The contamination consists of beta/gamma contamination, with readings to 4,000 to 20,000 counts per minute.

Code: UPR-200-E-88
Classification: Accepted
Names: UPR-200-E-88; TC-4 Spur Contaminated Railroad Track; UN-200-E-88. Ground Contamination Around the Western Purex Railroad Spur; UN-216-E-16; UN-216-E-88
Reclassification: None
Type: Unplanned Release
Start Date:
End Date:
Status: Inactive
Description: The unfenced portion of the spur was posted as a "Contamination Area." Additional posting on portions of the spur included "Soil Contamination Area" and "Buffer Area." The spur is tracked with the property number "F187418". The site was interim stabilized in December 1998. The stabilized area was posted as an Underground Radioactive Material area. A chain link fenced storage area is located on the north end of the spur (see site code 200-E-43).
Location: The site is located northwest of the 202-A Building at the TC-4 Railroad Spur.
Release Description: In 1981, Harold Maxfield stated that the large radiation zone associated with the TC-4 railroad spur has been incorrectly designated as an unplanned release site. The original perimeter of the zone was posted where the gamma dose rates from radioactive tank cars parked on the railroad spur would be less than 1 millirads/hour. The site in question was properly known as a Regulated Equipment Storage Area (see 200-E-43). On December 17, 2010, approximately 576,000 gallons of potable water discharged to the ground during a construction water line tie-in activity. The water flowed south, from the line break and flooded a portion of the TC-4 Spur Railcar Storage Area and the UPR-200-E-88 stabilized railroad track. Although no railcars are being stored here, the area is still fenced and radiologically posted.
Related Sites/Structures:
The site is associated with 200-E-43.
Waste Type: Water
Waste Description: The contamination spread consisted of radioactive particulates from contaminated railcars using the tracks. Surface radiological surveys performed in 1991 identified contamination of 20,000 to 60,000 disintegrations per minute on the railroad track near where the tank cars were being staged. South of the tank cars, along the railway, contaminated areas of 2,000 to 20,000 disintegrations/minute were also identified.
### Code: UPR-200-E-89
**Classification:** Accepted

**Reclassification:** None

**Names:** UPR-200-E-89; Contamination Migration to the North, East & West of BX-BY Tank Farms; UN-200-E-89; UN-216-E-17

**Type:** Unplanned Release

**Start Date:** 1/1/1978

**Status:** Inactive

**End Date:**

**Description:** The site is located north of the 241-BY Tank Farm. In 1991, the contaminated soil was consolidated on top of the 216-B-43 through 216-B-50 Cribs and stabilized with a layer of clean dirt. The site also includes an irregularly shaped drill pad area and a contaminated concrete pad that were also covered with clean dirt. All of the stabilized areas of UPR-200-E-89 were zoned off against casual entry and marked with "Underground Radioactive Material" signs.

**Location:** UPR-200-E-89 was originally identified in 1978 as an area of surface contamination east of the 241-BX Tank Farm. Wind blown contamination from tank farm operations spread the contamination to the north and northwest of the 241-BY Tank Farm. It eventually grew to be approximately 1.2 hectares (3 acres) in size.

**Release Description:** Airborne particulate matter contaminated the area bounding the north and northeast sides of the 241-BX Tank Farm. The airborne particulate matter was resuspended by wind from activities during the time of 241-BY Tank Farm operations. Airborne particulate matter from the 241-BX Tank Farm spread onto Baltimore Avenue roadway. Ground contamination was discovered at the 241-BX Tank Farm. The contamination was probably due to tank leakage.

**Related Sites/Structures:** UPR-200-E-89 is associated with the 241-BX Tank Farm and the 241-BY Tank Farm.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** Airborne particulate matter contaminated an area near the 241-BY Tank Farm. The matter was resuspended by wind. Beta and gamma contamination with readings of 500 to 2,000 counts per minute were detected at the site.

---

### Code: UPR-200-E-95
**Classification:** Accepted

**Reclassification:** None

**Names:** UPR-200-E-95; Ground Contamination Around RR Spur Between 218-E-2A and 218-E-2; UN-200-E-95; UN-216-E-23

**Type:** Unplanned Release

**Start Date:** 1/1/1980

**Status:** Inactive

**End Date:**

**Description:** The site is a railroad spur located south of the 218-E-2 and 218-E-5 Burial Grounds and north of the 218-E-2A Burial Ground. It had been barricaded with steel chain and posted as a Contamination Area. In 1998, the track was covered with gravel and reposted as an Underground Radioactive Material area.

**Location:** UPR-200-E-95 occurred at the railroad spur north of the 221-B Facility, located between the 216-E-2A and 216-E-5 Burial Grounds.

**Release Description:** The railroad spur was used as an aboveground storage zone for low level contaminated equipment. Equipment from the B Plant and PUREX Plant operations were stored, for the most part, on the beds of railroad flat cars. UPR-200-E-95 is associated with this storage area. The contamination is possibly the result of the accumulation of many small releases over time.
Related Sites/Structures: UPR-200-E-95 is associated with the 218-E-2A and the 218-E-5 Burial Grounds and B-Plant operations.

Waste Type: Water
Waste Description: The material stored on the rail cars contained unknown beta and gamma contamination with a maximum reading of 100,000 counts per minute. The contamination on the rail bed is the result of contaminated equipment being stored on the tracks over an extended amount of time.

Code: UPR-200-E-98
Names: UPR-200-E-98; Ground Contamination East of C Plant (Hot Semi Works); UN-200-E-98; UN-216-E-26
Type: Unplanned Release
Status: Inactive
Start Date: 1/1/1955
End Date: 1/1/1965
Description: The location of this site is currently within a large surface stabilized area known as 200-E-41. Much of the contamination was removed and placed into the 218-C-9 Burial Pit in 1992. The area has been surface stabilized with powerhouse ash. The covered area has "Underground Radioactive Material" warning signs posted.

Location: UPR-200-E-98 occurred on the east side of the Hot Semiworks Facility, near the base of the 291-C Stack and around the 216-C-2 Reverse Well. The 291-C Stack was demolished and currently lies in a burial trench adjacent to where it stood.

Release Description: Radioactive particulate matter from the "Hot Semiworks" operations (1955 to 1965) was inadvertently spread to the ground surface. It contaminated the ground near the base of the 291-C Stack and around the 216-C-2 Reverse Well.

Related Sites/Structures: UPR-200-E-98 was associated with the C Plant (Hot Semiworks) Facility, the 291-C Stack and the 216-C-2 Reverse Well. The surface stabilized area is now known as 200-E-41.

Waste Type: Water
Waste Description: The release consisted of radioactive particulate matter from the Hot Semiworks operation that was deposited onto the ground surface east of the facility. The contamination was primarily strontium-90.

Code: UPR-200-E-101
Names: UPR-200-E-101; Radioactive Spill Near 242-B Evaporator; UN-200-E-101; UN-216-E-101; UN-216-E-30
Type: Unplanned Release
Status: Inactive
Start Date: 1/1/1985
End Date: 
Description: The site, adjacent to the B Tank Farm perimeter fence, is currently a posted as an Underground Radioactive Material area.

Location: The site is located between the 242-B Evaporator and the 241-B Tank Farm fence.

Release Description: Surface contamination was identified between the 241-B Tank Farm fence and the 242-B Evaporator building. It was assigned the Unplanned Release Site Number UN-216-E-30 in August 1985. Windblown particulates from the tank farm or spills from the 242-B Evaporator may have been the cause of the contamination, but an exact cause for this area of contamination...
has not been determined. A routine radiological survey done in September 1986 found tumbleweeds growing at the site that were reading 1,000 counts per minute beta-gamma.

Related Sites/Structures: The site is associated with 241-B Tank Farm and 200-E-120.

Waste Type: Water
Waste Description: The release consisted of an unknown amount of radioactive particulates from the 241-B Tank Farm.

Description: The contaminated section of track and the Atlantic Avenue crossing were cleaned by noon, February 12, 1979.

Location: UPR-200-E-112 occurred on the railroad track from the 221-B Building to the 200 East Area Burial Ground.

Release Description: During a canyon equipment burial transfer, some contaminated liquid spilled out of a cesium ion exchange column that was being loaded into a burial box atop a rail car. The liquid spilled onto the tracks inside the B Plant railroad tunnel and was carried outside by one wheels of the railroad car, contaminating the track from B Plant to the east boundary of the burial ground. Contamination levels ranged from 40,000 counts per minute to 80,000 counts per minute. Approximately 15 meters (50 feet) of track that crossed Atlanta Ave. was decontaminated immediately. Occurrence Report 79-24 also recommends an effort to continue to clean the contaminated track.

Related Sites/Structures: UPR-200-E-112 was associated with the 221-B Building and the B Plant Aggregate Area Railroad Cut and Tunnel.

Waste Type: Construction Debris
Waste Description: The release consisted of a spill of liquid from a cesium ion exchange column with beta/gamma readings up to 80,000 counts per minute. The equipment was being transported to the burial ground on a railcar.

Description: Various radiological postings exist in this vicinity that are associated with the 244-A Lift Station and 241-C Tank Farm contamination migration. A WIDS sign has been placed at the approximate location of the release.

Location: Contamination was identified in a large area located south of the 244-A Lift Station and west of

**Release Description:** In October 1990, radiologically contaminated rabbit feces, with a maximum dose of 900 millirem per hour, was found south of the 244-A Lift Station and west of the 216-A-40 Basin. An investigation was initiated to identify the contaminating source. The size and shape of the zone varied over the next few months as clean-up efforts continued and new contamination is identified.

**Related Sites/Structures:** This release is associated with the 244-A Lift Station, 200-E Powerhouse Ditch and UPR-200-E-100.

**Waste Type:** Storage Tank

**Waste Description:** Contaminated rabbit feces and soil contamination were found in the area. Laboratory analysis of the feces found cesium-137 to be the most prevalent contaminant.

</tbody>
</table>

#### Waste Type: Steam Condensate

Waste Description: The unit is an underground liquid effluent control structure for the 216-A-24 Crib and contains radioactively contaminated piping and cement. The amounts of radionuclides present are not known. A document published in 1987 (K.H. Cramer) reported radiological readings of 500 counts per minute smearable contamination, 10,000 counts per minute direct beta/gamma on the surface structures.

<td>The weir controlled the effluent flow to the 216-A-24 crib.</td>
</tr>
</tbody>
</table>
The site is a diversion box that interconnects diversion boxes 241-B-151 and 241-B-152 with the 221-B Building. The unit is a rectangular, reinforced concrete structure. It was sprayed with gray, weatherizing foam. Later, a layer of shotcrete was placed over the diversion box, extending beyond the structure to include the surrounding ground surface.

The unit is located east of 221-B, at the intersection of Baltimore Avenue and Seventh Street.

This diversion box transferred waste solutions generated during fuel processing and decontamination activities from B Plant via 241-B-151 and 241-B-152 to the tank farms.

This unit transferred waste from processing and decontamination operations. Volumes of waste present in the system varied with production operations. Contamination in this unit is estimated to include high alpha, beta, and gamma activity levels.

This unit transferred process waste from B Plant to the tank farms. It is estimated that the diversion box also may contain approximately 23 kilograms (50 pounds) of lead shielding inside this unit.

This unit is an underground, horizontal carbon steel tank. The catch tank and the 241-B-154 Diversion Box are surrounded with post and chain. The surface of the area inside the chain has been covered with grave and sprayed with gray weatherizing material. The site is marked with radiological and IMUST signs.

This catch tank is located north of the 241-B-154 diversion box, adjacent to the corner of 7th Street and Baltimore Avenue.

This catch tank is associated with 241-B Tank Farm and 241-B-154 Diversion Box. The drain lines are V201 and V127.

This catch tank provided secondary containment for the 241-B-154 Diversion Box. Catch tanks are used to collect spills and leaks that occur in diversion boxes during waste transfer operations.

This unit collected leaking and excess waste solutions from processing and decontamination operations that passed through the 241-B-154 Diversion Box. Volumes were variable according to specific plant operation. In 1985, the volume of liquid inside the tank was estimated to be 16,027 liters (4240 gallons). Sludge content was estimated to be 2608 liters (690 gallons).

**Type:** Storage Tank  
**Status:** Inactive  
**Description:** The 241-CX-70 underground tank is surrounded with post and chain. It is posted with Hazardous Waste, Restricted Area-Inactive Tank signs.  
**Location:** The tank is located south of 7th Street, within the Hot Semiworks stabilized area (200-E-41).  
**Related Sites/Structures:** Associated structures include 201-C, 276-C, 2704-C, 241-CX-71, and 241-CX-72. The pipeline to 241-CX-70 is sitecode 200-E-244-PL. It is inside the 200-E-41 stabilized area.  
**Process Description:** The unit stored Semiworks Process waste. The 241-CX-70 Tank is constructed of concrete with a 2.5-centimeter (1-inch) thick stainless steel plate liner. The sides and top are 0.3 meters (1 foot) thick concrete and the bottom thickness varies from 0.6 meters (2 feet) at the edges to
23 centimeters (9 inches) at the center. The tank is located below grade, with several risers and vents visible above grade.

**Waste Type:** Process Effluent
**Waste Description:** The unit was used to store high-level process waste in support of the Semiworks process. Prior to sluicing, the unit contained approximately 1.45 meters (4.75 feet) of sludge, that is roughly equivalent to 39,000 liters (10,300 gallons) of waste. Contaminants included 20 curies of plutonium-239/240; 500 curies of cesium-137; 2,900 curies of strontium-90; 7,080 kilograms (7.8 tons) sodium nitrate; 1,000 kilograms (1.1 tons) sodium nitrite; 1,090 kilograms (1.2 tons) sodium fluoride; 450 kilograms (0.5 tons) aluminum sulfate; and 180 kilograms (0.2 tons) sodium chromate. After sluicing only a small quantity of solids and residual caustic/water remain. The estimated contamination levels for piping and equipment are 3 curies plutonium and 6,000 curies beta/gamma. The residual volume remaining after the tank was sluiced was estimated to be (500 gallons) of liquid and (250 gallons) of solids. Later more liquids and gravel-like solids were removed. The tank was dried and is considered to be empty.

</tbody>
</table>

**Type:** Neutralization Tank
**Status:** Inactive
**Description:** The underground tank is surrounded with steel posts and chain. It is posted with Hazardous Waste, Restricted Area-Inactive Tank signs.
**Location:** The tank is located south of 7th Street, within the Hot Semiworks stabilized area (200-E-41). It is near the northeast corner of the 216-C-1 Crib.
**Related Sites/Structures:** Associated structures include: 201-C, 276-C, 2704-C, 216-C-1, 216-C-5, 241-CX-70, and 241-CX-72. The pipeline to 241-CX-71 is sitecode 200-E-245-PL. It is inside the 200-E-41 stabilized area.
**Process Description:** This tank provided acidic waste neutralization via a flow-through limestone layer for 201-C process condensate and the coil and condenser cooling water stream prior to discharge to the 216-C-1 and 216-C-5 cribs. It may have also received process condensates from REDOX and PUREX pilot plant operations, decontamination flushes, and hot shop sink waste. Replacement limestone was added as needed through a large central riser pipe. This tank is constructed of stainless steel and lies below grade, on a reinforced concrete foundation pad.

**Waste Type:** Chemicals
**Waste Description:** The tank was used for neutralizing the 201-C process condensate and the coil and condenser cooling water via a limestone layer. It also received process condensates from the Reduction Oxidation (REDOX) and Plutonium Uranium Extraction (PUREX) pilot plant processes, which would include hexone and kerosene solvents. From November 1956 to June 1957, the unit received flush wastes during decontamination. This tank currently contains a bottom layer of sludge and the limestone layer. The remainder of the tank was filled with grout in 1986. In October 1990, a drill was used to collect samples from the bottom of the tank, through the grout. Low concentrations of methyl ethyl ketone, xylene and toluene were measured (7-54 parts per billion). Twenty one parts per million of cyanide was found.

</tr>
<tr>
<td>Location:</td>
<td>The tank is located south of 7th Street, within the Hot Semiworks stabilized area (200-E-41).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Release Description:</td>
<td>In 1988, during construction of the 291-C stack demolition berm, a portion of an agitator rod was accidentally snagged by heavy equipment. A piece of rod approximately 4.5 meters (15 feet) long was pulled out of the tank. Since the rod was found to be radiologically contaminated, an investigation was begun to assess the situation. The tank had previously been reported to be empty of waste. Failure to identify waste during the 1978 inspection was assumed to be from inadvertently inspecting the drywell adjacent to the tank, which remains free of waste by design. Since the rod had a significant amount of contamination on it, core sampling through the grout layer was planned. An eleven foot layer of fission product and TRU residue was found to be on the bottom of the tank.</td>

<td>Associated structures include: 201-C, 276-C, 2704-C, 241-CX-70, and 241-CX-71. The pipeline to 241-CX-72 is sitecode 200-E-246-PL. It is inside the 200-E-41 stabilized area.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The 241-CX-72 Tank was an experimental tank used to study the characteristics of self-concentrating waste from the Plutonium Uranium Extraction (PUREX) process. The 241-CX-72 Tank is vertically oriented with welded steel construction. The tank rests on a concrete pad inside a steel caisson with the tank top below grade. A cylindrical heater is located just above each stiffening ring. A number of penetrations extend through the tank top, including an agitator. This tank was used for approximately one year, during 1957 through 1958. The 241-CX Vault is located below grade adjacent to the 241-CX-72 tank. The vault is constructed of reinforced concrete, divided into two sections. In 1961, the inlet piping was cut and capped.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Process Effluent</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>The tank was filled with grout in 1986. Original content information was based on process knowledge. Some solid salt cake, similar to that found in tank farm tanks containing PUREX waste, is believed to remain inside the tank as well as the grout. Smears taken from an agitator rod (accidentally pulled out of the tank by heavy equipment) found a maximum of 8000 disintegrations per minute alpha and 5800 picocuries of gamma. Core samples were obtained from the tank in 1989. An 3.3 meter (eleven foot) layer of fission products and TRU isotopes was found in the bottom of the tank. Estimated radionuclides present include approximately 200 grams of plutonium-239 (as a fluoride compound).</td>

Hanford Site Waste Management Units Report
February 2015
**Description:** The two parallel underground pipelines are marked with metal posts and Underground Radioactive Material - Pipeline signs. (see subsites)

**Location:** The pipeline begins north of the 241-BY Tank Farm at the 216-BY-201 Flush Tank. It extends eastward to a point between the 216-B-8 Crib and the 216-B-51 French Drain. The pipeline turns southward and connects to a valve pit (see sitecode 200-E-223). A portion of the line diverts from the valve pit to the 241-C Tank Farm. Another portion of pipeline continues south and connects to the 216-BC-201 Siphon Tank in the BC Cribs and Trenches area. The BC Cribs and Trenches are located south of 200 East Area, south of Route 4 South.

**Release Description:** The Dyncorp Integrated Soil, Vegetation and Animal control group submitted two posted Contamination Areas located on this pipeline to WIDS as a Discovery Sites. In February 2000, they found growing contaminated vegetation on the underground pipeline northeast of 241-B Tank Farm, approximately 27 meters (90 feet) southeast of the 216-B-51 French Drain. The maximum contamination levels identified was 2000 counts per minute beta/gamma. Although some of the contaminated vegetation was removed, the area remains posted as a Contamination Area. A second area with growing contaminated vegetation was identified in October 2000. This area is located north of the 241-B Tank Farm, between the 216-B-8 Tile Field and the 216-B-51 French Drain.

**Related Sites/Structures:** The pipeline is associated with the 241-BY Tank Farm, 241-C Tank Farm, the BC Cribs and Trenches, 200-E-221-PL (to 216-B-51) and the 200-E-223 valve pit.

**Process Description:** The pipeline is constructed of two parallel, 10 centimeter (4 inch) diameter carbon steel pipes buried in the same soil trench. Encasements were constructed at areas where the pipeline crosses under roadways. During the Uranium Recovery project from 1952 through 1954, this pipeline was used to transfer waste from the 241-BY Tank Farm to the BC Cribs and Trenches area. The waste first cascaded through several tanks in the 241-BY Tank Farm to allow some contamination to settle inside the tank farm before being discharged to the cribs and trenches via the underground pipeline. The entire scavenging mission necessitated the construction of the transfer system using pipelines 2805-E1, 2805-E2, 2805-E3 and 2805-E4 (Sitecode 200-E-114-PL). The entire system can be traced on the series of H-2-2900 thru 2909. The valve box (Sitecode 200-E-223) allowed waste to move north to BY or south to BC cribs.

**Waste Type:** Process Effluent

**Waste Description:** The waste is the pipeline and adjacent soil contaminated from pipeline leaks. The pipeline carried scavenged uranium recovery process waste (tri-butyl phosphate solvent extraction).

**This Site has the Following SubSites:**

**Hanford Site Waste Management Units Report**

February 2015
216-BC-201 Flush Tank. It runs through the 200-E-223 Valve Pit. The pipeline is constructed of two parallel, 10 centimeter (4 inch) diameter pipes buried in the same soil trench.

**Location:** The north/south pipeline is begins east of the 241-BY tank farm and extends south, east of Baltimore Ave. It exits the 200 East Area fence and continues under Route 4 South and connects to the 216-BC-201 flush tank.

**Process Description:** The entire scavenging mission necessitated the construction of the transfer system using pipelines 2805-E1, 2805-E2, 2805-E3 and 2805-E4. The entire system can be traced on the series of H-2-2900 thru 2909. The valve box allowed waste to move north to BY or south to BC cribs.

**The SubSite is Part Of:**

**Code:** 200-E-114-PL

**Names:** 200-E-114-PL; 216-BC-2805; 2805-E1, 2805-E2, 2805-E3 and 2805-E4; Pipeline from 216-BY-201 to 216-BC-201; Pipeline from 241-BY Tank Farm to 241-C Tank Farm and BC Cribs Trenches

Code: 200-E-114-PL:2

**Names:** 200-E-114-PL:2; East/West Pipeline

**Type:** Radioactive Process Sewer

**Status:** Inactive

**Description:** Subsite 2 is the east-west portion of the pipeline that extends from the 200-E-223 Valve Pit to the 241-C Tank Farm. The pipeline is constructed of two parallel, 10 centimeter (4 inch) diameter pipes buried in the same soil trench.

**Location:** This segment is located inside 200 East Area, north of 7th Street. It extends from the 200-E-223 Valve Pit to the 241-C Tank Farm.

**Process Description:** The entire scavenging mission necessitated the construction of the transfer system using pipelines 2805-E1, 2805-E2, 2805-E3 and 2805-E4 (Sitecode 200-E-114-PL). The entire system can be traced on the series of H-2-2900 thru 2909. The valve box allowed waste to move north to BY or south to BC cribs.

**The SubSite is Part Of:**

**Code:** 200-E-114-PL

**Names:** 200-E-114-PL; 216-BC-2805; 2805-E1, 2805-E2, 2805-E3 and 2805-E4; Pipeline from 216-BY-201 to 216-BC-201; Pipeline from 241-BY Tank Farm to 241-C Tank Farm and BC Cribs Trenches

Code: 200-E-114-PL:3

**Names:** 200-E-114-PL:3; Underground Steel Line from Gate Valve (North of 216-BC-201 Siphon Tank) to 216-B-20 Trench

**Type:** Radioactive Process Sewer

**Status:** Inactive

**Description:** Four inch diameter underground steel line from gate valve (north of 216-BC-201 siphon tank) to 216-B-20 trench. A Notice of Radiological Problem was issued in January 2007. Wind had uncovered a portion of this old radioactive underground line. The maximum dose rate on the line was 60 mr/hr at contact. No removable contamination was identified.

**Location:** The BC Cribs and Trenches are located south of 200 East Area, south of Route 4 South. The
pipeline is located east of the BC cribs.

**Process Description:**
The pipeline subsite begins as an underground line connecting to the 216-BC-201 flush tank. It emerged as an aboveground line west of the encasement (H-2-3203) that diverted waste to the BC trenches.

**The SubSite is Part Of:**

- **Code:** 200-E-114-PL
- **Names:** 200-E-114-PL; 216-BC-2805; 2805-E1, 2805-E2, 2805-E3 and 2805-E4; Pipeline from 216-BY-201 to 216-BC-201; Pipeline from 241-BY Tank Farm to 241-C Tank Farm and BC Cribs Trenches

Code: 241-ER-151

- **Classification:** Accepted
- **Names:** 241-ER-151; 241-ER-151 Diversion Box
- **Reclassification:** None
- **Type:** Diversion Box
- **Start Date:** 1/1/1945
- **End Date:**

**Status:** Inactive

**Description:**
The diversion box is located inside a locked chain link fence. The fence is posted with "Caution - contact Radiological Control and Tank Farm Shift Office prior to entry" signs. The diversion box is surrounded with a metal safety barricade.

**Location:**
The site is located southwest of the B Plant and near the corner of 7th Street and Atlanta Avenue.

**Related Sites/Structures:**
This site is associated with the 241-ER-311 Catch Tank, the Cross Site Transfer Line, 241-EW-151 Vent Station, the 241-BX Double Contained Receiver Tank, and the 241-ER-152, the 241-ER-153, and the 241-UX-154 Diversion Boxes and the 241-ER-311 Catch Tank. It is also associated with pipelines 200-E-111-PL, 200-E-145-PL, 200-E-215-PL, 200-E-217-PL.

**Process Description:**
The 241-ER-151 diversion box distributed waste between locations inside 200 East Area or the waste could be transferred to 200 West Area, via the cross site transfer line. This unit received 200 West Area waste via the 241-UX-154 Diversion Box via transfer lines V360, V361, V362, V363, V364 and V366 and the 241-EW-151 Vent Station. The diversion box also received 200 East Area tank waste from the 241- B, BX, and BY Tank Farms via 244-BX Double Contained Receiver Tank. Drainage from the 241-ER-151 went to the 241-ER-311 Catch tank.

**Waste Type:** Process Effluent

**Waste Description:**
The diversion distributes chemical process waste between facilities and tank farms. Quantities of waste vary according to specific plant operations. This diversion box facilitates the transfer of waste solutions between the 200 East Area to the 200 West Areas via the Cross Site Transfer Line. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

Code: 241-ER-152

- **Classification:** Accepted
- **Names:** 241-ER-152; 241-ER-152 Diversion Box
- **Reclassification:** None
- **Type:** Diversion Box
- **Start Date:** 1/1/1945
- **End Date:**

**Status:** Inactive

**Description:**
Most of the reinforced concrete diversion box structure is underground. The floor and lower portions of the walls are lined with stainless steel. Cover blocks with lifting hooks are visible from the surface. The 241-ER-152 Diversion Box is surrounded with radiation rope and Contamination Area signs.
**Location:** This 241-ER-152 Diversion Box is southeast of the 224-B Building, and east of 241-ER-151 Diversion Box, near the corner of Atlanta Ave. and 7th Street.

**Release Description:** In 1996, intrusion from mice and harvester ants caused a contamination spread over an area measuring approximately .5 hectares (1.2 acres) southeast of the diversion box. The contaminated area was surface stabilized with clean gravel and downposted from a Contamination Area/Soil Contamination Area to an Underground Radioactive Material Area (URM) (see WIDS sitecode 200-E-29).

**Related Sites/Structures:** The 241-ER-152 Diversion Box is associated with the 241-ER-151 and 241-ER-153 diversion boxes, the 241-ER-311 Catch Tank and transfer lines (sitecodes 200-E-145-PL and 200-E-215-PL). It is also associated with the stabilized Contamination Area known as 200-E-29. The sump drain line for this diversion box is DR311 (see sitecode 200-E-305-PL). The drain line extends to the 241-ER-311 catch tank, located adjacent to the 241-ER-151 diversion box.

**Process Description:** Diversion boxes contain jumper piping that routed waste from one transfer line to another. Waste leaks that occur during high-level waste transfers are contained in catch tanks. The diversion boxes generally drain by gravity to nearby catch tanks where any spilled waste is stored.

**Waste Type:** Process Effluent

**Waste Description:** The diversion box distributes radioactive waste solutions from between facilities and tank farms. Quantities are variable according to specific plant operations. This diversion box facilitates the transfer of low-level waste for the B Plant to the Double-Shell Tank Farms.

---

**Code:** 241-ER-311  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 241-ER-311; 241-ER-311 Catch Tank; 241-ER-311A Replacement Tank; IMUST

**Type:** Catch Tank  
**Start Date:** 1/1/1954  
**End Date:** 1/1/2005

**Status:** Inactive

**Description:** The underground tank is located inside the 241-ER-151 locked chain link fence. The fence is posted as a Contamination Area and Underground Radioactive Material Area, and is labeled with IMUST signs. The placement of these structures within the fence is the 241-ER-311 Catch Tank is the furthest south, nearest the chain link fence. The 241-ER-311A Catch Tank is located adjacent to the north side of the 241-ER-311 tank (in the middle of the three structures). The 241-ER-151 Diversion Box is north of the 241-ER-311A Catch Tank.

**Location:** The tank is located south of the B Plant, and west of Atlanta Avenue, inside the 241-ER-151 diversion box fence.

**Related Sites/Structures:** The 241-ER-311 catch tank is associated with the 241-ER-311A Catch Tank, 241-ER-151, 241-ER-152, and 241-ER-153 diversion boxes, automatic liquid level sensors, leak detection, and a submersible pump. Pipelines associated with these structures are discussed in sitecode 200-E-228-PL and 200-E-305-PL.

**Process Description:** The catch tank collected spills and leaks that occurred in the 241-ER-151, the 241-ER-152, and the 241-ER-153 diversion boxes during waste transfer operations. The catch tank is an underground tank in a horizontal configuration. The tank is constructed from carbon steel, resting in a sand bed. Outer surfaces are coated with coal tar. The interior is unpainted. The drain line from 241-ER-152 is line DR-311 (see sitecode 200-E-305-PL).

**Waste Type:** Steam Condensate
Waste Description: The catch tank collected drainage and leaks from the 241-ER-151, 241-ER-152 and 241-ER-153 diversion boxes. Volumes were variable according to specific plant operation, when the tank was active. Decreasing tank volumes were noted in 2005. A tank leak investigation was done in late 2005 and early 2006. The tank is assumed to be leaking.

Code: 241-ER-311A Classification: Accepted

Names: 241-ER-311A; 241-ER-311A Catch Tank; IMUST; Inactive Miscellaneous Underground Storage Tank; Old 241-ER-311; Original 241-ER-311 Catch Tank

Reclassification: None

Type: Catch Tank Start Date: 1/1/1950

Status: Inactive End Date: 1/1/1954

Description: It is located within a chain link fence that is posted as a Contamination Area and Underground Radioactive Material Area, and is labeled with IMUST signs. The 241-ER-151 Diversion Box, the 241-ER-311 Catch Tank and the 241-ER-311A Catch Tank are all located inside this chain link fence. The placement of these structures within the fence is the 241-ER-311 Catch Tank is the furthest south, nearest the chain link fence. The 241-ER-311A Catch Tank is located adjacent to the north side of the 241-ER-311 tank (in the middle of the three structures). The 241-ER-151 Diversion Box is north of the 241-ER-311A Catch Tank.

Location: This unit is below grade. The tank is located southwest of the B Plant. It is south of 7th Street and west of Atlanta Avenue.

Related Sites/Structures: The tank is associated with the 241-ER-151 Diversion Box.

Process Description: The catch tank received drainage and leaks from the 241-ER-151 diversion box. The tank is a horizontal, carbon steel underground tank.

Waste Type: Process Effluent

Waste Description: The tank received waste from the 241-ER-151 Diversion Box that was caused from leaks and decontamination activities. The tank was abandoned in place in 1954. Although no records have been found identifying its contents of to verify the tank was pumped, it is unlikely any significant amount of was remains in the tank.

Code: 216-S-172 Classification: Accepted

Names: 216-S-172; 216-S-172 Control Structure; 216-S-172 Weir Box and Control Structure; 2904-S-172 Weir

Reclassification: None

Type: Control Structure Start Date: 1/1/1956

Status: Inactive End Date: 1/1/1976

Description: This site is an underground concrete structure with interior hand operated sluice gates. Float wells were attached to the outside north and south walls. The structure has been covered with soil and posted with Underground Radioactive Material/Cave-In Potential signs.

Location: The unit is located outside the southwest corner of the 200 West Area perimeter fence and north of 216-S-5 Crib.

Related Sites/Structures: The site is associated with the 202-S Building, 200-W-153-PL pipeline, and the 216-S-16 Ditch.
Process Description: The control structure was used to divert 202-S process vessel cooling water to 216-S-6 and steam condensate to the 216-S-16 Ditch.

Waste Type: Process Effluent

Waste Description: The unit contains unquantified amounts of low-level radioactive solid waste. In 1987, the Hanford Site Waste Management Units Report stated the maximum radiation reading on the structure was 25 millirads per hour.

Code: 240-S-151
Names: 240-S-151; 240-S-151 Diversion Box
Type: Diversion Box
Status: Inactive
Description: This unit is constructed of reinforced concrete and is rectangular in shape. The 240-S-151 Diversion Box has been weather covered.
Location: The 240-S-151 Diversion Box is located north of the 202-S Canyon Building, west of the 240-S-302 catch tank.
Related Sites/Structures: 200-W-153-PL, 200-W-187-PL, 200-W-190-PL, 200-W-212-PL, the 240-S-302 Catch Tank, UPR-200-W-82 and 241-S Tank Farm are associated with the 240-S-151 Diversion Box.
Process Description: This unit was used for the transfer of REDOX waste solutions from processing and product decontamination operations to the tank farms.
Waste Type: Storage Tank
Waste Description: Equipment associated with the diversion box includes transfer piping and nozzles. Waste lead is also stored in the diversion box.

Code: 240-S-152
Names: 240-S-152; 240-S-152 Diversion Box
Type: Diversion Box
Status: Inactive
Description: This unit is constructed of reinforced concrete and is rectangular in shape. The 240-S-152 Diversion Box has been weather covered.
Location: The 240-S-152 Diversion Box is located north of the 202-S Canyon Building and north of 240-S-151 Diversion Box.
Related Sites/Structures: 200-W-186-PL, 200-W-187-PL, 240-S-302 Catch Tank and 241-S Tank Farm are associated with the 240-S-152 Diversion Box.
Process Description: This unit was used for the transfer of waste solutions from 204-S to the 240-S-151 Diversion Box.
Waste Type: Chemicals
Waste Description: Equipment associated with the diversion box includes transfer piping and nozzles. Waste lead is also stored in the diversion box.

Waste Type: Chemicals

Waste Description: This unit was used for transfer of waste solutions from 204-S to the 240-S-152 Diversion Box.

<td></td>
</tr>
</tbody>
</table>
Process Description: The tank is currently being closed under interim status, containing small amounts of liquid mixed waste. The tank stored various liquid mixed wastes until 1992, when most of the waste was transferred to tank cars for off-site incineration. From 1951 to 1967 the tank was used to store reagent-grade hexone for makeup as a solvent at REDOX. The hexone was delivered to REDOX in rail cars that were unloaded into the 276-S-141 and 241-S-142 tanks via underground lines at the railcar unloading station.

Waste Type: Process Effluent

Waste Description: The unit contained radiologically contaminated liquids made up of normal paraffin hydrocarbons, hexone, and phosphate tar. In 1992, the 276-S-141 and 276-S-142 each contained between 19 to 114 liters (5 to 30 gallons) of 93% normal paraffin hydrocarbons and 7% hexone. They also contained up to 950 liters (250 gallons) of phosphate tar. A nitrogen gas blanket and offgas filtration was implemented in 1990 during the distillation phase. In 2002, the nitrogen suppression system was shut off and the tanks were filled with grout. The remaining 19 to 114 liters (5 to 30 gallons) of liquid is expected to be removed by evaporation over time due to the nitrogen purge process.

</tbody>
</table>

**Names:**
2904-S-160; 2904-S-160 Control Structure; 2904-S-160 Weir

**Type:** Control Structure

**Status:** Inactive

**Start Date:** 1/1/1954

**End Date:** 1/1/1976

**Description:** The unit is an inactive waste management unit consisting of a below grade pentagonal structure with reinforced concrete walls, floor, and roof. Sixty centimeter (24 inch) diameter vitrified clay pipes provided inlet and outlet flow for the structure. The site has been surface stabilized and is posted with Underground Radioactive Material/Cave-in Potential signs.

**Location:** The structure is located southwest of the southwest corner of the 200 West Area, outside the perimeter fence and north of the 216-S-5 crib.

**Related Sites/Structures:** The site is associated with the 216-S-172 control structure, the 216-S-17 and 216-S-16 Ponds, the 216-S-6 Crib, 200-W-155-PL and 200-W-152-PL pipelines.

**Process Description:** The unit was built to divert process vessel cooling waste and steam condensate from 202-S Building to the 216-S-17 Pond, 216-S-6 Crib, and 216-S-16 Pond.

**Waste Type:** Process Effluent

**Waste Description:** The unit contains low-level contaminated concrete and piping. The quantity of contaminated waste has not been determined. There is beta/gamma contamination in the soil and smearable contamination on the surfaces of the box. Contamination originated from effluents traveling through the weir.

**Names:**
2904-S-171; 2904-S-171 Control Structure; 2904-S-171 Weir Box; 216-S-171

**Type:** Control Structure

**Status:** Inactive

**Start Date:** 1/1/1954

**End Date:** 1/1/1976

**Description:** The 2904-S-171 Control Structure is a below grade, rectangular concrete weir structure. The inlet piping consisted of 46 centimeter (18 inch) diameter vitrified clay pipe. The outlet piping consisted of 46 centimeter (18 inch) diameter corrugated metal pipe. The site has been backfilled with clean material and is posted with Underground Radioactive Material signs.

**Location:** The site is located southwest of the 200 West Area, outside the perimeter fence, adjacent to the north side of the 216-S-6 Crib.

**Related Sites/Structures:** The structure is associated with the 216-S-6 Crib and the 200-W-153-PL and 200-W-156-PL pipelines.

**Process Description:** The unit was built to measure and regulate flow of process waste being routed to the 216-S-6 Crib. Pipeline 200-W-156-PL entered the control structure from the north. Pipeline 200-W-153-PL entered the control structure from the east.

**Waste Type:** Process Effluent

**Waste Description:** This unit contains low-level contaminated concrete and piping. The quantity of contaminated waste has not been determined. There were beta/gamma smearable contamination and recordable radiation readings with a Cutie Pie (hand-held radiation monitor) on the above ground portions of the structure before it was surface stabilized.

West Area Powerhouse Pond.

**Release Description:** Over the years, multiple releases associated with this diversion box and its pipelines have been documented. HW-60807, issued in 1959, states that contamination has spread from this diversion box to the surrounding ground on several occasions. Three sides of the diversion box were covered with black top in an effort to contain the contamination. In November 1952, contaminated nitric acid solution was pumped from the 241-TX-155 catch tank to an excavation nearby and covered with soil. The area was surrounded with a wooden fence and radiation signs in 1952, but is not currently marked. In 1954, a jumper leak in the diversion box caused an area measuring 9 meters by 30.5 meters (30 by 100 feet) to become contaminated. This area was also fenced and posted at the time of the occurrence, but the wooden fence is no longer present. In 1998, 1999 and 2000, several large areas of contamination was identified and posted around the diversion box and on its associated pipelines (See UPR-200-W-113).

**Related Sites/Structures:** The 241-TX-155 Diversion Box is associated with the 241-TX-302B and 241-TX-302BR Catch Tanks, the 241-T, 241-TX, and 241-TY Tank Farms, UPR-200-W-113, UPR-200-W-5, UPR-200-W-28, UPR-200-W-135 and UPR-200-W-76. The encased pipeline between 241-TX-154 Diversion Box and 241-TX-155 Diversion Box is sitecode 200-W-143-PL. Other transfer lines are 200-W-176-PL, 200-W-177-PL, 200-W-182-PL, 200-W-191-PL.

**Process Description:** This unit was to transfer waste solutions from processing and decontamination operations to various tank farm facilities via underground transfer lines.

Description: This unit is an underground horizontal, cylindrical tank made of carbon steel. The tank area has been sprayed with shotcrete to control surface contamination.
Location: The 241-TX-302 Catch tank is located southeast of the center of the 221-T Building.

Related Sites/Structures: The 241-TX-302-C Catch Tank is associated with the 241-TX-154 Diversion Box and UPR-200-W-38. The diversion box drain lines are V741 and V742.
Process Description: This unit received overflow from the 241-TX-154 Diversion Box.

---

Code: 216-TY-201
Names: 216-TY-201; IMUST; Inactive Miscellaneous Underground Storage Tank; Supernatant Disposal Flush Tank
Type: Settling Tank
Status: Inactive
Description: The 216-T-26, 216-T-27 and 216-T-28 cribs and the 216-TY-201 Tank are enclosed in a common area with steel post and chain barricade. The area is posted "Underground Radioactive Material". The 216-TY-201 flush tank is located in the northeast corner of the area. It has three risers protruding from a mound of earth. The 216-TY-201 tank is delineated with steel post and chain and marked with Inactive Miscellaneous Underground Storage Tank signs.
Location: The unit is located in the 200-West Area. It is east of Camden Ave and south of 23rd Street.

Process Description: HNF-2503 states the flush tank originally received supernate from the TY Tank Farm (1953-1955) and discharged the overflow to the 216-T-26 crib. The pipeline from 241-TY Farm was blanked near the 241-TY Tank Farm eastern fenceline in December 1955. After 1955, the flush tank received waste via another pipeline from tank 241-T-112 in the 241-T Tank Farm.
Overflow from the flush tank was discharged to the 216-T-27 and 216-T-28 cribs.

Waste Type: Not Specified

In 1955 and 1956, the 216-TY-201 Flush Tank received scavenged first cycle supernate from 221-T after it had cascaded through the 241-TY-101, 241-TY-103, and 241-TY-104 tanks in 241-TY Tank Farm. From 1960 through 1966 the 216-TY-201 Flush Tank received T Plant steam condensate and process decontamination waste via the 241-T-112 tank in the 241-T Tank Farm. In 1963, 2706-T equipment decontamination waste was added to the waste stream. In 1964, 300 Area laboratory waste was trucked to the 216-T-27 and 216-T-28 cribs and released to the cribs through a riser. The Authorization Basis Status Report (1998) assumes the solid and liquid composition to be the same as those found in tank 241-T-112. Solids are assumed to contain 5110 micrograms per gram (ug/g) aluminum, 28800 ug/g bismuth, 16400 ug/g iron, 41000 ug/g sodium, 395 ug/g lead, 313 ug/g strontium, 3100 ug/g uranium, and 36600 ug/g OH. Solid radionuclides are assumed to include 0.184 microcuries per gram (uCi/g) cesium-137, 6.0 uCi/g strontium-90, 5.71 E-04 uCi/g plutonium-138, 0.07 uCi/g plutonium-139 and 1.0 E-04 uCi/g americium-241. The Supernate is expected to contain 9.0 E-06 uCi/g americium-241.

Code: 241-U-151
Names: 241-U-151; 241-U-151 Diversion Box
Type: Diversion Box
Status: Inactive
Description: The diversion box is marked and radiologically posted. This unit is constructed of reinforced concrete with multiple encased liquid waste transfer lines. The diversion box structure is mostly below ground. It has three layers of cover blocks.
Location: The 241-U-151 Diversion Box is located northeast of the intersection of Camden Avenue and Sixteenth Street, east of the 241-U Tank Farm.
Related Sites/Structures: The 241-U-151 Diversion Box is associated with the 241-U-301 Catch Tank and the 244-S and 244-TX Double Contained Receiver Tanks. The unit is also associated with Diversion Boxes 241-U-152, and 241-TX-152, UPR-200-W-6, 200-W-99-PL, 200-W-130-PL, 200-W-183-PL, 200-W-184-PL.
Process Description: This unit was used to transfer waste solutions from processing and decontamination operations.
Waste Type: Not Specified
Waste Description: The unit transports waste solutions from processing and decontamination operations. Quantities are variable according to specific plant operations. Lead shielding may also be contained inside the diversion box.

Code: 241-U-152

</tr>
</tbody>
</table>
Process Description: The catch tank collected excess liquid from the 241-UX-154 Diversion Box and 291-U stack condensate drainage.

Code: 200-W-7  
Classification: Accepted

Names: 200-W-7; 241-S-TK-1; 243-S-TK1; 243S-TK-1; 246-L; IMUST; Inactive Miscellaneous Underground Storage Tank; 200-W Personnel Decontamination Facility Catch Tank

Reclassification: None

Type: Catch Tank  
Start Date: 1/1/1978

Status: Inactive  
End Date: 1/1/1988

Description: The underground tank is inside a chained area that measures approximately 3 meters by 3 meters (9 feet by 9 feet), with three risers extending to the surface. The tank is posted with Inactive Miscellaneous Underground Storage Tank (IMUST) signs and radiological postings.

Location: The site is located northwest of 242-S Evaporator and just north of MO-326.

Related Sites/Structures: The tank is associated with Trailer MO-0326. It was the Personnel Decontamination Facility for 200 West Tank Farms.

Process Description: The underground tank is a 2,082 liter (550 gallon) fiberglass catch tank was connected to trailer MO-0326. The trailer had been used as a personnel decontamination facility. The trailer had a sink and a shower. The trailer has been removed. The underground tank is covered with a minimum of 0.9 meters (3 feet) of overburden. The tank has three risers.

Code: 200-W-16  
Classification: Accepted

Names: 200-W-16; 292-T Underground Tanks; 292-TK-1; 292-TK-2; IMUST; Inactive Miscellaneous Underground Storage Tank

Reclassification: None

Type: Storage Tank  
Start Date: 1/1/1944

Status: Inactive  
End Date: 1/1/1970

Description: The site consists of two underground, stainless steel, 55-gallon drums, encased in a concrete block with lifting eyes. Two metal riser pipes extend about 0.5 meters (1.5 feet) above grade near the southeast corner of the 292-T building addition. Both are capped and one appears to have a pressure relief vent. These pipes extend from two buried tanks (292-TK-1 and 2). There is a chain link fence enclosing the area where the tanks are located. The fence is posted with Access Restricted signs. The site is within a chained area posted "Contamination Area".

Location: The underground tanks are near the southeast corner of the 292-T building addition. The 292-T building is south of the 291-T stack and north of 222-T.

Related Sites/Structures: The site is associated with 291-T, 221-T, and the 292-T facility (200-W-40).

Process Description: The 292-T building originally housed the 291-T stack gas sampling system and supported the 221-T off gas monitoring operations. When T plant was built, it was not known what material would escape during the reprocessing of the irradiated fuel. Accordingly the stack was equipped with state of the art monitoring equipment, including scrubbers containing 5% soda ash solutions that the stack effluent was passed through. The solution was dried using refrigeration, and then counted to determine Xenon-133 activity. Extensive reviews of documentation remaining from T Plant operations has not located any documents that quantify...
the amount of material that was placed in the tanks, but very little emphasis was placed on waste management at that time and it is doubtful that any documents were kept. In 1966, a building addition was added to the existing structure to house a fuel element testing facility, operated by Battelle Northwest. During the lab upgrade, the two underground storage tanks were relocated from southeast of the original 292-T building to their present position, southeast of the 292-T building addition. Fuel failure analysis of irradiated fuel rods was conducted in 292-T in the 1960's and early 1970's. Irradiated N Reactor fuel rods were heated in an induction furnace until rupture or failure occurred. After the rupture occurred, the fuel was transported to the 300 area for further analysis. The fragments that remained in the oven were removed, and any material that remained on the oven surface was dissolved with nitric acid. It is doubtful that much if any of the aluminum clad was dissolved, since aluminum will not dissolve in nitric acid without the use of a catalyst. The solution of trace amounts of irradiated fuel and nitric acid was taken to 200 West Area and poured into the 292-T-TK-1 and 2 tanks through the risers. The solution in the tanks was then neutralized with sodium hydroxide. Neutralization caused the dissolved metals to precipitate and deposit in the tank bottoms.

### Code: 200-W-58

**Classification:** Accepted

**Names:** 200-W-58; Z-Plant Diversion Box #1

**Type:** Valve Pit

**Status:** Inactive

**Description:** The Plutonium Finishing Plant had a gravel covered, fenced exclusion area. The concrete lid of the diversion box is visible above ground. The unit is buried to a depth of 2.7 meters (9 feet) with its upper surface (a thick concrete lid) being slightly above grade. A 20 foot long, 12 inch diameter VCP pipe, extends from the 200-W-58 diversion box to a small drain field.

**Location:** The site is located south of 234-5Z facility. It is directly south of the 241-Z-361 settling tank. It was between the two fences that made up the double enclosed exclusion area. Most of the fencing around 234-5Z has been removed.

### Code: 200-W-59

**Classification:** Accepted

**Names:** 200-W-59; Z-Plant Diversion Box #2

**Type:** Valve Pit

**Status:** Inactive

**Description:** The Plutonium Finishing Plant had a gravel covered, fenced exclusion area. The concrete lid of the diversion box is visible above ground. The unit is buried to a depth of 2.7 meters (9 feet) with its upper surface (a thick concrete lid) being slightly above grade. A 20 foot long, 12 inch diameter VCP pipe, extends from the 200-W-58 diversion box to a small drain field.

**Location:** The site is located southwest of the 234-5Z building. It is west of the 216-Z-361 settling tank and directly north of the 216-Z-12 crib. It was between the two fences that made up the double enclosed exclusion area. Most of the fencing around 234-5Z has been removed.
Process Description:
This unit is a concrete box with a floor drain that apparently discharges to the soil column. The structure directed the flow of process waste via the 241-Z-361 settling tank to the 216-Z-12 crib, via diversion box number 1 (sitecode 200-W-58). Thee structure is also referred to as a Valve Pit.

Related Sites/Structures:

Code: 200-W-84-PL
Names: 200-W-84-PL; U Plant Chemical Process Sewer to 216-U-14 Ditch; VCP Process Sewer; 200-W-84
Type: Radioactive Process Sewer
Status: Inactive
Description: The majority of the waste site is an underground, 30 centimeter (12 inch) diameter and 46 centimeter (18 inch) diameter, vitrified clay pipeline. A 20 centimeter (8 inch) diameter process sewer line from 224-U and 222-U connects to the main process sewer line. It terminated at a timber headwall where the flow entered the 216-U-14 Ditch. The surface of the pipeline is marked with Underground Radioactive Material and Pipeline signs. At intervals along the pipeline, there are 1.2 meter, (4 foot) diameter, yellow manholes. Feed lines are listed as subsites.
Location: The underground process sewer line extends from the northwest side of the 221-U Building to the 216-U-14 Ditch. The line runs south, under 16th Street, and turns west until it intersects with the south end of the ditch. A pipeline from 224-U and 222-U extends along the northwest side of these buildings and connects to the main process sewer line in a manhole north of 16th street.

Related Sites/Structures:

Process Description:
The pipeline transported process sewer waste from 221-U, 271-U, 224-U, 222-U and 292-U to the 216-U-14 Ditch. This pipeline bypasses the 207-U Retention basin.

This Site has the Following SubSites:
Code: 200-W-84-PL:1
Names: 200-W-84-PL:1; 12-Inch VCP
Code: 200-W-84-PL:2

February 2015  1152
piping, the concrete vaults, ancillary equipment and the soil directly below the tanks. The external pipelines leading from buildings in 234-5Z to the 241-Z facility are not considered part of this site.

Location: The site is located inside the Z-Plant Security Fence, near the south end of the complex.

Release Description: See UPR-200-W-74, UPR-200-W-75 and UPR-200-W-79.

Related Sites/Structures: The site is related to 241-Z-D-4, 241-Z-D-5, 241-D-6, 241-Z-D-7, and 241-Z-D-8. Unplanned Releases UPR-200-W-74, UPR-200-W-75 and UPR-200-W-79 are also associated with 241-Z. The sample building (241-ZA) located on the southeast corner of the 241-Z is also part of this site. The pipelines to 241-Z is described in sitecodes 200-W-219-PL. The waste transfer line from 241-Z to 241-TX Tank Farm is 200-W-178-PL. The pipeline from 241-Z to 241-Z-361 settling tank is sitecode 200-W-220-PL. Pipelines that fed 241-Z include 200-W-219-PL, 200-W-224-PL, 200-W-228-PL, and 200-W-229-PL.

Process Description: The 241-Z tanks are a waste treatment, storage and collection system containing below grade tanks in covered concrete cells. The operating capacity of the tank system was 17,000 gallons (65,000 liters). Liquid wastes generated from Plutonium Finishing Plant operations were collected in tank 241-Z-D-8 for interim storage. The waste was transferred to 241-Z-D-5 for treatment (pH adjustment) prior to discharge to the tank farms via 244-TX receiver tank. Tanks 241-Z-D-4 and 241-Z-D-7 were reserve waste accumulation tanks.

Code: HSVP
Names: HSVP; Semiworks Valve Pit; 201-C Diversion Box; 201-C Valve Box; Hot Semiworks Valve Pit
Type: Valve Pit
Status: Inactive
Start Date: 1/1/1951
End Date: 1/1/1986
Description: The site is a sealed, concrete-filled, vertically configured, stainless-steel cylinder that is buried beneath the ash barrier which was placed over the decommissioned 201-C Process Building (see 200-E-41). The surface stabilized area is posted with Underground Radioactive Material signs. The valve pit is not separately marked or posted.
Location: This valve pit is adjacent to the remains of the 201-C Building and southeast of the main canyon area. It is located within the surface stabilized area known as 200-E-41.
Related Sites/Structures: Structures associated with the decommissioned valve pit include: the 201-C Building, valves, transfer lines, the 244-CR Vault, 241-C Tank Farm, and the 241-CX-70 Tank. It is also associated with 200-E-41 Stabilized Area and pipeline 200-E-150-PL.
Process Description: This valve pit connected sources within the 201-C Building with discharge locations at the 244-CR Vault, the 241-C Tank Farm, and the 241-CX-70 Storage Tank.
Waste Type: Barrels/Drums/Buckets/Cans
Waste Description: This site has been decommissioned. During operation, this valve pit routed pilot REDOX wastes, pilot PUREX wastes, and wastes from strontium recovery efforts to tank farm facilities. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

</table>

**Description:** The release is not separately marked or posted.

**Location:** The release occurred on the south side of 221-B, between the 221-B Building and 241-BX-154.

**Release Description:** A failure of first-cycle waste line from the 221-B building to 241-BX-154 Diversion Box was identified. Efforts to excavate and inspect for the cause were abandoned when readings of 120 rads per hour were found with 46 centimeters (18 inches) of soil still remaining over the pipe.

**Waste Type:** Process Effluent

**Waste Description:** The release consisted of B Plant first cycle waste with dose rates up to 120 rad per hour at a distance of 0.4 meters (1.5 feet).

### Code: UPR-200-E-7

**Classification:** Accepted

**Names:** UPR-200-E-7; Cave-In Near 216-B-9 (241-B-361 Crib); Pipeline Leak; UN-200-E-7

</tbody>
</table>

**Description:** The site is an unplanned release to the soil from a waste line break. A single metal post with a WIDS sign marks an estimated release location near the 216-B-9 crib.

**Location:** The Unplanned Release occurred on the east side of Baltimore Ave., near the 216-B-9 crib. The 216-B-9 Crib has an alias name of the 241-B-361 Crib. In 1954, a cave-in was noted over the underground line near the 241-B-361 crib.

**Release Description:** On November 30, 1954, leakage from the waste line between 221-B and the 241-B-361 crib (alias 216-B-9 crib) caused the ground to cave-in near the 241-B-361 crib. Approximately 19,000 liters (5000 gallons) of liquid was lost to the ground. The maximum dose rate observed was 1.7 rads/hour over an area covering 2.7 square meters (30 square feet). The contamination was covered and delineated with a chain fence. The area was posted with "Underground Contamination" signs.

**Related Sites/Structures:** Based on HW-60807, this release is assumed to be associated with pipeline site 200-E-199-PL.

**Waste Type:** Steam Condensate

**Waste Description:** The release consisted of 18,925 liters (5000 gallons) of B Plant cell wash water from the 5-9 tank. The maximum dose rate was 1.7 rads/hour. Approximately, 2.8 square meters (30 square feet) of soil was contaminated by this release.

### Code: UPR-200-E-42

**Classification:** Accepted

**Names:** UPR-200-E-42; 241-AX-151 Release; UN-200-E-42

<table>
<thead>
<tr>
<th>Type</th>

</thead>
<tbody>
<tr>
<td>Unplanned Release</td>
<td>Inactive</td>
<td>1/1/1972</td>
<td></td>
</tr>
</tbody>
</table>

**Description:** A WIDS sign has been placed near the diversion box structure to document the release. The release area is surrounded with posts and chain. It is posted with multiple radiological postings.
including Radiation Area, Underground Radioactive Material Area and Contamination Area.

**Location:**
The 241-AX-151 Diversion Box is located near the corner of 4th Street and Buffalo Ave., adjacent to the 204-AR Unloading Station. The unplanned release site included a dirt bank east of the 241-AX-151 Diversion Box and weeds east of the established parking lot.

**Release Description:**
Surveys made at the 241-AX-151 Diverter Station on November 6, 1972 revealed direct and smearable contamination of 200 to 300 millirad per hour with a few spots in excess of 5 rad per hour. The green tape sealing the cover block cracks was contaminated to 20 rad per hour. The blacktop east of the diversion box was contaminated up to 3000 counts per minute. The dirt bank east of the posted radiation zone had contaminated spots up to 2000 counts per minute and weeds contaminated from 300 to 800 counts per minute. Follow up surveys indicate the contamination spread to be a result of a steam jet being left on at 244-AR, resulting in the pressurization of the 241-AX-151 Diverter Tank.

**Related Sites/Structures:**
The release is associated with 241-AX-151 and 244-AR.

**Process Description:**
241-AX-151 routed waste from PUREX to the 244-AR Vault and to the 241-AY and 241-AZ Tank Farms.

**Waste Type:**
Asbestos (non-friable)

**Waste Description:**
The contamination spread consisted of specks with beta/gamma levels ranging 300 millirad per hour at the diversion box and from 300 to 3,000 counts per minute found on asphalt and soil surfaces in the vicinity of the 241-AX-151 diversion box. The 241-AX-151 diversion box routed waste from PUREX to the 244-AR Vault and to the 241-AY and 241-AZ Tank Farms.

---

**Code:** UPR-200-E-45

**Classification:** Accepted

**Names:** UPR-200-E-45; Contamination Spread from the 241-B-154 Diversion Box; UN-200-E-45

**Reclassification:** None

**Type:** Unplanned Release

**Start Date:** 1/1/1974

**End Date:** 1/1/1974

**Description:** A large area on the northeast corner of 7th Street and Baltimore Avenue is surrounded with post and chain and marked as an Underground Radioactive Material (URM) area. The URM surrounds the 241-B-154 Diversion Box, that has been covered with a coating of gray grout. The original Unplanned Release is not separately marked or posted.

**Location:** The 241-B-154 Diversion Box is located at the corner of 7th Street and Baltimore Ave. The release involved loose contamination spreading in a southeasterly direction from the 241-B-154 Diversion Box.

**Release Description:** During a "clean out" operation at the 241-B-154 Diversion Box, wind spread loose contaminated around the work area. The activity involved decontaminating the inside of the diversion box and removing jumpers. The wind caused the spread of loose contamination over an area approximately 91.5 meters (300 feet) by 30.5 meters (100 feet). Five employees, a crane and a water truck were also contaminated. The ground surface between the diversion box and 7th Street levels of contamination ranged from 1,000 counts per minute to 40,000 counts per minute. The contamination on 7th Street (blacktop) ranged from 800 counts per minute to 30,000 counts per minute. An area of contamination on the south side of 7th Street was found to have contamination levels ranging from 300 to 3000 counts per minute.

**Related Sites/Structures:** This release is related to the 241-B-154 Diversion Box and UPR-200-E-77.
Waste Type: Stormwater Runoff
Waste Description: Loose, dried, contamination particles (specks) were spread from the inside of the diversion box to the ground in the vicinity of 7th and Baltimore. The contamination spread included beta/gamma readings up to 50,000 counts per minute on the soil surface.

Code: UPR-200-E-67
Names: UPR-200-E-67; Excavation of Radioactively Contaminated Pipe Encasement (V004, V005, V006, V007, V008); UN-200-E-67; UN-216-E-67
Type: Unplanned Release
Status: Inactive
Start Date: 1/1/1984
End Date: 1/1/1984
Description: The 1984 excavation has been backfilled. A WIDS sign has been placed at the approximate location of the excavation.
Location: This site was located in an excavation site, north of the 272-AW parking lot, near the corner of 4th Street and Canton Ave.
Release Description: The release occurred on May 7, 1984. An old, contaminated pipe encasement was encountered during the excavation. Contamination levels ranged from 1 to 1.5 milirad per hour.
Related Sites/Structures: The release is associated with pipeline site 200-E-207-PL.
Process Description: An encased pipeline (containing lines V004, V005, V006, V007 and V008) extends between the 241-A-151 Diversion Box, south of PUREX, to the 241-A-152 Diversion box that is located inside the 241-A Tank Farm. (see sitecode 200-E-207-PL)
Waste Type: Barrels/Drums/Buckets/Cans
Waste Description: The contamination levels consisted of beta/gamma readings ranging from 1,000 to 1,500 milliard per hour on the excavated pipe.

Code: UPR-200-E-77
Names: UPR-200-E-77; 241-B-154 Diversion Box Ground Contamination; UN-200-E-77; UN-216-E-5
Type: Unplanned Release
Status: Inactive
Start Date: 1/1/1946
End Date: 
Description: A large graveled area on the northeast corner of 7th Street and Baltimore Avenue is surrounded with post and chain and marked as an Underground Radioactive Material (URM) area. The URM surrounding the 241-B-154 Diversion Box has been covered with a coating of gray grout (shotcrete). The area appears to have been posted in stages. A large posted oval area (URM) extends north and east from the diversion box. Another posted area (URM) extends west to Baltimore Ave. and turns northward. In January 2000, a separate Contamination Area was posted around a power pole (adjacent to a manhole) within the larger URM. In 2002, the posting around the power pole was removed and a Fixed Contamination Area sign was attached to the pole.
Location: This site is located east of 221-B Building, at the northeast corner of Baltimore Avenue and Seventh Street. It surrounds the 241-B-154 Diversion Box.
**Process Description:** The contamination surrounding the diversion box is associated with the use of the diversion box to transfer contaminated waste via underground pipelines. Leaks and contamination spread occurred during diversion box activities over the years. The diversion box was actively used between 1948 and 1984. The size and shape of the radiological posting has varied over the years.

**Waste Type:** Water

**Waste Description:** The original release involved metal waste solution from 221-B with fission products measuring approximately 1 curie. A radiological survey of the area done in October 1975 found surface contamination up to 80,000 counts per minute.

**Release Description:** Metal waste solution contaminated the ground around the 241-B-154 Diversion Box as a result of work associated with a leaky jumper in the box.

**Related Sites/Structures:** The site is associated with the 241-B-154 Diversion Box.

**Names:** UPR-200-E-78; 241-BX-155 Diversion Box; 241-B-302-C Tank; UN-200-E-78; UN-216-E-6

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The diversion box has been isolated and covered with gray grout. The area around the diversion box and the surface area above the 241-B-302-C tank have been surface stabilized with gravel and posted with Underground Radioactive Material signs.

**Location:** This site is located in the area around the 241-BX-155 Diversion Box, south of the 241-BX Tank Farm, northeast of B-Plant between Atlanta and Baltimore Avenues.

**Release Description:** During pressure testing of lines and jumpers in the 241-BX-155 Diversion Box, a spill occurred causing the ground to become contaminated. The release affected an 18 square meter (200 square foot) area. At the time of the release, the maximum dose rate was 22.6 rad per hour.

**Waste Type:** Sanitary Sewage

**Waste Description:** The release included salt waste from B Plant containing approximately 10 curies of mixed fission product. The maximum dose rate was 22.6 rad per hour at the surface of the spill site (241-BX-155 Diversion Box) in 1955.

**Names:** UPR-200-E-84; 241-ER-151 Catch Tank Leak (241-ER-311A); UN-200-E-84; UN-216-E-12

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The 241-ER-151 Diversion Box and the 241-ER-311 and 241-ER-311A Catch Tanks are located inside a chain link fence that is radiologically posted. A WIDS sign has been placed at the approximate location of the release.

**Location:** The release occurred adjacent to the 241-ER-151 Diversion Box, southwest of the 221-B Building.
**Release Description:** This release occurred in March 1953. Contaminated acid leaked to the ground from the 241-ER-311(A) Catch Tank. At the time of the event, no ground surface contamination was detected.

**Related Sites/Structures:** The UPR-200-E-84 is associated with the 241-ER-311A Catch Tank and the 241-ER-151 Diversion Box.

**Process Description:** The original 241-ER-311 Catch Tank was replaced in 1953. The replacement tank was named 241-ER-311. The original catch tank was re-numbered as 241-ER-311A. Both catch tanks received drainage from the 241-ER-151 Diversion Box.

**Waste Type:** Water

**Waste Description:** The release consisted of contaminated acid with approximately 10 curies of fission products from the 241-ER-311(A) Catch Tank.

**Names:** UPR-200-E-145; VCP Pipeline Leak; W049H Green Soil

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The site currently is a flat, disturbed area, with no vegetation. The area is covered with sandy soil and some rocks and gravel. The release was identified in a pipeline excavation that was oriented north to south. The north end of the excavation was located at a power pole with a blue air sample cabinet. In December 2003, growing contaminated tumbleweeds were found on the surface of this underground pipeline. The weeds were removed and the surface was stabilized. An area measuring approximately 3 meters by 6 meters (10 feet by 20 feet) is posted with Underground Radioactive Material signs.

**Location:** The site is east of the 241-A Tank Farm entrance, northeast of the 242-A Evaporator Building, and east of Canton Avenue. The coordinates of the excavation were E575490, N136130 on the north end and E575490, N136118 on the south end. H-2-140342 shows a polygon called Deep Rad Zone that is most like the correct location for this release.

**Release Description:** In 1993, while excavating for the installation of a new pipeline (Project W-049H) and exposing existing utility lines, contaminated soil with a radiological reading of 300,000 disintegrations/minute beta-gamma was detected at a depth of 0.8 meter (2.5 feet). The contamination was found above an existing 38 centimeter (15 inch) vitrified clay pipe, which was suspected to be the source.

**Related Sites/Structures:** The 38 centimeter (15 inch) vitrified clay pipe is 200-E-166-PL, feeding the 216-A-34 trench.

**Process Description:** Leakage from the 38 centimeter (15 inch) vitrified clay pipe is the suspected cause of soil contamination. A 38 centimeter (15 inch) pipe runs east to west at this location that was connected to the 216-A-34 crib.

**Waste Type:** Chemicals

**Waste Description:** Contaminated soil reading 300,000 disintegrations per minute of beta/gamma was found in an excavation, above a buried vitrified clay pipeline. The pipeline carried waste from the 216-A-8 Proportional Sample Pit #2 to the 216-A-34 crib. The contaminated soil read 300,000 disintegrations per minute with a GM/P-11 probe instrument. Sample results indicate the contamination was primarily due to uranium oxide from past practices on the Hanford site.

<td>Description</td>
<td>The area around stairwell R-19 at the 221-T facility is currently paved with asphalt. A long, narrow Underground Radioactive Material area is posted around the R-19 area.</td>
<td></td>
</tr>
<tr>
<td>Location</td>
<td>The cave-in occurred on the southeast side of the 221-T facility, near stairwell R-19.</td>
<td></td>
</tr>
<tr>
<td>Release Description</td>
<td>On June 23, 1947, a minor ground cave-in occurred at the rear of the T-Plant Canyon Building opposite the R-19 stairwell and directly over one of the underground waste transfer lines. Gross soil contamination levels were found 3 to 3.3 meters (10 to 11 feet) beneath the surface confirming the presence of a leak in one or more of the underground process waste pipe lines. Plans were being formulated to establish the boundaries of the underground contamination at R-19 by the use of test holes. When this survey was completed (in 1947), temporary &quot;danger zone&quot; status was eliminated and a permanent danger zone was established similar to the zone established at B Plant door R-3.</td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures</td>
<td>This site is associated with 221-T and UPR-200-W-98. The pipeline associated with this leak may have been 200-W-132-PL.</td>
<td></td>
</tr>
<tr>
<td>Process Description</td>
<td>The monthly report for June 1947 states that this is the third documented failure of underground metal waste lines. Operations were stopped as soon as practical and an excavation of the cave-in site was made under careful survey control of the Health Instruments group. Gross soil contamination was found 3 meters (10 feet) below the surface, confirming the presence of one or more leaks in the underground process piping.</td>

Hanford Site Waste Management Units Report
February 2015
Process Description: The diversion box was constructed in 1949 and used to transfer waste solutions to and from various processing and decontamination facilities. Multiple releases have occurred at the diversion box and its related underground pipelines.

Waste Type: Process Effluent

Waste Description: Multiple releases from the 241-TX-155 Diversion Box and its associated underground pipelines has resulted in contamination being found in the soil in this vicinity. The contaminated area reference in HW-60807 was given an Unplanned Release number. However, the reference is describing an area where several release events occurred and not a particular event.

Location: The site is located at the southeast corner of the intersection of Camden Street and 23rd Street.

Release Description: On November 15, 1954, a broken, underground process line leading from the 241-T-152 Diversion Box to the 241-TX-153 Diversion Box caused a small cave-in (located 23 meters south of 23rd Street and 23 meters east of Camden Ave) over the pipeline. Run off from the release contaminated an area along the east side of Camden Street. An unencased, underground pipeline was being used to transport first cycle waste from the 241-T-105 tank to the 241-TX-118 tank for 242-T Evaporator processing. The waste transfer was begun around 2:45 pm on November 15, 1954, but was discontinued at 11:30 pm due to a leaking jumper. The cave in and waste runoff was not discovered until 10:00 am on November 16, 1954. A maximum dose rate of 11.5 rad per hour, at a distance of 5 centimeters (2 inches), was found over the run off area. It was calculated that less than 3,800 liters (1,000 gallons) of waste actually escaped from the line.

Waste Type: Storage Tank

Waste Description: The release consisted of first-cycle supernatant containing rare earth metals plus yttrium, cesium, antimony, cerium, ruthenium, niobium, and tellurium. Dose rates up to 11.5 rad per hour at 5 centimeters (2 inches), including 3.5 rad per hour, was measured over the run-off and fields up to 4.5 rad per hour at a distance of 0.9 meters (3 feet) near the cave-in was found. Less than 3,800 liters (1,000 gallons) of waste were estimated to have escaped from the line.
Line Break

| Type: Unplanned Release | Start Date: 1/1/1954 |
| Status: Inactive | End Date: |

**Description:** The release site is not currently marked or posted. The above ground pipeline has been removed.

**Location:** The release occurred near the northwest corner of the REDOX exclusion in 1954.

**Release Description:** During the summer of 1954, the above ground uranyl nitrate hexahydrate (UNH) transfer line connecting 224-U to REDOX broke, released an unknown amount of the UNH solution to the ground. The contaminated area was covered and marked as a radiation zone by use of magenta and yellow tape and radiation zone signs.

**Related Sites/Structures:** The site is associated with the 204-S facility.

**Waste Type:** Storage Tank

**Waste Description:** Soil contamination occurred when an unknown amount of uranyl nitrate hexahydrate (UNH) solution leaked from a leak in an above ground pipeline.

---

| Code: UPR-200-W-35 | Classification: Accepted |
| Names: UPR-200-W-35; Ground Contamination Near UNH Process Line; REDOX to 224-U UNH Line Leak; UN-200-W-35 | Reclassification: None |

**Type:** Unplanned Release

**Start Date:** 1/1/1955

**End Date:**

**Description:** Much of the area north of REDOX has been surface stabilized. The unplanned release site is not marked or posted.

**Location:** The site was located along the above ground uranyl nitrate hexahydrate (UNH) process line, that ran from REDOX to U Plant, at a location just outside and to the north of the REDOX exclusion area.

**Release Description:** In September 1955, a leak occurred in the above ground uranyl nitrate hexahydrate (UNH) line from REDOX to U Plant. The area of surface contamination and the quantity or activity of contaminants were not mentioned in reference material.

**Waste Type:** Process Effluent

**Waste Description:** The waste is described as an unknown amount and concentration/activity of uranyl nitrate hexahydrate (UNH) solution being routed from the Reduction Oxidation (REDOX) facility to the U Plant.

---

| Code: UPR-200-W-38 | Classification: Accepted |
| Names: UPR-200-W-38; UPR-200-W-40; 216-T-30; Line Break at 241-TX-302C; UN-200-W-38; UPR-200-W-160 | Reclassification: None |

**Type:** Unplanned Release

**Start Date:** 1/1/1955

**End Date:** 1/1/1955

**Description:** The area around the 241-TX-154 diversion box and the catch tank has been stabilized with...
sprayed concrete (shotcrete). The area is posted with Underground Radioactive Material signs. A WIDS sign has been placed at this location.

**Location:**
The release occurred on the southeast side of T Plant (221-T), between the 241-TX-154 Diversion Box and the 241-TX-302 Catch Tank. The liquid release affected a large area between the 221-T and 222-T buildings.

**Release Description:**
On December 30, 1955, a failure of an underground transfer line between the 241-TX-154 diversion box and the 241-TX-302 catch tank flooded an area approximately 139.35 square meters (1500 square feet) with radioactive metal waste solution. Contamination was spread during cleanup activities and increased the size of the contamination area to approximately 371.6 square meters (4,000 square feet). The incident report indicates that the volume of metal waste involved "appeared to be in the magnitude of several thousand gallons". Prior to this incident, the area had been covered with asphalt because of a previous contamination spread. The liquid was forced up through several feet of soil and pooled on top of this asphalt. An unreported thickness of soil was backfilled onto the area to prevent further contamination spread. It is reported that a hose with 33 rads/hour contamination was buried in the backfill. Additional asphalt was to be laid on top of the fill for contamination control.

**Related Sites/Structures:**
The release is associated with the 241-TX-154 Diversion Box and the 241-TX-302C Catch Tank. UPR-200-W-21 occurred in the same vicinity in 1953.

**Process Description:**
The 241-TX-302C Catch Tank collects drainage from the 241-TX-154 Diversion Box.

**Waste Type:** Storage Tank

**Waste Description:**
The 1955 release of liquid metal waste produced beta/gamma with a dose rate of 100 rad per hour at a distance of 1 foot (0.3 meters) above the contamination pool. Several thousand gallons of waste was lost to the ground. HW-60807 estimated the release to be 7520 liters (2000 gallons) RHO-CD-673 estimated 19,000 liters (5026 gallons). The waste was high in salt and is neutral to basic. The initial surface pool of liquid was estimated to be 9 meters (30 feet) by 4.5 meters (15 feet).

**Code:** UPR-200-W-64

**Classification:** Accepted

**Names:** UPR-200-W-64; Road Contamination at 23rd and Camden; UN-200-W-64

**Type:** Unplanned Release

**Start Date:** 1/1/1969

**Status:** Inactive

**End Date:**

**Description:**
The corner of 23rd and Camden has been stabilized with clean gravel due to two waste line leak events. The stabilized area is surrounded with chain and posted with Underground Radioactive Material signs. The road shoulders are not posted. A WIDS sign has been placed at the approximate location of the release.

**Location:**
The release is located between the east shoulder of Camden Avenue and the posted Underground Radioactive Material area (UPR-200-W-29/UPR-200-W-97), near the corner of 23rd Street and Camden Ave.

**Release Description:**
On February 13, 1969, contamination up to 600 counts per minute was found in mud samples next to Camden Avenue. The contamination was found to be on the shoulder of the roadway, but no detectable contamination was found on the road blacktop. It is believed that the contamination source was the adjacent radiation zone (UPR-200-W-29 and UPR-200-W-97) where two previous underground radioactive waste line leaks that occurred. Runoff from heavy snow may have caused the contamination movement. Dirt samples from the radiation zone to the east and roadway shoulder samples showed cesium-137 to be the only detectable
Mud samples collected in 1969 contained mostly cesium-137, with readings up to 600 counts per minute. No volume estimate was provide. The contamination source appears to be rain water run off from the adjacent area where two process line leaks occurred (see UPR-200-W-29 and UPR-200-W-97). The line leaks included first-cycle supernatant containing rare earth metals plus yttrium, cesium, antimony, cerium, ruthenium, niobium, and tellurium.

The waste released to the soil consisted of a high salt, neutral to basic liquid tank waste solution containing approximately 10 curies of fission products. The waste consisted of second cycle bismuth phosphate waste from the 241-T-107 tank. The maximum surface dose rate was 5 rad per hour beta/gamma with 3 rad per hour being gamma radiation.

The area around door R-19 is paved with asphalt and posted as an Underground Radioactive Material area. There is not a sign that specifically marks the area as an unplanned release site.

The release site is located near the southeast corner of the 221-T Canyon Building, at door R-19.
**Release Description:** In the spring of 1945, a leak occurred in an underground metal waste transfer line. The liquid surfaced and spread mixed fission contamination over a small surface area of ground.

**Related Sites/Structures:** UPR-200-W-98 was associated with underground pipelines near the R-19 section of the 221-T Canyon Building and UPR-200-W-2.

**Process Description:** Underground pipelines carried T Plant process material and waste to various destinations.

**Waste Type:** Chemicals

**Waste Description:** A broken underground process transfer line caused contaminated liquid to surface near R-19 at 221-T. The "metal waste" line contained approximately 10 curies of high salt, neutral to basic fission products with a maximum dose rate of 20 rad per hour at 2 inches (5 centimeters).

---

**Code:** UPR-200-W-102  
**Classification:** Accepted

**Names:** UPR-200-W-102; 224-T Underground Line Leak; UN-200-W-102; UN-216-W-12  
**Reclassification:** None

**Type:** Unplanned Release  
**Start Date:** 1/1/1972  
**End Date:** 1/1/1972

**Description:** The east and south sides of the 224-T Building are covered with gravel. The area along the east side of the 224-T building is posted as an Underground Radioactive Material area.

**Location:** UPR-200-W-102 occurred adjacent to the south and east sides of the 224-T Building.

**Release Description:** During the remodeling of the 224-T Building, gross alpha contamination was found in the soil on the back side of the building. This contamination is believed to have come from alpha-laden moisture that seeped through pipe joints from underground process tank vent lines during the years of process operation.

**Related Sites/Structures:** UPR-200-W-102 is associated with underground process lines at the 224-T Building. See 200-W-226-PL.

**Waste Type:** Oil

**Waste Description:** The release consisted of alpha-laden moisture from process tank lines that contaminated the soil around the pipeline. An estimated 72 grams of plutonium was contained in the contaminated soil that was removed when the leak was discovered.

---

**Code:** UPR-200-W-108  
**Classification:** Accepted

**Names:** UPR-200-W-108; Line Leak at 216-S-9 Crib; UN-200-W-108; UN-216-W-18  
**Reclassification:** None

**Type:** Unplanned Release  
**Start Date:** 1/1/1969  
**End Date:** 1/1/1969

**Description:** The release site is posted as a "Surface Contamination Area". The excavation was filled after the work was completed.

**Location:** UPR-200-W-108 occurred at the junction of the 216-S-9 and 216-S-23 Crib Liners, south of the 216-S-9 Crib and approximately 61 meters (200 feet) north of Thirteenth Street.

**Release Description:** On January 8, 1969, during the tie-in of the 216-S-9 Crib waste line to the new 216-S-23 Crib, contaminated water was encountered coming from a break at the junction of the two crib lines.
Further excavation disclosed a severe expansion buckle in the line at that point, and a similar buckle in the line near the 202-S Building. There is no way of determining how long the line had been leaking or how much waste was discharged to the ground.

**Related Sites/Structures:**
- UPR-200-W-108 was associated with pipeline 200-W-139-PL, the 216-S-9 Crib, the REDOX D-2 Receiver Tank, the 240-S-151 Diversion Box, the 216-S-23 Crib and UPR-200-W-109.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The waste was REDOX process condensate from the D-2 Receiver Tank in the 202-S Building with beta and gamma contamination and dose rate readings of 40 rads/hour at the bottom of the waste line.

<tr>
<td>Description:</td>
<td>The release was a transfer line break that occurred within the east chain barricade of the 218-W-9 Burial Ground. The 218-W-9 Area was interim stabilized in 1991 with 46 to 61 centimeters (18 to 24 inches) of uncontaminated backfill. The release site was covered with soil and revegetated along with 218-W-9.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>UPR-200-W-109 occurred just inside the east perimeter chain of the 218-W-9 Burial Ground, south of which is located north of the 216-S-7 Crib in 200 West Area.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Release Description:</td>
<td>UPR-200-W-109 is related to the UPR-200-W-108 incident. After repairing the initial buckled portions of the waste line, a pressure test indicated another leak in the line at some point upstream toward the 202-S Building. Further excavation and pressure testing finally determined a leak to be somewhere between the first discovered leak and the northwest corner of the REDOX area fence. Additional hydrostatic testing finally forced water to bubble to the ground surface. Excavation of the bubble site disclosed a vertical buckling of the pipeline with a sizable break in the line. The buckled and broken waste transfer line was from the 240-S Diversion Box. Dose rates on the liquid were 450 millirads per hour, but as the liquid sank into the ground, the dose rate dropped to 20 millirem per hour.</td>

_Hanford Site Waste Management Units Report_

February 2015
**Description:** The original contaminated area was surface stabilized in 1990. It is currently surrounded with concrete marker posts and posted as an Underground Radioactive Material area. In 1998, 1999 and 2000 additional surface contamination was identified in the vicinity of the original surface stabilized area. Smaller contamination areas on the north, south, east and west sides of the 241-TX-152 and 241-TX-155 diversion boxes. At that time, the additional contamination areas were considered extensions of UPR-200-W-113. Many of the contamination areas were found above underground transfer lines going into and out of the 241-TX-155 Diversion Box. They were originally labeled with UPR-200-W-113 signs. Some of the "UPR-200-W-113" signs are being replaced as more information is documented that ties posted contamination areas with other documented Unplanned Releases and pipeline sites that were added to WIDS in 2007.

**Location:** The site is an area east of the 241-TX Tank Farm, on the east side of Camden Ave. Several radiological posted, labeled UPR-200-W-113, areas are located north, south, west and east of the 241-TX-155 and 241-TX-152 Diversion Boxes.

**Release Description:** The original unplanned release description stated that during the spring and summer months of 1977, contaminated rabbit feces were found near the 241-TX-155 Diversion Box, prompting an extensive survey to determine the source of radioactive rabbit food. During this survey, low-level, beta/gamma ground surface contamination was found on the hillside below and to the west of the 241-TX-155 Diversion Box. As soil was removed in the attempt to decontaminate the site, radioactivity increased until it was evident that the source of contamination was subsurface, possibly an old leak from a nearby waste transfer line. In August 1977, Unusual Occurrence Report 77-180 was issued, documenting the contaminated rabbit feces problem. This discovery is also detailed in UPR-200-W-76.

**Related Sites/Structures:** The site is associated with the 241-TX-155 Diversion Box, 241-TX-152, UPR-200-W-28, UPR-200-W-76, UPR-200-W-135 and associated underground pipelines going into and out of the 241-TX-152 and 241-TX-155 diversion boxes.

**Process Description:** Underground pipelines transferred tank waste between tank farms through diversion boxes. Many pipelines leaked, allowing plant and animal intrusion to spread contamination to the surface.

**Waste Type:** Equipment

**Waste Description:** Contaminated animal feces and growing contaminated vegetation have been found in this area. The biological uptake is the result of multiple releases in this area associated with the 241-TX-155 Diversion Box and its underground pipelines.

**Code:** UPR-200-W-114

**Classification:** Accepted

**Reclassification:** None

**Start Date:**

**End Date:**

**Description:** This site is no longer marked or posted. The release site, for many years, had been a large area posted with a light chain and Surface Contamination Area signs. The 216-S-8, the 216-S-1, and the 216-S-2 cribs were located within the larger contamination zone. The surface contamination was scraped up and consolidated into other nearby waste sites. The cribs were individually surface stabilized and reposted with Underground Radioactive Material signs.

**Location:** UPR-200-W-114 was located east of the 241-SX Tank Farm.

**Release Description:** The site consisted of migrating radioactive particulate matter from operational activities at the 241-SX Tank Farm and the 241-SX-151 and 241-S-151 Diversion Boxes over many years. The...
contamination spread to the ground surface east of the 241-SX Tank Farm. The resulting large posted Surface Contamination Area (SCA) was assigned an unplanned release number in 1980.

**Related Sites/Structures:**
UPR-200-W-114 was associated with multiple releases from operation activities in the 241-SX Tank Farm, and the 241-SX-151 and 241-S-151 Diversion Boxes. Documented operational releases extending eastward from the tank farm include UPR-200-W-20, UPR-200-W-49, UPR-200-W-50, UPR-200-W-51, UPR-200-W-52, and UPR-200-W-82.

**Waste Type:** Barrels/Drums/Buckets/Cans
**Waste Description:** The waste consisted of radioactive particulate matter from operational activities in the adjacent 241-S/SX Tank Farms.

<td>None</td>
</tr>
</tbody>
</table>

**Type:** Unplanned Release  
**Status:** Inactive  
**Description:** The site had been delineated with light chain barricade and Surface Contamination warning signs. A waste site inspection, done in February 1998, found the area has been covered with gravel and posted as an Underground Radioactive Material area.

**Location:** UPR-200-W-115 is located above the encased transfer line that runs along the east side of Cooper Street. The pipeline (sitecode 200-W-179-PL) extends between the 242-S Evaporator Facility and the 241-U Tank Farm.

**Release Description:** The release refers to the radiologically posted soil above the underground, encased transfer line that runs from the 242-S Evaporator Building to the 241-U Tank Farm. In 1981, Harold Maxfield stated that he believed the area was incorrectly designated as an unplanned release. He based his opinion on a radiation survey performed on October 7, 1981. The survey report indicated the soil and the surface features of the pipeline (Clean Out Boxes) were free of removable contamination. The report stated the only radiation detected was a dose rate emitting from the Clean Out Boxes. There was no evidence of loss of radiological control at that time.

**Related Sites/Structures:** The release site was associated with the encased transfer lines from the 242-S Evaporator Building to 241-U. The pipelines associated with this release are discussed in sitecode 200-W-179-PL.

**Process Description:** The site is considered to be the soil above an encased transfer line extending from the 242-S Evaporator to the 241-U Tank Farm. The pipeline is equipped with a series of Clean Out Boxes (COBs) along the length of the line to allow access into the pipeline.

**Waste Type:** Misc. Trash and Debris
**Waste Description:** The soil was contaminated with material from the transfer line Clean Out Boxes.

*Hanford Site Waste Management Units Report*
February 2015
Description: A WIDS sign has been placed at the approximate location of the release.

Location: UPR-200-W-130 occurred in the soil on the east side of the 231-W-151 Sump, near the 231-Z Building.

Release Description: While hand excavating to uncover a waste line adjacent to the 231-W-151 Diversion Box, contamination was detected in the soil. The soil adjacent to the waste line contained 40,000 disintegrations per minute alpha contamination, and 150 millirem per hour beta/gamma contamination. The release was due to a leaking flange. The dose rate on the waste line was 1.5 rad per hour.

Related Sites/Structures: UPR-200-W-130 was associated with a waste line, the 231-W-151 Sump and the 231-Z Building.

Waste Type: Process Effluent

Waste Description: The soil had alpha readings up to 40,000 disintegrations per minute, with dose rates of 100 millirem/hour of beta and 50 millirem/hour of gamma.

Code: UPR-200-W-131                Classification: Accepted
Names: UPR-200-W-131; Release from 241-TX-155     Reclassification: None
Type: Unplanned Release    Start Date: 1/1/1953
Status: Inactive        End Date: 1/1/1953

Description: The 241-TX-155 Diversion Box and 241-TX-302B Catch Tank are surrounded with post and chain. Clean gravel has been placed around the diversion box with Underground Radioactive Material and Bio Barrier signs. A single, UPR-200-W-131 WIDS sign is attached to the chain boundary.

Location: The release occurred near the 241-TX-155 Diversion Box, located east of Camden Ave. and east of the 241-TX Tank Farm.

Release Description: In 1953, a severe leak in the tri-butyl phosphate (TBP) feed jumper caused the catch tank to become full. It was necessary to pump the liquid out of the catch tank via an overground line to the diversion box in order to empty the tank. The liquid in the tank was acidic. The first attempt to pump the tank caused a failure of the black iron pump. A decision was made to neutralize the solution with soda ash to prevent another pump failure. Two hundred pounds of soda ash was carefully added to the catch tank. While flushing the soda ash with water, a fine stream of solution erupted out of the 2.5 centimeter (one inch) electrode riser, causing ground contamination with a dose rate of 6 rad per hour. After plugging the riser, another bag of soda ash was added to a 30 centimeter (12 inch) riser. A foamy solution percolated out this riser and a different (10 centimeter) riser, causing ground contamination with readings of 25 rad per hour at a distance of 0.6 meters (2 feet). No further attempts were made to continue neutralizing or to empty the catch tank. (The release occurred in March 1953. Information related to the Catch Tanks indicate 241-302BR was damaged by acid and replaced with 241-TX-302B)

Related Sites/Structures: The release is associated with the 241-TX-155 Diversion Box, the 241-TX-302 Catch Tank and UPR-200-W-113.

Waste Type: Storage Tank

Waste Description: The release consisted of a dilute acidic waste solution. Ground contamination up to 25 rad per hour at 0.6 meters (2 feet) was observed.

Code: UPR-200-W-135                Classification: Accepted

<td>Inactive</td>
<td>End Date: 1/1/1954</td>
</tr>
<tr>
<td>Description:</td>
<td>There are three major encased transfer lines associated with the 241-TX-155 Diversion Box. There have been many areas of contamination identified on these transfer lines during 1999, 2000, and 2001. UPR-200-W-135 is located on transfer line 200-W-191-PL, directly west of the 241-TX-155 Diversion Box. It is surrounded with concrete marker posts and Underground Radioactive Material signs. A single metal post, labeled UPR-200-W-135, has been placed adjacent to the Contamination Area. Other signs surrounding the area are labeled UPR-200-W-113.</td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The oval, posted Underground Radioactive Material Area associated with UPR-200-W-135 is located approximately 46 meters (150 feet) northwest of the 241-TX-155 Diversion Box. The diversion box is located east of Camden Ave and east of the 241-TX Tank Farm.</td>
<td></td>
</tr>
<tr>
<td>Release Description:</td>
<td>While preparing to begin the 241-TX-302B catch tank replacement job near the 241-TX-155 Diversion Box, elevated dose rates were noticed in the area. The dose rate increased as the investigator descended the hill, moving away from the diversion box. A cave-in, with a diameter of 0.61 meters (2 feet), was noted along the encased pipeline (200-W-191-PL) that connects the 241-TX-155 Diversion Box to the 241-TY Tank Farm. A jumper connection in the diversion box had apparently failed and allowed liquid collect inside the diversion box and drain to the catch tank. The catch tank had a known leak. The liquid leaked out of the catch tank and flowed along the pipeline encasement that caused a visual soil cave-in approximately 46 meters (150 feet) down hill from the diversion box. The cave-in area measured approximately 0.6 meters (2 feet) in diameter. A liquid run off path was noted that measured approximately 12 meters (40 feet) long. The dose rate from the leaking process effluent was 5 rad per hour at a distance of 1 meter (3 feet). It was estimated to be 300 rad per hour at a distance of 10 centimeters (4 inches).</td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>UPR-200-W-135 is associated with the 241-TX-155 Diversion Box, 241-TX-302B Catch Tank and pipeline 200-W-191-PL.</td>
<td></td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Process Effluent</td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>The leaking connector (U-15) associated with this release was transferring blended metal waste supernatant from the 244-UR vault to the 241-WR vault when the leak occurred. The amount of liquid released is estimated, since the cave-in was discovered 10 days after the last transfer was made.</td>
<td></td>
</tr>

</table>

| Code: | UPR-200-W-161 | Classification: Accepted |
| Names: | UPR-200-W-161; Large Area East of 241-U Tank Farm; UN-200-W-161; UN-216-W-35 | Reclassification: None |
| Type:  | Unplanned Release | Start Date: 1/1/1990 |
| Status: | Inactive | End Date: |
| Description: | The site is a large radiologically controlled area posted with Underground Radioactive Material signs. A WIDS number sign has been posted at this location. |
| Location: | The site is located east of 241-U Tank Farm, on the east side of Camden Ave. It extends northward from the corner of 16th Street and Camden Ave. and the 241-U-152 Diversion Box. |
| Release Description: | During a January 12, 1990 radiation survey, an area of approximately 1.9 acres (0.77 hectares) east of the 241-U Tank Farm (and west of the 216-U-14 Ditch) was found to be contaminated. |
The general contamination was 250 to 450 counts per minute with spots of 600 to 800 counts per minute. One area, approximately 1.5 meters (5 feet) long by 1.5 meters (5 feet) wide, was contaminated up to 8,000 counts per minute. No Occurrence Report was issued, but the area was submitted to the WIDS database on 3-23-90 as an Unplanned Release Site and given the number UN-216-W-35.

**Related Sites/Structures:** UPR-200-W-161 is associated with the 241-U Tank Farm. Two pipelines associated with tank farm operations are buried in this approximate location (see 200-W-130-PL and 200-W-182-PL).

**Waste Type:** Equipment

**Waste Description:** Windblown contaminated particles effected the area east of 241-U tank farm. Soil sample results from 1990 indicate that the main radionuclide is strontium (2.93 E3 picocuries per gram). Other contaminates included 6.26 picocuries per gram of cesium-137, 3.27 picocuries per gram of plutonium and 2.6 E-07 grams per gram of uranium. Because this site is associated with the 241-U Tank Farm, the waste is assumed to be mixed waste.

<tr>
<td>Location</td>
<td>UPR-200-W-164 effect the soil beneath the aboveground uranyl nitrate hexahydrate (UNH) pipeline that extended from 204-S to 224-U. The UNH line was attached to a steam line, located north of 204-S.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Release</td>
<td>The above ground uranyl nitrate hexahydrate transfer line that extended from the 204-S Storage Tanks to the 224-U Building (hung from an existing steam line) was posted as a radiation zone from 1952 to 1967. The zone was established because of a low-level gamma field (dose rate) emanating from the transfer line. The September 1981 correspondence from Harold Maxfield states he believes the area was incorrectly designated as an Unplanned Release, because the posting was necessary due to a dose rate condition and not a release. Later, a small area of soil contamination was identified under the steam line, adjacent to the 216-S-9 crib.</td>
<td></td>
<td></td>

<tr>
<td>Waste Description</td>
<td>The original Unplanned Release was described as the gamma field (dose rate) emanating from the above ground uranyl nitrate hexahydrate (UNH) transfer line. Later, a small area of soil contamination was found under the steam line that the above ground line had been attached. Liquid UNH apparently had dripped onto the soil on an area located adjacent to the 216-S-9 crib.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
UPR-200-W-167 was located adjacent to the 241-TY Tank Farm fence, extending east and north from the fence.

In 1985 the contamination associated with UPR-200-W-167 was assumed to be the result of migration of contamination from 241-TY Tank Farm operations over a period of time.

UPR-200-W-167 was associated with the 241-TY Tank Farm operations and WIDS sitecode 200-W-78.

The waste consisted of radioactive contamination (specks) that migrated from the 241-TY Tank Farm. Later, contaminated ant hills and contaminated vegetation were also found in this area.

From December 1962 to December 1963, the site percolated and transported the above-listed streams plus 202-A seal cooling water from air sampler vacuum pumps. After December 1963, the site percolated and transported the above-listed streams minus 202-A seal cooling water.

**Code:** 216-B-3-2

**Names:** 216-B-3-2; B Swamp Ditch; 216-B Ditch; 216-B-1 Ditch; 216-B-2-2E

**Type:** Ditch

**Status:** Inactive

**Classification:** Accepted

**Reclassification:** None

**Start Date:** 1/1/1964

**End Date:** 1/1/1970

**Description:** The ditch has been backfilled and surface stabilized. It is located within a large Underground Radioactive Material Area that includes the 216-B-3-1, 216-B-3-2 and 216-B-3-3 covered ditches. The unit was open from the diverter station to the 216-B-3 Pond and was approximately 1.2 to 2.4 meters (4 to 8 feet) deep. It was backfilled in July 1970 after a release of strontium-90 from 221-B Plant.

**Location:** The ditch is located east of the 200 East Area perimeter fence. The ditch began east of the eastern 200 East Area perimeter fence and continued eastward to 216-B-3 Pond.

**Release Description:** UPR-200-E-138: On March 22, 1970, an estimated 1,000 curies strontium-90 release occurred at B Plant during an attempted measurement of the liquid level in Tank 8-1.

**Related Sites/Structures:** The site is associated with 216-B-2-2, 216-B-3 and UPR-200-E-138.

**Process Description:** The ditch received effluent from B Plant and PUREX and transported it to the 216-B-3 Main Pond.

**Waste Type:** Storage Tank

**Waste Description:** Until January 1965, the site transported 221-B Plant process cooling water, steam condensate, and chemical sewer; 241-CR Vault cooling water; 284-E Powerhouse water; and received and transported 202-A chemical sewer waste and fractionator condensate from 216-A-29 Ditch. From January 1965 to January 1966, the site transported the above mentioned streams plus 241-TY Tank Farm ITS Unit 1 condenser cooling water. From January 1966 to November 1967, the site transported the above mentioned streams plus condenser cooling water and air sampler vacuum pump seal cooling water from 202-A Building. From November 1967 to February 1968, the site transported the above mentioned streams minus 284-E Powerhouse wastewater. After February 1968, the site transported the above mentioned streams plus 241-BY Tank Farm ITS Unit 2 condenser cooling water.

**Code:** 216-B-3-3

**Names:** 216-B-3-3; 216-B-3-3 Ditch; B Swamp Ditch

**Type:** Ditch

**Status:** Inactive

**Classification:** Accepted

**Reclassification:** None

**Start Date:** 1/1/1970

**End Date:** 1/1/1994

**Description:** The ditch has been backfilled and surface stabilized. It is posted as an Underground Radioactive Material area.

**Location:** The ditch is located east of the 200 East Area perimeter fence. It continued east to 216-B-3
Pond, south of the 216-B-3-2 Ditch.

**Release Description:** UPR-200-E-51 occurred in 1977.

**Process Description:** The ditch received effluent from the B Plant and PUREX facilities. The unit was an open ditch from the diverter station to the 216-B-3 Pond. The unit was 1.2 to 2.4 meters (4 to 8 feet) deep and 0.3 meters (3 feet) wide at the bottom. The 216-A-29 Ditch fed into this unit approximately 305 meters (1,000 feet) upstream of the 216-B-3 Pond outfall.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** Until July 1973, the site transported and percolated 221-B cooling water, 202-A chemical sewer from the 216-A-29 Ditch, 241-BY Tank Farm ITS Units 1 and 2 cooling water, and 244-CR Vault cooling water. From July 1973 to May 1978, the site received the same as above minus ITS Units 1 and 2 cooling water. From May 19/78, the site received 221-B cooling water and 202-A chemical sewer from the 216-A-29 Ditch.

**Code:** 200-E-1  
**Classification:** Accepted  
**Names:** 200-E-1; 284-E Landfill; Asbestos in Excavation  
**Reclassification:** None  
**Type:** Dumping Area  
**Start Date:**  
**Status:** Inactive  
**End Date:**  
**Description:** There is no visible evidence of a landfill at this location. A covered concrete pad had been built over the area where the landfill was supposed to be located. The 284E Powerhouse was demolished in 2011 (see sitecode 200-E-296). The area was covered with a gravel cap.

**Location:** The site is located west of 284-E building.

**Related Sites/Structures:** The site is associated with the demolished 284-E Powerhouse and the gravel cap (sitecode 200-E-296).

**Process Description:** The unit consists of asbestos waste encountered during below grade trenching activities.

**Waste Type:** Water  
**Waste Description:** The waste at this unit consists of asbestos.

**Code:** 200-E-2  
**Classification:** Accepted  
**Names:** 200-E-2; MO-234 Parking Lot; Soil Stains at the 2101-M SW Parking Lot  
**Reclassification:** None  
**Type:** Unplanned Release  
**Start Date:**  
**Status:** Inactive  
**End Date:**  
**Description:** The site was originally described as a gravel covered parking lot that contained discolored soil. Two large dark circular stains were visible in front of the access ramp at the south end of MO-234.

**Location:** The site is at the northwest corner of the intersection of Baltimore and 2nd Street, in 200 East Area. The site is bound by MO-234 to the north and MO-413 and MO-021 to the west.
Process Description: The parking lot is actively being used for vehicle parking. Personnel that may have knowledge of past disposal in this unit were interviewed. Based on these interviews, the unit was used as a parking lot for the Telephone and Utilities Department. Used oil has been used for dust abatement; no other dumping is known to have occurred.

Waste Type: Steam Condensate

Waste Description: The unit waste includes used oil for dust abatement. BHI Regulatory Support (B. Vedder) had two concerns about the site. Polychlorinated biphenyls (PCBs) were the biggest concern and heavy metals of lesser concern. PCBs were common in high heat grade hydraulic fluids. Unless there is some strong evidence that only used vehicle motor oil was applied, this site will need to be sampled to verify that there is no PCB contamination. On August 24, 2006, sample number B1KHY0 was collected and analyzed at WSCF lab.

**Description:** The site has been evaluated and reclassified to Rejected. It consists of three features, one open bottom pit, one closed bottom pit and an underground equipment storage room. The pits are located 34.6 meters (114 feet) apart. Both pits are constructed from corrugated steel cylinders that were buried and backfilled with soil. Instrument cables were weighted with lead bricks. In February 2001, the underground, equipment storage room access hatch and vents were found inside a chained area, just west of the dirt access road. The closed bottom pit is north of the equipment room, enclosed in a triangular shaped chained area. Lysimeter access pipes are protruding up through the soil and the rim of the closed bottom lysimeter caisson are visible.

The open bottom lysimeter has been decommissioned. The closed bottom lysimeter remained in a "Standby" mode. In 2007, it was still operational, but is not being used.

**Location:** The site is located southeast of 200 East Area, within the BC Radiologically Controlled Area, approximately one half mile south of Route 3. It is 91.5 meters (300 feet) northwest of well #699-32-49D.

**Process Description:** The lysimeter pits were used to collect soil information. The sensors in the pits were hard wired to the instrument recorders, located inside the underground equipment storage room. Three 4-centimeter (1.6-inch) diameter aluminum pipes were installed to a depth of 18.3 meters (60 feet) to allow access of a Neutron Moisture Probe. Other pipes contained soil temperature thermocouples and pressure sensor tubes. The closed bottom lysimeter has a 20-centimeter (8-inch) poured concrete slab at the bottom. Holes were bored through the cement slab so the instruments could access the soil below the caisson. The instrument room housed the recording and measurement instruments. The room was buried approximately 0.3 meters (1 foot) below ground level to eliminate climatological influences, such as wind and temperature that could interfere with readings. The room measures 4.5 meters (14.8 feet) by 4.8 meters (15.8 feet) and was located between the two lysimeter pits.

**Waste Type:** Process Effluent

**Waste Description:** In 1999, PNNL said the neutron probe has been left inside the closed bottom pit, but in 2008 PNNL said the probe had been removed. The cables were weighted with 500-gram (1.1 pound) lead bricks that were backfilled in place, inside the pits. This equipment could be considered hazardous.

**Description:** This waste site was reclassified to Interim Closed Out in 2011. The area was down posted to a non-controlled area In October 2003. The radiological posting signs were removed. The site had been surrounded with light duty steel chain and posts and posted as a Contamination Area. The Contamination Area was surrounded with light duty steel chain and posts and is posted as a Radiological Buffer Area. The area had also been posted as a Radiologically Controlled Area. The ground is sandy soil with rocks and chunks of concrete. The area is free of growing vegetation and the tumbleweeds have been removed. Only tumbleweed fragments remained.
**Location:** The site is located just off the northeast corner of 200 East Area, east of Canton Avenue and northeast of Gate 810.

**Waste Type:** Process Effluent

**Waste Description:** The waste consisted of dried, compacted tumbleweeds.

**Closure Info:** In July and August 2009, the 200-E-110 and UPR-600-21 waste sites were investigated through observation, field screening and radiological surveys for the purpose of determining if radiological contaminants were present above the removal action levels (RALs). The survey results analysis confirmed that soil contaminant concentrations are at or below the RALs and that no further action is required. Both 200-E-110 and UPR-600-21 waste sites achieved compliance with the removal action levels (RALs) and thus met the removal action objectives (RAOs). These results support reclassification to Interim Closed Out status.

**Reclassification:** 200-E-126-PL-A; Segments of 200-E-126-PL Pipeline Located in the Outer Area

---

**Code:** 200-E-126-PL-A  
**Classification:** Accepted  
**Names:** 200-E-126-PL-A; Segments of 200-E-126-PL Pipeline Located in the Outer Area  
**Reclassification:** None  
**Type:** Radioactive Process Sewer  
**Status:** Inactive  
**Start Date:**  
**End Date:**

**Description:** Due to the restructuring of Operable Units, as described in the Agreement for Central Plateau Cleanup, the original pipeline site has been split into segments. 216-E-126-PL-A is the segments of pipeline located in the Outer Area. The segments of pipeline associated with 200-E-126-PL-A include the forty eight inch diameter corrugated metal pipes that could feed the lobes of the 216-E-28 Contingency Pond, the thirty inch diameter High Density Polyethylene pipe that fed the 216-B-3B pond lobe and the two thirty inch diameter corrugated metal pipes that connected the 216-B-3A pond lobe to the 216-B-3C pond lobe.

**Location:** The 200-E-126-PL-A pipeline segments are located east of the 200 East Area fence line, beyond the Inner/Outer Area boundary.

**Related Sites/Structures:** This waste site is associated with the 200-E-126-PL-B, 216-E-28 Contingency Pond, 216-B-3A Lobe and 216-B-3B Lobe.

**Process Description:** The pipeline conveyed B Plant effluent to the 216-B-3 Pond and Ditch system. B Plant cooling water effluent was originally routed through the 207-B Retention Basin to the 216-B-2-1, 216-B-2-2 and 216-B-2-3 ditches. In 1987, the 216-B-2-3 ditch was closed and was replaced by this, 22 inch diameter plastic underground pipeline. It extended from the 207-B basin to Diverter Station #2. By 1994, all of the open ditches (216-B-2-1, 216-B-2-2, 216-B-2-3, 216-B-3-1, 216-B-3-2 and 216-B-3-3) had been backfilled and surface stabilized. After 1994, all the effluent was conveyed to the 216-B-3A and 216-B-3C pond lobes only through underground pipelines. In 1995 the ponds were closed. The remaining effluent was transferred to the Treated Effluent Disposal Facility (TEDF). Parts of the pipelines east of 200 East Area, that had fed the ponds, were re-used to feed the TEDF disposal basin. The TEDF portion begins at Manhole #8 and extends to Pump Station #3. In the event of a failure at Pump Station #3, the effluent can be routed to 216-B-3C (C lobe). The section that connects the southeast corner of 216-B-3A to the northwest corner of 216-B-3C is constructed of 76 centimeter (30 inch) corrugated metal pipe.

---

**Description:** Due to the restructuring of Operable Units, as described in the Agreement for Central Plateau Cleanup, the original pipeline site (200-E-127-PL) has been split into segments. 200-E-127-PL-A is the segments of pipeline located in the Outer Area. The pipeline is marked with steel posts and Underground Radioactive Material - Pipeline signs. The majority of the pipeline is constructed of large diameter corrugated metal pipe. The 36 inch diameter corrugated metal pipe enlarges to 42 inch diameter corrugated metal pipe at Manhole #8 (north of the 600-118 diverter station). The pipeline divides into two sections (a Y shape) near where it crosses Route 11A. Two sections of pipe fed the pond. Near the 810 gate, an area of contaminated vegetation growing on and adjacent to the pipeline was stabilized with biobarrier and posted with Underground Radioactive Material Area signs. A portion of the pipeline is under the Liquid Effluent Retention Facility (LERF) berm and extends into the LERF/ETF facility boundary.

**Location:** 200-E-127-PL-A is located east and north of the 200 East Area. This segment extends northward from Manhole 5 to the 216-A-25 (Gable Mountain Pond).

**Process Description:** This portion of pipeline conveyed PUREX and B Plant effluent to the (216-A-25) Gable Pond. The effluent stream could be directed to Gable Mountain Pond or B Pond via Diverter Station #3. From Diverter Station #3 northward to the 216-A-25 Pond, the pipeline is constructed of 107 centimeter (42 inch) diameter corrugated metal pipe.

### 2607-E1 Septic Tank and Tile Field

**Description:** This septic tank was properly abandoned in 1997. It was constructed of reinforced concrete with walls and floors. The associated drain field is 778 square meters (8,376 square feet).

**Location:** This septic tank is located north of 4th Street and east of Baltimore Avenue. The tile field is north of the tank.

**Related Sites/Structures:** The 2607-E1 Septic Tank is associated with the 2607-E1 Tile Field, the 200 East shops and 282-E.

**Process Description:** The 2607-E1 Septic Tank and associated drain field were designed to accept and treat sanitary sewer effluent from facilities in central 200 East Area.

**Waste Type:** Storage Tank

**Waste Description:** This unit received sanitary wastewater and sewage at an estimate rate of 21,556 liters (5,695 gallons) per day. It service the 200 East Area shops and powerhouse.

**Closure Info:** The reclassification to Closed Out is documented on form 2004-116. The system was abandoned in 1997 in accordance with Washington Administrative Code 246-272-18501. This system was tied into 2607-E1A.

**Waste Description:**

**Closure Info:** The reclassification to Closed Out is documented on form 2004-116. The system was abandoned in 1997 in accordance with Washington Administrative Code 246-272-18501. This system was tied into 2607-E1A.
Pond

Inactive

The site is a pond of water surrounded by a white perimeter ring of dried alkali salt residue. The size and volume of the pond change with the seasons and groundwater levels.

The site is located south of the western end of Gable Mountain and northwest of 216-A-25. It is east of Route 4 North. An unnamed dirt road leads to West Lake from Route 4 North.

The Gable Mountain Pond (216-A-25) and 600-262 are associated with the unit.

This unit did not receive effluent from any contaminated facilities, but may have received discharge from the 606 Central Mix cement plant (see drawing H-11-4327). This pipeline could also be part of the Export Water line (see HW-70186). Prior to construction of Gable Mountain Pond, it was an intermittent, seasonal pond, only appearing in the winter and spring when the water table was elevated. Early Hanford construction camps disposed of sanitary sewage sludge in this area. This practice is believed to have contributed to the high alkaline and phosphate levels and elevated pH levels in the pond. After Gable Mountain Pond (216-A-25) became active in 1958, West Lake enlarged as a result of the raised water table and became a permanent pond.

Chemicals

Prior to the appearance of West Pond, this area was used as a disposal site for sewage sludge from the early Hanford construction camp. High alkaline and phosphate levels, as well as elevated pH values, may be attributed to this use of the pond area. Hanford drawing H-11-4327 shows a water line extending from the 606 Central Mix cement plant settling basins to Honeyhill. It implies the lake may have received water from the cement plant. However, this pipeline could also be part of the Export Water line (see HW-70186). Even though this unit never received direct discharges of contaminated effluents, it contains relatively high amounts of radionuclides (1,055 to 1,098 picocuries/liter in 1976), having the highest gross alpha (naturally occurring except for tritium) concentrations of all the 200 Area ponds. The actual source of existing activity is unknown. A possible main contributor is the leaching of naturally occurring radionuclides from the soil that has been concentrated by evaporation during the entire history of the unit.

Ditch

Inactive

The portion of the ditch nearest the 200 West Area perimeter fence is an open, unlined open ditch. Two thirds of the original ditch has been backfilled. The covered portion is posted with Underground Radioactive Material signs. The open portion is marked, but not radiologically posted.

The 216-S-10 Ditch begins southwest of the 202-S Building and extends south of the 200 West Area perimeter fence.

See UPR-200-W-34.
Process Description: The site started receiving waste from 202-S in August 1951. In February 1954, it became apparent that the 216-S-10 Chemical Sewer (200-W-157-PL) needed a larger leaching area. Thus four leaching ponds (fingers) were dug southwest of the 216-S-10 Ditch, adding approximately 3 acres of leaching surface. By May 1954, the area became swamped again. Two more leach trenches were added that became known as 216-S-11. The May 1954 REDOX Monthly Report indicated contamination levels in the trench to be a maximum of 500 to 800 mrad/hour in spots with lower levels of 80,000 counts per minute in a one acre overflow area that resulted from a break in the east trench (southeast 216-S-11 per Maxfield); see UPR-200-W-34. ANN solution was inadvertently dumped into the Chemical sewer in 1954 and seriously plugged the soil at the terminus of the chemical sewer.

Related Sites/Structures: The ditch is associated with the REDOX facility, the REDOX chemical sewer 200-W-157-PL, 216-S-11 and the 216-S-10 Pond.

Waste Type: Storage Tank

Waste Description: In the past, 420 liters (110 gallons) of hazardous waste salts including sodium nitrite (NaNO2) and sodium hydroxide (NaOH) were discharged to the unit. Until 1965, the site received chemical sewer waste from 202-S and overflow from the high water tower. Since October 1991, the site no longer acted as a ditch because the 216-S-10 Pond was stabilized. No dangerous wastes have been discharged to this unit since February 1987. NOTE: The 216-S-11 Pond was credited with all the liquid effluent inventory for the 216-S-10 Pond and Ditch system for many years.

Code: 216-S-10P
Names: 216-S-10P; 216-S-10P Pond; Chemical Sewer Trench; 202-S Chemical Sump #1 and Ditch
Type: Pond
Status: Inactive
Start Date: 1/1/1952
End Date: 1/1/1984
Classification: Accepted
Reclassification: None

Description: The pond was an irregular shape with four trenches known as fingers. The unit has been backfilled and stabilized and posted with Underground Radioactive Material signs.

Location: The unit is located outside the 200 West Area perimeter fence, southwest of the 202-S Building.

Release Description: The unit received one documented discharge of dangerous waste. This discharge consisted of simulated double-shell tank slurry which exhibited dangerous waste characteristics of ignitability, corrosivity, characteristic waste and toxic state-only waste. Approximately 450 kilograms (1,000 pounds) were discharged.

Related Sites/Structures: The pond is associated with the REDOX facility, the 216-S-10 Ditch and UPR-200-W-34.

Process Description: In February 1954, it became apparent that the 216-S-10 Chemical Sewer need more leaching area, so four leaching ponds (fingers) were dug off the southwest end of the 216-S-10 Ditch. The fingers added approximately 3 acres of leaching surface. By May 1954, the area became swamped again. Two more leach trenches were added that became known as 216-S-11. The May 1954 REDOX Monthly Report indicated contamination levels in the trench to be a maximum of 500 to 800 mrad/hour in spots with lower levels of 80,000 counts per minute in a one acre overflow area that resulted from a break in the east trench (southeast 216-S-11 per Maxfield).

Waste Type: Storage Tank

Waste Description: Until 1965, the site received the chemical sewer waste from 202-S and overflow from the high water tower via the 216-S-10 Ditch. From 1960's, the site received the bearing cooling water...
from 202-S. RHO-CD-673 documents two releases of radioactive liquid into the S-10 Disposal System. NOTE: The 216-S-11 Pond was credited with all the liquid effluent inventory for the 216-S-10 Pond and Ditch system for many years.

| Waste Description | January 1957 is considered the most accurate start date for this waste unit. The site received process cooling water and steam condensate from 202-S Building until June 1967. After the 202-S Building (REDOX) was put on standby in July 1967, the site received condenser and vessel cooling water from concentrator boil-down operations in the 202-S Building. In 1973, the 216-U-9 ditch was connected to the 216-S-16 ditch to allow the 216-U-10 pond overflow to
reach the 216-S-16 pond.

<td>Release Description:</td>
<td>Document HW-60807 states &quot;The 222-S Swamp, located outside 200 West Area, about 1000 yards south of the 222-S laboratory, is used for disposal of drainage from lab sinks and wall drains. In December 1953, contamination up to 200 millirad per hour at the ground surface was discovered over an area measuring approximately 300 feet long and 3 feet wide.&quot; Reference 9 on sketch G of this document indicates the location to be the 216-S-19 pond.</td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The associated structures are the 222-S Building, 207-SL Retention Basin, 216-S-26 crib and pipeline sitecode 200-W-147-PL.</td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The pond was opened in February 1952 and closed in October 1984. Until December 1954, the site received effluent from the 222-S/SA Laboratory ventilation cooling water and miscellaneous wastes from laboratory hoods and decontamination sinks via the 207-SL Retention Basin. From December 1954 to October 1955, the site was inactive because the radionuclide concentration in the 207-SL Retention Basin liquid waste was above the prescribed disposal guidelines, and building effluents were rerouted to the 216-S-20 Crib. From October 1955 to October 1984, the site received ventilation cooling water and miscellaneous wastes from laboratory hoods and decontamination sinks in the 222-S Laboratory Building via the 207-SL Retention Basin.</td>

<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The removal action at the 216-S-19 waste site was conducted from November 2010 through August 2011. Twelve focused confirmatory samples were collected from the north end of the pond, near the discharge pipe. The results of initial sampling indicated concentrations of uranium U-233/234, and U-238 in excess of their respective Removal Action Levels thus initiating RTD. Removal of impacted soils at the 216-S-19 was excavated to a depth of approximately 0.31 to 0.61 meters (1 to 2 ft) below the floor of the pond, at Focused Sample 6, in an attempt to spot clean the area of contamination. The area of excavation was later expanded laterally to encompass the entire floor of the pond. The vertical extent of excavation was refined by in process sampling, conducted during RTD activities. The depth of excavation ranged from approximately 3 to 4 meters (10 to 13 ft) below original grade.</td>

Hanford Site Waste Management Units Report
February 2015
Inactive Status: 6/1/1995 End Date:

Description: This crib has been evaluated under a removal action and Interim Closed Out. The crib is no longer marked or posted. The crib had been surrounded with metal posts and chain and was posted with Underground Radioactive Material signs. A 15 centimeter (6 inch) vitrified clay, perforated distribution pipe runs the length of the unit, 46 centimeters (18 inches) above the bottom of the crib. Eight centimeters (4 inches) of gravel covered a membrane barrier. The crib had been filled with 2.9 meters (9.5 feet) of soil. One gage well with a liquid level indicator was located 30 meters (100 ft) from the west end, and a vent riser was located at the east end.

Location: The crib was located southeast of 222-S Building, outside the 200 West Area perimeter fence.

Release Description: During the week of 10/20/84, a spill occurred at the 222-S Lab resulting in the release of water contaminated with Sr-90 to the 207-SL Retention Basin. Concentrations averaged 2 to 3 times the Sr-90 guide but did not exceed RHO-MA-139 standards. The water was released to the new 216-S-26 Crib.

Related Sites/Structures: The pipeline associated with this crib is WIDS pipeline sitecode 200-W-148-PL.

Process Description: The crib received waste from the 222-S laboratory via the 207-SL retention basin. In 1988, crib infiltration rate problems were noted due to caustic flush water being periodically disposed to the 207-SL basin.

Waste Type: Process Effluent

Waste Description: The site received steam condensate and sink wastes, which are byproduct radioactive wastes, from the 222-S Laboratory via the 207-SL Retention Basin. The wastes contain a variety of chemicals, including acetone, nitric acid, and lesser amounts of sulfuric and hydrofluoric acids.

Closure Info: The removal action at the 216-S-26 and 200-W-148-PL waste sites was conducted from March 2011 through August 2011 and included the removal of overburden soil, and the pipe itself, followed by collection of samples from locations within the excavation. Implementation of the selected Remove, Treat, Dispose (RTD) alternative was performed. Soil and piping were removed from the two waste sites. Direct visual inspection of the site surface was performed as a guide for visual cues such as staining, discoloration, absence of vegetation, presence of debris, and other anomalies. Radiological field screening was performed at the excavation surface of the waste site to provide an indication of the extent of radiological contaminants. Soil was removed to a depth of approximately 4.6 meters (15 ft) below ground surface. Characterization sampling was performed at depths of 4.6, 4.9, 5.5, and 6.1 meters (15, 16, 18, and 20 ft) and the analytical results evaluated to demonstrate achievement of Removal Action Objectives. Backfill of the 216-S-26 and 200-W-148-PL waste sites was completed on August 30, 2011.

Code: 216-T-1 Classification: Accepted

Names: 216-T-1; 216-T-1 Trench; 221-T Ditch; 221-T Trench Reclassification: None

Type: Ditch Start Date: 1/1/1944

Status: Inactive End Date: 1/1/1995

Description: The ditch has been backfilled. It is currently marked and posted with Underground Radioactive Material signs.

Location: The ditch is located on the north side of 221-T Building, west of Beloit Avenue.

Related Sites/Structures: The ditch was associated with the 221-T facility operations. The pipeline associated with the ditch is 200-W-180-PL.
Process Description: The ditch received cooling water and steam condensate discharge from 221-T and 271-T.

Waste Type: Chemicals

Waste Description: From 1944 until 6/56, the site received miscellaneous waste from pilot plant experimental work, intermittent decontamination waste, and waste from the head end of the 221-T Building. From 6/56 to 1/64 the ditch was inactive due to the production operations at T Plant being shut down. From 1/64 to 6/70, the site received cooling water from the blowdown vessel in the 271-T Building and miscellaneous waste from PNL head end operations in the 221-T Building. After 6/70, the site received condensate from steam-heated radiators at the head end of 221-T Building. During standdown of PNL operations, the discharge of 271-T and other 221-T head end waste was discontinued. The site also received sodium hydroxide wash water waste solution (less than 1,000 gal/month [3,800 L/month]) from the Sodium-Air-Water Reaction Emergency Air Cleaning Development-HEDL. This waste water was nonradioactive and generally wet only the bottom of the unit to approximately 150 ft (46 m) from the outfall.

---

**Code:** 200-W ADB  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 200-W ADB; 200-W Ash Disposal Basin  
**Type:** Coal Ash Pit  
**Start Date:** 1/1/1944  
**End Date:** 1/1/2000  
**Description:** The site is an area of dark soil with cheatgrass growing on the surface. A small depression can be seen in the middle of the site.  
**Location:** The site is located inside 200 West Area, northeast of the 221-U Facility. It is on the east side of Beloit Ave. south of 20th Street.  
**Related Sites/Structures:** The site is associated with the 284-W Powerhouse operation the 200-W Ash Pit. The open pit adjacent to the south side of the 200-W ADB is known as the 200-W Burn Pit (200-W BP).  
**Process Description:** The Ash Disposal Basin received coal ash slurry and ash from the operation of the coal fired 284-W Powerhouse. A 1954 drawing shows an underground ash slurry pipeline extending from the northeast corner of the 284-W Powerhouse to the northwest corner of the Ash Disposal Basin. Later, the site received trucked material, dredged from the 200 West Powerhouse Ash Pit, located south of the powerhouse, on the west side of Beloit Ave.

---

**Code:** 200-W BP  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 200-W BP; 200-W Burning Pit; Gravel Pit 34; Pit 34  
**Type:** Burn Pit  
**Start Date:** 1/1/1950  
**End Date:**  
**Description:** The site is a large open pit.  
**Location:** The site is located within the 200 West Area Ash Disposal Basin, southeast of the 284-W Powerhouse, on the east side of Beloit Ave.  
**Release Description:** UPR-200-W-37 and UPR-200-W-70 have been associated with the 200 West Burn Pit in some documents. It is possible that an early burn pit, located southeast of U Plant, was actually the site of these releases. See 200-W-71.
Process Description: 200 Area office waste and non-radioactive construction debris and tumbleweeds have been brought to this site and burned. According to Dave Phipps in April 2002, this site is used as a staging area for uncontaminated tumbleweeds from the 200 Area fences. They are burned semiannually in the spring and the fall. The area is also used as a source of clean backfill (gravel) material. In 1984, a one time chemical demolition event occurred inside the northern portion of the current 200-W Burn Pit. However, the title of the closure document is the 200 West Area Ashpit Demolition Site Closure Plan (DOE/RL-92-54). A review of this document confirms the location of the chemical demolition was inside the 200-W Burn Pit. Drawing H-2-1495 and historical photograph #3755 show another disposal pit/burn pit, located south of 16th Street, east of Beloit Ave. Early references to the 200 West Burn Pit could be referring to this location.

Related Sites/Structures: The burn pit is associated with the 200-W Ash Disposal Basin (200-W ADB), 200-W ADS and 200-W-71.

Code: 200-W-3
Names: 200-W-3; 220-W-1; 2713-W North Parking Lot
Type: Dumping Area
Status: Inactive
Description: The waste site is the gravel parking lot, containing an area where discolored soil was identified in an excavation between 10 to 15 centimeters (4 to 6 inches) below the surface.
Location: The waste site is located east of Beloit Ave. and north of 20th Street. It is north of where the 2713-W garage had been located before it was demolished.
Related Sites/Structures: Building 2713-W and a waste oil storage tank are associated with this unit.
Process Description: The 2713-W building had been a gas station and also contained an oil changing pit for government vehicle maintenance. Oil was often used on gravel areas for dust abatement.

Code: 200-W-33
Names: 200-W-33; Debris Near 609 Gate; Solid Waste Dumping Area
Type: Dumping Area
Status: Inactive
Description: The waste site has been evaluated under a removal action and reclassified to Interim Closed Out. The site originally consisted of an area of debris covering approximately one acre in a stand of open sagebrush. A grass fire burned the area in 2007. Many more cans and drums became visible after the fire, increasing the size of the waste site significantly to approximately 12 acres.
Location: The site is located near the northwest corner of 200 West Area. It is outside the 609 Gate, west of Dayton Ave.
Closure Info: The selected alternative for the 200-W-33 waste site was confirmatory sampling/no further action (CS/NFA). The results of the confirmatory sampling indicated COPC concentrations greater than the RALs in two of the sampled areas. Per the provisions of the Action Memorandum, the removal action activities progressed to implementation of the RTD alternative for those areas, and for debris removal at the waste site. Upon completion of RTD
activities, verification sampling was conducted to demonstrate that contaminant concentrations in soil at the 200-W-33 waste site were less than or equal to the RALs, thus demonstrating that the RAOs were met.

The removal action at the 200-W-33 waste site was conducted from February 2010 through March 2011 and included the collection of focused and random samples from locations within the waste site. Remedial activities included the collection of judgmental soil samples based on historical and process knowledge, and visual indicators; excavation of soil under the RTD alternative in zones of potential contamination (ZPCs) 5 and 9; removal of debris scattered throughout the waste site, along with underlying soil and collecting of random samples from ZPCs 5 and 9 for verification purposes.

No radiological postings were present at the waste site. Radiological field screening surveys were performed at the 200-W-33 waste site. No radiological readings greater than the measured background, and no radiological contamination was found.

Debris and approximately 0.3 meters (1 foot) of underlying soil was removed from the ZPCs and the remainder of the waste site during implementation of the RTD alternative.

Revegetation at the 200-W-33 waste site is not required, however, the 200-W-33 waste site has been reseeded.

---

**Reclassification:** 200-W-64; 2724-W Contaminated Laundry Facility Building Foundation

**Code:** 200-W-64

**Classification:** Accepted

**Names:** 200-W-64; 2724-W Contaminated Laundry Facility Building Foundation

**Reclassification:** None

**Type:** Foundation

**Start Date:** 1/1/1950

**Status:** Inactive

**End Date:** 1/1/1994

**Description:** The building foundation is posted with "Underground Radioactive Material" signs. There is also an area approximately 3 meters (10 feet) by 4.5 meters (15 feet) on the north side of the foundation that is posted as "Fixed Contamination". Several drains and pipes were observed on the concrete pad. All drains and pipes were either capped or grouted. There are three radiologically posted manholes adjacent to the northwest corner of the foundation. The manholes are likely to be a portion of the process sewer. Six conex storage units and several equipment items such as pipe, valves, flanges, fence posts were observed on the southeastern portion of the pad.

**Location:** The building foundation is located in 200 West Area, at the corner of Beloit Ave. and 20th Street.

**Related Sites/Structures:** The site is associated with the demolished contaminated laundry facility complex which included 2724-WA, 2724 WB Laundry facilities, and the MO-412 Mask Cleaning facility. It replaced the 2723-W (Old Laundry" Facility and mask cleaning station) which was located northeast of the 2724-W facility. Effluent was discharged via 200-W-102 to the U-14 Ditch until 1981 when it was diverted to the 216-W-LWC (Laundry Waste Crib).

**Process Description:** WHC-EP-0342 states the 2724-W building was built in 1952 and expanded several times. ARH-2155, however, indicates that the new laundry facility (2724-W) began discharging effluent in 1950. This building (2724-W) replaced the 2723-W "Old Laundry" facility which was then used as the mask washing facility. The laundry effluent was discharged via an underground pipeline (200-W-102) to the 216-U-14 Ditch, until it was diverted to the new Laundry Waste Crib (216-W-LWC) in 1981. By 1981, the Laundry Complex included the 2724-W, 2724-WA, 2724-WB and MO-406. MO-412 was placed adjacent to the Laundry Complex in 1984 and housed the Mask Cleaning and Maintenance Facility. Soiled protective
work clothing (coveralls, gloves, hoods, canvas boots and rubber shoe covers) were sent to the laundry facility from all the Hanford work areas. Two thirds of the laundry received was radioactively contaminated. One third consisted of "blue" (non contaminated) coveralls and towels. The non-contaminated laundry was washed separately from the contaminated laundry. By 1981, approximately three million pounds of laundry was processed per year in 600 pound capacity washing machines and 400 pound capacity dryers. An average of 26,250,000 liters (691,000 gallons) of waste water was discharged to the 216-W-LWC crib each month.
