INTRODUCTION

SCOPE AND PURPOSE

The Hanford Site Waste Management Units Report (HSWMUR) has been created to meet the requirements of the Tri-Party Agreement (TPA) Action Plan, Section 3.5, which states: “The Hanford Site Waste Management Units Report shall be generated, in a format agreed upon by the Parties, as a calendar year report and issued annually by the DOE by the end of February of each year, and posted electronically for regulator and public access. This report shall reflect all changes made in waste management unit status during the previous year.”

This February 2015 version of the HSWMUR contains a comprehensive inventory of the 3446 sites and 572 subsites in the Waste Information Data System (WIDS). The information for each site contains a description of each unit and the waste it contains, where applicable. The WIDS database provides additional information concerning the sites contained in this report and is maintained with daily changes to these sites.

DEFINITIONS

The HSWMUR shows the classification and reclassification designations for each site. These designations are based on definitions in TPA procedure TPA-MP-14. Simplified definitions are provided below. Full definitions can be found in the procedure which is available at the following URL: http://www.hanford.gov/files.cfm/TPA-MP14.pdf.

Classification designations are as follows:

- Accepted – The site has been evaluated and found to be a waste management unit. For sites added to WIDS since February 2, 2007, the approval date for TPA-MP-14 Rev. 1, this evaluation has also been approved by the appropriate regulatory agency. Sites added prior to February 2, 2007 were classified as Accepted based only on a contractor review.

- Accepted (Proposed) – The site has been evaluated and tentatively identified as being a waste management unit, but this evaluation has not yet been approved by the appropriate regulatory agency.

- Rejected – The site has been evaluated and found not to be a waste management unit. This evaluation has been approved by the appropriate regulatory agency.

- Rejected (Proposed) – The site has been evaluated and tentatively identified as not being a waste management unit, but this evaluation has not yet been approved by the appropriate regulatory agency.

- Discovery - The site has not yet had the evaluation completed.
Reclassification designations are as follows:

- **Interim No Action** – The site does not require any action based on an assessment of quantitative data (e.g. analytical samples) against the cleanup standards specified in an Interim Action Record of Decision.

- **Final No Action** – The site does not require any action based on an assessment of quantitative data (e.g. analytical samples) against the cleanup standards specified in a Final Record of Decision.

- **Interim Closed Out** – The site meets cleanup standards specified in an Interim Action Record of Decision.

- **Final Closed Out** – The site meets cleanup standards specified in a Final Record of Decision.

- **Closed Out** – The site meets other applicable cleanup standards or closure requirements.

- **RCRA Postclosure** – The site is a TSD unit that has been closed with waste in place and postclosure care, including monitoring and institutional controls, is being implemented.

- **Rejected** – The site does not require remediation based on qualitative information such as a review of historical records, photographs, drawings, walkdowns, ground penetrating radar scans, radiation surveys, and shallow test pits.

- **Consolidated** – The site will be dispositioned as part of another WIDS site.

- **Deleted from NPL** – The site is deleted from the National Priorities List or included in a final action published in the Federal Register.

- **None** – The site has not been reclassified.

**ORGANIZATION**

The waste management units at the Hanford Site are grouped into operable units (OUs) or waste management areas (WMAs). The groupings may be based on geographic location, types of waste received, and/or the ability to achieve economies of scale during remediation. Sites flagged as TBD (To Be Determined) haven’t been assigned to an OU or WMA. Sites flagged as Not Applicable do not fit the criteria to be assigned to an OU or WMA. The HSWMUR organization is based on the waste site grouping within the operable units and waste management areas.

</tr>
<tr>
<td>Status:</td>
<td>Inactive</td>
<td>End Date:</td>
<td></td>
</tr>
<tr>
<td>Description:</td>
<td>The waste site has been evaluated in the Calculation Brief for the 100-B-3 Hot Thimble Burial Ground (0100B-CA-V-0116) and reclassified with a Waste Site Reclassification form to No Action. It was a vertically buried structure that was removed prior to 1956.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The site was located south of the 105-B Reactor and west of the southwest corner of the 115-B Building.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Sanitary Sewage</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>A highly contaminated vertical thimble was removed from the 105-B Reactor Building in 1952 and temporarily buried in a trench. The thimble was later removed and taken to another burial ground. Radioactive contaminants may remain in the trench.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| Closure Info:   | The vertical thimble that was placed at this site in 1952 was removed prior to 1956. Based on process knowledge, the radionuclides that are associated with vertical thimbles are Mn-54, Co-
60, and Zn-65. These are the contaminants of concern that would have been the residual contamination remaining in the excavation after removal of the thimble. They would have decayed away in the 51 years (approximately 10 half-lives, for Co-60, the longest-lived of the three) since burial. A 2003 geophysical survey of the area shows no evidence of the thimble remaining.

The 100-B-3 Hot Thimble Burial Ground requires no further action to meet the cleanup standards specified in the Interim Action Record of Decision for the 100-BC-1 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

The calculation brief was based on a review of historical data and facility information, no sampling was necessary to confirm the status of this site because original documentation explained that the vertical thimble was buried in 1952 and removed prior to 1956. Also that the contamination remaining in the excavation (where the thimble was removed) were short-lived radionuclides, all with half-lives of less than 5.27 years. After 10 half-lives have elapsed, a radionuclide is considered to have decayed away. A geophysical survey over a larger area showed no evidence of a remaining buried thimble nor the conclusive location of an old burial site. Thus, while a possible location for the burial site can be estimated from old photographs, the actual location is unknown. Test pit results, even if the correct location was sampled, would prove inconclusive since the thimble has been removed and the short-lived radionuclides have decayed.

The calculation brief demonstrated that, based on a preponderance of the information, the 100-B-3 Buried Thimble Site no longer exists. No concentrations of the potential contaminants of concern for this site could remain above the RAGS established in the approved ROD and Remedial Design Report/Remedial Action Work Plan for the 100 Area, RDR/RAWP due to decay of the short-lived radionuclides. These results also indicate that the site will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that the site poses no threat to groundwater or the Columbia River.

| Code:      | 100-B-5                                                                 |
| Classification: | Accepted                                                                 |
| Names:    | 100-B-5; 105-B Effluent Vent Trench; 116-B-9; Effluent Vent Disposal Trench |
| Type:     | Trench                                                                 |
| Status:   | Inactive                                                                |
| Start Date: | 1/1/1954                                                                |
| End Date: | 1/1/1956                                                                |
| Description: | The site has been remediated and closed out. The waste site was the result of leakage that occurred at a junction box [probably at the 0.61 meter (2-foot) vent pipe], where the 1.4 meter (54-inch) 100-B Reactor cross tie pipeline effluent joined the 1.7 meter (66-inch) 100-C Reactor pipeline effluent, resulting in contamination of the area (Dorian and Richards). |
| Location: | The site was believed to be located east of the 105-B Reactor Building, west of the 100-C Reactor effluent pipeline, north of the 100-B Reactor effluent cross tie pipeline, and north of the junction box where the east-west 100-B effluent pipeline joined the north-south 100-C effluent pipeline. The site location was identified as site number 23 on site drawing H-1-4049. |
| Related Sites/Structures: | Associated sites include the 100-C-6 and 100-B-8 Reactor Cooling Water Effluent Underground Pipelines. |
| Process Description: | The junction box (part of site 100-C-6, 100-C Reactor Cooling Water Effluent Underground Pipelines, but pertinent to this site) was a concrete structure that was 5.6 meters (18.5 feet) long by 5.6 meters (18.5 feet) wide by 8.2 meters (27 feet) deep. The outer walls of the structure were 0.46 meters (1.5 feet) thick. Two sides of the structure were double-walled providing the... |
structure with two chambers. The 1.4-meter (54-inch) 100-B Reactor cross tie pipeline (invert) entered from the west through a double concrete wall, while the 1.7-meter (66-inch) 100-C Reactor pipeline (invert) entered the structure from the south through a single concrete wall. A single 1.7-meter (66-inch) pipeline exited the structure to the north through the double walled portion of the structure. The interior of the structure was accessible via metal ladder rungs. The original structure had a 0.61-meter (2-foot) vent pipe. The vent pipe was located approximately 2.35 meters (7.7 feet) southwest of the southwest corner of the junction box. The vent was above grade 1.4 meters (4.6 feet) and had a valve on the top. A new 0.31-meter (12-inch) vent pipe was added later. The vent pipe was located approximately 2.3 meters (7.5 feet) south and 1.8 meters (6 feet) east of the southwest corner of the junction box. The vent was above grade approximately 1 meter (3.3 feet) (pipe + valve handle) and had a valve handle on the top. The effluent flowed out of the junction box via the 1.7-meter (66-inch) pipeline and downhill (gravity flow since there was no pump station at 100-B) to the retention basins. On the 100-C effluent pipeline north of the junction box about 80 meters (262 feet) was an inspection manhole. The manhole (riser) was marked "Confined Space 063" and "Fixed Contamination Area FCA-B-0003".

**Waste Type:** Construction Debris

**Waste Description:** The waste was process effluent contaminated soil. Sample numbers (Dorian and Richards) and depths were: B - 4.6, 6.1, 8.4 meters (15, 20, 27.5 feet); C - 3.05 meters (10 feet); D - 4.6, 6.1, 8.4 meters (15, 20, 27.5 feet); E - 4.6, 5.3, 7.6 meters (15, 17.5, 25 feet); F - 4.6, 6.1, 8.4 meters (15, 20, 27.5 feet); H - 6.1 meters (20 feet). Samples were analyzed for plutonium-238, plutonium-239/240, strontium-90, hydrogen-3, europium-152, cobalt-60, europium-154, cesium-234, cesium-137, europium-155, and uranium.

**Closure Info:** Remedial action at the 100-B-5 site was conducted in May 2003. Excavation of the 100-B-5 site involved removing the overburden materials, removing sections of the 100-C-6 and 100-B-8 Reactor effluent pipelines, removing a pipeline junction box, and removing contaminated soil. Contaminated materials including the pipeline sections and concrete junction box were disposed of at the ERDF. Cleanup demonstration of the reactor effluent pipelines will be included in a future CVP and will reference this CVP for the small section of pipelines remediated with the 100-B-5 site.

Remedial action objectives (RAOs) and goals (RAGs) for the site were documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100 HR-1, 100 HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP). Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

At the completion of the remedial action, the total excavation was approximately 4,450 square meters (47,900 square feet) in area with a maximum depth of 8.5 meters (27.9 feet) below ground surface. Approximately 16,320 metric tons (17,950 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. In addition to the 100-B-5 site, the portions of the 100 B-8 and 100-C-6 Reactor cooling water effluent pipelines beneath the site were remediated with the 100-B-5 site. Cleanup verification of the rest of the adjacent large pipeline sites (100-C-6 and 100-B-8) will be included in the CVPs for those sites.

The CVP has demonstrated that remedial action at the site has met the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils at the site have been sampled, analyzed, and modeled. The results of this effort indicated that the material from the site containing COCs at concentrations exceeding RAGs have been excavated and disposed at the ERDF. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site do not pose a threat to groundwater or the
Columbia River.

<tr>
<td>Description</td>
<td>100-B-8 was divided into two subsites. Both subsites have been remediated and Interim Closed Out, therefore the parent site is also considered Interim Closed Out. The waste site is comprised of the underground 100-B Reactor cooling water effluent pipelines. Subsite 1 was the effluent lines south of 105-B. Subsite 2 was the effluent lines north of 105-B. The waste site included the effluent pipelines that transported 118-B-8 (105-B Reactor) cooling water from the reactor core to the 116-B-11 (107-B) Retention Basin, and from the basin to the 116-B-7 (1904-B) outfall structure. This waste site included all associated expansion and valve boxes and excluded the retention basin, outfall structure, and those effluent pipelines that were within the confines of the 105-B Reactor Building or that run from the outfall structure to the bottom of the river. It also excludes all reactor influent pipelines that are upstream (untreated and treated water pipelines) of the 105-B Reactor Building.</td>

<table>
<thead>
<tr>
<th>Waste Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Waste Description</td>
<td>The waste is radioactively contaminated steel piping, concrete, and soil. Reactor cooling water became radioactively contaminated as it passed through the reactor core. Activation products created in the water included calcium-41, chromium-51, and zinc-65. Activation products from the reactor core that were picked up and transported by the cooling water included tritium, carbon-14, cobalt-60, nickel-63, and europium-152/154/155. Fuel element fission products, such as strontium-90, and cesium-137, as well as transuranics such as plutonium-239/240 were introduced into cooling water due to fuel cladding failures. Concentrations of radionuclides in cooling water during normal reactor operations were approximately 0.2 microcuries/liter. Concentrations of radionuclides have built up in rust flakes and scale on the inner surfaces of the pipelines and in sludge in the diversion and junction boxes. Average beta-gamma concentrations for the effluent pipeline scale and junction/diversion boxes were 83,000 and 120,000 picocuries/liter, respectively. Average plutonium-239/240 concentrations were 66 picocuries/gram for the effluent pipeline scale and 720 picocuries/gram for the sludge at the bottom of the diversion and junction boxes. Direct readings of the bottom of the effluent pipelines averaged approximately 40,000 counts/minute with a Geiger-Mueller probe.</td>
</tr>
</tbody>
</table>
Additional chemicals were added to the effluent for purposes of water treatment. These included aluminum sulfate (alum), with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine residual was approximately 0.2 milligrams/liter.

This Site has the Following SubSites:

- **Code:** 100-B-8:1
  - **Names:** 100-B-8:1; 100-B Area South Effluent Pipelines
  - **Type:** Radioactive Process Sewer
  - **Status:** Inactive
  - **Description:** The subsite has been remediated and Interim Closed Out. The site included the underground 105-B Reactor effluent pipelines running from within 7.5 meters (25 feet) of the reactor building north to B Avenue, including all associated expansion joints and valve boxes. Also included are the cross-tie underground lines that connected the 105-B Reactor effluent system to the 105-C Reactor effluent pipeline system.
  - **Location:** Subsite 100-B-8:1 includes the underground effluent pipelines surrounding the 105-B Reactor (excluding a 7.6 meter [25 foot] buffer zone around the reactor foundation), and running north from the reactor to B Avenue, including all associated expansion joints and valve boxes.
  - **Waste Type:** Sanitary Sewage
  - **Waste Description:** The waste is radioactively contaminated steel piping, concrete, and soil.
  - **Closure Info:** At the completion of remedial action, the excavation was approximately 48,260 square meters (519,466 square feet) in area. Approximately 244,656 metric tons (269,742 tons) of material, including soil, debris, and piping were removed from the 100-B/C south pipelines site and disposed of at the Environmental Restoration Disposal Facility. The remaining soils at these sites have been sampled, analyzed, and modeled, while contaminated material has been excavated and disposed at ERDF. These results also indicated that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The site was verified to be remediated in accordance with the ROD and may be backfilled.

- **Classification:** Accepted

Hanford Site Waste Management Units Report
February 2015
Description: Cleanup Verification Package 2003-00019 (CVP) documented completion of remedial action for the 100-B/C Effluent Pipeline subsites located north of B Avenue (100-B-8:2, 100-C-6:2, 100-C-6:3, and 100-C-6:4 collectively referred to as the 100-B/C north pipelines site). The 100-B-8:2 subsite portion includes the 105-B Reactor effluent pipelines from B Avenue north to the 116-B-1 Trench, the pipelines from the 116-B-11 Retention Basin to the 116-B-7 Outfall (located just north of pipelines 3 and 4 terminations), and the east-west connecting pipeline from 100-B-8:2 to the diversion box for the 100-C-6 pipelines, which was just south of the 116-C-5 Retention Basin. It also includes the pipeline connecting this diversion box to the 116-C-5 Retention Basin and the northernmost section of pipe 11 that drained into the 116-C-5 Retention Basin; these pipelines were removed and backfilled but not entirely sampled as part of the 116-C-5 remedial action (BHI 1997).

Cleanup verification for pipes 11 and 25 were conducted as part of CVP-2003-00019. Drawings identifying previous sampling locations were used to ensure that pipe 11 and pipe 25 corridors were excavated to below clean backfill elevations prior to verification sampling.

Location: These pipelines were north of the 105-B Reactor, north of B Avenue to the outfall structure.

Waste Type: Sanitary Sewage

Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil.

Closure Info: Remedial action at the 100-B/C north pipelines site began on February 26, 2001. Excavation of the site involved removing the overburden materials, piping, debris, and underlying contaminated soil. Based on field screening overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. At the completion of remedial activities at the 100-B/C pipeline waste sites, more than 364 metric tons (400 tons) of concrete and fence posts with associated concrete debris were removed and segregated as part of the 100-B/C Pipeline Remediation Project (100-BC-1/100-BC-2 Operable Units). The majority of the fence posts are associated with security fencing that surrounded many of the pipelines and waste sites. None of the fence material has been known to be contaminated. External radiological surveys indicate that none of the concrete and fence posts show any, signs of radioactive contamination. Radiological release surveys of the fence posts and concrete were performed to allow them to be used as clean backfill. The Environmental Restoration Contractor radiological survey records for 100-B/C remediation between the dates of February 26, 2001 and November 6, 2003, contain survey results for the fencing debris used as backfill. The excavation was completed on February 6, 2003.

Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and non-radionuclide contaminants of concern (COCs). Cleanup verification samples including QA/QC samples consisted of 193 shallow zone samples, 104 deep zone samples, 260 overburden samples, and 72 discovery area samples. The final verification samples were collected between August 12, 2002, and concluded on July 24, 2003, and were analyzed for the established contaminants of concern. The sample numbers are too numerous to list, however they are available in appendix A of CVP-2003-00019. At the completion of remedial action, the excavation was approximately 135,000 square meters (443,000 square feet) in area with an average depth of approximately 7.5 meters (25 feet). Approximately 244,656 metric tons (269,742 tons) of material including soil, debris, and piping were removed from the 100 B/C north pipelines site.
Names: 100-B-8; 100-B Reactor Cooling Water Effluent Underground Pipelines

Code: 100-B-10
Classification: Accepted

Names: 100-B-10; 107-B Basin Leak and Warm Springs

Type: Unplanned Release
Start Date: 1/1/1949

Status: Inactive
End Date:

Description: The waste site was evaluated and determined to require No Action. The site is an unknown location along the Columbia River shoreline. It was reported in February 1949 as a warm springs below the 116-B-11 Retention Basin, and was attributed to leaks in the wall of the north basin. This spring no longer exists and the precise location is unknown. The reported spring is assumed to have stopped flowing after the basins were shut down. The groundwater that fed the spring is a separate Operable Unit (100-BC-5).

Location: The springs were observed along the Columbia River below the 100-B Area Retention Basin (116-B-11).

Related Sites/Structures: The springs were attributed to leaks in the walls of the north basin at 107-B (116-B-11).

Process Description: In 1991 in preparation for a spring sampling study, the entire shoreline of the River in the 100 Areas was searched for springs. Three were found at the 100-BC Area, all upstream (about 700 meters [2,300 feet]) of the estimated location of this spring. No springs were found below the 116-B-11 Retention Basin. The reported spring is assumed to have stopped flowing after the basins were shut down.

Waste Type: Process Effluent

Waste Description: A sample of the water showed beta activity of 4E-03 microcuries/liter.

Closure Info: This was determined to be a No Action site.

This is not a site where wastes have been disposed or spilled, but was the location where groundwater contaminated from the 116-B-11 Retention Basin exited the riverbank in 1949. Previous radiation surveys of the shoreline in 1966 (J.D. Lodge, Radiation Survey of the Columbia River Shoreline Near the Hanford Reactor Areas, BNWL-CC-835) showed no elevated radiation in this area. In 1980 (per PNL-3127) a reading of 125 uR/hour was documented but the actual location was not provided. Only a general location below the retention basin was listed. More detailed tables of the 100-B shoreline radiation readings in PNL-3127 show from 5 to 100 uR/hour. In preparation for a 1991 spring sampling study, the entire shoreline of the River in the 100 Areas was searched for springs. Three were found at the 100-BC Area, all upstream (about 700 meters [2,300 feet]) of the estimated location of this spring. No springs were found at or near the River shoreline below the 116-B-11 Retention Basin.

The 116-B-11 Retention Basin and underlying plumes that led to the river from old spills have been remediated and closed out to the cleanup standards as specified in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (EPA 1995), and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL 1998). It’s expected that since the underlying plumes have been excavated and remediated until they met cleanup criteria, any deeper zones (closer to the river and farther from the source retention basin) would have less remaining contamination. In addition, the groundwater that fed the spring is a separate Operable Unit (100-BC-5); it and associated remaining contaminants
will be addressed as part of that project.

**Names:**
- 100-B-11; 115-B Tank; 115-B/C Caisson Site;
- 115-B/C Caisson Valve Pit; 115-BC Drywell;
- 115-BC Sump

**Type:** Storage Tank  
**Status:** Inactive  
**Start Date:** 1/1/1944  
**End Date:** 1/1/1969

**Description:** The site has been evaluated and reclassified to No Action. This caisson was identified during a pre-demolition walk-through of the 115-B/C Gas Recirculation Building and was removed during building demolition. The site had been a steel pipe structure (caisson) about 1.2 meters (4 feet) in diameter and 1.5 meters (5 feet) deep with a bottom and a steel plate placed over the top. The site was self contained without any incoming or outgoing piping. This caisson was identified during a pre-demolition walk-through of the 115-B/C Gas Recirculation Building.

**Location:** The site was located just east of the 115-B/C Building Dryer Room #1 and approximately 60 meters (197 feet) south-southeast of the 105-B Reactor Building.

**Release Description:** The releases to the caisson are unknown. Sample results taken of soil from underneath and near the sides of the caisson were below Washington Administrative Code (WAC) limits for chromium.

**Related Sites/Structures:** The site was probably related to the 115-B/C Gas Recirculation Facility (132-B-5) that was demolished in 1989. The caisson was contaminated with sodium dichromate. Sodium dichromate was not normally used at the 115 B/C Gas Recirculation Facility.

**Process Description:** The site was a steel pipe structure (caisson) about 1.2 meters (4 ft) in diameter and about 1.7 meters (5.5 ft) deep with a bottom and a steel plate placed over the top. The site was self-contained without any incoming or outgoing piping. Its original purpose is not known, but it was located just outside of Dryer Room #1 of the 115-B/C Facility. This caisson was identified during a pre-demolition walk-through of the 115-B/C Gas Recirculation Building, and was removed during building demolition. The caisson contained sludge and water that was heavily contaminated with chromium, which was removed and disposed of during the demolition of the 115-B/C Building. Contaminated soil was also sampled and removed during excavation of the caisson.

**Waste Type:** Sanitary Sewage

**Waste Description:** Originally, the caisson contained a yellowish-colored soil which was sampled for pH and EP toxic metals. Sample results indicated a pH of 8 and 72,500 milligrams/liter of chromium. Additional samples were taken (after caisson removal) from soil directly underneath and around the outside of the caisson. Results from these samples showed chromium levels ranging from 0.08 milligrams/liter to 9.14 milligrams/liter. The caisson contained approximately 0.37 cubic meters (13 cubic feet) of chromate contaminated soil.

**Closure Info:** This caisson was identified during a pre-demolition walk-through of the 115-B/C Gas Recirculation Building and was removed during building demolition. The caisson contained sludge and water that was heavily contaminated with chromium, which was removed and disposed of during the 115-B/C Building demolition. The No Action decision for the 100-B-11 site is supported based on reviews of site history, field observations, and characterization results. The maximum detected results from underlying soil samples collected at locations suspected of having the greatest potential for residual contamination levels were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.
The waste site has been Interim Closed Out. The site was a Radiological Materials area (RMA) with four metal boxes containing filters, that rested on shoring that sat on the bare soil. An additional six filter frames, marked as having fixed contamination, rested directly on the soil. The contaminated filter frames were removed and disposed at ERDF.

The waste site encompassed pre-reactor underground process and sanitary pipelines and sewers. The waste was divided into seven subsites. All the subsites have been evaluated and reclassified to either Interim Closed Out or No Action. Therefore, the parent site has been reclassified to Interim Closed Out. The area was revegetated in 2007.

The subsites are:

Subsite 1 - Main Process Sewer Collection Pipelines
Subsite 2 - 115-B Sanitary Sewer Pipelines
Subsite 3 - West Process Sewer Feeder Pipelines from 182-B and 183-B, Subsite 4 - Cooling Water Pipelines and Tunnels from 190-B
Subsite 5 - Sodium Dichromate and Sodium Silicate Pipelines
Subsite 6 - Process Sewer Feeder Pipeline from 184-B and 184-B Ash Slurry Line
Subsite 7 - Process Sewer Feeder Pipelines from 185-B and 190-B.

These pipelines were located mostly north and west of the 105-B Reactor and north of the 183-B Filter House. Most joined to empty into the 116-B-7 Outfall. Others emptied into the 126-B-1 Power House Ash Pit, and the 1607-B2 and 1607-B7 Septic Systems. The sodium dichromate pipeline connected the 108-B Laboratory and the 190-B building, and the treated reactor cooling water ran from the 190-B Facility to the 105-B Reactor.
Process Description: These pipelines carried a variety of non-radioactive waste fluids, product (sodium dichromate), treated cooling water (pre-reactor), and sewage.

Waste Type: Sanitary Sewage

Waste Description: The waste site consisted of abandoned process and sanitary sewer pipelines, and residual chemicals remaining on the pipes. Chemical additives to the reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, the free chlorine residual was approximately 0.2 milligrams/liter, and sodium dichromate was added at a rate of about 2 milligrams/liter. One length of the product piping held undiluted sodium dichromate: the pipe from the 185-B/190-B to the 108-B Building (per drawing M2913, Sheet 5). This pipeline was in use only for a few years, until the sodium dichromate was added to the cooling water at the 185-B Building. (Note: Reference: WHC-SD-EN-TI-169 is for 100-F, and applies equally to 100-B).

This Site has the Following SubSites:

Code: 100-B-14:1
Names: 100-B-14:1; Main Process Sewer Pipelines

Code: 100-B-14:2
Names: 100-B-14:2; Sanitary Sewer Pipelines

Code: 100-B-14:3
Names: 100-B-14:3; West Process Sewer Pipelines from 182-B and 183-B

Code: 100-B-14:4
Names: 100-B-14:4; Cooling Water Pipelines and Tunnels from 190-B

Code: 100-B-14:5
Names: 100-B-14:5; Sodium Dichromate and Sodium Silicate Pipelines

Code: 100-B-14:6
Names: 100-B-14:6; 184-B and 184-B Ash Slurry Line; Powerhouse Pipelines

Code: 100-B-14:7
Names: 100-B-14:7; 185-B and 190-B Sump and Pipelines

Code: 100-B-14:1
Classification: Accepted
Reclassification: Interim Closed Out (2/22/2007)

Type: Process Sewer
Status: Inactive

Description: The subsite has been remediated and Interim Closed Out. The subsite encompassed the process sewer mainline that provided service to the 105-B, 108-B, 182-B, 183-B, 184-B and 185/190-B facilities and discharging to the 116-B-7 Outfall Structure and some feeder lines. The main process line site consisted of 1270 meters (4166 ft) of pipe ranging from 0.3 m (12 in.) diameter vitrified-clay pipe to 1.82 meter (72 in) diameter reinforced concrete pipe (RCP).

Location: The subsite consisted of the reinforced concrete process sewer main that formerly serviced the 105-B Reactor Building; the 108-B Chemical Pumphouse and Tritium Separation Facility; and
100-B water treatment facilities then discharged to the 116-B-7 Outfall Structure. Vitrified clay feeder pipelines associated with the 108-B facility were also included in the subsite.

**Waste Type:** Sanitary Sewage

**Waste Description:** The waste site consists of abandoned process and sanitary sewer pipelines, and residual chemicals remaining on the pipes.

**Closure Info:** Remediation of the subsite was performed from January 2005 through April 2006 as part of the 100-B/C Area Remaining Pipes and Sewers remediation. The remediation of the pipelines consisted of the excavation and stockpiling (on-site) of overburden soils presumed to contain no residual contamination above cleanup levels, removal of soils around and approximately 0.3 meters (1 foot) below the pipelines; and disposal of the pipeline and suspect potentially contaminated soil at the Environmental Restoration Disposal Facility (ERDF).

Excavation at the upgradient (southeastern) end of the pipeline near the former 108-B facility was restricted within the shallow zone (less than 4.6 meters [15 feet] below ground surface [bgs]), and extended into the deep zone further downgradient, near the influent of the feeder line associated with the 105-B Reactor Building. The maximum depth of excavation was approximately 7.6 meters (25 feet) bgs, near the outfall of the pipeline at the northern end of the site. Due to co-location and concurrent remediation of differing functional pipeline groups, excavated and disposed material quantities could not be explicitly separated for the subsite. Following a determination that cleanup criteria had been attained, the excavation was backfilled with stockpiled overburden and borrow material. Railroad rails discovered and stockpiled during excavation of the site were also backfilled in the western portion of the excavation.

Initial cleanup verification sampling was conducted concurrently with variance sampling from May 30 to June 19, 2006. Additional verification sampling for carbon-14 in stockpiled overburden material was conducted from September 19 to 29, 2006. All verification samples were submitted to offsite laboratories for analysis using approved U.S. Environmental Protection Agency analytical methods as required per the Sampling and Analysis Plan (SAP). Based on process knowledge and the results of the confirmatory sampling activity for the subsite, this pipeline received radioactive waste stream discharges. Accordingly, the radioactive liquid waste effluent sites cleanup and closeout approach was implemented for the site, as described in the SAP.

The results of verification sampling illustrated that residual contaminant concentrations does not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. The acceptability of unrestricted exposure to deep zone portions of this site has not been demonstrated; therefore, institutional controls are required to prevent uncontrolled drilling/excavation into the deep zone.

**The SubSite is Part Of:**

**Code:** 100-B-14

**Names:** 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines

five service areas.

Service Area 1 is the 108-B and 17-3-B sanitary sewer pipelines and pipelines found during the 100-B-21 remediation.
Service Area 2 is the 1607-B7 sanitary sewer pipelines.
Service Area 3 is the 1700-B Series Support Buildings and 108-B Building were serviced by 15 and 20 centimeter (6 and 8 inch) vitrified clay pipes of various lengths.
Service Area 4 is the 190-B Pumphouse was serviced by 10, 15, and 20 centimeter (4, 6 and 8 inch) vitrified clay sewer pipes of various lengths.
Service Area 5 is the 115-B Gas Recirculation sanitary sewer site consists of approximately 311 meters (1020 feet) of 20 centimeter (8 inch) vitrified clay sewer pipe.

Location: The pipelines in this subsite were located in four areas: east of the 183-B Clearwells; north and east of the 190-B Pumphouse. The pipes exited the 115-B Gas Recirculation Facility and extended north on the east side of the 105-B Reactor. The 108-B Building and 1700-B Series supported buildings located about 150 meters (500 feet) north of the 105-B Reactor.

Waste Type: Soil
Waste Description: the waste is the sanitary sewer pipelines, pipeline contents, pipeline debris, and surrounding soils.

Closure Info: Remediation of the 100-B-14:2 and 1607-B2 waste sites was performed in stages from January 2005 through June 2006. All excavation was restricted within the shallow zone (less than 4.6 meters [15 feet] bgs), with an average depth of approximately 2.5 meters [8 feet] bgs, and a maximum depth of approximately 4 meters [13 feet] bgs at the septic tank. Excavation at the northern portion of the site continued to greater depth due to concurrent remediation of the underlying 100-B-14:1 process sewer. Excavated and disposed material quantities could not be explicitly separated for each site due to co-location and concurrent remediation of differing functional pipeline groups.

Based on the results of confirmatory sampling and previous investigations, it was decided that remedial action was necessary at areas 1, 2, 4, and 5 and that no further action was required at area 3. Area 1 was removed with the remediation of the 100-B-8:1 effluent lines. A decision was also made that remediation was necessary at the 1607-B2 waste site without further investigation based on the confirmatory sampling results for the influent feeder pipelines.

Due to its proximity to the reactor building, the southernmost portion of the 1607-B2 collection line, which formerly serviced the 105-B Reactor Building, was not removed. This portion of the pipeline will be addressed in the 118-B-8, 105-B Reactor waste site.

Site remediation consisted of the removal of the sewer piping, septic tank, and drain field where applicable, as well as adjacent, potentially-contaminated soils for disposal at the Environmental Restoration Disposal Facility (ERDF). Remedial actions were performed so as to not preclude any future uses (as bounded by the rural-residential scenario) and to allow unrestricted use of shallow zone soils [i.e., surface to 4.6 meters (15 feet) deep].

</table>
Type: Process Sewer
Status: Inactive

Description: The subsite has been evaluated and reclassified to No Action. It consisted of the process sewer pipelines that exited from the 182-B reservoir and 183-B water treatment facilities. These process sewer lines were collected into a single 1.67 meter (5.5-foot) reinforced concrete box sewer that fed into the main process sewer collection line serving the 185-B/190-B Pumphouse, 105-B Reactor, and the 108-B Tritium Separation Facility. The basis for separating this subsite from the main process sewer line was that these lines carried effluent from facilities known to be potential sources of radioactive and chemical contaminants.

Location: These pipelines are located north of the 182-B and 183-B facilities, as well as between the 182-B and 183-B buildings, and east of the 183-B Clearwells. The individual pipeline segments are mapped in the WCH Geographic Information System (GIS) database.

Waste Type: Soil
Description: The waste includes the pipelines and the contaminated scale contained within them.

Closure Info: Confirmatory sampling was conducted in October 2003. The sampling approach consisted of collecting three samples of pipe scale material from each of three manholes and one soil sample from below one manhole/pipe. The maximum detected results from the scale and soil samples were used to support waste site reclassification. A summary of the evaluation of the scale and soil sample results were compared against the applicable remedial action goals (RAGs). A focused sampling approach was selected for this site, biased toward worst-case sample locations and locations that were accessible.

The No Action decision for the 100-13-14:3 site is supported based on reviews of site history, field observations, and characterization results. The maximum detected results from pipe scale and underlying/surrounding soil samples collected at locations suspected of having the greatest potential for residual contamination levels were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

The SubSite is Part Of:
Code: 100-B-14
Names: 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines

Code: 100-B-14:4
Names: 100-B-14:4; Cooling Water Pipelines and Tunnels from 190-B
Type: Process Sewer
Status: Inactive

Description: The subsite has been evaluated and reclassified to No Action. This subsite included the pipes and tunnels from the 190-B Building to the road east of the 105-B Reactor. The 100-B-14:4 pipelines were removed and the tunnels collapsed in 1993 during deactivation and decommissioning of the 190-B pump house. There were twin tunnels at each reactor. The tunnel dimensions varied, but were about 3.3 meters wide by 3.6 meters high (10 ft by 12 ft). They covered a distance of about 140.2 meters (460 ft) from the pumphouses to the reactor. Each tunnel from the 190-C pumphouse held one 20.3 cm (8 in) steam line and three 61 cm (24 in) water pipes. Each tunnel from the 190-B pumphouse and annex held twelve 30.5 cm (12 in), and two 45.7 cm (18 in) pipelines for cooling water to the 105-B Reactor. The pipes from the edge of the road to the reactor will be included in 118-B-8, as they cannot be removed until the
reactor is addressed.

**Location:** This subsite includes the pipes and tunnels from the 190-B Building to the road east of the 105-B Reactor, and from the edge of the road to the reactor.

**Waste Type:** Equipment

**Waste Description:** The waste includes the pipelines, and their contents (scale, sediment).

**Closure Info:** The 100-B-14:4 pipelines were removed and the tunnels collapsed in 1993 during deactivation and decommissioning of the 190-B pump house. The Cooling Water Pipe Tunnels Site (100-B-14:4) meets the Remedial Action Objectives specified in the Remaining Sites ROD, U.S. Environmental Protection Agency, Region 10, Seattle, Washington. There is no history of radiological contamination associated with the 100-B Reactor cooling water tunnels and no radiological contamination was detected during decommissioning of the tunnels. There were no known process incidents at 105-8 Reactor that would have introduced radiological contamination from the reactor into the tunnels. Additionally, since the 105-B cooling water tunnels had the same source of water as the 105-C cooling water tunnels, the 105-B tunnels are analogous to the 105-C tunnels. Historical sampling indicated that no unacceptable levels of residual hexavalent chromium exist in the 105-C tunnels.

Reclassification form 2004-0008 states the 105-C tunnels have been determined to meet the cleanup criteria, therefore the 100-B-14:4 site also meets the cleanup criteria and the remaining contaminant levels are protective of groundwater and the Columbia River. All samples were less than the criteria of 2.0 mg/kg for protection of groundwater and Columbia River. This result is for the main sample associated with the duplicate soil sample.

**The SubSite is Part Of:**

### Code: 100-B-14

Hanford Site Waste Management Units Report
February 2015
Closure Info: The No Action decision for the 100-B-14:5 site is supported based on reviews of site history, field observations, and characterization results. The maximum detected results from soil samples collected underneath the sodium dichromate and sodium silicate product pipelines at locations suspected of having the greatest potential for residual contamination levels were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

Confirmatory sampling was conducted in October 2003. The original sampling approach consisted of collecting one sample of pipe scale and one soil sample from below each pipe at two sampling locations. Since no scale or sediment was found in the piping at the selected locations, two alternative soil locations along the piping were sampled. The maximum detected results from soil samples were used to support waste site reclassification.

The SubSite is Part Of:

Code: 100-B-14
Names: 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines

Code: 100-B-14:6
Names: 100-B-14:6; 184-B and 184-B Ash Slurry Line; Powerhouse Pipelines
Type: Process Sewer
Status: Inactive
Classification: Accepted
Start Date: 
End Date: 

Description: The subsite has been evaluated and reclassified to No Action. This subsite included the process sewer pipelines from the 184-B Powerhouse, flowing north to the ash pit east to the main trunk line (100-B-14:1).

Location: The segments were located on the north and south sides of the powerhouse.

Process Description: Process Sewer Pipelines exited the 184-B Power House and eventually discharged into the main 100-B-14 process sewer pipeline connecting to the 116-B-7 outfall. The underground piping for the 184-B Powerhouse included sanitary (clean) waterlines, a sanitary sewer line and process sewer lines. These pipelines consist of: Sanitary waterline pipelines: These pipelines consist of sanitary water pipelines, filtered water pipelines, and raw and condensor water pipelines. Proceeding from west to east along the south side of the building the pipelines include: 1607-B-3 Sanitary Sewer PipeLine: This piping is a 20.3 cm (8 in) diameter vitrified clay pipe that exited the southwest corner of the 184-B Powerhouse to the 1607-B-3 Septic Tank. 184-B Powerhouse Ash Pipeline: This pipeline is an 20.3 cm (8 in) diameter ashcolite pipe that was used to discharge coal ash that was mixed with raw water and sluiced from the 184-B Powerhouse to the 126 B Ash Pit. 184-B Process Sewer Pipelines: There are four locations where process sewer pipelines exit the 184-B Powerhouse and eventually discharge into the main 100-B-14 Process Sewer Pipeline connecting to the 116-B-7 Outfall. There is also a pipeline that discharges from the powerhouse blow-off tank into the 184-B Process Sewer Pipelines. These pipelines required confirmatory sampling and included: Two pipelines, a 15.2 cm (6 in) diameter vitrified clay pipe and a 20.3 cm (8 in) diameter vitrified clay pipe, both on the left south side of the building, that discharged into a 30.5 cm (12 in) diameter vitrified clay pipe and eventually into the main process sewer line. A 30.5 cm (12 in) diameter steel pipe near the center south side of the building that discharged into a 130.5 cm (2 in) diameter vitrified clay pipe and eventually into the main process sewer line. A 38.1 cm (15 in) diameter vitrified clay pipe on the north side of the building that discharged directly into the main process sewer pipeline.

Waste Type: Soil
Waste Description: The waste was the remaining pipelines and any potentially contaminated soil.

Closure Info: The No Action decision for the 100-B-14:6 site is supported based on reviews of site history, field observations, and characterization results. The maximum detected results from pipe scale and underlying/surrounding soil samples collected at locations suspected of having the greatest potential for residual contamination levels were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

Confirmatory sampling was conducted in September and October 2003. The maximum detected results from the scale and soil samples were used to support waste site reclassification.

The SubSite is Part Of:

Code: 100-B-14
Names: 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines

Code: 100-B-14:7
Names: 100-B-14:7; 185-B and 190-B Sump and Pipelines
Type: Process Sewer
Status: Inactive
Classification: Accepted
Start Date: 
End Date: 

Description: The subsite has been evaluated and reclassified to No Action. This subsite consisted of the pipelines that were used to control the temperature of process water used in association with the 185-B Deaeration Building and the 190-B Pumphouse. The subsite included the sump. The sump was a 14.3 m by 10.4 m by 4.6 m deep (47 ft by 34 ft by 15 ft deep) reinforced concrete reservoir, and was open to the environment. An 80 m (260 ft) long, 61 cm (24 in) diameter cast-iron pipe exited the south side of the 185-B Building and fed the sump. A 10 m (30 ft) long, 76 cm (30 in) diameter cast-iron pipe that exited the south side of the 190-B Pumphouse joined this pipe. The pipe entered the sump on the south side near the west corner at approximately 3 m (9 ft) below ground surface (coordinates N144444.427; E565173.872).

Location: The pipelines were from the south side of the 185-B and 190-B facilities and ended at the sump on the southeast corner of 190-B.

Waste Type: Process Effluent
Waste Description: the waste is the pipelines, and their contents, and the 190-B sump.

Closure Info: The No Action decision for the 100-B-14:7 site is supported based on reviews of site history, field observations, and sampling results. The maximum detected results from pipe scale and underlying/surrounding soil samples collected at locations suspected of having the greatest potential for residual contamination levels were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

Confirmatory sampling was conducted during October 2003. The contaminants of potential concern (COPCs) were identified based on existing analytical data, historical process information, and historical uses and practices associated with the 185 B/190-B sump and pipeline facilities. The COPCs included inductively coupled plasma (ICP) metals, mercury, and hexavalent chromium. At the location where a 46-centimeter (18-inch) pipe entered the sump, some suspect fibrous insulating material was observed. This fibrous material was sampled for asbestos analysis. The absence of radionuclide contamination was confirmed using gamma energy analysis (GEA) and gross alpha and gross beta analyses. On this basis, no radionuclide
COPCs were identified for this site.

The SubSite is Part Of:

Names: 100-B-15; 100BC River Effluent Pipelines; 100BC River Lines

Type: Radioactive Process Sewer
Status: Inactive

Description: This site includes the 100-B/C Area river effluent pipelines (river lines) that extend from each of the three outfalls into the main channel of the Columbia River.

Location: The river lines are located in the Columbia River, adjacent to the 100BC area. The lines extend north into the main channel of the river from three outfall structures located near the river shore.

Related Sites/Structures: The site is associated with the 116-B-7 (1904-B1 outfall), 132-B-6 (the 1904-B2 outfall), and 132-C-2 (the 1904-C outfall); the 100-B Reactor Cooling Water Effluent Underground Pipelines (100-B-8), the 100 B Area Process and Sanitary Sewer Underground Pipelines (100-B-14), the 100-C Reactor Cooling Water Effluent Underground Pipelines (100-C-6), and the 100-C Area Process and Sanitary Sewer Underground Pipelines (100-C-9); the 107-B Retention Basin (116 B-11), the 107-B Liquid Waste Disposal Trench (116-B-1), the 107-C Retention Basins (116-C-5), and the 107-C Liquid Waste Disposal Trench; and 100-B-24 (the 1904-B1 Spillway), 100-B-25 (the 1904-B2 Spillway), 100-B-26 (and the 1904 C Spillway).

Process Description: The river effluent pipeline from 116-B-7 (1904-B1) provided for the discharge of reactor cooling water and the B Area process sewers until 1955. After that time, it provided only for the discharge of B Area process sewers, and reactor cooling water was rerouted through a new, higher capacity 132-B-6 (1904-B2) pipeline. In 1952 the 1904-C pipelines (and the 132-C-2 outfall) discharging reactor cooling water for the new C Reactor and C Area process sewers. In the event any of the pipelines became plugged or had to be removed from service during operation, the effluent overflowed the effected outfall and entered the river via an attached spillway.

Waste Type: Process Effluent
Waste Description: The waste includes the pipelines and the contaminated scale contained within them. Contaminants of concern/potential concern are based on those for the outfalls themselves. They include americium-241, cesium-137, cobalt-60, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, tritium, uranium-234, uranium-235, uranium-238, hexavalent chromium, total chromium, mercury, and lead.

Code: 100-B-16
Names: 100-B-16; Utility Poles and Fixtures Debris Pile
Type: Dumping Area
Status: Inactive

Description: The site has been remediated and interim closed out. The site consisted of four surface debris piles that included unsheathed wire ropes, metal light poles, aluminum utility framing, rubber-insulated wires, ceramic insulators, broken light bulbs, light fixtures, lead bolts, and other wood. Two were known as northern debris piles and two were known as southern debris piles.
**Location:** The northern debris pile was situated 80 meters (262 feet) north of Bell Ave and 100 meters (328 feet) west of Beaver Ave. The southern debris pile was directly south of Bell Ave. 90 meters (295 feet) and 95 meters (311 feet) west of Beaver Ave. Both areas were northwest of the 105-B Reactor.

**Process Description:** The site consisted of four surface debris piles. Two piles were situated north of Bell Ave, the other two were directly south and across Bell Ave. The surface debris materials were composed of telephone poles (most of which were grouped together) and associated utility debris in piles adjacent to the telephone poles. Associated debris included unsheathed wire ropes, metal light poles, aluminum utility framing, rubber-insulated wires, ceramic insulators, broken light bulbs, light fixtures, lead bolts, and other wood pieces (including pressure-treated lumber).

**Waste Type:** Process Effluent

**Waste Description:** The waste includes creosote-treated wood poles and cross beams, lead-tipped bolts and other debris. A few small boxes were seen that could be transformers. The possible transformers do not seem to be leaking any oil. Other debris included particle board, conduit, light fixtures, wire, insulators, junction boxes, chain link fencing and incandescent light bulbs.

**Closure Info:** Remedial action activities for the site began November 11, 2004 until November 19, 2004. All of the debris piles were removed, and 639 bank cubic meters (BCM) of pile material was collected, sorted, and disposed of at Environmental Restoration Disposal Facility. Following remediation, verification sampling was conducted on January 25, 2005. Analytical results of the verification samples (J02FN3) collected in sample location 4 exceeded the asbestos criteria. Consequently, additional remediation was warranted for this site. Additional remediation was conducted on March 7, 2005. Approximately 135 BCM of soil was removed. Following remediation, an additional verification sample (J03034) was collected for asbestos analysis on March 7, 2005.

**Code:** 100-B-18  
**Classification:** Accepted

**Names:** 100-B-18; 184-B Powerhouse Debris Pile  
**Reclassification:** Interim Closed Out (11/30/2007)

**Type:** Dumping Area  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site consisted of a debris pile containing miscellaneous demolition waste from the decommissioning activities of the 184-B Building and the 184-B Power House.

**Location:** The 184-B surface debris pile was located northwest of the 184-B Power House. The coordinates at the center of the debris site were E 564449.562, N 144962.219.

**Related Sites/Structures:** Some of the waste (especially corrugated ACM) at this site was similar to waste found at WIDS site 100-B-17, which was approximately 165 meters (541 feet) due north.

**Process Description:** The 105-B Reactor operated between 1944 and 1968, and the 105-C Reactor operated between 1952 and 1969. Constructed in 1944, the coal-fired 184-B Power House provided steam and emergency electrical power for the secondary coolant system located at 181-B. The 184-B Power House also supplied office heat and other heating needs for 100 B/C Area facilities through overhead steam lines that looped through the 100 B/C Area. A small turbine generator in 184-B also supplied emergency electrical power for area building lights and motors. Soon after the 105-B and 105-C Reactors were deactivated in 1969, the 184 B Building and other ancillary facilities were gradually phased out. The 184-B Building was closed in the mid 1970s, and parts of the 184 B Power House and all of the equipment were removed in 1979. Demolition and removal of all above ground structures including the stack was complete in 1983, leaving the foundation slabs, footprints, tunnels, pits, and other associated concrete
structures at or near grade level. During 1988, the foundation and the other below-grade features, including the salt dissolving pits, were demolished to at least 0.9 meters (3 feet) below grade, backfilled with rubble, and buried in situ. Four 184-B Process Sewer Pipelines exited the 184-B Power House and eventually discharged into the main 100-B-14 process sewer pipeline connecting to the 116-B-7 outfall.

**Waste Type:** Equipment

**Waste Description:** Suspect asbestos-containing materials such as siding, roofing, lagging, and wrapping were interspersed in the debris pile.

**Closure Info:** Remediation of the site was begun on June 26, 2007, and July 16, 2007. Because the majority of the material to be disposed was inert demolition debris (e.g., concrete blocks and asphalt rubble), the Environmental Protection Agency (EPA) and the Department of Energy, Richland Operations Office (DOE-RL) agreed that site remediation would be accomplished by selective removal of suspect hazardous items (specifically, light ballasts and tar/mastic material) and potentially impacted soils. No cleanup action for the non-friable asbestos-containing material (ACM) was required because it did not present a potential release to the environment.

Remediation activities included the removal of 70 BCM (bank cubic meter) of tar/mastic material along with underlying soils. Although expected, no light ballasts were found during remediation. The numerous intact and broken fluorescent light tubes located at the site (approximately 50) were picked up and disposed. No other hazardous debris or stained soil requiring remediation was identified at the site. The asphalt was not removed because it had been used for structural and construction purposes. Therefore, it was excluded from consideration as a dangerous waste based on the Washington Administrative Code (WAC) 173-303-071(3)(e), it is listed as an inert waste in WAC 173-350-990(2)(b), and does not present a significant risk to human health or the environment.

Because the majority of the material was inert demolition debris (e.g., concrete blocks and asphalt rubble), site remediation was accomplished by selective removal of suspect hazardous items (specifically, light ballasts and tar/mastic material) and potentially impacted soils. The asbestos-containing materials present at the site were in a non-friable form and did not present a potential release to the environment. Therefore, no cleanup action was required.

Excavation was performed in June 2007 with removal of additional light tubes in July 2007. Seventy BCM (bank cubic meter) of tar/mastic material along with surrounding contaminated soils were disposal at the Environmental Restoration Disposal Facility (ERDF). Light ballasts were expected at the site, however, none were found. The numerous intact and broken fluorescent light tubes located at the site (approximately 50) were picked up and disposed. Inert debris material was left in-place at the site. No other hazardous debris or stained soil requiring remediation was identified at the site.

<td>Description</td>
<td>The waste site has been remediated and Interim Closed Out. Prior to remediation the 100-B-19 waste site consisted of six stained soil locations that were dispersed within the 100-B/C Area. The stained soil was identified during a WCH 2004 orphan sites field visit of the 100-B/C Area. Three of the locations (SS-100BC-001, SS-100BC-002, and SS-100BC-003) contained reddish-to purple-colored coarse-grained garnet material on the surface. The other three locations (SS-</td>
<td></td>
</tr>
</tbody>
</table>
100BC-004, SS-100BC-005, and SS-100BC-006) had yellow-stained surface soil that was ultimately determined to originate from sulfuric acid.

An agreement was made among the Environmental Protection Agency (EPA), the U.S. Department of Energy, Richland Operations Office (DOE-RL), and the Environmental Restoration Contractor Team on May 5, 2005, that a general cleanup action to remove the garnet-like material and yellow-stained soils would occur at each of the six locations. Additionally, one multi-aliquot sample would be collected of the underlying soils at each of the six locations.

**Location:**

(SS-100BC-001): Potential garnet material was found on the surface at coordinates E 566706.139, N 145169.459 in the northeast corner of the 100-B/C Area (using handheld GIS equipment).

(SS-100BC-002): Potential garnet grit-blasting material was visible on the soil surface at coordinates E 564420.28, N 144545.33 about 150 meters (475 feet) west of the southwest corner of the 182-B Reservoir in the 100-B/C Area.

(SS-100BC-003): Potential garnet grit-blasting material was visible on soil surface at E 565968.41, N 144,046.68 about 32 meters (105 feet) northeast of the north boundary of the 128-C-1 WIDS waste site, which is east of the 105-C Reactor.

(SS-100BC-004): This surface stained soil area was on the north side of the railroad tracks at E 564802.438, N 144346.781 (centroid). The north area was connected (by a clay pipe culvert under railroad tracks) to a soil stained area on the south side of the railroad tracks at E 564803.312, N 144327.703 (centroid). The pipe culvert was located between the head houses for the 183-B and 183-C Water Treatment Plants. The pipe culvert was about 175 meters (575 feet) west of the northwest corner of the 151-B Substation yard. The combined area was about 28 square meters (296 square feet).

(SS-100BC-005): This surface stained soil area at E 564803.062, N 144444.156 (centroid) is located 135 meters (443 feet) north and 40 meters (131 feet) east of the 183-C Head House (center). The east-west centerline of the stained surface area runs parallel and about 6.6 meters (22 feet) north of the east-west paved road (center) between the 183-C Water Plant and the 151 B Substation. The total stained area is about 58 square meters (619 square feet). The area between the two locations (i.e., the culvert) is not included in the total area. If soil analyses for potential contaminants of concern for either or both areas indicate cleanup is required, then the culvert area should be included in the cleanup action.

(SS-100BC-006): There is stained soil in a hole is about 0.7 meters (2 feet) in diameter and about 1.5 meters (5 feet) deep located at E 564804.06, N 144374.71. It is about 7.5 meters (25 feet) north of the east-west paved road (center) that runs between the 183-B Water Plant and the 151-B Substation.

**Process Description:** Garnet grit was commonly used in grit-blasting operations to clean the surface of metal components of rust, paint, or contamination. The garnet is not a hazardous substance, but there is a potential for contamination from the surface material that was cleaned by grit blasting. Analogous waste site information is available for WIDS site 100-K-29, a garnet grit blasting surface soil site in the 100-K Area that was remediated under the Remaining Sites Record of Decision. Yellow stains on soil in this area may be due to spills of concentrated sodium dichromate solution (hexavalent chromium) and/or concentrated sulfuric acid used at the water treatment plants for reactor coolant water cleaning and for corrosion control. These chemicals were received in railroad tank cars and in tanker trucks for off-loading to storage tanks at the 183-B, 185-B, 190-B, 183-C, and 190-C water plant facilities. Chemical spills and leaks to the surrounding soil are known to have occurred during loading and unloading operations and
during equipment maintenance at the 100-K Area and similar problems likely occurred at the
100-B/C water plant facilities. Analogous hexavalent chromium waste sites include the 100-C-7 hexavalent chromium waste site for the sodium dichromate equipment area in the 183-C Filter
House and surrounding soil. Hexavalent chromium on concrete, steel, and soil was
successfully remediated for the 190 C Pump House and Water Tunnels (BHI 1997). Analogous
concentrated sulfuric acid waste sites that have been remediated include the 100 K Area sulfuric
acid storage tank sites (WIDS waste sites 100-K-30, 100-K-31, 100-K-32, and 100 K-33)
associated with the water treatment plant for the 100-K Area. The contaminants of concern for
concentrated sulfuric acid are lead and mercury that were present as impurities in the acid.

Waste Type: Soil
Waste Description: The waste is contaminated (stained) soil. Contaminants of potential concern (COPCs) include hexavalent chromium, lead, and mercury for yellow stained sites.

Closure Info: An agreement was made between the EPA, DOE-RL, and the Environmental Restoration Contractor Team on May 5, 2005, that a general cleanup action to remove the garnet-like material and yellow-stained soils would occur at each of the six 100-B-19 locations. Therefore, confirmatory sampling was not required. The site was included in the Explanation of Significant Differences for the 100 Area Remaining Sites Interim Remedial Action Record of Decision, Hanford Site, Benton County, Washington (EPA 2009) as a waste site for remediation, treatment, and disposal.

All remediation was guided by visual inspection, and, where applicable, X-ray fluorescence (XRF) field measurements. Initial remediation of the 100-B-19 waste site was performed between June and October 2007. Approximately 11,390 metric tons (12,550 US tons) of material was excavated and disposed at the Environmental Restoration Disposal Facility (ERDF) from all locations in the entire waste site. All waste soils were directly loaded out, except at location SS-100BC-004.

In 2009, further remediation was performed at locations SS-100BC-002 and SS-100BC-004 resulting in the removal of approximately 1,150 metric tons (1,270 US tons) of soil. Remediation at location SS-100BC-002 was performed from February to May. Additional material removal revealed a more extensive subsurface lens of garnet mixed with soil, as was previously observed at locations SS-100BC-001 and SS-100BC-003. All visible garnet material was removed over an area of approximately 450 square meters (4,800 ft²) to a maximum depth of approximately 1 meters (3 ft) below original grade. Approximately 650 bank cubic yards (500 bank cubic meters) of soil mixed with garnet grit was excavated and staged north of the site. Loadout of the material was completed in July 2009. A total of 12,540 metric tons (13,820 tons) of material from the six stained soil locations were disposed at ERDF.

---

Waste Type: 
Waste Description: The site has been remediated and Interim Closed Out. The site consisted of an underground gas and/or oil tanks near the garage. The garage was used for maintenance of 100-B area vehicles. The facility and tanks have been removed.

Location: The site was located approximately 300 meters (984 feet) northwest of the 105-B Reactor Building on the south side of B Avenue.
Process Description: The 1716-B Maintenance Shop was built in 1944 and provided automotive repair and light vehicle maintenance and lubrication service for 100-B/C Area vehicles until deactivation of B Reactor in 1968. Drawing H-1-10983 identified the building as a Bus Garage. Whalen noted the "lubrication of vehicles was accomplished from a grease pit dug in a high-bay area of the garage". Drawing HW-71669 references Drawing H-1-5055, Lube. Pit Lte. Electrical, which shows that 1716-D and 1716-F had lubrication pits, but there was no reference to one at 1716-B. The "L"-shaped 12.2 meter by 16.3 meter (40 foot by 53.5 foot), single-story, wood frame building, which measured approximately 167.2 square meters (1,800 square feet), contained one large rectangular room (high bay) and a small adjoining room (office). Drawing W-71300 shows two service bays that were large enough to accommodate buses. In 1979, the building was declared surplus, the equipment was excessed, and the entire facility was removed by a salvage operator. Removal of the gas and oil tanks nor the associated piping were mentioned.

Waste Type: Soil

Waste Description: While the records indicate that the underground gasoline tank was removed and no contamination was found in soil samples, no documentation of when the oil storage tank was removed could be found. Additional potential contamination sources include the former grease pit, lubricating fluids, battery acid in the high bay area, and asbestos shake siding. Contaminants of potential concern (COPCs) would include total petroleum hydrocarbons (TPH) and polychlorinated biphenyls (PCBs).

Closure Info: The site was evaluated through field observations and focused sampling and analysis to determine if hazardous contaminants were present at the site. One test trench, in the most likely location of the underground oil storage tank (UST), was excavated in sample area 1. The UST was discovered within the excavation trench at an approximate depth of 1.7 to 1.8 meters (5.5 to 6.0 feet). The tank consisted of two separate compartments, each of which contained waste material. The larger compartment had an approximate capacity of 946 to 1136 liters (250 to 300 gallons) and contained 189 to 227 Liters (50 to 60 gallon) of sludge. The smaller compartment had an approximate capacity of 379 to 568 Liters (100 to 150 gallons) and contained 19 to 38 Liters (5 to 10 gallons) of a soil/water/diesel mixture. After removal of the UST, the remaining soils underlying the tank footprint were sampled. A total of five samples were collected at the UST excavation (sample area 1) and consisted of a soil sample from underneath the tank, two soil samples from the excavation sidewalls, one duplicate and one blank. An additional soil sample (sample area 2) was collected at the 100-B-20 waste site from subsurface stained soils. The excavation was backfilled upon completion of sampling with clean soil from the 100-B Area borrow pit.

The UST was unable to be sampled in place and was removed to gain access to the internal contents. A composite sample was collected from the material in the two compartments and analyzed for waste characterization purposes. According to remedial field notes the tank contents were removed, and the empty tank and waste contents were placed into a B-25 box. In addition to the tank removal, approximately 0.3 meters (1 foot) of soil was excavated from the location underlying the UST and placed into a second B-25 box. The contents of the B-25 boxes will be managed and disposed of separately in accordance with the Washington State Department of Ecology "Dangerous Waste Regulations" (Washington Administrative Code [WAC] 173-303) and as according to CERCLA requirements, the waste will be disposed at the Environmental Restoration Disposal Facility.

The depth of the oil tank was approximately 1.8 meters (6.0 feet) and the soils collected underlying the tank were at a depth of 2.1 meters (6.9 feet). The sample results at the boundaries of the excavation indicated that the remedial action objectives for the site have been met. No further excavation is required.
Reclassification: Interim No Action (2/14/2006)

Names: 100-B-21; 100-B/C Miscellaneous Pipelines
Type: Process Sewer
Status: Inactive

Description: All of the subsites have been evaluated and reclassified. The waste site included 21 pipeline segments. They consisted of a variety of underground pipelines that were discovered during removal of other 100-B/C Reactor effluent pipelines and soil sites. The pipeline segments did not belong to previously established waste sites. They have been grouped together based on the type of pipeline and potential closeout pathways for each. The waste site was split into four subsites.

Location: The multiple locations were described in terms of easting (E), northing (N), and elevation (meters). Elevations are NAVD88.

Process Description: The pipelines in this waste site were discovered during the removal of other effluent pipelines and soil sites. As pipeline removal progressed, an effort was made to photograph, accurately locate (at least the exposed end), and in some cases perform limited chemical and radiological investigations of the pipelines. Many of the pipelines were not identified on drawings. Some of the pipelines were included in other waste sites, thus, gaps exist in the numbering of the pipelines included in this waste site. Large-diameter pipeline generally means pipeline greater than 50.8 centimeters (20 inches).

Waste Type: Soil

Waste Description: Contaminants of Potential Concern are listed only for sites known to have contaminants. (DS-100BC-002) Contaminants of potential concern are asbestos, semivolatile organic analytes, phenanthrene, fluoranthene, pyrene, benzo (a, b, and k) anthracene, chrysene, mercury, and lead. (DS-100BC-016) The potential contaminants of concern are asbestos, lead, and arsenic. (DS-100BC-019) The potential contaminants of concern are americium-241, and asbestos. (DS-100BC-022) The potential contaminants of concern include asbestos.

This Site has the Following SubSites:

Code: 100-B-21
Names: 100-B-21; Steel Pipeline Segment

Code: 100-B-21:1
Names: 100-B-21:1; Steel Pipeline Segment

Code: 100-B-21:2
Names: 100-B-21:2; Asbestos/Tar Wrapped Pipeline

Code: 100-B-21:3
Names: 100-B-21:3; Asbestos Wrapped Steel Pipeline

Code: 100-B-21:4
Names: 100-B-21:4; Pipeline from the 105-C Reactor East to 116-C-2B Sump

Code: 100-B-21:1
Names: 100-B-21:1; Steel Pipeline Segment
Type: Process Sewer
Status: Inactive

Description: The two pipeline segments in this subsite have been evaluated and reclassified to No Action. The evaluation of these pipelines included site histories, analytical data, process knowledge, and field observations based on field screening, and laboratory data. In June 2007, during remedial activities, it was discovered that the DS-100BC-019 pipeline and DS-100BC-016...
pipeline were connected. Therefore, the DS-100BC-016 pipeline was incorporated with segment DS-100BC-019 that is part of the 100-B-21:3 subsite. Both DS-100BC-016 and DS-100BC-019 pipeline segments were removed.

The DS-100BC-016 pipeline segment consisted of a 20-centimeter (8-inch) diameter, east-west-running steel pipe found during excavation of waste site 100-C-6, the 100-C Reactor effluent underground pipelines. The pipe had an asbestos-containing tar-based spiral wrap. The pipeline segment that crossed the excavation of the 100-C-6 pipelines was removed. The pipeline was left in place at coordinates E565473, N144463.

The DS-100BC-022 pipeline segment consisted of a 2.5-centimeter (1-inch) diameter pipeline discovered during the remediation of the 100-C-3 site. The pipeline was documented in an area to the southeast of the 105-C Reactor near the former location of the 119-C sample building. The pipeline connected to a larger 10.2-centimeter (4-inch) pipeline south of where the smaller section of pipeline was discovered. The larger pipeline was a water supply line, and no contaminants of potential concern were identified beyond the asbestos commonly found in the wrapping on this type of pipe. The small pipeline was considered analogous to the larger pipeline.

**Location:** The pipeline crosses along the east edge of 100-C-3. Coordinates are E 565396, N143951. The elevation is about 1.5 m (5 ft) below grade.

**Waste Type:** Soil

**Waste Description:** The waste is piping and potentially contaminated soil.

**Closure Info:**

NOTE: In June 2007, during remedial activities, it was discovered that the DS-100BC-019 pipeline and DS-100BC-016 pipeline were connected. Therefore, the DS-100BC-016 pipeline segment was incorporated into the 100-B-21:3 subsite and both pipeline segments were removed. The DS-100BC-016 pipeline, mapped at Washington State Plane coordinates N 14463, E 565473, had been investigated separately and reclassified to No Action in the 100-B-21:1 subsite in 2006.

DS-100BC-016: Approximately 50 meters (164 feet) of the pipeline was disposed at the Environmental Restoration Disposal Facility. The potential contaminants of concern were asbestos, lead, and arsenic. On 9/24/2003, samples J00YH1 (Chemistry) and J00YJ0 (Field Screening) were collected. The pipeline analytical data results detected total chromium (26.4-mg/kg) and lead (48.4 mg/kg) above-background levels and confirmed asbestos (4-8% chrysotile) in the pipe wrap. The total chromium and lead results were above background, but below direct exposure levels. RESidual RADioactivity (RESRAD) analysis illustrated that total chromium and lead will not reach groundwater or the river within 1,000 years. Therefore, they are considered protective of groundwater and the river. The risk associated with asbestos was that of direct exposure to friable asbestos fibers. Because the asbestos on this pipe was suspended in a tar-based compound, it was considered nonfriable. The segment, therefore, does not require further remediation and was recommended for a No Action decision.

DS-100BC-022: A sample of the pipe wrap was taken in 2003 and tested for asbestos. The analytical result confirmed 3% to 8% chrysotile in the tar wrap on the pipe. The asbestos is in a nonfriable form and does not represent a risk warranting CERCLA action. The pipeline segment, therefore, does not require further remediation and is recommended for a No Action decision.

Evaluation of pipeline segments DS-100BC-016 and DS-100BC-22 used analytical data, process knowledge, and field observations that supports the reclassification to No Action. The evaluation has found this subsite to meet the cleanup objectives for direct exposure.
groundwater protection, and river protection.

Soil cleanup levels were established in the interim action ROD based on a limited ecological risk assessment. A baseline risk assessment for the river corridor portion of Hanford began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final ROD for the site.

The SubSite is Part Of:

| Code:     | 100-B-21 |
| Names:    | 100-B-21; 100-B/C Miscellaneous Pipelines |

| Code:     | 100-B-21:2 |
| Classification: | Accepted |
| Names:    | 100-B-21:2; Asbestos/Tar Wrapped Pipeline |
| Reclassification: | Interim Closed Out (6/16/2008) |
| Type:     | Process Sewer |
| Status:   | Inactive |
| Start Date: |
| End Date: |
| Description: | The 100-B-21:2 waste site has been remediated and Interim Closed Out. It consisted of the single pipeline segment originally designated as DS-100BC-002. This pipeline segment was described as a 2.5 cm (1-inch) diameter asbestos-wrapped metal pipe protruding 1.5 meters (5 ft) horizontally from the bank of the Columbia River. The northern end of the 100-B-21:2 pipeline, originally discovered at N145362, E565307, was located west of the 116-B-7 outfall structure and north of the 100-BC perimeter road. During remediation the pipeline was determined to extend due south, under the 100-BC perimeter road to the edge of 116-B-11 Retention Basin excavation boundary. |
| Location: | The pipeline is north of the 100-B/C perimeter road and north of the former location of 116-B-11 Retention Basin. The location was measured at 30.5 m (100 ft) east of the 116-B-7 flume east edge and 34 m (111 ft) north of the road. The pipeline was sampled at coordinates E 565307, N 145362, and elevation 132.086 m. |
| Process Description: | The history of the 100-B-21:2 pipeline, prior to its discovery in 2003, is unknown. The pipeline did not appear on the historical construction drawings. The location and orientation of the pipeline suggested that it was associated with the 116-B-11 Retention Basin and discharged to the river embankment. It was smaller than most drain lines, suggesting it was a pressurized water pipe, though the exact purpose remained unknown. |
| Waste Type: | Barrels/Drums/Buckets/Cans |
| Waste Description: | The waste is a small diameter pipeline and potentially contaminated soil. |
| Closure Info: | Remediation of the 100-B-21:2 waste site was performed from June 11 through June 18, 2007. The 100B/C perimeter road was closed to allow remediation. Asphalt removed from the road surface was segregated into a stockpile on the adjacent road surface for disposal at the Environmental Restoration Disposal Facility (ERDF). Overburden soils were removed from above the pipeline and placed into two stockpiles on the west side of the excavation. The pipeline, soil in contact with the pipe, and soil 0.3 meters (1 foot) below the pipeline were removed and disposed of at ERDF. A total of approximately 91 metric tons (100 US tons) of material was disposed at ERDF. No anomalies were discovered during the remedial action. An additional geophysical survey in March 2007 of the 100-B-21:2 pipeline segment was performed using ground penetrating radar with results similar to those found in 2003. The geophysical interpretation identified the pipeline and noted low amplitude anomalies (thought to be large boulders) in the subsurface. |

**Description:**  
The subsite has been remediated and Interim Closed Out. In 2003, the DS-100BC-019 pipeline was described as a 20 cm (8-in.) diameter steel pipe with an asbestos-containing, tar-based spiral pipeline wrap and mechanical joints. This pipeline protruded from a sidewall of a railroad track bed cut, located just south of the 116-B-15 Percolation Pit, and ran in a north-south direction.

In June 2007, during remedial activities, it was discovered that the DS-100BC-019 pipeline and DS-100BC-016 pipeline were connected. Therefore, the DS-100BC-016 pipeline segment was incorporated into the 100-B-21:3 subsite and both pipeline segments were removed. The DS-100BC-016 pipeline, mapped at Washington State Plane coordinates N 14463, E 565473, had previously been investigated separately and reclassified as No Action in the 100-B-21:1 subsite.

**Location:**  
The subsite is directly south of the 116-B-15 waste site. DS-100BC-019 located at Washington State Plane coordinates N 144494, E 565528. DS-100BC-016 located at Washington State Plane coordinates N 14463, E 565473.

**Waste Type:** Demolition and Inert Waste

**Waste Description:**  
The waste is piping and potentially contaminated soil.

**Closure Info:**  
In March 2007, geophysical surveys were performed over the site using ground-penetrating radar (GPR). A linear anomaly that was interpreted to be the target pipeline was oriented north-south and continued to the southern edge of the investigation area where it was obscured by a highly reflective horizon. It was uncertain whether the pipeline continued past the southern boundary of the survey area; however, during remedial activities it was verified that the pipeline extended past the boundary. In September 2007, GPR was used to trace the pipeline from the last exposed point in the excavation; the line was interpreted to bend to the west and extended approximately 60 m (200 ft) to the location of the DS-100BC-016 pipeline.

In June 2007, during remedial activities, it was discovered that the DS-100BC-019 pipeline and DS-100BC-016 pipeline were connected. Therefore, the DS-100BC-016 pipeline was incorporated into the 100-B-21:3 subsite and both pipeline segments were removed. The DS-100BC-016 pipeline, mapped at Washington State Plane coordinates N 14463, E 565473, had previously been investigated separately and reclassified as No Action in the 100-B-21:1 subsite. In June 2007, overburden soils were removed from above the pipeline and placed into two stockpile areas. Remedial activities continued through January 2008, with a total of approximately 850 metric tons (940 US tons) of material being disposed at the Environmental Restoration Disposal Facility. The waste consisted of the DS-100BC-019 and DS-100BC-016 pipelines, soil in contact with the pipelines, and soil 0.3 meter (1 ft) below the pipeline. On June 13, 2007, approximately 40 liters (10 gal) of liquid was released to the soil from the DS-100BC-019 pipeline. Although the liquid was suspected to be dust-suppression water that had been applied during remediation, the impacted soil was placed in a plastic-lined area east of the excavation. The liquid and soil were sampled, and analytical results indicated no contaminants...
above cleanup level. The soil and plastic liner were disposed at ERDF. The area that contained
the staged soil was not included in the verification sampling design due to the fact that it had
been lined with plastic prior to placement of soil, and data results indicated that the impacted
soil had no contamination above cleanup levels.

<td>Description:</td>
<td>The 100-B-21:4 subsite has been remediated and Interim Closed Out. It was previously identified as the DS-100BC-044 discovery pipeline segment. The 20-cm (8-in.) stainless steel, radioactive chemical waste pipeline was at a depth of 6.1 m (20 ft) below ground surface (bgs). The pipeline ran from the northwestern corner of the 105-C Reactor Building, under the 105-C Metal Examination Facility (MEF), and discharged into the 116-C-2B Pluto Crib Pump Station. Although there is documentation of a smaller pipeline exiting the MEF and connecting to the DS-100BC-44 pipeline, this smaller pipeline or residual connection joints were not found during remediation, and they are assumed to have never been present. Drain lines from the MEF to the 116-C-2B sump and other facilities are believed to have been removed during decontamination and decommissioning activities at the 105-C Reactor Building or during field remediation of the 100-C-6:1 process effluent pipelines.</td>

<td>Closure Info:</td>
<td>Remedial action at the waste site was performed in April 2009. The site was excavated to a depth of 7.5 meters (25 ft), generating approximately 7,095 bank cubic meters (BCM) (9,280 bank cubic yards [BCY]) of overburden material stockpiled for evaluation for use as clean backfill. The excavation encountered and disposed of approximately 64 meters (210 ft) of 20-cm (8-in.) stainless steel pipeline encased in concrete. Approximately 400 BCM (523 BCY) of debris and soil were sent for disposal at the Environmental Restoration Disposal Facility (ERDF).</td>

Description: To facilitate remedial activities, the site was divided into two subsites. Subsite 1 consists of the underground transfer piping that interconnected the 100-B Area Water Treatment Facilities and associated soils and was reclassified to No Action. Subsite 2 consisted of the water treatment facility structures (183-B Filter House, 185-B Deaeration Building, 195-B Process Pump House). The facilities associated with 100-B-22:2 were demolished and Subsite 2 was Interim Closed Out. Since both subsites have been reclassified, the parent site is also considered Interim Closed Out.

Location: The water treatment facilities occupied an area approximately 275 meters (900 feet) wide by 365 meters (1200 feet) long and were 91 meters (300 feet) directly west of the 105-B Reactor Building.

The location of each facility include:

The 183-B Filter Plant structures were located along the centerline N144511 and between E564776 and E564846.
The headhouse was located at E564781 N144511.
The 12 flocculation basins were located at E564790 N144511.
The 12 sedimentation basins were located at E564809 N144511.
The filter building was located at E564839 N144511.
Storage tanks were located at E565112 N144511.
The process pump house was located at E565144 N144511.

Release Description: One dichromate release was noted as "a large spill in September 1966" (WHC-MR-0425), but was believed to have occurred on the north side of the 183-C Headhouse (per employee discussion September 2004).

Related Sites/Structures: 126-B-2 (183-B Clear Water Reservoir), 132-B-1 and 100-B-14 (108-B Chemical Pump House), 105-B Reactor

Process Description: The 100-B Area Water Treatment Facilities were operated from 1944 until 1968, they provided large volumes of high-quality cooling water to the 105-B Reactor. The primary facilities (in the order of the treated water flow) included: 181-B River Pump House or Head House, Flocculation and Sedimentation Basins, Filter Building, 183-B Clear Water Reservoir (126-B-2) and Pump Room; the 185-B Deaeration Facility, the 190-B Process Pump House; and the 108-B Chemical Pump House (132-B-1). Water was removed from the Columbia River by pumps at the 181-B River Pump House and stored temporarily at the 182-B Reservoir. From 182-B, the water was pumped to the 183-B Filter House, where it was treated for use as process cooling water for the B Reactor. Here, chlorine was added to control algae, and sulfuric acid was added to lower the water pH to 7.5 for the coagulation and filtration process. Coagulants included alum, ferric sulfate, and Separan. Following coagulation and settling, the water passed through filters consisting of anthracite coal, sand, and gravel. After filtration, lime was added to raise the pH back to 7.8, and the water was stored temporarily in underground clearwells. The clarified water was next passed through the 185-B Deaeration Plant, where sodium dichromate was added at a rate of 2 parts per million. Until 1950 the sodium dichromate was mixed at the 108-B Chemical Pump House and sent via underground piping to storage tanks inside the 183-B Building. After 1950, sodium dichromate mixing was moved to 183-B. The actual injection points for the sodium dichromate were at the intake header for the storage tanks in the 190-B Process Pump House.

Waste Type: Sanitary Sewage

Waste Description: Decommissioning of the 185-B Deaeration Plant, 190-B Process Pump House, and associated pipe tunnels, generally allowed any portion of a structure that was 1 meter (3 feet) below grade to be left in place. Foundation concrete for both buildings, as well as the demolished parts of the tunnels, remain underground, generally within the area bounded by E565103 and E565245,
and N144444 and N144584.

**Waste Type:** Sanitary Sewage

**Waste Description:** Two 75,700 liter (20,000 gallon) acid storage tanks, believed to contain concentrated sulfuric acid, were located 12.2 meters (40 feet) south of the south end of the 185-B Deaeration Plant. Acid was unloaded from railroad cars near this location and acid was transferred from these tanks into the Deaeration Plant. The sulfuric acid was contaminated with significant concentrations of lead and mercury. It is prudent to assume unplanned and unreported leaks and spills of this acid may have occurred during the many years of operation of this plant. No records have been found to indicate that soil samples for lead and mercury were taken from this area during or after decommissioning. The tanks were located at E565113, N144451.

**Waste Type:** Sanitary Sewage

**Waste Description:** Contaminants of Potential Concern: Contaminants of potential concern (COPCs) include lead, mercury, hexavalent chromium, and polychlorinated biphenyls (PCBs). Fill material was placed over potentially contaminated soil. Sulfuric acid was added at the 183-B Head house for more than 20 years. Much of the sulfuric acid was known to be contaminated with significant amounts of lead and mercury. The sulfuric acid was unloaded at the facility from two railroad car locations. It is reasonable to assume that, during the early hectic years of operation, some unplanned and unreported spills may have occurred. No record has been found that the soil in the area of the headhouse was sampled and tested for lead and mercury prior to backfilling.

**Waste Type:** Sanitary Sewage

**Waste Description:** Best available information (Sharpe and Linville 2000, Plate 4) indicates that the underground piping connecting the 183-B Filter House and the 185-B/190-B Process Pump House is still in place. The lines are up to 600 meters (1,968 feet) long, and include reinforced concrete, cast iron, and steel pipes up to 137 centimeters (54 inches) in diameter. The paths of the lines are generally north of and parallel to an existing road, N144406; and south of and parallel to an existing road, N144631.

**Waste Type:** Sanitary Sewage

**Waste Description:** Fill material placed over potentially contaminated soil and demolished concrete structures. The concrete flocculation and sedimentation basins were collapsed into themselves, and backfilled at least partially with waste material. No record has been found characterizing this waste material, nor has a record been found that any soil samples were taken.

**Description:** The pipelines in this subsite were evaluated and determined to require No Action. The subsite consists of the underground transfer piping that interconnected the 100-B Area Water Treatment Facilities and associated soils. The 100-B-22:1 Pipelines and Associated Soils waste

*Hanford Site Waste Management Units Report*
February 2015
site is limited to pipelines that interconnected the 183-B Filter House (including the 126-B-2 Clearwells), the 185-B Deaeration Plant, and the 190-B Process Pumphouse. All of the 100-B-22:1 pipelines are larger than 0.15 meter (6 in.) in diameter and were used for cooling water.

Location: The 100-B-22:1 pipelines are located in the 100-BC-1 Operable Unit in the 100-B/C Area of the Hanford Site, west of the 105-B Reactor.

Process Description: Process knowledge indicated that the pipelines were upstream of facilities where sodium dichromate was added to the process water and of the 105-B Reactor. Also, process knowledge confirms that the chemical additives used to produce the process/cooling water were distributed in smaller volumes than the process water and were transferred in much smaller pipelines. Generally, the chemical transfer lines were 0.08 meters (3in.) or smaller in size. The pipelines, therefore, would not have received discharges containing elevated levels of radionuclides or metals, including lead and hexavalent chromium. Originally, the sodium dichromate was brought into the 185-B/190-B Buildings as a concentrated solution through the sodium dichromate lines (100-B-14:5) that entered on the north side of the building. Cooling water pipelines between the 190-B Building and the 105-B Reactor were part of 100-B-14:4 waste site.

Waste Type: Sanitary Sewage

Waste Description: The waste is the underground piping and associated soils.

Closure Info: The RSVP indicated that the only additives to the process water in the pipelines came from the 183-B facility. Chemicals added at the 183-B facility included chlorine, sulfuric acid, alum, ferric sulfate, Separan (a coagulant), and lime. Sulfuric acid used for water treatment at the Hanford site, historically had lead and mercury contamination. Where sulfuric acid was spilled or otherwise allowed to collect, lead and mercury have been found above the remedial action goals. These areas were most commonly associated with the transportation and handling of concentrated sulfuric acid. Trace contamination from the sulfuric acid that was added to adjust the pH of the water, would be dilute in the cooling water. There was no evidence to suggest that the pipelines were ever a source of human health risk due to the addition of sulfuric acid.

Considering that the process water routed in the 100-B-22:1 pipelines was relatively clean, the primary risk from pipelines in the area of the 100-B Water Treatment Facilities was identified as the chemical transfer lines. The chemical transfer lines distributed concentrated sodium dichromate solution, sodium silicate solution, and sulfuric acid to buildings in the area.

Examination of excavated trenches as well as historical documents and drawings indicated that all of the pipelines were larger than 0.15 meters (6 inches) in diameter and were used for cooling water, not for the transfer of concentrated chemical solutions. Three small-diameter pipelines, used as chemical transfer lines, were found plumbed into the 183-B and 190-B Buildings. Two of these pipelines, the sodium dichromate and the sodium silicate pipelines connected the 108-B Building to the 185-B/190-B Buildings and are part of sitecode 100-B-14:5. The third small-diameter pipeline was determined to be the sodium dichromate line, designated as the 100-B-28 waste site. Remediation of the 100-B-28 site is expected in 2007.

Three other small-diameter pipelines, used as chemical transfer lines, were found plumbed into the 183-B and 190-B Buildings. Two of these pipelines, the sodium dichromate and the sodium silicate pipelines (100-B-14:5) connected the 108-B Building to the 185-B/190-B Buildings. The 100-B-14:5 site has been determined to require no action based on confirmatory evaluation. The third small-diameter pipeline has been identified as the sodium dichromate line designated as the 100-B-28 waste site. Remediation of the 100-B-28 site was approved in 2010.

The basis for the No Action determination precluded the need for sampling at this site.
Therefore a comparison between soil data and ecological screening levels was not necessary. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which included a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final closeout decision for this site.

Reclassification evaluations have illustrated that residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario. The evaluations also demonstrated that residual contaminant concentrations support unrestricted future use and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

**Names:** 100-B-22:2; 183-B Filter House, 185-B Deaeration Building, 195-B Process Pump House and Associated Soils; Water Treatment Facilities and Surrounding Soils

**Type:** Dumping Area

**Status:** Inactive

**Description:** 100-B-22:2 subsite has been remediated and Interim Closed Out. It consisted of the 183-B Filter House, 185-B Deaeration Plant, and 190-B Process Pumphouse footprints and associated soils. The 183-B clearwells are excluded from this waste site, as they are addressed separately as the 126-B-2 waste site. These facilities were designed to supply, treat, store, and transport cooling water to the 105-B Reactor. The facilities have been decommissioned and demolished to approximately 1 meter (3 ft) below ground surface.

In 2006 and 2009, confirmatory samples were collected from test pits that targeted the entry points for process chemicals into the facilities. Visual investigation and focused sampling was done. Based on confirmatory sample results, it was determined that soil remediation was required only for a small drain line associated with the 183-B headhouse. The remediation was performed in May 2009, by excavating approximately 40 bank cubic meters (50 bank cubic yards) of pipe debris and soil and disposing it at the Environmental Restoration Disposal Facility.

**Location:** The 185-B/190-B Building was approximately 100 meters (330 feet) west of the 105-B Reactor; the 183-B Building was approximately 400 meters (1/4 mile) west of the Reactor.

**Process Description:** The 105 B Reactor was a single-pass reactor, so cooling water was not recycled after its initial use. All water had to be treated and conditioned prior to use in the reactor to prevent pipes within the reactor from corroding and to prevent constituents dissolved in the water from precipitating and eventually restricting flow through the aluminum pipelines used for cooling the core of the reactor. Cooling water was pumped from the Columbia River via the 181-B river pumphouse into the 182-B reservoir. From the reservoir, water flowed into the 183-B Treatment Plant where it was treated with chlorine, sulfuric acid, and coagulants such as alum, ferric sulfate, and Separan. After flocculation, particle settling, and filtration, the clarified water was stored in large underground clearwells. From the clearwells, water flowed to the 185-B Deaeration Plant via the 100-B-22:1 cooling water pipelines. The 185-B Deaeration Plant was never used for deaeration as originally intended. It did, however, contain two 3,785 liters (1,000-gal) storage tanks where concentrated sodium dichromate solution was stored. Originally, the sodium dichromate solution was mixed and piped in from the 108-B Building. In
the early 1950's, the sodium dichromate mixing was moved into the 185-B Building. The sodium dichromate solution was added to the cooling water lines at the common wall of the 185-B and 190-B facilities. Cooling water was stored in the 190-B Process Pumphouse in four 6.62 million liters (1.75 million gallons) tanks. Water stored in the 190-B Process Pumphouse was available for use in the 105 B Reactor on an as-needed basis via piping in underground tunnels (100-B-14:4 subsite).

**Waste Type:** Sanitary Sewage

**Waste Description:** The remaining footprint of these facilities contains inert concrete debris and structural material below 1 meter (3 feet) below ground surface, along with other clean fill used to bring the site to grade. Fill material placed over potentially contaminated soil and demolished concrete structures.

**Closure Info:** In 2006 and 2009, confirmatory sampling was collected from four Test Pits. Visual investigation and focused sampling was done. The samples targeted the entry points for process chemicals into the facilities. Based on confirmatory sample results, it was determined that soil remediation was required only for a small drain line associated with the 183-B headhouse. The drain was located within the railcar park at the 183-B headhouse. The contamination was likely related to spillage and washout collection, rather than a leak in the line. It was excavated in September and November 2006, revealing a 7.6 centimeter (3-in.) cast iron pipe extending approximately 0.6 meters (2 ft) below ground surface (bgs). The pipeline was excavated up to the edge of an exterior concrete pad at the former 183-B headhouse, where it entered the facility. It presumably connected with one of the sumps associated with the 100-B-14:3 Process sewers. Samples were collected from stained soils beneath the former railroad tracks near the drain and from soil underlying the pipeline where it entered the 183-B facility.

Soil staining was observed beneath railroad ties, as previously observed and sampled during confirmatory sampling. Results from confirmatory sampling of this material and sampling analogous staining associated with railroad ties at other 100-B/C locations have demonstrated that no hazardous constituents are present above cleanup levels in these soils. Stained soils and decayed wood material were also observed along the southern side of the concrete footing beneath the drain line. Stained soils and concrete were also observed at the southeastern corner of the excavation. No samples were collected from this material at the time of remediation.

The remediation was performed in May 2009, by excavating approximately 40 bank cubic meters (50 bank cubic yards) of pipe debris and soil and disposing it at the Environmental Restoration Disposal Facility. Remediation proceeded to a maximum depth of approximately 0.9 meters (3 ft) at the eastern end, removing at least 0.3 meters (1 ft) of soil underlying the drain line and soils disturbed during previous confirmatory sampling activities. The 183-B facility foundation was observed to continue beyond the depth of excavation at the eastern end, and a concrete footing is evident beneath the drain line where it enters the facility.

**The SubSite is Part Of:**

**Names:** 100-B-22; 100-B Water Treatment Facilities, Pipelines, and Surrounding Soils

---

Hanford Site Waste Management Units Report

February 2015
led from the 116-B-7 outfall structure to the river shoreline. The flume was decommissioned and backfilled in 1979.

Location: The site was located northwest of 116-B-11 Retention Basin and upstream of the 132-B-6 Outfall. The remaining portion of the spillway is 18 meters (60 feet) downstream of, and parallel to, the river effluent pipeline.

Related Sites/Structures: The site was associated with the 100-B-15 River Effluent Pipelines and the 116-B-7 Outfall Structure.

Process Description: The spillway was an alternate discharge point for the 116-B-7 Outfall Structure. The spillway was to be for an emergency effluent release or if the 100-B-15 river effluent pipelines were blocked, damaged, or undergoing maintenance. There was no corroborated physical or historical evidence that the spillway was ever used.

Waste Type: Demolition and Inert Waste

Waste Description: No evidence has been found that the flume was ever put into service. If it had been used the COPCs for the 100-B-24 spillway would be the same as those for the 116-B-7 outfall structure, which are as follows: americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, strontium-90, total chromium, hexavalent chromium, lead, and mercury.

Closure Info: Between July and December of 2001, the 116-B-7 outfall structure was removed and disposed along with the upper portion of the spillway. The remaining concrete spillway structure was partially covered with clean fill down to the normal water level at the river shoreline. The spillway was excavated, sampled, and analyzed for chemicals and radionuclides. The contamination was bound in the concrete structure. It was concluded that remedial action to remove the concrete had the possibility of destabilizing the riverbank. To avoid and minimize the impacts on the river and the local ecosystem of the release of soils and sediments into the river, it was reasonable to conclude that there was a greater risk posed to the river and the local ecosystem by a removal action than was posed by leaving it in its current state.

---

Code: 100-B-25  Classification: Accepted
Names: 100-B-25; 132-B-6 Spillway (Flume)  Reclassification: Interim Closed Out (1/13/2010)
Type: Outfall  Start Date: 
Status: Inactive  End Date: 
Description: The site has been remediated and reclassified to Interim Closed Out. The site consisted of a concrete Spillway (also referred to as a flume) that led from the 132-B-6 outfall structure, via a heavy riprap extension on the end of the concrete spillway, to the river shoreline. During decommissioning projects in the 1979, the spillway walls were collapsed and the structure was covered with clean soil.

Location: The site was located north of the northeast corner of the 116-B-11 (107-B Retention Basin) and downstream of 116-B-7 (the 1904-B1 Outfall).

Related Sites/Structures: The site is associated with the 100-B-15 River Effluent Pipelines and the 132-B-6 Outfall Structure.

Process Description: The spillway was an alternate discharge point for the 132-B-6 Outfall Structure. It was planned to be used only if the 100-B-15 river effluent pipelines were blocked, damaged, or undergoing maintenance. There is no corroborated historical information that the spillway was ever used.

Waste Type: Sanitary Sewage
**Waste Description:** Possible chemical and/or radionuclide contamination (see Contaminants of Potential Concern). No evidence has been found that the flume was ever put into service. If it had been used, the COPCs for the 100-B-25 spillway would be the same as those for the 132-B-6 outfall structure, which are as follows: Americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, strontium-90, total chromium, hexavalent chromium, lead, and mercury.

**Closure Info:** Radiological surveys were performed along the 100-B/C Area shoreline during 2002 and 2003, as part of the 100-B/C pilot study. Gamma readings up to 8,170 counts per minute were observed at the surface in the exposed riprap, portions of the 100-B-25 Overflow Spillway. Based upon this information, the decision was made to include the 100-B-25 overflow spillway for the remove, treat, and dispose process. Excavation of the 132-B-6 Outfall sump in 2001 included removal of the upstream portion of the 100-B-25 spillway that was located within the excavation layback. Remedial action at the 100-B-25 waste site was performed between February 3 and March 14, 2009. Remediation encompassed the removal of a large volume of overburden that had been added in 2001, after the upper portion of the spillway was removed during the 132-B-6 Outfall remediation. The remaining spillway structure was unearthed and removed. Basalt rocks that formed the riprap on the slope to the Columbia River were removed for disposal due to elevated radiological readings. The site was excavated to a maximum depth of approximately 5 meters (16 ft) below grade, resulting in the removal of approximately 2,682 bank cubic meters (BCM) (3,504 bank cubic yards [BCY]) of material for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 4,991 BCM (6,521 BCY) of soil (overburden) was stockpiled for evaluation as clean backfill. Material awaiting disposal in the waste staging piles was removed and disposed at ERDF in July 2009.

**Code:** 100-B-26  
**Classification:** Accepted  
**Names:** 100-B-26; 132-C-2 Spillway (Flume)  
**Reclassification:** Interim No Action (9/18/2006)  
**Type:** Outfall  
**Start Date:**  
**Status:** Inactive  
**End Date:**  
**Description:** The site has been sampled and found to meet the requirements for reclassification to No Action. The flume was decommissioned and backfilled in 1979. The 100-B-26 Spillway (also referred to as a flume) was constructed of concrete and led from the 132-C-2 outfall structure to the river shoreline. During 2001, the 132-C-2 Outfall Structure was removed and disposed. At the same time, most of the upper portion of the spillway was also removed and disposed.  
**Location:** The site was located just north of 116-B-11 (the 107-B Retention Basin) and downstream of 132-B-6 (the 1904-B2 Outfall). The remaining portion of the spillway was along a centerline from E 565724, N 145498, a minimum of 7 meters (23 feet) due north to E 565724, N 145505. The top half of the remaining spillway was concrete, and the bottom half was heavy riprap.  
**Related Sites/Structures:** The site was associated with 100-B-15 (the 100-B/C River Effluent Pipelines) and 132-C-2 (the 1904-C Outfall Structure).  
**Process Description:** The spillway (also referred to as a flume) was constructed of concrete and led from the 132-C-2 outfall structure, via a heavy riprap extension on the end of the concrete spillway, to the river shoreline. During decommissioning projects in the 1979, the spillway walls were collapsed and the structure was covered with clean soil. The upper portion of the spillway was removed in 2001 as part of remediation of the outfall structure, and the remainder of the spillway/riprap was backfilled with clean soil. The spillway was an alternate discharge point for the 132-C-2 Outfall Structure. It was planned to be used as
an alternate for effluent only if the 100-B-15 river effluent pipelines were blocked, damaged, or undergoing maintenance. There was no historical information that the spillway was ever used.

Waste Type: Sanitary Sewage

Waste Description: If ever put into service, the COPCs for the 100-B-26 spillway would be the same as those for the 132-C-2 Outfall, which are as follows: Americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, strontium-90, total chromium, hexavalent chromium, lead, and mercury.

Closure Info: Confirmatory sampling of the waste site was conducted on January 17, 2006. Heavy equipment was used to excavate through the riprap, and the underlying soils were sampled. The sample results indicated that six constituents slightly exceeded remedial action goals for the protection of groundwater and the Columbia River. The contamination is bound to the concrete structure. The residual contaminants within the spillway present little risk to human health and the environment compared to the effect remediating the spillway could have on the Columbia River and its shoreline.

The riprap section of the spillway remains, with the upper portion covered by clean fill. A rudimentary road crosses the otherwise exposed lower riprap section. The site was reclassified to No Action because remediation to remove the riprap and underlying soils presented the possibility of destabilizing the riverbank and disturbing the existing ecosystem.

Code: 100-B-27

Names: 100-B-27; Sodium Dichromate Spill
Type: Unplanned Release
Status: Inactive

Description: The site has been remediated and Interim Closed Out. It was an unplanned release of sodium dichromate that was discovered while removing the western staging pile associated with the cleanup of the 126-B-3 Coal Pit.

Soil contamination associated with the spill consisted of a fairly narrow, near-vertical plume in the upper vadose zone (to approximately 11 meters [36 ft] below ground surface [bgs]). Below this depth, the plume continued downward in a generally northeasterly direction. Soil contamination was found down to the groundwater table, located approximately 13.5 meters (44 ft) bgs.

Location: The site was located 50 meters (164 ft) west of the former 126-B-3, Coal Pit.

Related Sites/Structures: The site may be related to a temporary receiving and storage warehouse. The Plot Plan for 100-B Area shows a material storage platform on the west end of the receiving warehouse. Initially, sodium dichromate was used in dry form thus, the platform was likely used for material offloading from railroad cars. A railroad spur diverted from the main railroad track north of the material handling platform. It extended east with 305 meters (1000 ft) of track before it rejoined the main track. The site was associated with 126-B-3.

Process Description: The source of contamination was unknown, but may have been related to a temporary receiving and storage warehouse that was located near the northern railroad spur. The warehouse was likely used for material offloading and storage from the railroad cars. Sodium dichromate was used in dry form at 100-B/C and transported via railroad until about 1955, when receipt of incoming sodium dichromate as a liquid solution began. The 100-B-27 waste site is believed to be associated with spillage and/or dumping of unknown amounts of sodium dichromate.
Waste Type: Sanitary Sewage

Waste Description: The contaminant of potential concern is Cr6. Sample results for J030K6 show greater than 500 mg/kg total chromium (15,000 ug/L chromium by TCLP). Elevated chromium concentrations were also detected in waste characterization samples that were collected from segregated soil (J03CP6 and J03CP7). The waste was soil contaminated with sodium dichromate. The suspected source of the sodium dichromate is consistent with handling and delivery of this material in bagged dry form. Sodium dichromate was delivered in dry form until about 1955 when modifications were made to use liquid sodium dichromate.

Closure Info: Initial remediation was performed from June 18 to 20, 2007, with excavation extending to approximately 4.6 meters (15 ft) below ground surface (bgs). Approximately 900 metric tons (1,000 U.S. tons) of contaminated material was removed. Additional characterization showed that contamination extended to groundwater, so a decision was made to postpone remedial action until 2009.

Remediation resumed in February 2009, removing contaminated material until the groundwater table was encountered at approximately 14 meters (46 ft) below ground surface. As remediation proceeded, rising Columbia River levels resulted in groundwater seeping into the excavation at approximately 13.5 m (44 ft) bgs. Excavation activities were completed on June 9, 2009. A total of approximately 10,190 bank cubic meters (BCM) (13,330 bank cubic yards [BCY]) of contaminated soil and 40,180 BCM (52,550 BCY) of overburden/layback soil were excavated. The contaminated soil disposed at the Environmental Restoration Disposal Facility.

Well 199-B5-1 (C7505) was drilled to a depth of 189 feet in January 2010 to assess the depth of contamination.

---

Reclassification:

100-B-28; 183-C Headhouse to 183-B Pumphouse Sodium Dichromate Transfer Pipeline

Product Piping

Inactive

Classification: Accepted

Reclassification: Interim Closed Out (3/22/2010)

Start Date:

End Date:

Description: The waste site has been remediated and Interim Closed Out. It consisted of an underground sodium dichromate pipeline from the 183-C Head House to the 183-B Filter Plant/Pump House. The pipeline was originally a soft water supply line from the 184-B Power House to the 183-C Head House.

The 7.6-centimeter (3-inch) steel line for supplying soft water from the 184-B Power House to the 183-C Head House was modified per the drawing (H-1-10350) at a point due east of the 183-B Filter Plant/Pump House in about 1962. The line from the 184-B Power House was blanked and a new line was run to the 183-B Filter Plant to allow use of the southern extent of the 3-inch steel line as a sodium dichromate transfer line from the 183-C Head House to the 183-B Filter Plant.

Location: The northern end of the waste site was located approximately 430 meters (1,410 ft) directly west of the 105-B Reactor. The southern end of the pipeline was 9 meters (28 ft) northwest of the former 183-C Filter Plant. The remaining southern portion of the pipeline is considered within the footprint of the 100-C-7:1 waste site.

Release Description: Concentrated sodium dichromate solution was drained from the "softwater" pipeline (1,2) that was excavated and opened during July-August 2005 at the 100-C-7 waste site (dichromate unplanned release) north of the 183-C Head House. The piping drawing (3) indicates the 7.6-cm (3-in) softwater line was modified in 1962 to serve as a sodium dichromate solution transfer method of delivery from the 184-B Power House to the 183-C Head House.
Process Description: Sodium dichromate solids and concentrated solutions were received, stored, and mixed with the reactor cooling water as a corrosion inhibitor for the reactor fuel and piping. Initially, granular sodium dichromate was mixed with water to prepare a 15 Weight Percent solution that was metered into the volute of the primary pumps in the 190-B Pump House to provide a 2 part per million (ppm) concentration of sodium dichromate in the reactor cooling water. Later, the solid sodium dichromate feedstock was replaced with a concentrated (70% by weight) sodium dichromate solution that was metered into the cooling water to produce the 2 ppm concentration of sodium dichromate. The southern section of the soft water line was isolated from the 184-B Power House supply line at a point east of the 183-B Filter Plant and the northern section was blanked. A new pipeline segment was installed to connect the southern section of the pipeline to the 183-B Filter Plant.

Related Sites/Structures: 183-C Head House; 183-C Filter Building/Pump Facility; 184-B Power House

Waste Type: Sanitary Sewage

Waste Description: Concentrated sodium dichromate solution was drained from the converted softwater pipeline (1-3) excavated and opened at the 100-C-7 waste site (dichromate unplanned release) north of the 183-C Head House. The 7.6-cm (3-in) softwater line was modified in 1962 to serve as a sodium dichromate solution transfer line from the 183-C Head House to the 183-B Filter Plant.

Closure Info: Remedial action at the site was performed from February to April 2009. Remediation included removing and staging overburden material, hot tapping, draining, and collecting the pipeline liquid; size-reducing and removing the pipeline, and removing and staging contaminated material for disposal at the Environmental Restoration Disposal Facility (ERDF). Two sections of pipeline beneath active utility lines were grouted in-place. The potential for pipe leakages beneath these sections could not be addressed while the utilities remain active. Therefore, in agreement with DOE-RL and EPA, these two sections will be administratively removed from the site and placed in a new waste site created to collect components from various waste sites that cannot be remediated while utilities remain active.

The grout-filling campaign for the two sections of pipeline that were left in place was initiated on April 13, 2009, and completed on April 14, 2009. The grout was pumped into the northern section of the 100-B-28 pipeline. This section of pipeline, approximately 26 meters (85 ft) in length, was located beneath an active pipeline supplying water for fire suppression water. During grout addition, approximately 76 liters (20 gal) of sodium dichromate liquid was displaced, collected, and drummed. The second section of pipeline, approximately 26 meters (85 ft) long, ran beneath the export water line located at the southern end of the excavation. Approximately 38 liters (10 gal) of sodium dichromate liquid was displaced during grout addition. It was also collected and drummed.

During the excavation of the southern portion of the site, discolored soil was encountered at the base of the 7.6-cm (3-in.) pipeline. The worst of the discolored material soil was sampled (J18N79) for ICP metals and TCLP metals. Data results showed TCLP values for chromium at 130 mg/L. The material was Land Disposal Restricted requiring treatment for disposal at ERDF. Sampling was not performed on the less-impacted soils. However, it was conceded the material would qualify as LDR material. Approximately 40 BCM (52 BCY) of material required treatment. During removal of contaminated soil and a concrete encasement surrounding the grout-filled pipeline, a 6.1-meter (20-ft) section sheared off the end. This section was placed into an ERDF container. The remainder of the pipeline was grouted.

<td>Description:</td>
<td>The waste site has been remediated and Interim Closed Out. The site had been a Surface Contamination Area (SCA) found on the haul route from the 118-B-1 Burial Ground to the container transfer area. The area was previously posted as an SCA due to multiple locations of elevated radiological activity identified by LARADS. Field instrumentation indicated a location with approximately 3.4 million dpm/100 square centimeters beta/gamma activity at this spot. The hot spot measured approximately 25 square centimeters. The contamination at this location was matrixed with the asphalt and is believed to be a legacy of past practices and operations. Down-posting efforts following completion of remediation and closure activities in the area confirmed an area of significantly elevated radiological activity at the location listed. No other areas of significant elevated activity were identified along the posted haul route at the locations previously identified based on 2005 LARADS data.</td>

*Hanford Site Waste Management Units Report*
February 2015 40
Waste Description: The waste is contaminated soil. The contaminants of potential concern are radiological contaminants. The source of this material is unknown.

Closure Info: Remedial action was performed from May to August 2009. Remediation consisted of removing soils with elevated radiological activity identified with field instrumentation. Approximately 310 bank cubic meters (410 bank cubic yards) of contaminated soil was excavated and staged on site before being disposed at the Environmental Restoration Disposal Facility.

Two surface characterization samples were collected in April 2009. A post remediation radiological survey was done in August 2009. Following remediation, verification sampling was conducted in September 2009.

Names: 116-B-1; Process Effluent Trench; 107-B Liquid Waste Disposal Trench
Reclassification: Interim Closed Out (12/8/1999)
Start Date: 1/1/1950
End Date: 1/1/1968

Description: The site has been remediated and closed out. The 116-B-1 Liquid Waste Disposal Trench was dug to receive effluent routed from 116-B-11 (107-B Retention Basin). The unit ran from southwest to northeast. The site included the 40.6 centimeter (16 inch) diameter steel piping from 116-B-11. Historical documents described the trench as a french drain or an excavation that was partly or completely filled with coarse gravel and had dimensions of 61 meters (200 feet) long by 9.1 meters (30 feet) wide by 4.6 meters (15 feet) deep. A geophysical investigation of 116-B-1 performed in November and December 1996 showed the trench was almost twice as long as indicated by historical information (see Dimensions). The Ground Penetrating Radar (GPR) survey identified a pipeline, labeled #10 in the survey report, entering the trench at its southwest end. No other pipelines were evident. A significant volume of buried debris was present in the northeastern half of the trench.

Location: The site was located east of the 107-B Retention Basin.

Related Sites/Structures: The site was associated with the 107-B Retention Basin and the 107-C Retention Basin.

Waste Type: Demolition and Inert Waste
Waste Description: The site received effluent from the 107-B Retention Basin at times of high activity due to fuel element failures. The fission products of 54 fuel ruptures were routed to this site.

Waste Type: Demolition and Inert Waste
Waste Description: Geophysical investigation identified a high concentration of subsurface debris in the northeastern half of the trench.

Closure Info: Excavation of the 116-B-1 site began on October 6, 1998, by removing the overburden materials and underlying contaminated soil. Based on field screening, overburden materials that were identified as potentially clean were placed in stockpiles for potential use as backfill. Overburden materials that were found to be contaminated were disposed of at ERDF. On January 6, 1999, the excavation had reached the design limit at El. 128.0 m (438 ft). Soils not meeting direct exposure RAGs based on field screening results were excavated, loaded into shipping containers, and disposed of at ERDF. Cleanup verification sampling began on February 1, 1999, and was finished on February 24, 1999. At the completion of the remedial action and removal of the engineered structure, the excavation area floor was approximately 1,863.3 square meters (20,056 ft or 0.460 acres) at a depth of approximately 4.6 meters (15 ft),
and approximately 43,033 metric tons (47,436 tons) of material from the site were disposed of at ERDF. The excavation will be backfilled in the near future to the reference grade of El. 132.5 meters (438 ft). Clean backfill may be taken from the clean overburden pile and other sources of clean material that have been surveyed in accordance with the SAP (DOE-RL 1998a) and that are appropriate for use as backfill. Overburden from 116-B-1, 116-C-5, and pipeline excavation was segregated and sampled for potential use as clean backfill.

The maximum dose rate (all pathways) predicted from the RESRAD dose assessment model is 5 mrem/year in 1999, and decreases to 0.014 mrem/year in 1,000 years, based on samples taken from the excavation walls and floor. Hexavalent chromium is the only non-radionuclide carcinogenic contaminant of concern; the risk value was three orders of magnitude below the individual and cumulative risk limits.

<tr>
<td>Closure Info:</td>
<td>Excavation of the 116-B-2 site began on February 17, 1999, by removing the overburden materials and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. After completion of the initial excavation to design limits, several contaminated areas (i.e., plumes) were discovered. Each of the plumes was excavated and the new surfaces were screened for contamination. On May 20, 1999, the excavation had reached the final limit at El. 138.4 meters (454.2 feet). Cleanup verification sampling began on May 21, 1999, and was finished on June 24, 1999. At the completion of the remedial action, the excavation floor area was approximately 459 square meters (4,940 square feet) at a depth of approximately 4.9 meters (16 feet), and approximately 9,393 metric tons (10,354 tons) of material from the site had been disposed of at ERDF. The excavation was backfilled with clean fill materials to the reference grade of El. 143.3 meters (470.2 feet). Clean backfill may be taken from the clean overburden pile and other...</td>

sources of clean material that have been verified clean in accordance with the SAP (DOE-RL 1998) and that are appropriate for use as backfill.

The cleanup verification package (CVP) demonstrated that remedial action at the 116-B-2 site has achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and RDR/RAWP. Materials that contained COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils have been sampled, analyzed, and modeled to show that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. This scenario, described in Section 4.2 of the CVP, assumes multiple exposure pathways (e.g., ingestion, inhalation, direct exposure) for shallow zone soils. (The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone [i.e., below 4.6 meters (5 feet)] are required.) The verification package also demonstrated that residual COC concentrations pose no threat to groundwater or the Columbia River. Thus, the 116-B-2 site was verified to be remediated and may be backfilled.

---

**Code:** 116-B-3  
**Classification:** Accepted

**Names:** 116-B-3; 105-B Pluto Crib  
**Reclassification:** Interim Closed Out (2/24/2000)

**Type:** Crib  
**Start Date:** 1/1/1951

**Status:** Inactive  
**End Date:** 1/1/1952

**Description:** The 116-B-3 Pluto Crib has been remediated and was closed out on February 24, 2000. It is no longer marked or posted.

This unit was a wooden crib shored with railroad ties, filled with gravel and covered to grade with clean soil. A concrete marker indicates the position of the crib. Clukey (1954) indicates that the crib is a french drain, otherwise defined as a "tile or pipe buried vertically, sometimes gravel-filled". After its use, the crib was reportedly unearthed and shored with wooden ties.

**Location:** This unit was located within the 105-B Area exclusion fence, about 30 meters (100 feet) east of the 105-B Building and about 847 meters (2,780 feet) from the 100-year flood level of the Columbia River.

**Process Description:** This pluto crib received 105-B cooling water wastes that had been contaminated by cladding ruptures of fuel elements. Cooling water diversion occurred when a fuel element rupture was detected within a process tube. The water was diverted from the affected process tube through a valve on the rear of the reactor face known as a "pluto valve" and through rubber hose to the crib. The wooden crib was buried so that its upper surface was approximately at grade. A hatch on the upper surface was opened to receive the rubber hose and the crib was allowed to flood.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The site received effluent from reactor tubes containing ruptured fuel elements.

**Closure Info:** Excavation of the 116-B-3 site began on February 17, 1999, by removing the overburden materials and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. Cleanup verification sampling began on April 13, 1999, and was finished on May 12, 1999. At the completion of the remedial action, the area of the excavation was approximately 112.38 square meters (1,209.6 square feet) at a maximum depth of approximately 4.6 meters (15 ft).
Approximately 244 metric tons of material from the site were disposed at the ERDF. The excavation was to be backfilled with clean fill materials to the reference grade of El. 143 meters (469 feet).

The remaining soils have been sampled, analyzed, and modeled to show that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone [i.e., below 4.6 meters (15 feet)] are required. The verification package also demonstrated that residual COPC concentrations pose no threat to groundwater or the Columbia River. Thus, the 116-B-3 site has been verified to be remediated and may be backfilled.

### Code: 116-B-4
### Names: 116-B-4; 105-B Dummy Decontamination Disposal Crib; 105-B Dummy Decontamination French Drain
### Type: French Drain
### Status: Inactive
### Classification: Accepted
### Start Date: 1/1/1957
### End Date: 1/1/1968

**Description:** This site has been remediated and closed out. It is no longer marked or posted. The unit had a graded rock and sand bottom. It was marked with four yellow steel posts and had a curved stainless steel pipe in the center along with a painted concrete marker. The site included a feed pipe that originated at the 105-B Building.

**Location:** The 116-B-4 site was located near the center of the 100-B Area and was approximately 806.6 meters (2,646 feet) from the Columbia River and approximately 21 m (69 ft) south of 116-B-3 Pluto Crib.

**Related Sites/Structures:** The site was associated with the 105-B Building (118-B-8).

**Process Description:** The 116-B-4 French Drain received spent acid rinse water from the 105-B Dummy Decontamination Facility, which was used for the decontamination of fuel element spacers and other reactor hardware. The french drain was fed by a single, underground stainless steel pipe. Acids were neutralized within the 105-B Dummy Decontamination Facility prior to discharge to the french drain.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The site received spent acid and rinse water from the 105-B Dummy (fuel element spacers and reactor hardware) Decontamination Facility.

**Closure Info:** Initial, partial remediation of the 116-B-4 site was completed under the 100-B/C Demonstration Project. This phase began on July 11, 1995, and was completed on July 28, 1995. Additional contaminated materials (i.e., plumes) were identified during the 100-B/C Demonstration Project, but excavation was deferred until 1999. Deep zone cleanup verification samples were taken from the bottom of the 100-B/C Demonstration Project excavation in July 1995. Sampling and analysis activities were completed in accordance with the applicable Sampling and Analysis Plan and Quality Assurance Project Plan in the 100-BC-1 Excavation Demonstration Project Plan (DOE-RL 1995). Remediation began on July 11, 1995, under the 100-B/C Demonstration Project. Excavation of the initial waste site footprint was completed July 28, 1995. Additional contaminated material was identified to the north, south, east, and west.
After discussions with the decision makers, partial excavation of the plumes commenced on September 25, 1995. Excavation for the demonstration project was completed on December 18, 1995. Screening samples collected during excavation were analyzed at the Hanford Environmental Analysis Laboratory, and post-exavication verification samples were analyzed at the offsite Quanterra Laboratory. After verification sampling, the site was backfilled. Excavation to complete the remediation of the 116-8-4 site plumes began on February 17, 1999, by removing the overburden materials and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On April 4, 1999, the excavation had reached the design limit at El. 138.43 meters (454 ft). Cleanup verification sampling began on April 12, 1999, and was finished on May 6, 1999.

In February 1999, excavation began to complete the remediation of the 116-B-4 site plumes by removing the overburden materials and underlying contaminated soil. On April 4, 1999, the excavation had reached the design limit at El. 138.43 meters (454 feet). Cleanup verification sampling began on April 12, 1999, and was finished on May 6, 1999. The resulting data were used together with the 1995 data to support cleanup verification for the entire site.

At the completion of the remedial action, the excavation area floor was approximately 1,062 square meters (11,433 square feet) at a depth of approximately 4.6 meters (15 feet), and approximately 8,700 metric tons (9,590 tons) of material from the site had been disposed at ERDF.

<tr>
<td>Waste Description:</td>
<td>The site received liquid tritium wastes from the 108 Building. Only wastes of less than 1 microcuries/cubic centimeter were discharged to this unit.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>In June 1995, the site was excavated as part of the 100-B/C Demonstration Project. Remedial action was accomplished by excavating approximately 300 cubic meters (10,600 cubic feet) of soil from the crib and demolishing the concrete crib structure, leaving an open excavation approximately 34 meters (112 feet) by 8 meters (26 feet) to a 5 meter (16 feet) depth. The soils within and surrounding the crib were sampled and analyzed. The soils from cells C and D containing levels of tritium above cleanup standards were taken to the Environmental Restoration Disposal Facility (ERDF). All other soils sampled were within cleanup standards.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>A &quot;100 NPL Agreement/Change Control Form&quot; documenting the close out of the 116-B-5 Crib was submitted on January 8, 1997 and signed by the Environmental Protection Agency Project Manager on January 14, 1997. The form also authorized the backfilling of the waste site.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
This site has been remediated and closed out. An in-situ vitrification treatability test that was conducted in April, 1990.

The site was located immediately north of the 111-B Building Site.

The 116-B-6A Crib received radioactive liquid wastes from equipment decontamination performed in the 111-B Building, as well as from the decontamination of fuel element spacers.

This unit received radioactive liquid wastes from equipment decontamination performed in the 111-B Building, as well as from the decontamination of fuel element spacers performed at the 111-B Building Decontamination Station.

Excavation of the 116-B-6A/116-B-16 site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials shown to be contaminated were disposed of at the ERDF. On May 12, 1999, the excavation reached the design limit at El. 141.4 meters (464 ft). Cleanup verification sampling began on May 20, 1999, and was finished on June 18, 1999.

The cleanup verification package for the 116-B-6A Crib and 116-B-16 Fuel Examination Tank, because of their close proximity to each other and similar contaminants of concern (COCs), were excavated as one remedial action site and are hereinafter referred to as the 116-B-6A/116-B-16 site.

At the completion of the remedial action, the total excavation was approximately 603.5 square meters (6,496 square feet or 0.15 acres) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 5,072 metric tons (5,591 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The excavation will be backfilled in the near future (written June 6, 2000) with appropriate materials to the reference grade El. 146 meters (479 feet).

Results of the sampling, laboratory analyses, and data evaluations for the 116-B-6A/116-B-16 site indicate that all remedial action objectives and goals for direct exposure, protection of ground water, and protection of the Columbia River have been met. However, this site close out includes a deed restriction against drilling or digging into the deep zone soils (below 4.6 m [15 ft] depth).

This site has been remediated and closed out. The site was commonly known as the 116-B-6B Crib, although it has also been known as 111-B Crib No. 2 and as 116-B-6-2.
Location: The site is located approximately 9.2 meters (30 feet) southeast of the former 111-B Building site.

Related Sites/Structures: The site was associated with the 111-B Building.

Process Description: The unlined crib received radioactive wastes from equipment decontamination performed in the 111-B decontamination station, as well as liquid wastes from the decontamination of fuel element spacers.

Waste Type: Demolition and Inert Waste

Waste Description: The site received radioactive wastes from equipment decontamination performed in the 111-B Building as well as liquid wastes from fuel element spacer decontamination.

Closure Info: The Cleanup Verification Package (CVP-99-00017) demonstrates that remedial action at the 116-B-6B site has achieved the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) as established in the Interim Action ROD (ROD) (EPA 1995) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 1998).

Excavation of the 116-B-6B site began on March 11, 1999, by removing the materials and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. On March 12, 1999, the excavation reached the design limits at El. 144.28 meters (473 feet) and cleanup verification sampling was initiated. At the completion of the remedial action, the excavation floor was approximately 25 square meters (270 square feet) at a depth of 3 meters (9.8 feet). A total of approximately 263 metric tons (259 tons) of material were disposed at the Environmental Restoration Disposal Facility (ERDF). The excavation was to be backfilled with clean fill materials to the reference grade of El. 147.3 meters (483 feet).

Code: 116-B-7
Names: 116-B-7; 1904-B1; 1904-B-1 Outfall Structure
Type: Outfall
Status: Inactive
Description: The site has been remediated and closed out. The outfall was excavated, sampled and backfilled to match the surrounding grade.
Location: The site was located at the top of the river bank, northwest of 116-B-11 (107-B Retention Basin), upstream of 132-B-6 (1904-B-2 Outfall).
Related Sites/Structures: The site received effluent from the 100B process effluent lines (100-B-8), the 100B process sewer lines (100-B-14), and discharged effluent via the 100BC river effluent pipelines (100-B-15) and flumes (100-B-15:1).
Process Description: Outfalls were open, reinforced concrete structures that directed the water through either the river discharge pipelines or through spillways. The spillways were concrete flumes used when the river pipelines were blocked, damaged or undergoing maintenance.

Cooling water released from the reactor went to a retention basin located between the reactor building and the river. Water retention permitted thermal cooling and decay of short-lived radioisotopes prior to river discharge.

As reactor production increased, the hold-up period decreased. The basins also served to hold...
up flow of effluent with high radioactive isotope concentrations resulting from fuel element failure. This effluent was isolated and diverted, either by gravity or pumping, to an open pond area or crib. The pond or crib filtered the effluent through the ground. The cooling water discharged into the upper chamber of the concrete outfall structure, flowed through a bar grillwork and fell about 20 feet to the lower chamber of the outfall structure. The cooling water then overflowed from the lower chamber into the discharge pipe to the river.

### Waste Type:
Sanitary Sewage

### Waste Description:
The outfall was originally used for both process sewer and reactor cooling water disposal until 1954 when it was used exclusively for process sewer disposal.

### Closure Info:
Remedial action at the B/C Outfall sites began on June 4, 2001. Excavation of the three outfall sites (132-B-6, 116-B-7, and 132-C-2) involved removing the overburden materials and debris, the contaminated structure, and underlying contaminated soil. Overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at the ERDF. Cleanup verification sampling for the deep and shallow zones was done on January 14 and 15, 2002. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the SAP.

The concrete flumes extending from each of the outfall structures are a subsite of the 100-B-15 River Effluent Pipelines waste and will be closed at later date. Portions of the flumes within the layback area were removed to the extent necessary to facilitate removal of the outfall structures. The effluent pipelines leading to the outfalls were left in place and grouted at the ends. They will be removed as part of the 100-B-8 and 100-C-6 Pipeline remediation.

The cleanup verification package (CVP-2002-00003) for the sites, also referred to as B/C Outfall, has demonstrated that remedial action has met the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) as established in the approved interim action Interim Action Record of Decision (ROD) (EPA 1999) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17 Rev. 3).

<td></td>
<td></td>
</tr>
</tbody>
</table>
Rev. 24

Waste Type: Sanitary Sewage
Waste Description: The site received waste water from the P-10 Storage Building drain. Since the P-10 project involved tritium production, tritium may be a potential contaminant. The drain is not currently posted as being contaminated. An evaluation to determine potential contaminants for the 100 Area SAP resulted in four COPCs: coalt-60, cesium-137, europium-152, and strontium-90.

Closure Info: Excavation of the 116-B-9 site began on March 10, 1999, by removing the overburden materials and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. On March 11, 1999, the excavation had reached the design limit at El. 139 meters (455.8 feet). Cleanup verification sampling began on March 15, 1999, and was finished on April 23, 1999.

At the completion of the remedial action and removal of the engineered structure, the excavation area was approximately 51.5 square meters (554 square feet or 0.013 acres) at a depth of approximately 2.44 meters (8.0 feet). The excavation will be backfilled with clean fill materials to the reference grade of El. 141.1 meters (462.8 feet). Clean backfill may be taken from the clean overburden pile and other sources of clean material that have been surveyed in accordance with the SAP (DOE-RL 1998) and that are appropriate for use as backfill.

Site remediation was performed in accordance with an Interim Action Record of Decision (ROD) (EPA 1995). The ROD provides the U.S. Department of Energy, Richland Operations Office (RL) the authority and guidelines to conduct this remedial action at the site. The preferred remedy specified in the ROD is excavation and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF). The Remedial Action Objectives (RAOs) were established in the Interim Action ROD (EPA 1995) and are summarized in the Cleanup Verification Package (CVP) along with the corresponding Remedial Action Goals (RAGs). Methods to attain the RAOs are presented in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 1998) and are discussed in further detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL 1998). The CVP demonstrates that remedial action at the 116-B-9 site has achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and the RDR/RAWP (DOE-RL 1998). Materials that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils have been sampled, analyzed, and modeled to show that residual COC concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. This scenario, described in the Cleanup Verification Package (CVP), assumes multiple exposure pathways (e.g., ingestion, inhalation, and direct exposure) for shallow zone soils. The verification package demonstrates that residual COC concentrations pose no threat to groundwater or the Columbia River. Thus, the 116-B-9 site is verified to be remediated in accordance with the ROD.

<tr>
<td>Description: The site was remediated in 1999 and closed out in February 2000. It is no longer marked or posted. The site was a french drain with a metal manhole type cover and constructed of a 61-centimeter (24-inch) vitrified clay pipe on subsurface concrete slab. It was covered with a plywood cover and clean backfill material. A 3.8-centimeter (1.5-inch) drain line was added in the mid-50s that came from the experimental tube and other hardware decontamination facility. All piping leading into the drain was removed at the time of the 108-B demolition.</td>
<td></td>
</tr>
</tbody>
</table>
**Location:** The unit is located in the northwest corner of Room 15-C of 108-B Building.

**Process Description:** The quench tank was used to collect liquid decontamination wastes from the 108-B Tube Examination and Experimental Facility.

**Waste Type:** Sanitary Sewage

**Waste Description:** This site received liquid decontamination wastes from the 108-B Tube Examination and Experimental Facility. During the tritium recovery programs, the site also received liquid decontamination wastes from the mask and small tool decontamination station located on the second floor and storm runoff from the fan room roof. The 108-B Building was involved with tritium recovery activities so tritium is a possible contaminant of concern.

**Closure Info:** The cleanup verification package (CVP-99-00010) has demonstrated that remedial action at the 116-B-10 site has met the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) as established in the approved interim action Interim Action Record of Decision (ROD) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

Excavation of the site began on March 10, 1999. After completion of the initial excavation to design limits, several other contaminated areas (plumes) were discovered and also excavated. For this phase cleanup verification sampling began on May 20, 1999, and was finished on June 22, 1999.

At the completion of the remedial action, the excavation floor was approximately 153 square meters (1650 square feet) at a depth of 2.4 meters (8 feet), and approximately 692 metric tons (763 tons) of material were disposed at the Environmental Restoration and Disposal Facility (ERDF).

The remaining soils have been sampled, analyzed, and modeled to show that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. This scenario, described in Section 4.2 of the CVP, assumes multiple exposure pathways (e.g., ingestion, inhalation, direct exposure) for shallow zone soils.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

**Code:** 116-B-11  
**Names:** 116-B-11; 116-B-11 Retention Basin; 107-B Retention Basin  
**Type:** Retention Basin  
**Status:** Inactive  
**Description:** The site has been remediated and closed out. It included the retention basin and the two effluent pipes running parallel to, and adjacent to, the north side of the basins. These pipes were removed as part of the plume removal during the retention basin remedial action.

The 116-B-11 Retention Basin were located near the northern edge of the 100-B Area and is located north of 116-C-5 (107-C Retention Basin).
Process Description: The 116-B-11 Retention Basin was constructed to hold cooling water effluent from the 105-B Reactor to allow for thermal cooling and radioactive decay prior to release to the Columbia River. This unit was a concrete-lined basin with wooden baffles. The basin was divided lengthwise into two halves designed to operate independently. The floor and walls consist of concrete slabs, their joints were originally closed with neoprene water seals. From the basin floor to approximately 3 meters (10 feet) above the floor, the walls sloped and were approximately 0.1 meter (4 inches) thick. The upper 3 meter (10-foot) sections of the walls were vertical and ranged in thickness from about 1.7 meters (5 feet 8 inches) at the bottom to 0.3 meter (1 foot) at the top. The unit was backfilled with soil to a depth of almost 1.2 meters (4 feet).

Waste Type: Sanitary Sewage

Waste Description: This unit received cooling water effluent from the 105-B Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Total radionuclide inventories in the vicinity of the unit ranged from 5 to over 400 curies. Eighty percent of the total radionuclide inventory is contained within the soil adjacent to the unit. Approximately 10 curies have leached into the concrete floor and walls.

Closure Info: Excavation of the 116-B-11 site began on November 26, 1997, to remove overburden materials and underlying contaminated soil. All overburden materials were determined to be contaminated and were disposed of at the ERDF. On October 28, 1998, removal of contaminated soil had reached the design limits at the base of the engineered structure (El. 127.5 m [418.3 ft]). Soils not meeting direct exposure RAGs based on field screening results were excavated, loaded into shipping containers, and disposed of at ERDF. Cleanup verification sampling Was conducted on November 19 and 20, 1998, for the deep zone, and on December 8, 1998, for the shallow zone. Contaminated soil associated with the process effluent pipelines was partially removed; the rest remains for final remediation with pipelines and a separate cleanup verification package. The 100-BC process effluent pipelines are scheduled to be removed within the next few years. The 116-B-11 sidewall areas that are adjacent to future pipeline excavation areas were not sampled as part of the cleanup verification effort. These areas will be sampled and verified clean as part of the effluent pipeline remediation efforts. At the completion of the remedial action and removal of the engineered structure, the excavation area was approximately 14,000 square meters (150,696 ft²) at a depth of 5.0 m (16.4 ft), and approximately 165,178 metric tons (182,109 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 132.5 m (434.7 ft). Backfill will be provided by use of clean source material from an area located near the 116-B-11 site that has been surveyed in accordance with the SAP (DOE-RL 1998a) and that is appropriate for use as backfill.

The site has been excavated and remediated. Results of the sampling, testing, and analyses for the 116-B-11 site cleanup indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of surface waters (including the Columbia River) have been met.

The material removed from the site (approximately 165,178 metric tons [182,109 tons]) was disposed of in the Environmental Restoration Disposal Facility (ERDF). The excavation will be backfilled with clean material to the reference grade of elevation 132.5 meters (434.7 feet).

Code: 116-B-12
Names: 116-B-12; 117-B Crib; 117-B Seal Pit Crib
Classification: Accepted
Reclassification: Interim Closed Out (2/24/2000)
Type: Crib
Status: Inactive
Description: This site has been remediated and closed out. The site was a crib with bottom measurements of 6.1 meters (20 feet) by 15.24 meters (50 feet).
Location: The site is located northeast of the 105-B Reactor Building. The site is adjacent to the 118-B-5 Burial Ground.
Related Sites/Structures: The site was associated with the 117-B (132-B-4 Air Filtration Ventilation) Building, which has been demolished.
Process Description: The crib received drainage from the confinement system seal pits in the 132-B-4 Air Filtration Ventilation Building.
Waste Type: Demolition and Inert Waste
Waste Description: The site received drainage from the confinement system in the 117-B Building seal pits. From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP (DOE-RL 1998) include strontium-90, uranium-238, and hexavalent chromium (Cr+6).
Closure Info: This site was remediated to meet the cleanup standards and closed out on February 24, 2000. Excavation of the 116-B-12 site began on February 17, 1999, by removing the overburden materials and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On March 5, 1999, the excavation had reached the design limit at El. 139.93 meters (459.1 feet). Cleanup verification sampling began on March 15, 1999, and was finished on April 13, 1999.

At the completion of the remedial action, the excavation floor area was approximately 520.8 square meters (5,605.8 square feet or 0.129 acres) at a depth of approximately 4.6 meters (15 feet), and approximately 8,696 metric tons (9,586 tons) of material from the site had been disposed of at ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 144.5 meters (474 feet).

Site remediation was performed in accordance with an Interim Action Record of Decision (ROD) (EPA 1995). The ROD provides the U.S. Department of Energy, Richland Operations Office (RL) the authority and guidelines to conduct this remedial action at the site. The preferred remedy specified in the ROD is excavation and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF). The Remedial Action Objectives (RAOs) were established in the Interim Action ROD (EPA 1995) and are summarized in the Cleanup Verification Package (CVP) along with the corresponding Remedial Action Goals (RAGs). Methods to attain the RAOs are presented in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 1998) and are discussed in further detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL 1998).

The Cleanup Verification Package (CVP) demonstrated that remedial action at the 116-B-12 site has achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and the RDR/RAWP (DOE-RL 1998). Materials that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils have been sampled, analyzed, and modeled to show that residual COC concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. This scenario, described in the CVP, assumes multiple exposure pathways (e.g., ingestion, inhalation, and direct exposure) for shallow zone soils.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone.
[i.e., below 4.6 meters (15 feet)] are required. The verification package demonstrates that residual COC concentrations pose no threat to groundwater or the Columbia River. Thus, the 116-B-12 site was verified to be remediated in accordance with the ROD.

Hanford Site Waste Management Units Report
February 2015
Status: Inactive                      End Date: 1/1/1948

Description: The site has been remediated and closed out. The 116-B-14 site appears as an open field covered with cobbles and sparse vegetation.

Location: The 116-B-14 site was located immediately north of 116-B-11 (107-B Retention Basin) and is outside the exclusion area fence that encloses the 116-B-11 and 116-C-5 (107-C Retention Basin). The center line for the trench is believed to be approximately 12 meters (40 feet) north of the exclusion area fenceline. The exact locations of the site boundaries are uncertain.

Related Sites/Structures: The site was related to 116-B-11 (107-B) Retention Basin.

Waste Type: Sanitary Sewage

Waste Description: The unit received low-level sludge waste from the bottom of 116-B-11 (107-B Retention Basin). During maintenance clean out operations, sludge was disposed of in the trench. There is no indication from available records that this site directly received any regular and/or high-volume effluent wastes. After its use, the waste site was covered with about 1.8 meters (6 feet) of soil. Potential contaminants of concern included: americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, uranium-238, total chromium, hexavalent chromium (Cr+6), mercury, and lead.

Closure Info: The cleanup verification package (CVP-1999-00003) has documented that the 116-B-14 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision (ROD) (EPA 1995) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17). 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22). Excavation began on May 27, 1998, and reached the design limits below the base of the engineered structure (elevation 126.5 meters [415 feet]) on September 17, 1998. At the completion of the remedial action, the excavation area floor was approximately 132 square meters (1,422 square feet) at a depth of 6 meters (19.7 feet), and approximately 3,795 metric tons (4,183 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled to the reference grade of (elevation 132.5 meters [435 feet]). Clean backfill was taken from the clean overburden pile and other sources of clean material (e.g., demolition rubble from the 108-F Building) that have been surveyed in accordance with the Sampling Analysis Plan (DOE/RL-96-22). Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, WIDS had shown IC restrictions but the sites were remediated to shallow zone criteria so that no ICs were required. The ICs for this site have been revised accordingly.

Code: 116-B-15
Names: 116-B-15; 105-B Fuel Storage Basin Cleanout Percolation Pit; 105-B Fuel Storage Discharge Pond; 105-B Pond
Type: Pond
Status: Inactive
Description: This site has been evaluated and determined to meet remedial action objectives. The evaluation and sampling results support the reclassification to No Action. The unit was a large, open, excavated pit, rectangular in shape. The site was used from November 1984 to December 1985.
Location: The site was located east of the 105-B Reactor Building.
Process Description: During the cleaning of the 105-B Fuel Storage Basin, the radiologically contaminated shielding water was processed through a system that utilized ion exchange columns. Before the water was discharged to this site, composite samples were taken to ensure that radionuclide concentrations were below release criteria.

Waste Type: Chemicals

Waste Description: The unit received processed water from the 105-B Fuel Storage Basin. During the cleaning of this basin, the radiologically contaminated shielding water was processed through a system that utilized ion exchange columns. Before discharging the water to the unit, composite samples were taken to ensure that radionuclide concentrations were below release criteria in Table II of DOE Order 5480.1. No known chemical substances were present in the water; however, chemical analysis during that period was not a standard practice, and there is no evidence that it was performed.

Closure Info: This site has been evaluated and determined to meet remedial action objectives. The "No Action" reclassification was supported by a review of the site history, an extensive site evaluation, confirmatory soil sampling and the site reclassification form (control number 2003-052) with a supporting documentation package. The current site soil conditions achieve the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units.

Residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario and pose no threat to groundwater or the Columbia River.

Code: 116-B-16
Names: 116-B-16; 111-B Fuel Examination Tank
Type: Storage Tank
Status: Inactive
Classification: Accepted
Start Date: 1/1/1968
End Date: 1/1/1968

Description: This site has been remediated and closed out. The unit was a vegetation free, cobble-covered field located within a barricaded area at the former site of the 111-B Building. The floor, foundation, and tank were the only remaining portions of the building. The fuel examination tank was located along the west side of the barricaded area. A curved, capped ventilation pipe extended about 25 centimeters (10 inches) above ground just north and east of the tank location. The barricaded area was surrounded by light duty steel posts with light duty chain and has been posted with "Caution: Underground Radioactive Material" signs. The tank was constructed of concrete. It is believed that the tank was filled with either sand or concrete before the site was abandoned.

Location: The site was located below the northwest corner of the 111-B Metallurgical Examination Building floor, southeast of the 105-B Reactor Building, adjacent to 116-B-6A, and within the 105 B/C Exclusion Area.

Related Sites/Structures: The site was associated with the 111-B Metallurgical Examination Building.

Process Description: The 116-B-16 Fuel Examination Tank, was a low-level liquid waste disposal site that was operational during the lifetime of the 111-B Metallurgical Examination Building. The tank
received liquid wastes from the decontamination of fuel element spacers and other equipment as well as from other 111-B Building activities.

**Waste Type:** Chemical Release

**Waste Description:** The unit is believed to have received wastes similar to those identified in 116-B-6A (111-B Crib No. 1); i.e., radioactive waste from equipment decontamination, the 111-B Building, and liquid wastes from fuel element spacer decontamination.

**Closure Info:** Excavation of the 116-B-6A/116-B-16 site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials shown to be contaminated were disposed of at the ERDF. On May 12, 1999, the excavation reached the design limit at El. 141.4 meters (464 ft). Cleanup verification sampling began on May 20, 1999, and was finished on June 18, 1999.

The cleanup verification package for the 116-B-6A Crib and 116-B-16 Fuel Examination Tank, because of their close proximity to each other and similar contaminants of concern (COCs), were excavated as one remedial action site and are hereinafter referred to as the 116-B-6A/116-B-16 site.

At the completion of the remedial action, the total excavation was approximately 603.5 square meters (6,496 square feet or 0.15 acres) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 5,072 metric tons (5,591 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The excavation will be backfilled in the near future (written June 6, 2000) with appropriate materials to the reference grade El. 146 meters (479 feet).

Results of the sampling, laboratory analyses, and data evaluations for the 116-B-6A/116-B-16 site indicate that all remedial action objectives and goals for direct exposure, protection of ground water, and protection of the Columbia River have been met. However, this site close out includes a deed restriction against drilling or digging into the deep zone soils (below 4.6 m [15 ft] depth).

**Code:** 118-B-5  
**Classification:** Accepted

**Names:** 118-B-5; Ball 3X Burial Ground  
**Reclassification:** Interim Closed Out (5/24/2004)

**Type:** Burial Ground  
**Start Date:** 1/1/1953

**Status:** Inactive  
**End Date:** 1/1/1953

**Description:** The site has been remediated and Interim Closed Out. The 118-B-5 (Ball 3X) Burial Ground contained one trench, which was covered with 1.5 meters (5 feet) of soil after its use was discontinued. The site appeared as a vegetation free "L" shaped mound of cobbles, about 0.9 meters (3 feet) high, that was surrounded by permanent concrete markers and was outside the reactor exclusion area. The long south side of the burial ground was about 4.6 meters (15 feet) from a section of the reactor exclusion area fence that ran from north to south. Following remediation, authorization to remove the radiological postings was given in October 2012.

**Location:** The burial ground was located east of the 115-B Gas Recirculation Building. The west side was about 6.1 meters (20 feet) from the fence. The site was posted with signs reading "118-B-5 Ball 3X Burial Grounds".

**Process Description:** This burial ground received irradiated equipment and metallic wastes removed from the 105-B Reactor during the Ball 3X Project.
**Waste Type:** Sanitary Sewage

**Waste Description:** The unit received 40.00 cubic meters (1410 cubic feet) of highly contaminated metallic wastes, including thimbles and step plugs that were removed from the 100-B Reactor during the performance of work for the Ball 3X project. The Ball 3X project replaced the liquid boron system for emergency reactor control with a system using solid boron-steel and carbon-steel balls. Potential contaminants include: C-14, Co-60, Ni-63.

**Closure Info:** The excavation was completed in December 2003. At the completion of the remedial action, the total excavation was approximately 753 square meters (8,101 square feet) in area for the shallow zone and approximately 3,419 square meters (37,783 square feet) in area for the staging pile area, with a burial ground depth of approximately 4.8 meters (15.7 feet). Approximately 5,046 metric tons (5,563 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. Excavation during remediation of the site found only miscellaneous debris associated with the Ball 3X Project and lead solids.

**Names:** 118-B-9; 104-B-1 Tritium Vault and 104-B-2 Tritium Laboratory; 104-B2 Storage Building

**Type:** Storage

**Status:** Inactive

**Start Date:** 1/1/1950

**End Date:** 1/1/1955

**Description:** The waste site has been evaluated and Reclassified to No Action. It is a gravel-covered field. The site originally consisted of two concrete masonry facilities identified as 104-B-1 Tritium Vault and 104-B-2 Tritium Laboratory. Both structures were demolished in 1996 and their associated foundations removed to 1 meter (3 feet) below grade. The excavated areas were then backfilled and graded to match the existing terrain.

**Location:** The site was located in the extreme northwest corner of the 105-B Exclusion Area. The 104-B-2 Product Storage Building was located immediately northwest of the 91.4-meter (300-foot) 108-B Stack. The 104-B-1 Tritium Vault was located due north of the 103-B Building and just outside the fence for 103-B. Both structures have been demolished.

**Release Description:** There have been no known unplanned releases from these facilities.

**Related Sites/Structures:** The two facilities (104-B-1 and 104-B-2) were related to each other (both supported the P-10 Project). The 104-B-2 Facility was related to 108-B, Tritium Separations Facility. The 104-B-2 Facility housed the air sampling equipment for the 108-B Stack. These two facilities were connected through a vent pipe leading from the 108-B Stack to 104-B-2 Tritium Laboratory (annex). Photograph (83E17058CN) 100 Area, 104-B-2, View of the 104-B-2 Tritium Lab from the roof of 108-B, shows the vent line that went from the 104-B-2 Tritium Laboratory to the 108-B, Tritium Separations Facility. A french drain, identified as the 116-B-9 French Drain, was associated with this unit (104-B-2). This site is located at the east end of the 104-B-2 Tritium Laboratory (the end containing the annex that housed the air sampling equipment for the 108-B stack). Drawing H-1-2659 shows a french drain associated with this facility. BHI-00835 states that no evidence of the french drain was found when the team performed the walkthroughs (prior to demolition of 104-B-2) or when the vent line from the storage cells to the 108-F Stack (demolished in the 1980's) was opened and surveyed. No french drain was identified during demolition. Ground Penetrating Radar (GPR) surveys were performed in 1994 and 1996 identified an anomaly consistent with the shape of a french drain. In preparation for sampling the french drain, the site has been located and uncovered. Site 116-B-9 has photo images (#2 and #3) of the exposed french drain. Early WIDS documentation states that the french drain was not visible from the surface.
Process Description: The 104-B-1 Tritium Vault had a concrete foundation and concrete block walls. The 104-B-2 Tritium Laboratory was also a concrete structure with a small steel framed transite sided annex located on the east end. The Tritium Laboratory contained sixty-three (63) special cells recessed in the laboratory floor. These were used to store the vacuum casks which contained the irradiated target elements for the P-10 Project. The 104-B-2 Tritium Laboratory housed the air sampling equipment for the 108-B Stack. In the P-10 program, irradiation of lithium-aluminum fuel targets, took place in the 105-B, H and F Reactors. The irradiated fuel targets were put in special vacuum casks and taken to the 104-B-2 Tritium Laboratory where they were put into special storage wells. The vacuum casks were then moved to the 108-B Tritium Separations Facility and charged into a furnace with an inert atmosphere and a stainless steel furnace tube connected to a complex series of glass tubing and flasks fitted with palladium valves. As soon as the furnace was charged, the entire line was pumped down to an extremely high vacuum to remove impurities, and the furnace was out gassed to drive off absorbent gases. At that point, the actual extraction began. The furnace temperature was raised until all of the tritium gas had been driven from the irradiated targets, and the gas was drawn down the glass lines, through palladium valves, and collected in shipping flasks. These shipping flasks were stored in storage racks located on the north and south walls of the 104-B-1 Tritium Vault, prior to use. Prior to demolition, the laboratory had been deactivated, posted as radiologically contaminated, and used to store contaminated reactor refueling components from the 105-B and 105-C Reactors.

Waste Type: Sanitary Sewage
Waste Description: The building was constructed of concrete block and the foundation was concrete. Following demolition activities, 110 cubic meters (144 cubic yards) of concrete rubble was disposed of in the 100-F Clearwell.

Waste Type: Sanitary Sewage
Waste Description: Lead based paint was found on the roof trim, vents, and exterior doors. Following demolition activities, 0.7646 cubic meters (1 cubic yard) of lead base painted wood was disposed to an offsite vendor's container (where other 100-B/C small buildings hazardous waste was temporarily stored). This material was identified as number 200E-96-0015 and was packaged in a Laidlaw box and shipped offsite to Laidlaw Lone Mountain Facility on Manifest A6344 on 12/9/96.

Waste Type: Sanitary Sewage
Waste Description: Following demolition activities, 0.7646 cubic meters (1 cubic yard) of miscellaneous metal from the two buildings was taken and staged with the 190-C recycle material.

Waste Type: Sanitary Sewage
Waste Description: The unit (104-B-2) contained trace amounts of radioactive waste. It was used to store containers of reactor refueling components from 105-B and 105-C Reactors. No liquid contaminants were involved. Bird droppings were also found in small quantities. Following demolition activities, two 1.2 by 1.2 by 2.44-meter (4 by 4 by 8-foot) plywood burial boxes equivalent to 7.25 cubic meters (9.5 cubic yards) were taken to a burial ground. The burial boxes have numbers 100B-96-0002 and 100B-96-0017 and were shipped on 12/3/96 to burial ground 218-W-5, trench 29.

Waste Type: Sanitary Sewage
Waste Description: The facility (104-B-1) contained asbestos, consisting of caulking around exterior vents. Following demolition activities, 0.92 cubic meters (1.2 cubic yards) of non-friable cement asbestos board (CAB) were put into a dumpster and hauled away. The material was then shipped to Basin Disposal, Pasco for eventual disposal in the RABANCO landfill, Roosevelt, WA. Total asbestos material identified was non-friable Category I: asphalt roofing 55 square meters (592 square feet), non-friable Category II: joint caulking 1.21 square meters (13 square
feet), non-friable Category II: transite wall board 63.92 square meters (688 square feet). The total category I was 55 square meters (592 square feet) and Category I was 65.13 square meters (701 square feet).

**Closure Info:** Both structures (104-B-1 and 104-B-2) were demolished in 1996 and their associated foundations removed to 1 meter (3 feet) below grade. The excavated areas were then backfilled and graded to match the existing terrain. Confirmatory sampling was conducted at the 118-B-9 site in September 2003. One of the two judgmentally located sampling locations was in the center of the 104-B-1 Tritium Vault site and the second was below the exhaust vent pipe of 104-B-2 Tritium Laboratory site. The randomly located test pits were dug under the former location of the floor storage cells of the 104-B-2 Tritium Laboratory site. Soil samples were collected from a depth of 1.2 meters (4 ft) below ground surface.

During excavation of the foundations, radiological surveys were done to verify that no residual contamination existed in the footings or soil proximate to the foundations. No contamination was found.

The no action decision for the 118-B-9 site is supported based on reviews of site history, field observations, and characterization results. The maximum detected results from underlying soil samples collected at locations suspected of having the greatest potential for residual contamination levels were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

**Code:** 118-B-10  
**Classification:** Accepted

**Names:** 118-B-10; Ball 3X Storage Vault  
**Reclassification:** Interim Closed Out (5/24/2004)

**Type:** Storage Tank  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site has been remediated and Interim Closed Out. Before remediation, the location of this burial ground was marked with a concrete pad and a metal medallion at the ground surface in a gravel field. Following remediation, authorization to remove the radiological postings was given in October 2012.

In November 2001 the site appeared as a vegetation-free area that had been covered with cobbles piled to 0.6 meters (2 feet) above grade. However, this location was wrong. As shown on Drawing H-1-19820 and confirmed by ground-penetrating radar (GPR), the mound of cobble is backfill over a process sewer that was constructed over the ventilation tunnel to 115-B. The pipeline had to be close to the surface because of the tunnel, so it was encased in concrete and covered with 18 inches of backfill.

**Location:** This site was south of the 105-B Reactor. See the photos for the top of this feature that is at ground level.

**Process Description:** The site was a metal tank used to store highly radioactive balls.

**Waste Type:** Demolition and Inert Waste  
**Waste Description:** The waste is a radioactive metal storage tank used to store radioactive boron balls from the ball 3X system.

**Closure Info:** The site was remediated on December 1 and 2, 2003. Excavation included removing the overburden and the burial ground site materials. The average depth of the excavation was 10.5 feet. At the completion of remedial action, the excavation was approximately 137 square meters.
(1,475 square feet) in area with an average depth of approximately 3.21 meters (10.5 feet). Approximately 266 metric tons (293 tons) of material, including soil and burial ground debris, were removed from the site and disposed of at the Environmental Restoration Disposal Facility.

<td>The site has been remediated and interim closed. The sump and underlying soils were removed on June 13, 2006. The site was backfilled with clean soil from the 100-B Area borrow pit.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The site was located west of the 105-B Building, adjacent to the main switchgear room.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The sump was located on the northwest corner of 118-B-8 (105-B Reactor).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The battery acid sump was a standard limestone acid neutralization pit. It was used from approximately 1944 to 1969 to neutralize the spent sulfuric acid from lead cell batteries of emergency power packs and the emergency lighting system. The neutralized battery acid waste (containing calcium sulfate, metal sulfates, and water) was periodically jetted out to the process sewer. The sump was designed as a concrete box with hinged metal covers. During a site visit it was observed that concrete repairs had been made to each of the four corners. The repairs suggested that the integrity of the structure may have been compromised, creating the potential for leakage to the surrounding soils.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Chemicals</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>The site contained unknown amounts of sulfuric acid from spillage during use and servicing of an emergency power battery bank inside the 105-B Building. The residual liquid and sludge were analyzed for heavy metals in 1986 using the EP Toxicity Test and chromium was found.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>When the sump was cleaned out in 1986, the residual limestone was removed and both the solution section (south end) and the solids (limestone) section (north end) were flushed with water and jetted out to the process sewer using the sump's water-operated eductor. Both sections of the concrete box were lined with acid-resistant brick including the partition between the two sections. The air and water supply to the sump (air sparger and water eductor) were shut off. The sump contained a 10-centimeter (4-inch) waste inlet pipe from the 105-B Building; it was located in the south wall of the sump about 50.8 centimeters (20 inches) below the metal access doors. The outlet pipe was located near the top of the west wall of the northern section of the sump. The associated inlet and outlet pipes were removed to the boundaries of the remediation footprint and grouted. After verification samples were collected, the excavation was backfilled.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In support of confirmatory sampling, the sump was opened in March 2003. Standing water was observed in both sections of the sump. Due to the presence of corrosive water in the sump and the results of confirmatory sampling, it was determined that remedial action was necessary. On June 1, 2006, the standing water present in the sump (approximately 6,400 liters [1,700 gal]) was treated with lime to adjust the pH and removed. On June 13, 2006, the remainder of the site (consisting of the sump structure) was excavated and removed along with a small volume of soil directly in contact with the sump. The site was excavated to a maximum depth of 3.0 meters (10 ft) below ground surface in order to preclude any potential impact to the integrity of the 105-B Building walls and nearby transformer pad. The pipelines were removed to the extent of the excavation boundaries and grouted prior to backfilling. The site was backfilled immediately following the verification sampling with clean backfill material from the 100-B.
Area borrow pit. Approximately 32 bank cubic meters (42 bank cubic yards) of material was excavated and disposed at the Environmental Restoration Disposal Facility.

The inlet and outlet pipelines associated with the sump were sampled but were not included as part of the closeout for the 120-B-1 waste site. The inlet and outlet pipelines were grouted and are included as a subsite within the 118-B-8, 105-B Reactor Building waste site.

<tr>
<td>Description:</td>
<td>The site has been evaluated and reclassified to No Action. The site consisted of two underground concrete reservoirs, or clearwells, separated in the center by the remains of a demolished pump room. A concrete piping structure was located above ground at the southeast corner of the clearwell site.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The site was located approximately 430 meters (1,410 feet) directly west of the 105-B Reactor Facility and southeast of the 182-B Retention Basin.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>This unit was part of the 100-B Water Treatment Facility.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>This site was part of the 100-B Water Treatment Facility. River water stored in the 182-B Retention Basin was transferred sequentially to the 183-B Head House for chemical additions, then to flocculation and sedimentation basins, through anthracite filters, and finally into the clearwells. The 183-B Filter Pump House then fed most of the stored potable water to the 185/190 B facilities, which provided final treatment and storage before use as cooling water for the 105-B Reactor. The pump room was constructed of concrete and was approximately 6.7 meters (22 feet) below grade. The remaining portion of the pump house contained debris from the demolition of the above-ground portion and was believed to include steel, concrete, and asbestos-containing siding (transite). The clearwells were each 1.9E+7 liter (5E+6 gallon) concrete rectangular boxes, with flat concrete roofs. The concrete roofs were surmounted by an above-grade water-resistant roof, which may have been made of asbestos-containing materials in asphalt-saturated board, covered by tarred felt. Water stored in the 183-B Clearwells would have contained additives from the flocculation and sedimentation steps that occurred at the 183-B facility. Chlorine, sulfuric acid, alum, ferric sulfate, Sepran O 1 (a coagulant), and lime were used in the treatment process. After the filtration step, the additives and any trace contamination from the additives would have been very dilute in the treated water. The Clearwells were upstream of sodium dichromate additions and of the 105-B Reactor. There was no evidence to suggest that the water stored in the clearwells ever contained sufficient quantities of radionuclide or no radionuclide hazardous chemicals to present a human health risk.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Demolition and Inert Waste</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>No waste was deposited at the clearwells in the past. However, this unit is scheduled for future use as a disposal site for demolition and inert solid waste after the 126-B-3 Coal Pit and demolition landfill is closed. The remaining portion of the pumphouse currently contains waste from the demolition of the above ground portion. These wastes were believed to include steel, concrete, and asbestos transite.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>On September 15, 2005, a meeting among the Washington Closure Hanford (WCH) Field Remediation Closure Project, the U.S. Environmental Protection Agency (EPA), and the U.S. Department of Energy, Richland Operations Office (DOE-RL) was conducted to discuss a path forward for the 126-B-2 Clearwells and the 100-B-22, 100-B Water Treatment Facilities and...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Surrounding Soils. Background information presented to facilitate the discussion included a description of the water treatment facilities, the 126-B-2 Clearwells, and current information from the 100-B-14 excavations occurring in the area. The status of pipelines in the immediate area of the 126-B-2, 183-B Clearwells was also presented. The parties agreed all of the pipelines in the area were part 100-B-14, 100-B-28 or 100-B-22:1 and not part of the 126-B-2 Clearwells waste site.

It was further discussed that under the original and final configurations of the water treatment facilities, sodium dichromate was added to the process water downstream of the Clearwells in the 190-B facility. The 100-B-28 pipeline appeared to have transferred sodium dichromate solution from the 100-C Area to the 183-B Pumphouse. If sodium dichromate had been added to the process at the pumphouse, it would have been pumped to the 190-B facility for storage. Therefore, water in the Clearwells would not have been expected to contain hexavalent chromium or radionuclides, even at low concentrations. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which included a comprehensive ecological risk assessment. That baseline risk assessment will be used as part of the final closeout decision for this site.

---

**Reclassification:**

126-B-3; 184-B Coal Pit Dumping Area

**Names:**

126-B-3; 184-B Coal Pit

**Type:** Dumping Area

**Status:** Inactive

**Start Date:** 1/1/1943

**End Date:** 1/1/1968

**Description:**

The site has been remediated and Interim Closed Out. The site consisted of a pit originally excavated to store coal for use in the 184-B powerhouse from 1943 through 1968. After coal storage was discontinued, the site was used as a demolition landfill.

**Location:**

The site was located just west of the 184-B Power House (demolished) and northeast of the 182-B Pump House and Reservoir.

**Related Sites/Structures:**

The site was associated with the 184-B Power House and 100-B-27 Chromium-contaminated Soil.

**Process Description:**

The site was used for coal storage from 1943 to 1968. Beginning in the early to mid 1970's, the site was used as a dumping area (burial ground) for demolished 100B/C Area facilities. The decommissioning of the 108-B building was completed in May 1985. All the above-grade portions of the building were demolished to a minimum of 3 meters (10 feet) below grade. The clean rubble and debris were disposed in the 184-B Coal Pit.

**Waste Type:**

Chemicals

**Waste Description:**

This unit contains waste from demolished 100-B Facilities. These include released portions of 108-B, 117-B, 117-C, 115-BC, and 184-B. This unit is likely to contain lead acid batteries. There are aluminum filter frames from the 117-B and 117-C Facilities on the surface on the south side. Steel staircases and ladders have been deposited on the surface on the northeast side of the site.

**Closure Info:**

Initial remediation of the burn pit area was performed from September 4 to September 17, 2003; removing approximately 43,100 bank cubic meters (56,400 bank cubic yards) of material. The remediation consisted of the removal of suspect hazardous material and impacted soils within the disposal pit to depths of up to 7 meters (23 feet). Material removed included batteries, lead bricks, rubber gaskets, a compressor, metal scrap, concrete rubble, miscellaneous asbestos-containing material, ash, and contaminated soil.

After this remediation, an area of chromium-contaminated soil was identified in the northern
portion of the western staging area. It was unrelated to waste staging or historical disposal activities at the site. This area was classified as a discovery site and designated as the 100-B-27 Chromium-Contaminated Soil waste site and was not considered within the closeout documentation of the 126-B-3 waste site.

Following the removal of an additional 4,640 bank cubic meters (6,060 bank cubic yards) of material, including a suspect drywell discovered within the staging pile footprint, the additional removal brought the total material removed to approximately 47,740 bank cubic meters (62,440 bank cubic yards) of soil and debris disposed at the ERDF.

<tr>
<td>Waste Description:</td>
<td>The site received nonradioactive, combustible materials. Old paint cans and sandblast sand can still be seen at the site. Office waste, paint waste, chemicals, and solvent were burned at this site. It appears that clean fill material has been added to the site, indicating that the site may have also been used as a solid waste landfill.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The 128-B-2 Burn Pit also referred to as 100-B Burn Pit #2, was historically used for the disposal of combustible and noncombustible waste. The operational use of the Burn Pit was not completely known it was used as a burn pit for office and paint wastes, chemicals, and solvents. Landfilled noncombustible material, including concrete and metallic debris, was also discovered during remediation of the site. The presence of garnet sand also suggests that sandblasting activities may have been performed at this site.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Remedial action of the 128-B-2 site was initiated in November 2004 and continued through April 2005, with 5,627 bank cubic meters (7,360 bank cubic yards) of material excavated and disposed at the Environmental Restoration Disposal Facility (ERDF). Scrap metal, wood debris, tar paper, copper wire, plastic pipe, colored sand (believed to be garnet or other sandblasting abrasive), concrete rubble, cyclone fencing, barbed wire, bricks, vitrified clay pipe tiles, fence posts, potentially contaminated soil, and other miscellaneous materials were removed. Excavated materials were sorted and segregated based on visual inspection and site location and staged onsite for transport to the ERDF. The site was excavated to a maximum depth of 3.5 meters (11.5 ft) at areas of buried foreign material. Surficial soils surrounding the primary excavations were also removed to a depth of 0.30 to 0.45 meters (1 to 1.5 ft) due to the presence of visible surficial foreign material.</td>

Status: Inactive      End Date: 1/1/1968

Description: The site has been remediated and reclassified to Interim Closed Out. Institutional Controls are to be maintained on the river embankment area to prevent activities that would mobilize residual contaminants to travel to groundwater or the river. Institutional controls will be maintained until such time that the results of a baseline risk assessment can be considered (for a final site remedy, closure).

The 128-B-3 Coal Ash and Demolition Waste Site was an area where dumping and burning of waste material had occurred. The site was visible in a 1968 aerial photo and appeared to have been divided into a construction debris dumping area to the south and a combustible waste burning area to the north. The site was separated into the two sections by an ash covered roadway. At the site's southern edge was an area of vegetation-free gravel, covered with what was described as a "white-colored spray".

Location: This site was northeast of the northeast corner of the 100-B perimeter road on the plateau above the river shoreline.

Waste Type: Demolition and Inert Waste

Waste Description: Coal ash, burning evidence, and demolition rubble can be seen at the surface of the site. A 1952 shop manual was found among the waste.

Closure Info: The waste site, located immediately adjacent to the Columbia River, was formerly used as a disposal site for the 100-B/C Area. Site history indicates that the site was used for the dumping and burning of miscellaneous wastes, including office waste, paints, solvents, coal ash, and demolition debris.

Remediation of the site was performed from November 2004 to May 2006, consisting of the removal of approximately 21,000 BCM (bank cubic meters) (27,500 BCY [bank cubic yards]) of material from four former disposal pits, the river embankment, and the upland surface to disposal at the Environmental Restoration Disposal Facility. Initial remedial efforts at the upland area of the site were extended to include the river embankment following the results of geophysical investigation and focused sampling of visible debris at the embankment. Multiple chemical contaminants were detected above action levels in the in-process and waste characterization samples, including metals, hexavalent chromium, polycyclic aromatic hydrocarbons, total petroleum hydrocarbons (TPH), pesticides, and polychlorinated biphenyls.

The verification sample results indicated that the waste removal action achieved compliance with the RAOs and the Remaining Sites ROD, except at the river embankment area. Residual concentrations of metals, TPH, and aroclor-1254 slightly exceeded soil RAGs for protection of groundwater and the Columbia River at this location. However, further remediation activities to remove trace remaining contamination are likely to inflict greater environmental damage than leaving said contamination in place. The results for the entirety of the site show that residual contaminant concentrations do not exceed cleanup levels for direct exposure (i.e., ingestion of the soil). Statistical and judgmental sampling to verify the completeness of remediation was performed, and analytical results for upland areas were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. Analytical results for the remediated river embankment were shown to meet the cleanup objectives for direct exposure and to not significantly exceed soil RAGs for protection of groundwater and the Columbia River.

Accordingly, an interim closure reclassification is supported for the site, with imposition of institutional controls on the river embankment area to prevent activities that would mobilize residual contaminants to travel to groundwater or the river. Institutional controls will be maintained until such time that the results of a baseline risk assessment can be considered (for a
The remainder of the site does not have a deep zone or residual contaminant concentrations that would require any institutional controls. The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 in [15 ft] deep). The results also demonstrate that residual contaminant concentrations are sufficiently protective of groundwater and the Columbia River to preclude further remedial action.

<td>Process Description:</td>
<td>The intended use of this facility was to provide facilities for the mixing and addition of chemicals used in the treatment of the reactor cooling water. Shortly after the reactor began operation, it was determined that the chemical mixing and addition function could be better performed elsewhere in the cooling water supply system. The 108-B Building was then converted to a tritium recovery processing facility and was utilized as such until 1954. After the tritium processing facility was closed down, operational activity was limited to the first floor. The tube examination hot cell and laboratory rooms located there were utilized until the early 1970's.</td>

<tr>
<td>Waste Description:</td>
<td>The main radionuclide present at the site is tritium.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>As part of decommissioning activities, hazardous material was removed and properly disposed. Extensive radiological surveys were performed to collect data to evaluate the potential radiological dose to a hypothetical, maximally exposed site resident if the site was released for unrestricted use after the demolition and burial in situ of the facility. The final release survey was completed in early 1985. The results indicated that the facility was ready for demolition. Demolition and site grading were completed in May 1985 using conventional heavy equipment. The rubble was buried under at least 1 meter (3 ft) of clean fill and the site was graded to blend with the natural terrain. All the above-grade portions of the building were demolished to a minimum of 3 meters (10 feet) below grade. Any residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that based on RESidual RADioactivity (RESRAD) modeling, residual concentrations at the site pose no threat to groundwater or the Columbia River.</td>

Code: 132-B-3 | Classification: Accepted
Names: 132-B-3; Ventilation Exhaust Stack Site; 108-B Tritium Pilot Facility; 108-B Ventilation Exhaust Stack Site

Type: Burial Ground

Start Date:

Status: Inactive

End Date:

Description: The stack was demolished with explosives on September 9, 1983. This site has been evaluated and determined to meet remedial action objectives. The evaluation supports reclassification to No Action.

The site consisted of a trench, which was used to bury low-level contaminated rubble from the demolition of the 108-B Ventilation Exhaust Stack, also known as the 108-B Tritium Pilot Facility Ventilation Exhaust Stack. The trench was 9.1 meters (30 feet) wide, 5.5 meters (18 feet) deep, and 76 meters (250 feet) long. The stack foundation was found to be free of contamination. It was destroyed separately, buried in place and covered with clean fill material. Although it was on the opposite side of the road, it was considered to be part of this site.

Location: The burial trench was north of 105-B, west of 108-B Crib, across the road from the stack foundation site.

Waste Type: Ash

Waste Description: The 91-meter (300-foot) stack was demolished in 1983 and buried at this site. The stack was built of reinforced concrete and had a stainless steel liner. The total radionuclide inventory of the buried stack rubble is 21 millicuries.

Closure Info: Prior to demolition, surveys were conducted in the void beneath the liner and in the area inside the stack from the bottom of the liner to the 16 foot level. After removal of a layer of dust and dirt from an area around the liner floor drain, direct beta-gamma readings were <100 cpm/probe area inside the stack up to the 16 foot level. Alpha radiation was not detected with portable survey instruments. To determine the depth of penetration, concrete cores were collected from the inner stack surface to a depth of 3/8 inches at the 32-ft and 64-ft levels and submitted for analysis. The stack was demolished with explosives on September 9, 1983, under the allowable residual contamination level (ARCL) method in conjunction with in-situ decommissioning for permanent disposal. A valve and a drain line had been removed by the time the stack was demolished. Some rubble from the stack fell across the perimeter road and was pushed into the 132-B-3 Trench with heavy earth moving equipment. Most of the rubble, however, fell directly into the trench. After the stack was destroyed and buried, the foundation was demolished in place. The entire area was covered with clean fill material. The uncontaminated stack foundation was demolished separately in place.

Code: 132-B-4

Classification: Accepted

Names: 132-B-4; 117-B Filter Building

Type: Process Unit/Plant

Start Date: 1/1/1961

Status: Inactive

End Date: 1/1/1968

Description: The site has been evaluated and determined to require No Action. Historical data compiled for the Calculation Brief 0100B-CA-V0128 was of sufficient quality and quantity to support reclassification of the waste site to No Action. The 117-B building was demolished in two phases, beginning in 1985 and continuing through 1988. The ventilation exhaust filter building housed blowers and particulate filters used to treat the ventilation exhausted from the B Reactor Building. Included in this site were the 117-B Building, the intake ventilation duct from the 105-D Reactor Building, and the exhaust ventilation ducts to the 116-B Reactor Exhaust Stack.
Location: The site was located south of the 105-B Reactor, southwest of the 116-B Stack (132-B-2).

Related Sites/Structures: The site was associated with the 105-B Reactor (118-B-8), the 116-B Stack (132-B-2), the 119-B Sample Building, and the 117-B Seal Pit Crib (116-B-12).

Process Description: The building and below grade duct work were made of reinforced concrete, 0.3 to 0.6 meters (1 to 2 feet) thick; above grade ducts were constructed of 10 gauge black steel. The building was 16.76 meters (55 feet) long, 7.01 meters (23 feet) wide, and 11.0 meters (36 feet) high with 2.4 meters (8 feet) above grade. A soil berm was built up around the building from grade level to the top of the structure.

The building was divided into two large filter cells with a smaller operating area between them. The filter cells each held six filter frames (two wide and three deep). The filter frames were designed to hold twenty-eight filters that were 0.6 meters (2 feet) square by 0.3 meters (1 foot) thick. There were spaces between the frames to allow access for filter maintenance.

The operating area between the two cells was divided into two levels. The upper level, called the access gallery had ten doors that lead from it. Four doors opened into each of the filter cells and the two other doors provided access to the intake and exhaust ducts. The operating gallery was located below the access gallery. A sump was located at each end of the operating gallery to collect incidental drainage from above. A large open area extended the full length of the structure above the access gallery and the filter cells. It ranged in height between 2.5 and 2.4 meters (8.1 and 7.8 feet) due to the structure's sloping roof. The space provided access to the cement cover blocks that were positioned over each of the filter frames.

Before the filter building was used, unfiltered ventilation was exhausted directly from the reactor to the atmosphere. The reactor confinement system diverted the exhaust just before the stack and routed it to the filter building where it passed through a series of filters. The filtered exhaust was then routed back to the ventilation exhaust stack where it was discharged to the atmosphere. Sealwells within the filter building provided the ability to direct the exhaust into one or both of the filter cells.

Waste Type: Demolition and Inert Waste

Waste Description: The site contained radiologically contaminated debris. Total radionuclide inventory in this unit was estimated to be 92 nanocuries. The radionuclides comprising this inventory were tritium, carbon-14, cesium-137, strontium-90, and plutonium-239/240. Of these radionuclides, strontium-90 was the most restrictive in the allowable residual contamination level (ARCL) calculations. Cobalt-60, europium-152, europium-153, and europium-155 were not identified in any of the samples analyzed.

Closure Info: Reclassification form 2003-10 and the attached Calculation Brief document the reclassification to No Action. The 117-B Filter Building and associated below-grade ductwork were demolished in two phases beginning in March 1985 and continuing through January 1988. Phase I included work necessary prior to demolition activities and included extensive radiological surveying and sampling, the removal of assorted equipment (e.g., HEPA filters) for disposal in the 200 West Area burial grounds, and decontamination and/or fixing contamination. As part of Phase I activities, a calculation methodology known as Allowable Residual Contamination Level (ARCL) was used to evaluate the potential radiological dose to a hypothetical, maximally exposed site resident if the site were released for unrestricted use after the demolition and burial in situ of the facility. The ARCL calculations were prepared in accordance with Allowable Residual Contamination Levels for Decommissioning Facilities in the 100 Areas of the Hanford Site (UNC 1983) and authorized by the U.S. Department of Energy, Richland Operations Office. The radionuclide inventories in the 117-B Filter Building and the inlet/outlet ducts were determined from radiological surveys, isotopic analyses, and from previously collected data that are discussed in UNC (1978).
Paint and concrete samples were collected and analyzed for Cobalt-60, Cesium-137, Europium 152 and 154, 155. Selected samples were analyzed for gross alpha, Tritium, Sr-90 and carbon-14.

The building was demolished in 1989. This waste site has been evaluated and determined to meet remedial action objectives. The evaluation supports reclassification to "No Action".

The waste site was a single-story reinforced concrete structure with a basement. It was 6.1 meters (20 feet) above and 3.4 meters (11 feet) below grade, and the width ranged from 22 meters (72 feet) to 30 meters (98 feet). It included vacuum and pressure seal pit and tunnels.

The site was located south of 105-B.

Waste Type: Sanitary Sewage
Waste Description: The resident radionuclides are tritium, carbon-14, cobalt-60, strontium-90, cesium-137, europium-152, and plutonium-239.

As part of Phase I Decommissioning activities, a calculation methodology known as "allowable residual contamination level" (ARCL) was used to evaluate the potential radiological dose to a hypothetical, maximally exposed site resident, if the site was released for unrestricted use after the demolition and burial in situ of the facility. The ARCL calculation results indicated that the facility was ready for demolition activities. The Phase I demolition and grading were performed using conventional heavy equipment and completed in 1989. The above-grade structure was demolished to within a foot or two of the protective concrete cap (added during Phase I) on the process cell floors. The rubble and remaining clean equipment were removed for disposal in the area landfill. The at- and below-grade structure (floor slabs, foundation walls, footing pedestal, tunnel roof and walls, and piping) was demolished to at least 1 m (3.3 ft) below grade, and the resulting rubble was placed in the basement for in situ disposal. The area was backfilled to grade with clean fill material from a nearby borrow pit at the Hanford Site. The project decommissioned in situ the tunnel from the 115-B/C Building north for approximately 15.2 meters (50 ft). Tunnel demolition was restricted due to a suspected burial site of radioactive waste (100-B-11) located directly over directly over the tunnel about 28.9 meters (75 ft) north of the 115-B/C Building. The 115-B/C Building below grade piping connecting the gas facility with the 105-B and 105-C reactors are internally contaminated. In general, the levels of radiation are relatively low, less than 1 mR/hr. Ten pipeline samples were taken from each of the "B" and "C" pipeline loops and were radiologically characterized.
Description: The site has been remediated and closed out. A dirt road leading to the site is crossed by a vegetation-free outfall structure wall that was left intact when the structure was backfilled to grade.

Location: The site is located north of the northeast corner of 116-B-11 (107-B Retention Basin) bank, directly north of the east end of 116-B-11 (107-B Retention Basin), and downstream of 116-B-7 (1904-B1 Outfall Structure), at the top of the riverbank.

Related Sites/Structures: The site received effluent from the 100-B process effluent lines (100-B-8), the 100-B process sewer lines (100-B-14), and discharged effluent via the 100-BC river effluent pipelines (100-B-15) and flumes (100-B-15:1).

Waste Type: Ash

Waste Description: The unit received and discharged reactor coolant effluent wastes to the river. The 1904-B2 Outfall received cooling water and process drainage from B Reactor and discharged through a 168-centimeter (66-inch) effluent line (100-B-15) to the middle of the Columbia River. A 1992 report states, "surface contamination is known to be present at the 132-B-6 spillway." Other documents reviewed provided no information about wastes or contamination.

Closure Info: Remedial action at the B/C Outfall sites began on June 4, 2001. Excavation of the three outfall sites (132-B-6, 116-B -7, and 132-C-2) involved removing the overburden materials and debris, the contaminated structure, and underlying contaminated soil. Overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at the ERDF. Cleanup verification sampling for the deep and shallow zones was done on January 14 and 15, 2002. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the SAP.

The concrete flumes extending from each of the outfall structures are a subsite of the 100-B-15 River Effluent Pipelines waste at and will be closed at later date. Portions of the flumes within the layback area were removed to the extent necessary to facilitate removal of the outfall structures. The effluent pipelines leading to the outfalls were left in place and grouted at the ends. They will be removed as part of the 100-B-8 and 100-C-6 Pipeline remediation.

The cleanup verification package (CVP-2002-00003) for the sites, also referred to as B/C Outfall, has demonstrated that remedial action has met the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) as established in the approved interim action Interim Action Record of Decision (ROD) (EPA 1999) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17 Rev. 3).

Code: 1607-B1

Names: 1607-B1; 1607-B1 Sanitary Sewer System; 1607-B1 Septic Tank System; 124-B-1

Type: Septic Tank

Status: Inactive

Description: The waste site has been evaluated and reclassified to No Action. It included a septic tank, tile field, and associated pipelines from the 1701-B badge house, the 1720-B patrol building, the 1709-B Fire headquarters, and the change rooms. The septic tank, drain field and piping were removed in 2007. The site appeared as a vegetation and gravel covered area that is raised about 1.2 meters (4 feet) above the surrounding terrain. The septic tank was clearly marked on historical drawings in the...
location of the raised mound.

**Location:** The site was located north of the 1720-B Building site near the entrance to the 100 B/C Area.

**Related Sites/Structures:** The site received effluent from the change rooms, 1701-B Badgehouse, 1720-B patrol building, 1709-B Fire Station Headquarters.

**Process Description:** The septic tank was constructed of reinforced concrete and had a 125 person capacity (132 liters [35 gallons] per capita) or approximately 16,504 Liters with an average detention period of 24 hours. The walls and floor were 25 centimeters (10 inches) thick. The tile field was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe or drain tile with a minimum of 2.4 meters (8 linear feet) per capita. The laterals were open-jointed and spaced 2.4 meters (8 feet) apart.

**Waste Type:** Soil

**Waste Description:** According to documentation, the site received unknown amounts of sanitary sewage from the 1701-B Badgehouse (security checkpoint), the 1709-B Fire Station, the 1720-B Patrol Change Room, and offices.

**Closure Info:** Excavation and confirmatory sampling at the site was conducted on May 21, 2007. Excavation began with a test pit at the suspected location of the septic tank. The septic tank was encountered less than 0.3 meters (1 foot) below ground surface (bgs). The top of the tank was found to have been entirely removed and the tank contained mostly soil backfill with small quantities of miscellaneous, nonhazardous debris (i.e., bollards, concrete debris, rebar, and VCP pieces). A single sample was collected from the bottom of the tank which was reached at 3.4 meters (11 feet) bgs. Excavation at the drain field revealed vitrified clay pipe containing no sediment. The rest of the samples consisted of soil underlying the tank, soil underlying pipelines, and the soil underlying the drain field.

---

**Code:** 1607-B2  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (3/13/2007)  
**Names:** 1607-B2; 1607-B2 Sanitary Sewer System; 1607-B2 Septic Tank System; 124-B-2  
**Start Date:** 1/1/1944  
**End Date:**  
**Type:** Septic Tank  
**Status:** Inactive  
**Description:** The site has been remediated and Interim Closed Out. The site included a septic tank and drain field. The site was divided into subsite 1 - Septic drain field and subsite 2- the septic tank and pipeline.

**Location:** The septic tank was located 390 meters (1280 feet) north of the 105-B Building. The drain field was located 240 meters (787.4 feet) northwest of the septic tank.

**Related Sites/Structures:** The septic tank received sanitary sewage effluent from the 105-B Reactor Building, the 190-B Pumphouse and the 100-B Area office buildings. The office buildings have been removed.

**Process Description:** The septic tank system received effluent from the 100-B/C Area office buildings, 105-B Reactor Building, and the 190-B Pumphouse. The septic tank had a capacity of 59,620.24 liters (15,750 gallons). The system had the potential to support 450 persons assuming input of 132.5 liters (35 gallons) per capita per day and a one day retention period.

**Waste Type:** Ash  
**Waste Description:** This unit received sanitary sewage from the 100 B/C Area office buildings, the 105-B Reactor Building, and the 190-B Pumphouse. All office buildings have been removed; however, the sewer lines to the respective buildings remained in place.
Closure Info: Remediation of the 100-B-14:2 and 1607-B2 waste sites was performed in stages from January 2005 through June 2006. All excavation was restricted within the shallow zone (less than 4.6 meters [15 feet] bgs), with an average depth of approximately 2.5 meters [8 feet] bgs, and a maximum depth of approximately 4 meters [13 feet] bgs at the septic tank. Excavation at the northern portion of the site continued to greater depth due to concurrent remediation of the underlying 100-B-14:1 process sewer. Excavated and disposed material quantities could not be explicitly separated for each site due to co-location and concurrent remediation of differing functional pipeline groups.

Based on the results of confirmatory sampling and previous investigations, it was decided that remedial action was necessary at areas 1, 2, 4, and 5 and that no further action was required at area 3. Area 1 was removed with the remediation of the 100-B-8:1 effluent lines. A decision was also made that remediation was necessary at the 1607-B2 waste site without further investigation based on the confirmatory sampling results for the influent feeder pipelines.

Due to its proximity to the reactor building, the southernmost portion of the 1607-B2 collection line, which formerly serviced the 105-B Reactor Building, was not removed. This portion of the pipeline will be addressed in the 118-B-8, 105-B Reactor waste site.

Site remediation consisted of the removal of the sewer piping, septic tank, and drain field where applicable, as well as adjacent, potentially-contaminated soils for disposal at the Environmental Restoration Disposal Facility (ERDF). Remedial actions were performed so as to not preclude any future uses (as bounded by the rural-residential scenario) and to allow unrestricted use of shallow zone soils [i.e., surface to 4.6 meters (15 feet) deep].

This Site has the Following SubSites:

Code: 1607-B2:1
Names: 1607-B2:1; 1607-B2 Drain Field

Code: 1607-B2:2
Names: 1607-B2:2; 1607-B2 Septic Tank and Pipeline

Code: 1607-B2:1
Classification: Accepted
Reclassification: Interim Closed Out (3/13/2007)

Names: 1607-B2:1; 1607-B2 Drain Field
Type: Septic Tank
Status: Inactive
Start Date: 
End Date: 

Description: A historical drawing states that the drain field was "to be located in field" near the septic tank, but does not show exact location. The drain field is constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a total of 1097.3 meters (3600 linear feet) of piping (2.4 meters [8 linear feet] per capita). The laterals are open-jointed and spaced 2.4 meter (8 feet) apart. The drain field was a vegetation-covered area surrounded with light-duty steel posts and light-duty barricade chain. During the March 2000 field visit, it was noted that some of the barricade has fallen. The site was identified with "Drain Field" signs.

Location: The drain field is located 240 meters (787 feet) northwest of the septic tank.

The SubSite is Part Of:

Code: 1607-B2
Names: 1607-B2; 1607-B2 Sanitary Sewer System; 1607-B2 Septic Tank System; 124-B-2

Code: 1607-B2:2
Classification: Accepted
**Names:** 1607-B2; 1607-B2 Septic Tank and Pipeline  
**Reclassification:** Interim Closed Out (3/13/2007)

**Type:** Septic Tank

**Status:** Inactive

**Start Date:**

**End Date:**

**Description:** The septic tank had a capacity of 59,620.24 liters (15,750 gallons). The system could support 450 persons assuming input of 132.5 liters (35 gallons) per capita per day and a one day retention period. The septic tank was constructed of reinforced concrete. The walls and floor are 25 centimeters (10 inches) thick. During the March 2000 field visit, it was observed that the top of the septic tank was at grade level except on the north side, where it was above grade. In many areas the edges of the concrete were obscured by soil and vegetation. There were three manholes in the top of the tank covered by metal covers with handles. The septic tank was surrounded by six black and yellow striped posts, each about 0.9 meter (3 feet) high, and a light-duty barricade chain. The site was identified with a blue and white "Septic Tank" sign.

**Location:** The septic tank was located 390 meters (1280 feet) north of the 105-B Building.

---

**The SubSite is Part Of:**

**Code:** 1607-B2

**Names:** 1607-B2; 1607-B2 Sanitary Sewer System; 1607-B2 Septic Tank System; 124-B-2

---

**Code:** 1607-B5

**Classification:** Accepted

**Reclassification:** None

**Names:** 1607-B5; 1607-B5 Septic Tank System; 124-B-4; 1607-B4; 1607-B4 Sanitary Sewer System; 1607-B4 Septic Tank System

**Type:** Septic Tank

**Start Date:** 1/1/1944

**End Date:**

**Description:** The septic tank can be identified by a 20 centimeter (8 inch) capped steel vent pipe. The cap is stamped with the words septic tank. It is surrounded by a vegetation-free graveled parking lot. The pipe extends above grade about 0.76 meters (2.5 feet). The drain field runs southeast of the tank. The residue in the tank was sampled in January 2001. Elevated levels of cesium resulted in the tank being posted with Underground Radioactive Material signs. The tank was not backfilled. In 2007, analysis of additional samples of tank contents found no radiological constituents above background in either the liquid or sludge waste in the tank. For this reason, the site was down posted from URMA status. HEIS numbers for the 2007 sampling effort are: liquid--J14XJ3, J14XJ4, J14XJ5, and J14XJ6; sludge--J14XH9, J14XJ0, J14XJ1, and J14XJ2.

**Location:** The site is located southeast of the 181-B/C Pump House.

**Related Sites/Structures:** The site is associated with the 181-B pump house building.

**Process Description:** The unit received sanitary sewage from the 181 B/C Pumphouse.

**Waste Type:** Chemicals

**Waste Description:** This unit received sanitary sewage from 181-B/C River Pumphouse. The flow rate to the unit was estimated at approximately 35 gal/day (130 L/day). In January 2001, the tank was sampled and analyzed for radionuclides. All radionuclides were undetected except for cesium-137, which was 38.3 picocuries per liter and gross beta, which was 1.8 picocuries per liter.
Code: 1607-B7  
Classification: Accepted  

Names: 1607-B7; 1607-B7 Sanitary Sewer System; 1607-B7 Septic Tank System; 124-C-1  
Type: Septic Tank  
Status: Inactive  
Start Date: 1/1/1944  
End Date: 1/1/1969  

Description: The site has been remediated and interim closed out. The waste site consisted of a septic tank and drain field. The tank was constructed of reinforced concrete with a brick manhole access. The drain field was located due east of the tank.  
Location: The unit was located northeast of the 183-B Filter Plant.  
Related Sites/Structures: The 183-B water treatment facility discharged effluent to the septic system via the 100-B-14 pipeline.  
Process Description: The tank walls were 20 centimeters (8 inches) thick, the floor was 15 centimeters (6 inches) thick, and 2.5 meters (8 feet 3 inches) deep. It had a 12-person capacity (130 liters [35 gallons] per capita) with an average detention period of 24 hours. The drain field was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a minimum of 2.4 meter (8 linear feet) per capita. The laterals were open jointed and spaced about 2.4 meters (8 feet) apart.  
Waste Type: Soil  
Waste Description: This unit received an unknown amount of sanitary sewage from 183-B Water Treatment Plant.  
Closure Info: Remedial action at the 1607-B7 site was conducted in March 2003. Excavation of the site involved removing the overburden materials, the septic system (tank and drain field), and underlying contaminated soil. Contaminated materials including the septic tank and drain field piping were disposed of at the ERDF. Remedial action objectives and goals for the 1607-B7 site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17). The selected remedial action for the 1607-B7 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. Waste site COPCs for the 1607-B7 site were identified through process knowledge and analogous site data and are included in the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort (BHI 2003). From BHI (2003), the COPCs for this site consist of metals, pesticides, polychlorinated biphenyls (PCBs), and semivolatile organic compounds (SVOCs). Additional COPCs for this site included at the request of the regulatory agency are radionuclides (gross alpha, gross beta, and gamma emitters) and hexavalent chromium. Gross alpha and gross beta analyses were conducted for screening purposes.
At the completion of the remedial action, the total excavation was approximately 369 square meters (3,709 square feet) in area with a depth of 3.5 meters (11.5 feet). Approximately 198 metric tons (218 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The septic system inlet pipe was partially removed, see map and co-ordinates in the Cleanup Verification Package (CVP) for a more precise location. The remainder of the pipeline (100-B-14) from the 183-B water treatment facility will be dispositioned with the other pipelines in that site.

Results of the sampling, laboratory analyses, and data evaluations for the 1607-B7 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

**Table:**

| Type: Trench | Start Date: 1/1/1952 |
| Status: Inactive | End Date: 1/1/1968 |
| **Description:** | This site has been remediated and Interim Closed Out. It has been backfilled and revegetated. The remediation of the 116-C-1 trench began with the 100-B/C Demonstration Project in 1996. The final remediation project occurred in three stages; removing and disposing of the engineered structure, excavation and disposal of eight contaminated soil plumes and a characterization test pit. The final remediation project was completed in January 1998. |
| **Location:** | 116-C-1 was located northeast of the 116-C-5 retention Basins approximately 253 meters (830 feet) from the 100-year flood level of the Columbia River. |
| **Release Description:** | The 116-C-1 Trench received 700 million liters (184 million gallons) of contaminated cooling water from the 100-B/C Area Retention Basins. The site continued to receive contaminated cooling water until reactor operations ceased in 1968. An additional 40 billion liters (more than 10 billion gallons) of high-temperature reactor cooling water was discharged to the site during a 150 day infiltration test in 1967. |
| **Related Sites/Structures:** | The site was associated with 116-C-5 (107-C Retention Basins). |
| **Process Description:** | The 116-C-1 site was constructed in 1952. The 16 meter long, 32 meter wide, 5 meter deep (548 ft long, 105 ft wide, 16.4 ft deep) trench was an unlined process effluent disposal trench that received 700 million liters (184 million gallons) of contaminated cooling water from the 100-B/C Area Retention Basins after ruptured fuel elements were detected in the reactors. The 116-C-1 site continued to receive contaminated cooling water until reactor operations ceased in 1968. An additional 40 billion liters (more than 10 billion gallons) of high-temperature reactor cooling water was discharged to the site during a 150 day infiltration test in 1967. This test likely influenced the distribution of contaminants beneath the site. Influent water was transferred to the trench via two, 107 centimeters (42 inches) steel pipes leading from the 168 centimeters (66 inches) outfall pipelines that connected the 116-C-5 Retention Basins to the river. Two additional 61 centimeters (24 inches) pipes discharged influent water to the site. The contaminated water discharged to the site soils continued from 1952 to 1968. After operations ceased in 1968, the site was decommissioned as part of the Radiation Area Remedial Action (RARA) Program. The RARA activities at the 116-C-1 site included the placement of at least 1.5 meters (4.9 feet) of fill material (shielding) over the entire base of the trench to stabilize the exposed contaminated surfaces of the engineered structure. |
| **Waste Type:** | Chemicals |
**Waste Description:**
The site received effluent overflow from 116-C-5 (107-C Retention Basin) during reactor outages due to ruptured fuel elements. Beginning in 1955, this site also served 116-B-11 (107-B Retention Basin). The trench was used in 1967 for an infiltration test in which the total cooling water volume from B-Reactor was disposed in the trench. During the test, an estimated 4.4E+10 liters (1.17E+10 gallons) of effluent water were released. From process knowledge, the waste site contaminants of concern (COCs) identified are: Americium-241, Cobalt-60, Cesium-137, Europium-152, -154, -155, Nickel-63, Plutonium-238, -239/240, Strontium-90, Uranium-238, Total Chromium, Hexavalent chromium, Mercury, and Lead.

**Closure Info:**
The 116-C-1 site cleanup activities began with the 100-B/C Demonstration Project in 1966. The purpose of the 100-B/C Demonstration Project was to initiate a limited remedial action in the 100 areas to address uncertainties in remedial design and planning. An area measuring 38 by 38 meters (124 by 124 ft) in the southwest corner of the 116-C-1 trench was excavated in 1996.

The final remediation project occurred in three phases. The excavation and disposal of the engineered structure began on July 15, 1996 and was completed on November 15, 1996. The second phase addressed eight contaminated soil plumes. The plumes extended beyond the engineered structure and were identified during the subsequent field screening and sampling efforts. The excavation and disposal of the plume areas began on April 23, 1997 and were completed on October 28, 1997. After the soil plume excavation was completed, the third phase began. The third phase excavated a test pit down to groundwater to further characterize the subsurface. The test pit was centered at an area of elevated radiological activity near the 116-C-1 inlet pipes. The test pit effort began on December 15, 1997, and was completed on January 15, 1998. Soil samples were taken from each quadrant of the test pit and composited for each of the eight 1 meter (3 ft) test pit lifts. When the final test pit samples were obtained, 1 meter of clean native soil from identified borrow pits to the south was placed in the bottom of the pit. Backfill of the test pit occurred in approximately the same sequence as when the soils were removed using the stockpiled materials.

At the completion of the remediation project, the excavation footprint was approximately 11,116 square meters with a depth of 5 meters (16.4 ft). Approximately 97,515 metric tons of material was disposed at ERDF. The influent pipelines will be addressed in a separate remediation project.

| Code: 116-C-5 | Classification: Accepted |
| Names: 116-C-5; 116-C-5 Retention Basins; 107-C Retention Basins | Reclassification: Interim Closed Out (12/8/1999) |
| Type: Retention Basin | Start Date: 1/1/1952 |
| Status: Inactive | End Date: 1/1/1969 |

**Description:**
The site has been remediated, backfilled, and revegetated.

**Location:**
The 116-C-5 Retention Basins were located approximately 1,040 meters (3,400 feet) north of the 105-C Reactor and southeast of 116-B-11 (107-B Retention Basin).

**Related Sites/Structures:**
The 116-C-5 Retention Basins are associated with the 105-C Reactor, 105-B Reactor, 116-C-1 Liquid Waste Disposal Trench, 132-B-6 (1904-B2) Outfall, and the 132-C-2 (1904-C) Outfall.

**Process Description:**
The 116-C-5 Retention Basins were constructed to hold cooling water effluent from the 105-C Reactor to allow for thermal cooling and radioactive decay prior to release to the Columbia River. When in operation, the retention basins were two circular, 3.8E+07 liter (1.0E+07 gallon), open-topped tanks. Each tank had a diameter of 100 meters (330 feet), a depth of 4.9 meters (16 feet), and had internal baffles to prevent water from channeling across the tanks into the discharge lines. The tanks were constructed of welded carbon steel and were set on a
reinforced concrete foundation with a crushed rock subfloor.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** The basins received cooling water effluent from the 105-B and 105-C Reactors for radioactive decays and thermal cooling prior to release to the Columbia River. The total radionuclide inventories in the vicinity of the basins ranged from 5 to over 400 curies. Eighty percent of the total radionuclide inventory is contained within the soil adjacent to the basins. Approximately 10 curies leached into the basins' floors and walls.

**Closure Info:** The site has been excavated, remediated, and closed out. The material removed from the site was disposed of in the Environmental Restoration Disposal Facility (ERDF). Excavation of the 116-C-5 site began on September 21, 1996, by removing the overburden materials and underlying contaminated soil. Based on field screening, overburden materials that were identified as potentially clean were placed in stockpiles for potential use as backfill. Overburden materials that were found to be contaminated were disposed of at ERDF. On March 21, 1998, the excavation had reached the design limit at El. 129 meters (423 ft). Soils not meeting direct exposure RAGs based on field screening results were excavated, loaded into shipping containers, and disposed of at ERDF. Cleanup verification sampling began on August 18, 1998, and was finished on January 20, 1999 (as stated, the adjacent pipeline areas will be addressed at a later date). Contaminated soil associated with the process effluent pipelines was partially removed; the rest remains for final remediation with pipelines and a separate cleanup verification package. The 100-BC process effluent pipelines are scheduled to be removed within the next few years. The 116-C-5 sidewall areas that are adjacent to future pipeline excavation areas were not sampled as part of this cleanup verification effort. These areas will be sampled and verified clean as part of the effluent pipeline remediation efforts.

In accordance with the Interim Action Record of Decision and Remedial Design Report/Remedial Action Work Plan, a rural residential exposure scenario was assumed in calculating cleanup levels. Results of the sampling, testing, and analyses for the 116-C-5 site cleanup indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of surface waters (including the Columbia River) have been met.

At the completion of the remedial action, the excavation floor area was approximately 26,000 square meters (6.4 acres) at a depth of 4.6 meters (15 feet), and approximately 224,709 metric tons (246,695 tons) of material from the site, including pipelines within the excavation footprint, were disposed of at the ERDF. The excavation is to be backfilled to the reference grade of 133.5 meters (438 feet).

**Code:** 132-C-2  
**Classification:** Accepted

**Names:** 132-C-2; 1904-C Outfall; 116-C-4  
**Reclassification:** Interim Closed Out (7/25/2002)

**Type:** Outfall  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site has been remediated and closed out.

**Location:** The site was located just north of the 116-B-11 (107-B Retention Basin) and downstream of 116-B-7 (1904-B1 Outfall) and 132-B-6 (1904-B2 Outfall).

**Related Sites/Structures:** The site received effluent from the 100-C process effluent lines (100-C-6) and discharged effluent via the 132-C-2 Outfall, 100B/C river effluent pipelines (100-B-15) and/or flumes (100-B-26).

**Waste Type:** Water
Remedial action at the B/C Outfall sites began on June 4, 2001. Excavation of the three outfall sites (132-B-6, 116-B -7, and 132-C-2) involved removing the overburden materials and debris, the contaminated structure, and underlying contaminated soil. Overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at the ERDF. Cleanup verification sampling for the deep and shallow zones was done on January 14 and 15, 2002. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the SAP.

The concrete flumes extending from each of the outfall structures are a subsite of the 100-B-15 River Effluent Pipelines waste at and will be closed at later date. Portions of the flumes within the layback area were removed to the extent necessary to facilitate removal of the outfall structures. The effluent pipelines leading to the outfalls were left in place and grouted at the ends. They will be removed as part of the 100-B-8 and 100-C-6 Pipeline remediation.

The cleanup verification package (CVP-2002-00003) for the sites, also referred to as B/C Outfall, has demonstrated that remedial action has met the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) as established in the approved interim action Interim Action Record of Decision (ROD) (EPA 1999) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17 Rev. 3).

The site has been evaluated and reclassified to "No Action". The site consisted of an area of household debris typical of items found at pre-Manhattan Project farm sites.

The site was located on the right bank of the Columbia River (facing downstream) between 100B Area and 100K Area, approximately 1/3 mile west of the old Hanford Irrigation Project Pumphouse and approximately 40 yards from the river.

The area appeared to have been used as a dumping area for domestic waste before the Manhattan Project.

Empty food cans, paint cans, buckets and glass.

Miscellaneous household garbage including, one C cell battery was found.

The waste site was evaluated and reclassified to No Action with correspondences attached to the signed WIDS Reclassification form 2006-041.
100-BC-2

**Code:** 100-B-1  
**Classification:** Accepted

**Names:** 100-B-1; Laydown Yard; Surface Chemical and Solid Waste Dumping Area  
**Reclassification:** Interim Closed Out (4/26/2006)

**Type:** Dumping Area  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site has been remediated and Interim Closed Out. It was an old laydown yard and adjacent dumping area. Miscellaneous debris was scattered in the southern area of the site. There were many areas of stressed vegetation and discolored soil.

In February 2003, the northwest portion was being used as a soil staging area. It was removed from the 100-B-1 site description, reducing the size of the site.

**Location:** The site was located east of the 105-C Building. The export water line ran through the center of the area. Some debris and stressed vegetation was identified north of the export water line and some debris and stressed vegetation was found south of the export water line.

**Process Description:** The 100-B Technical Baseline Report describes two areas located east of 105-C. One area is described as "Undocumented Solid Waste Site: Laydown Yard". The laydown yard contains miscellaneous items such as wood, power poles, light fixtures, wire, broken glass, broken transite and plexiglass filter columns. The other is described as Undocumented Solid and Liquid Waste Site: Surface Chemical Dumping Area”. The chemical dump area, located 100 meters (300 feet) northeast of the laydown yard, contains areas of distressed vegetation and oil contaminated soil. Both areas were combined into WIDS site code 100-B-1.

**Waste Type:** Sanitary Sewage  
**Waste Description:** Petroleum contaminated soil was also noted and verified with field screening tests. Areas of soil appear to be discolored by oil. A field screening test on the soil with ENSYS Petro and Polyaromatic Hydrocarbons (PAH) kits indicated petroleum contamination. The Petro results were greater than 10 parts per million and less 100 parts per million total petroleum hydrocarbons (TPH). The PAH results were greater than 1 part per million and less than 10 parts per million polyaromatic hydrocarbons.

**Waste Type:** Sanitary Sewage  
**Waste Description:** The solid waste at the site consists of miscellaneous debris such as wooden power poles, lighting fixtures, coils of wire, broken glass, small amounts of broken transite, a bottle of hand cream, and four 20-centimeter (8-inch) Plexiglas filter columns.

**Closure Info:** Remedial action began on June 9, 2003, with three additional excavations throughout 2005 due to elevated total petroleum hydrocarbon concentrations. Five Sample Areas were identified. Sample collection was done in Test Pits.

Remedial actions were performed so as to not preclude any future uses (as bounded by the rural-residential scenario) and to allow unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). Because of the presence of TPH, pesticides, SVOCs, and PCBs at concentrations exceeding RAGs and visual observations of debris during confirmatory sampling. From 2003 through 2005, approximately 51,099 metric tons (56,327 US tons) of material was removed for disposal at ERDF. The site was excavated to a maximum depth of 3.7 to 4 meters (12 to 13 feet) below ground surface.

**Code:** 100-B-23  
**Classification:** Accepted
Names: 100-B-23; 100-B/C Surface Debris

Type: Dumping Area

Status: Inactive

Reclassification: Interim Closed Out (6/16/2008)

Start Date: 

End Date: 

Description: The site consisted of various sizes and forms of scattered surface debris in the 100-B/C Area which has been identified as CERCLA waste or potentially dangerous under Washington Administrative Code (WAC) regulations.

Location: The surface debris included in this site was scattered over the 100 B/C Area. A GPS was used to record the location of field observations.

Process Description: A field walk-down of the 100-B/C Area was conducted during July and August 2004 as a final closure screening activity. Scattered surface debris that was created during the construction, operating, decontamination and decommissioning (D), and remedial action (RA) activities at the 100-B/C Area was identified as potentially dangerous/CERCLA waste. The locations of the debris were recorded using Global Positioning System (GPS) technology and a description was entered into a field logbook. For some features, additional information was obtained using digital photography. Subsequent evaluation of the collected data yielded 4 generic groupings of wastes: asbestos-containing material, lead, oil and oil filters, and treated wood.

The field walk-down of the 100-B/C Area did not include the 30-meter by 30-meter grids where cleanup activities were being conducted or within posted areas. The field walk-down was limited to observations; no sampling was conducted. Observations of potential physical hazards, cultural artifacts, and nonhazardous, nondangerous solid waste were GPSd and noted in a logbook. A spreadsheet was created listing the coordinates of the debris that had been observed. The spreadsheet is in the WIDS library file.

Waste Type: Sanitary Sewage

Waste Description: Contaminants of potential concern (COPCs) include asbestos, lead, oil, and creosote. Debris is scattered across the 100-B/C area.

Waste Type: Sanitary Sewage

Waste Description: Pieces of lead sheet.

Waste Type: Sanitary Sewage

Waste Description: The treated wood locations are isolated; that is, not within existing or abandoned railroad beds or utility laydown yards. These locations contain one or more horizontal railroad ties, posts, or poles imbedded or resting on the surface, more or less weathered. The locations do not include posts, poles, plywood, or other wood materials that does not appear to have been a treated wood.

Waste Type: Sanitary Sewage

Waste Description: Oil from automobile oil filters on soil surface; scattered oil filters.

Closure Info: A meeting between the U.S. Environmental Protection Agency (EPA), the U.S. Department of Energy, Richland Operations Office (DOE-RL), and the Environmental Restoration Contractor (ERC) Team was held on May 5, 2005, to determine a path forward for the 100-B-23 waste site. EPA and DOE-RL agreed that a general cleanup action would occur at the 100-B-23 waste site to remove the friable ACM, oil filters, oil-stained soil, lead debris, and treated wood debris.

Remediation of the 100-B-23 waste site was performed in accordance with the site-specific remediation approach as outlined in the work instruction and the site specific soil-sampling documents. The design consisted of the removal of suspect hazardous material identified at the
surface of the site (friable ACM, lead sheeting and batteries, oil filters, and treated wood) along with any associated stained soils. Verification sampling of underlying stained soils was performed concurrently with the cleanup action to support waste site closure. Two locations contained friable asbestos. All nonfriable ACM material and most of the inert wood material was left in-place at the site. The nonfriable ACM and inert wood material did not present a potential release to the environment, therefore, no cleanup action was required for these items.

Remediation and verification sampling of the site was performed between June 2007 and February 2008. Evaluation of the collected information for the surface debris features yielded four generic waste groupings: asbestos-containing material (ACM), lead debris, oil and oil filters, and treated wood. The various forms of scattered surface debris are believed to be created during the construction, operating, decontamination and decommissioning, at the 100-B/C Area.

No geophysical survey was performed because the position and character of debris was well established by visual reconnaissance.

A total of approximately 680 metric tons (750 US tons) of debris and stained soils were removed from the site and disposed at the Environmental Restoration Disposal Facility.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The verification sampling results supported a reclassification to Interim Closed Out. The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. Site contamination did not extend into the deep-zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone were not required.

<tr>
<td>Process Description: The exact process that caused the garnet sand to be located at this site is unknown. However, garnet sand (grit) was used in sandblasting operations throughout the Hanford site.</td>
<td>Waste Type: Sanitary Sewage</td>
</tr>
<tr>
<td>Waste Description: The waste is garnet sand mixed with the material that was sandblasted. Confirmatory sampling is needed to determine if there are any contaminants of potential concern.</td>
<td>Closure Info: The 100-B-31 waste site was an area of scattered garnet sand on the 183-C Clearwell concrete pads and surrounding soils. The garnet sand was suspected to be the result of sandblasting operations at the former clearwell tanks. The site has been remediated with shallow scraping and does not require backfill. The site measured 134 meters (440 ft) in length by 122 meters</td>
</tr>
</tbody>
</table>
(400 ft) in width, for a total area of 16,400 square meters (176,000 sq ft).

Remedial action at the site was performed from May to July 2009. Remediation included scraping along the edge of the clearwell pads and removal of garnet sand, asphalt, and contaminated soil from the area. In total, approximately 2,330 bank cubic meters (3,050 bank cubic yards) of contaminated material was removed from the site. This material, composed of garnet sand, soil, and asphalt, was stockpiled on the northeastern and southeastern tank pads before being disposed at the Environmental Restoration Disposal Facility.

</tbody>
</table>
| Process Description: | This waste site operated from 1944 to 1973, receiving general radioactive and non-radioactive wastes from the 105-B and 105-N Reactors, construction wastes from modification of the 105-B Reactor Building, and process wastes from the P-10 Tritium Separation Project. The original burial ground contained six to eight trenches that ran in a east-west direction, receiving general reactor waste from the B Reactor which included: aluminum tubes, lead bricks, thermocouples, vertical and horizontal aluminum thimbles, stainless-steel gun barrels and expendables (e.g., plastic, wood, and cardboard). It was expanded over time to include more than 20 trenches. Spline silos were also constructed at the burial ground, which were vertical metal culverts, 3 to 3.7 meters (10 to 12 feet) in diameter, built presumably to receive reactor poison splines and other metal wastes. One extension to the south side of the original burial ground was known as the 108-B Solid Waste Burial Ground, measuring 46 meters (150 feet) long by 73 meters (240 feet) wide by 6.1 meters (20 feet) deep. The burial ground contained three trenches oriented from east to west. This burial ground received contaminated tritium pots, irradiated process tubing (in 1952), contaminated fuel spacers (perfs), solid tritium wastes, and high-level liquid tritium wastes that were sealed in a 7.6-centimeter (3-inch)-diameter iron pipe. The second extension to the burial ground was added in 1956 and was referred to as the "extension to Burial Ground No. 1." It measured 61 meters (200 feet) long by 15 meters (50 feet) wide and ran in a north-south direction, adjacent to and at the midpoint of the original burial ground's west side. This extension contained two trenches that ran in a north-south direction and was used for the burial of contaminated yokes from B Reactor. The third extension was added to the north side of the original burial ground in the mid 1960s and measured 106 meters (350 feet) long by 91 meters (300 feet) wide, with trenches running in an east-west direction. Historical data on the contents of these trenches are not as detailed as with earlier extensions but are presumed to include "general" reactor and construction waste from modifications to B Reactor. During remediation, it was discovered that 2 of the 23 trenches had not been used for waste disposal. Waste materials from the Tritium Separation (P-10) Project were also buried here, including
lithium-aluminum alloy, lead, mercury, aluminum cladding, and palladium.

Waste Type: Chemicals

Waste Description: The burial ground received general reactor waste from the 105B and 105N reactors, including the following: aluminum tubes, irradiated facilities, thermocouples, vertical and horizontal aluminum thimbles, stainless steel gun barrels, wastes from operation of the P-10 tritium separation project, and expendables such as plastic, wood, and cardboard. Waste materials were typically buried 6.1 meters (20 feet) below grade and were covered with a minimum of 1.2 meters (4 feet) of clean soil; actual soil cover ranged from 0.6 meters (2 feet) to greater than 4.3 meters (14 feet). Potential Contaminants include Ag-108m, C-14, Co-60, Cs-137, Eu-152, Eu-154, Eu-155, H-3, Ni-59, Ni-63, Sr-90, cadmium, Cr+6, lead, mercury, boron, graphite, PCBs, SVOAs, TPH, and VOAs. Permanent concrete markers surrounded the site, and "Caution: Underground Radioactive Material" signs were posted. Blue and green ground penetrating radar survey stakes had been placed around the perimeter and in lines crossing the site. A 12 by 4.6-meter (40 by 15-foot), vegetation-free, cobble-covered portion about 46 meters (50 yards) north of the southeast corner is bounded by steel posts and light-duty barricade chain; warning signs are posted on that section.

Closure Info: In late 1994 and early 1995, this burial ground was used for a treatability investigation. A total of 1,530 cubic meters (2,000 cubic yards) of waste was excavated, sorted, characterized and reburied. The overall lateral footprint of the burial ground prior to remediation was approximately 225 meters by 90 meters (740 feet by 300 feet).

The Remedial Action began on February 2, 2004 with overburden removal. Approximately 20,000 bank cubic meters (BCM) [26,200 bank cubic yards (BCY)] of overburden material was removed before beginning excavation. During remediation, it was discovered that 2 of the 23 trenches had not been used for waste disposal. The burial ground also consisted of several spline silos constructed from 3 to 3.7 meter (10 to 12 foot) diameter metal culvert piping and 3 spacer pits shored with railroad ties. Sorting of the burial ground contents began on March 16, 2004. Approximately 1,500 anomalous items were discovered during excavation and sorting operations. Approximately 1,000 of the items were tubes used for packaging and disposal of tritium gas. Approximately 350 were barium desiccant tubes, 81 were tubes used for packaging and disposal of mercury, approximately 50 were glass/plastic bottles, and approximately 70 were unique anomalous containers or solids.

Suspect spent nuclear fuel (SNF) was discovered on September 15, 2004. Remedial activities suspended until the Authorization Basis could be assessed and revised to address spent nuclear fuel (SNF). The suspect SNF was staged in two bunkers within the 118-B-1 waste staging pile area. Six pieces of confirmed SNF and two fractional pieces were identified following characterization. This material was transferred to the 100-K fuel storage basins for interim storage prior to final packaging and disposal. Load-out operations resumed on April 11, 2005 for previously sorted and segregated material. All remedial activities (excavation, sorting, and load-out) resumed on August 24, 2005. The remediation was completed on June 7, 2007, with the exception of characterization and dispositioning of the SNF and approximately 100 remaining anomalous containers.

Over 120,000 metric tons (132,300 tons) of debris and contaminated soil from the Burial Ground was removed and disposed at ERDF. At the conclusion of remediation activities, the excavated area was approximately 10 meters (33 feet) at its deepest, with a lateral footprint of approximately 21,600 square meters (5.3 acres). Approximately 136,000 square meters (33.6 acres) in total at the site were disturbed, including stockpiles and waste sorting and staging areas.
### Names:
118-B-2; Construction Burial Ground No. 1; Minor Construction Burial Ground No. 1

### Reclassification:
Interim Closed Out (4/5/2005)

### Type:
Burial Ground

### Start Date:
1/1/1952

### End Date:
1/1/1956

### Status:
Inactive

### Description:
The site has been remediated and Interim Closed Out. The unit was a burial ground containing a trench that ran east and west. Characterization data found that the 118-B-2 Burial Ground was located within the mapped boundaries of the 118-B-3 Burial Ground. Therefore, the two waste sites were combined in closure documentation and collectively referred to as the 118-B-3 Burial Ground. Following remediation, authorization to remove the radiological postings was given in October 2012.

### Location:
Site characterization data collected in 2001 and 2002 indicated the trench may have actually been within the 118-B-3 Burial Ground. The site was originally thought to be located approximately 128 meters (420 feet) east of the 105-B Building and immediately west of the 118-B-3 Burial Ground.

### Related Sites/Structures:
Received waste from the 107-B Basin repairs and from the 115-B Gas Recirculation Facility alterations.

### Process Description:
This burial ground received dry waste from the 107-B Basin repairs and from the 115-B Gas Recirculation Facility alterations. Operation of the unit began in 1952 and ended in the Summer of 1956.

### Waste Type:
Sanitary Sewage

### Waste Description:
The unit was used for disposal of 100 cubic meters (131 cubic yards) of dry waste from the 107-B Basin repairs and waste from the 115-B Gas Recirculation Facility alterations. Potential Contaminants are: Co-60, Cs-137, Eu-152, Eu-154, Eu-155, Sr-90, chromium, Cr+6, lead, mercury, PCBs.

### Closure Info:
Results of geophysical investigations and test pit excavations conducted in 2001 and 2002 indicated that the 118-B-2 Burial Ground was located within the mapped boundaries of the 118-B-3 Burial Ground. Therefore, the two waste sites were combined in closure documentation and collectively referred to as the 118-B-3 Burial Ground.

Remedial action activities occurred between April 19, 2004 and June 24, 2004. At the completion of remedial action, the excavation was 4,803.8 square meters (51,708 square feet) in area with an average depth of less than 4.6 meters (15 feet). Approximately 9,525 metric tons (10,500 tons) of material, including soil and burial ground debris, were removed from the burial ground and disposed of at the ERDF. Results of the sampling, laboratory analyses, and data evaluations for the site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

---

### Code:
118-B-3

### Classification:
Accepted

### Names:
118-B-3; Construction Burial Ground No. 2

### Reclassification:
Interim Closed Out (4/5/2005)

### Type:
Burial Ground

### Start Date:
1/1/1956

### End Date:
1/1/1960

### Status:
Inactive

### Description:
The site has been remediated and Interim Closed Out. The unit contained many trenches running east and west. Characterization data found that the 118-B-2 Burial Ground was located within the mapped boundaries of the 118-B-3 Burial Ground. Therefore, the two waste sites were combined in closure documentation and collectively referred to as the 118-B-3 Burial Ground. Following remediation, authorization to remove the radiological postings was given in
Location: This unit was located approximately 160 meters (525 feet) northeast of the 105-B Building and directly east of 118-B-2.

Process Description: The burial ground was in operation from the summer of 1956 until 1960 and was used for disposal of solid waste from effluent pipeline modifications and for disposal of reactor-generated solid waste during various modification programs.

Waste Type: Chemicals

Waste Description: The unit was used for the disposal of solid waste from the effluent line modification and for disposal of reactor-generated solid waste during various modification programs. Potential contaminants include: Co-60, Cs-137, Eu-152, Eu-154, Eu-155, Ni-63, Pu-238, Pu-239/240, Sr-90, chromium, lead, mercury, PCBs.

Closure Info: Results of geophysical investigations and test pit excavations conducted in 2001 and 2002 indicated that the 118-B-2 Burial Ground was located within the mapped boundaries of the 118-B-3 Burial Ground. Therefore, the two waste sites were combined in closure documentation and collectively referred to as the 118-B-3 Burial Ground.

Remedial action activities occurred between April 19, 2004 and June 24, 2004. At the completion of remedial action, the excavation was 4,803.8 square meters (51,708 square feet) in area with an average depth of less than 4.6 meters (15 feet). Approximately 9,525 metric tons (10,500 tons) of material, including soil and burial ground debris, were removed from the burial ground and disposed of at the ERDF. Results of the sampling, laboratory analyses, and data evaluations for the site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

Reclassification: 118-B-4; 105-B Dummy Burial Ground; 105-B Spacer Burial Ground

Names: 118-B-4; 105-B Dummy Burial Ground; 105-B Spacer Burial Ground

Type: Burial Ground

Status: Inactive

Start Date: 1/1/1956

End Date: 1/1/1958

Description: The site has been remediated and Interim Closed Out. The waste site consisted of six dummy storage pits installed vertically below ground. The pits were constructed of metal culverts 4.6 meters (15 feet) deep and 1.8 meters (6 feet) in diameter. During remediation, five wood and three metal caissons containing metallic debris were found. Following remediation, authorization to remove the radiological postings was given in October 2012.

Location: The site was located 91 meters (300 feet) northeast of the 105-B Reactor Building within the 105-B exclusion area fence.

Process Description: This site received irradiated aluminum fuel spacers from the 105-B Reactor.

Waste Type: Sanitary Sewage

Waste Description: The unit was used for disposal of fuel spacers dummies. Potential contaminants included: Co-60, Cr+6.

Closure Info: During excavation of the burial ground, five wood and three metal caissons containing metallic debris were found. The caissons contained aluminum fuel spacers, splines, and lead-cadmium "poison pieces" used during operation of the 105-B Reactor. The pieces were found to be intact, which substantially reduced the leachability potential of the slugs. This observation and
Designation of the waste form determined they were fully encapsulated by the aluminum jacket. Therefore, the waste did not technically require macro encapsulation treatment for disposal at ERDF. At the completion of remedial action, the excavation was approximately 531.5 square meters (5,721 square feet) in area with an average depth of approximately 3.9 meters (13 feet). Approximately 3,171 metric tons (3,495 tons) of material, including soil and burial ground debris, were removed from the site and disposed of at ERDF.

Code: 118-B-6
Classification: Accepted
Start Date: 1/1/1950
End Date: 1/1/1953
Type: Burial Ground
Status: Inactive
Description: The site has been remediated and Interim Closed Out. The site has been excavated, backfilled and leveled to grade. The unit consisted of two concrete caissons (pipes). They were constructed of 5.5 meters (18 feet) long by 1.8 meters (6 feet) in diameter pipes that were buried vertically in the ground and capped with a concrete pad. The concrete pad had two pear-shaped steel lids that provided access to the caissons. Following remediation, authorization to remove the radiological postings was given in October 2012.

Location: This site was located approximately 107 meters (350 feet) northeast of the B Reactor.

Process Description: This site was used for disposal of wastes from the "metal line" of the P-10 Tritium Separation Project. At the time of remediation, one of the vertical caissons was filled with waste and capped and the other was partially filled with waste. Both were capped by a concrete pad. The pad measured about 4.6 by 3.0 meters (15 by 10 feet) with two pear-shaped steel lids that provided access to the caissons’ burial chambers.

Waste Type: Sanitary Sewage
Waste Description: The unit received the following types and amounts of wastes: 26,500 kilograms (58,500 pounds) of spent lithium-aluminum alloy, 21,300 kilograms (47,000 pounds) of lead from pots, 45 kilograms (100 pounds) of mercury from manometers and Toepler pumps, 1,720 kilograms (3,800 pounds) of aluminum cladding, and 1,360 kilograms (3,000 pounds) of palladium. Additionally, it contains a total of 21,200 kilograms (23.4 tons) of wastes generated as a result of the P-10 tritium production project in the 108-B Facility. Potential contaminants include: H-3, lead, mercury.

Closure Info: Remedial action at the site began in November 2004. Excavation of the site involved removing the uncontaminated overburden, caissons, concrete pad, buried materials, and underlying contaminated soil. Although the majority of the excavation was completed by December 2004, leach tests done on soil samples taken from the bottom of the excavation showed levels of tritium that required an additional 1.5 meters (5 feet) of soil removal. This additional excavation was completed in June 2005.

One of the concrete caissons was filled with waste and capped, while the other was partially filled with waste, covered with a thin layer of concrete, and left for future use. A test pit was dug at the bottom of the 18 foot excavation. Tritium samples were collected at depths of 21 feet, 27 feet and 31 feet below ground surface.

At the conclusion of excavation activities, the elevation of the bottom of the excavation was at 136 meters (446 feet). The excavation was approximately 885 square meters (9,523 square feet) in area with a depth of approximately 7 meters (23 feet). Nearly 577 metric tons (636 tons) of
contaminated material was disposed at ERDF.

<tr>
<td>Closure Info:</td>
<td>The Cleanup Verification Package (CVP-2003-05) has documented that the site meets the remedial action objectives (RAOs) and remedial action goals (RAGs) for the site as established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP). At the completion of remedial action, the total excavation was approximately 255 square meters (2,740 square feet) in area with a depth of 2.5 meters (8.2 feet). Approximately 361 metric tons (397 tons) of site materials were disposed at the Environmental Restoration Disposal Facility. The septic system inlet pipe was removed to the extent of the site excavation. The approximately 12 meters of remaining pipeline between the 190-C Pump House and the 1607-B8 site has been included in the 100-C-9 pipeline site and will be dispositioned with the other pipelines in that site. At the conclusion of excavation activities, the bottom elevation of the excavation was at 143.7 meters (471.3 feet). The excavation was approximately 255 square meters (2,740 square feet) in area with a depth of approximately 2.5 meters (8.2 feet). The remaining soils at the site have been sampled, analyzed, and modeled. The results of this effort indicated that the materials from the site containing contaminants at concentrations exceeding RAGs have been excavated and disposed at the ERDF. These results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The 1607-B8 site is verified to be remediated in accordance with the ROD and may be backfilled.</td>

**Code:** 1607-B10

**Names:** 1607-B10; 1607-B10 Septic Tank System; Sewage Disposal Field

**Classification:** Accepted

**Reclassification:** Interim Closed Out (7/29/2003)
Rev. 24

DOE/RL-88-30

Septic Tank

Inactive

Start Date: 1/1/1952
End Date: 1/1/1969

Description: The site has been remediated and interim closed out. The site consisted of a septic tank and tile field. A steel pipe riser 20 centimeters (8 inches) in diameter and 84 centimeters (33 inches) above grade marked the location of the tank.

Location: The unit was located south of the former site of the 183-C Head House and east of the road that passed the 183-C Water Plant in a north/south direction.

Related Sites/ Structures: The 183-C Head House discharged sanitary effluent to the septic system via the 100-C-9 pipeline.

Waste Type: Process Effluent

Waste Description: The unit received only sanitary sewer wastes from the headhouse of the 183-C Water Treatment Plant. There were no known discharges of hazardous chemicals or radionuclides.

Closure Info: At the completion of the remedial action, the total excavation was approximately 178 square meters (1,915 square feet) in area with a depth of 2.5 meters (8.2 feet) and the bottom elevation of the excavation was 145.0 meters (475.6 feet). Approximately 328 metric tons (361 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The 1607-B10 septic system inlet pipe was removed to the extent of the site excavation. The remainder of the pipeline between the 183-C Head House and the 1607-B10 site is included in the 100-C-9 pipelines site and will be dispositioned with the other pipelines in that site.

Remedial action objectives and goals for the 1607-B10 site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL-96-17).

The selected remedial action for the 1607-B10 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to the average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and no radionuclide contaminants of potential concern (COPCs).

The CVP demonstrates that remedial action at the 1607-B10 site has achieved the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils at the 1607-B10 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 1607-B10 site containing COPCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The 1607-B10 site is verified to be remediated in accordance with the ROD and may be backfilled.

**Description:**
The site has been remediated and interim closed out. Remedial action at the 1607-B11 site was conducted in March 2003. Excavation of the site involved removing the overburden materials, septic system (septic tank and drain field), and underlying contaminated soil. Contaminated materials including the septic tank and drain field piping were disposed of at the ERDF. The site consisted of a septic tank and drain field.

**Location:**
The unit was located north of the 183-C Filter Building site, west of the 183-C Filter Building site entrance road. The drain field was located northwest of the tank.

**Related Sites/Structures:**
The septic system was associated with the 183-C Filter Building, Pump Room and 100-C-9 pipeline site.

**Process Description:**
A steel riser 20 centimeters (8 inches) in diameter and 46 centimeters (18 inches) above grade marked the location of the tank. The vertical tank was constructed of steel and had a capacity of 1,325 liters (350 gallons).

**Waste Type:**
Construction Debris

**Waste Description:**
There were no known discharges of hazardous chemicals or radionuclides into the unit. The unit received only sanitary sewer wastes from the 183-C Filter Building & Pump Room (183-C Water Treatment Plant).

**Closure Info:**
Remedial action at the 1607-B11 site was conducted in March 2003. Excavation of the site involved removing the overburden materials, septic system (septic tank and drain field), and underlying contaminated soil. Contaminated materials including the septic tank and drain field piping were disposed of at the ERDF.

Remedial action objectives and goals for the 1607-B11 site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL-96-17).

The selected remedial action for the 1607-B11 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to the average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and no radionuclide contaminants of potential concern (COPCs).

Waste site COPCs for the 1607-B11 site were identified through process knowledge and analogous site data and are included in the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort (BHI 01249). The COPCs for this site consisted of metals, pesticides, polychlorinated biphenyls (PCBs), and semivolatile organic compounds (SVOCs). Additional COPCs for this site included at the request of the regulatory agency are radionuclides (gross alpha, gross beta, and gamma emitters) and hexavalent chromium. Gross alpha and gross beta analyses were conducted for screening purposes.

Of the metals analyzed for (arsenic, barium, cadmium, total chromium, lead, mercury, selenium,
and silver), only lead was detected at levels greater than Hanford Site or Washington State background. Because concentrations of lead in soil were greater than background, it is included as a cleanup verification contaminant of concern (COC) for the 1607-B11 site. Because the other metals were not detected above soil background concentrations, they were not included as site COCs.

None of the 21 pesticides, 7 PCB Aroclors, or 64 SVOCs (with the exception of bis[2-ethylhexyl]phthalate) analyzed for were detected in cleanup verification samples at concentrations greater than the analytical method practical quantitation limits (PQLs). Bis[2-ethylhexyl]phthalate is included as a cleanup verification COC because of the detections above the analytical method PQL. None of the other pesticides, PCBs, or SVOCs were detected at concentrations greater than the analytical method PQL and are therefore not included as site COCs. These analyses were performed using the EPA SW-846 Methods 8081 for pesticides, 8082 for PCBs, and 8270 for SVOCs (EPA, 1986). With the exception of the SVOC analysis for one verification sample, the analyses met the specified detection limits included in the 100 Area Remedial Action Sampling and Analysis Plan (DOE-RL-96-22) or the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort (BHI 01249) (Appendix B has additional discussion). The PCB, pesticide, and SVOC results are included in Appendix A of BHI 01249.

With the exception of cesium-137 in one sample, none of the radionuclides analyzed for were detected at concentrations greater than the analytical method minimum detectable activity or greater than Hanford Site background for naturally occurring radionuclides. The radionuclide analyses met the radionuclide detection limits specified in SAP or are well below cleanup criteria. Cleanup verification sample results for cesium-137, cobalt-60, europium 152, europium 154, and europium 155 are included in Appendix A of the CVP and are included as cleanup verification COCs for the 1607-B11 site. These radionuclides were included as COCs because they are common COCs for liquid waste sites throughout the 100 Area.

Hexavalent chromium was not detected in the 1607-B11 cleanup verification samples at concentrations greater than the analytical method PQL. Hexavalent chromium was detected in the split sample used for quality assurance purposes at a concentration of 0.38 mg/kg, well below applicable cleanup criteria. Because hexavalent chromium is a common contaminant for 100 Area liquid waste sites, it is included as a cleanup verification COC for the 1607-B11 site. Hexavalent chromium was analyzed for using the EPA SW-846 Method 7196 (EPA, 1986). Hexavalent chromium cleanup verification results are included in Appendix A of the CVP.

For the various reasons given above, lead, bis(2-ethylhexyl)phthalate, hexavalent chromium, and the individual radionuclides (cesium-137, cobalt-60, europium 152, europium 154, and europium 155) are carried throughout the CVP as COCs for the 1607-B11 site. The final 1607-B11 cleanup verification COCs include: cesium-137, cobalt-60, europium-152, europium-154, europium-155, lead, hexavalent chromium, bis(2-ethylhexyl)phthalate.

At the completion of the remedial action, the total excavation was approximately 136 square meters (1,460 square feet) in area with approximate depth of 3.0 meters (9.8 feet). Approximately 131 metric tons (144 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF). The 1607-B11 septic system inlet pipeline was removed to the extent of the site excavation. The remainder of the pipeline is included in the 100-C-9 pipelines site and will be dispositioned with it.

The CVP demonstrates that remedial action at the 1607-B11 site has achieved the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils at the 1607-B11 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 1607-B11 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual
concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site do not pose a threat to groundwater or the Columbia River. The 1607-B11 site is verified to be remediated in accordance with the ROD and may be backfilled.

**Code:** 100-C-3  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (7/28/2003)

**Names:** 100-C-3; 119-C French Drain; 119-C Sample Building French Drain  
**Type:** French Drain  
**Status:** Inactive  
**Start Date:** 1/1/1960  
**End Date:**

**Description:** The site has been remediated and interim closed out. The french drain and surrounding soil were excavated and disposed at ERDF. The 100-C-3 French Drain was a 0.61 meter (2 ft) diameter gravel-filled pit that received effluent from the 119 C Sample Building.

**Location:** The site was located east of the 105-C Building.

**Related Sites/ Structures:** The 119-C Sample Building discharged effluent to this site.

**Process Description:** The 100-C-3 French Drain was a 0.61 meter (2 ft) diameter gravel-filled pit that received effluent from the 119 C Sample Building. The 119-C Sample Building was built in 1960 and contained water-cooled air sample monitoring equipment. Effluent from the sampling equipment, the building's swamp cooler, and possibly janitorial waste would have been disposed to the 100-C-3 French Drain.

**Waste Type:** Process Effluent  
**Waste Description:** The 119-C Sample Building was built in 1960 and contained "water cooled" air sample monitoring equipment. Effluent from the sampling equipment, the building's swamp cooler, and janitorial waste would have been disposed to this drain.

**Closure Info:** The french drain and surrounding soil were excavated and disposed at ERDF.

Remedial action objectives and goals for the 100-C-3 site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17).

The selected remedial action for the 100-C-3 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify contaminants of potential concern (COPCs). Because none of the metals were detected in the cleanup verification samples above soil background concentrations, they were not included as site contaminants of concern (COCs). Verification sample results and soil background concentrations for metals are included in appendix A of the CVP.

Although low levels of methylene chloride, acetone, and toluene were detected, their presence...
have been attributed to laboratory-introduced contamination and are not considered waste site contaminants or COCs for cleanup verification. Hexavalent chromium, a common contaminant for the 100 Area liquid waste sites, and the individual radionuclides (cesium-137, cobalt 60, europium 152, europium 154, and europium 155) are included as cleanup verification COCs.

At the completion of remedial action, the total excavation was approximately 94 square meters (1,011 square feet) in area with a depth of approximately 3 meters (9.8 feet). Approximately 49 metric tons (54 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

The CVP demonstrates that remedial action at the site has achieved the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils at the site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials containing contaminants at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site do not pose a threat to groundwater or the Columbia River. As stated in CVP 2003-00009 the site has been verified to be remediated in accordance with the ROD and may be backfilled.

The waste was contaminated steel piping, concrete, and soil. Reactor cooling water became radioactively contaminated as it passed through the reactor core. Activation products created in the water included calcium-41, chromium-51, and zinc-65. Activation products from the reactor core that were picked up and transported by the cooling water included tritium, carbon-14, cobalt-60, nickel-63, and europium-152/154/155. Fuel element fission products such as strontium-90, and cesium-137, as well as transuranics such as plutonium-239/240 were introduced into cooling water due to fuel cladding failures. Concentrations of radionuclides in cooling water during normal reactor operations were approximately (0.2 microcuries/liter). Concentrations of radionuclides have built up in rust flakes and scale on the inner surfaces of the pipelines and in sludge in the diversion and junction boxes. Average beta-gamma concentrations for the effluent line scale and junction/diversion boxes are 83,000 and 120,000 picocuries/liter, respectively. Average plutonium-239/240 concentrations are 66 picocuries/gram for the effluent line scale and 720 picocuries/gram for the sludge at the bottom of the diversion and junction boxes. Direct readings of the bottom of the effluent lines averaged approximately 40,000 counts/minute with a Geiger-Mueller probe. Additional chemicals were added to the effluent for purposes of water treatment. These included aluminum sulfate (alum), with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine residual was approximately 0.2 milligrams/liter. The waste is any remaining process effluent and the contaminated pipelines.

The Cleanup Verification Package 2003-00022 (CVP), documented completion of remedial action for the 100-C-6:1 subsite. Also included are the cross-tie underground lines that connected the 105-B Reactor effluent system to the 105-C Reactor effluent pipeline system. Sites that are excluded from the CVP are the associated retention basin and outfall structure, which was treated as unique waste sites. The 105-C Reactor effluent pipeline subsites (100-C-6:2, 100-C-6:3, 100-C-6:4) were located north of B Avenue and addressed in a separate CVP.

Location: The site includes the underground pipelines from the 105-C Reactor to B Avenue.
Waste Type: Process Effluent
Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil.

Closure Info: At the completion of remedial action, the excavation was approximately 48,260 square meters (519,466 square feet) in area. Approximately 244,656 metric tons (269,742 tons) of material, including soil, debris, and piping were removed from the 100-B/C south pipelines site and disposed of at the Environmental Restoration Disposal Facility. The remaining soils at these sites have been sampled, analyzed, and modeled, while contaminated material has been excavated and disposed at ERDF. These results also indicated that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The site was verified to be remediated in accordance with the ROD and may be backfilled.

The SubSite is Part Of:
Code: 100-C-6
Names: 100-C-6; 100-C Reactor Cooling Water Effluent Underground Pipelines

Code: 100-C-6:2
Names: 100-C-6:2; 100-C Area North Effluent Pipelines
Type: Radioactive Process Sewer
Status: Inactive
Classification: Accepted
Description: Cleanup Verification Package 2003-00019 (CVP) documented completion of remedial action for the 100-B/C Effluent Pipeline subsites located north of B Avenue (100-B-8:2, 100-C-6:2, 100-C-6:3, and 100-C-6:4 collectively referred to as the 100-B/C north pipelines site). The 100-C-6:2 subsite included the 105-C Reactor effluent pipelines from B Avenue north to the 116-C-5 Retention Basin, and included the diversion box just south of the 116-C-5 Retention Basin.
Location: These pipelines were north of the 105-C Reactor, north of B Avenue, to the 116-C-5 Retention Basin, and the diversion box is located just south of the 116-C-5 Retention Basin.
Waste Type: Vegetation
Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil.

Closure Info: Remedial action at the 100-B/C north pipelines site began on February 26, 2001. Excavation of the site involved removing the overburden materials, piping, debris, and underlying contaminated soil. Based on field screening overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill Contaminated materials were disposed of at ERDF. At the completion of remedial activities at the 100-B/C pipeline waste sites, more than 364 metric tons (400 tons) of concrete and fence posts with associated concrete debris were removed and segregated as part of the 100-B/C Pipeline Remediation Project (100-BC-1/100-BC-2 Operable Units). The majority of the fence posts are associated with security fencing that surrounded many of the pipelines and waste sites. None of the fence material has been known to be contaminated. External radiological surveys indicate that none of the concrete and fence posts show any, signs of radioactive contamination. Radiological release surveys of the fence posts and concrete were performed to allow them to be used as clean backfill. The Environmental Restoration Contractor radiological survey records for 100-B/C remediation between the dates of February 26, 2001 and November 6, 2003, contain survey results for the fencing debris used as backfill. The excavation was completed on February 6,
Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and non-radionuclide contaminants of concern (COCs). Cleanup verification samples including QA/QC samples consisted of 193 shallow zone samples, 104 deep zone samples, 260 overburden samples, and 72 discovery area samples. The final verification samples were collected between August 12, 2002, and concluded on July 24, 2003, and were analyzed for the established contaminants of concern. The sample numbers are too numerous to list, however they are available in appendix A of CVP-2003-00019. At the completion of remedial action, the excavation was approximately 135,000 square meters (443,000 square feet) in area with an average depth of approximately 7.5 meters (25 feet). Approximately 244,656 metric tons (269,742 tons) of material including soil, debris, and piping were removed from the 100 B/C north pipelines site and disposed at the Environmental Restoration Disposal Facility.

2003.

Start Date: End Date:

Description: Cleanup Verification Package 2003-00019 (CVP) documented completion of remedial action for the 100-B/C Effluent Pipeline subsites located north of B Avenue (100-B-8:2, 100-C-6:2, 100-C-6:3, and 100-C-6:4, collectively referred to as the 100-B/C north pipelines site). This CVP also included eleven areas discovered to have radiological contamination above background, called "discovery areas." They are collectively identified as subsite 100-C-6:4.

Some areas were identified prior to commencement of the 100-B/C pipeline remediation activities, while others were found during the pipeline remediation process. The source of contamination for these areas has not been established, although the adjacent effluent piping and the 116-C-5 Retention Basins are suspected sources.

Location: These eleven pipeline segments are about 650 meters (2,145 feet) north-northeast of the 105-B Reactor, surrounding the 107-C and 107-B Retention basins.

Waste Type: Soil

Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil.

Closure Info: Remedial action at the 100-B/C north pipelines site began on February 26, 2001. Excavation of
the site involved removing the overburden materials, piping, debris, and underlying contaminated soil. Based on field screening overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. At the completion of remedial activities at the 100-B/C pipeline waste sites, more than 364 metric tons (400 tons) of concrete and fence posts with associated concrete debris were removed and segregated as part of the 100-B/C Pipeline Remediation Project (100-BC-1/100-BC-2 Operable Units). The majority of the fence posts are associated with security fencing that surrounded many of the pipelines and waste sites. None of the fence material has been known to be contaminated. External radiological surveys indicate that none of the concrete and fence posts show any, signs of radioactive contamination. Radiological release surveys of the fence posts and concrete were performed to allow them to be used as clean backfill. The Environmental Restoration Contractor radiological survey records for 100-B/C remediation between the dates of February 26, 2001 and November 6, 2003, contain survey results for the fencing debris used as backfill. The excavation was completed on February 6, 2003.

Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and non-radionuclide contaminants of concern (COCs). Names: 100-C-7; 183-C Filter Building /Pumproom Facility Foundation and Demolition Waste; 183-C Monolith

Type: Dumping Area
Status: Inactive

Description: The 100-C-7 main site and subsite have been remediated and Interim Closed Out. The concrete foundation and contaminated soil that remained after the 1997 building demolition has been remediated and Interim Closed Out. The 100-C-7 waste site Reclassification status was updated in March 2014, when the stained soil (100-C-7 Subsite 1) remediation was completed. The 100-C-7 waste site is the residual sodium dichromate contamination associated with concrete that was left in place after the 1997 decommissioning and demolition of the 183-C Filter Building/Pumproom. The building foundation had been backfilled and graded to match the surrounding terrain. An area of yellow stained soil was observed near the sedimentation basins and became 100-C-7 Subsite 1.

Location: The foundation of the 183-C pump room was located in the southwestern portion of the 100B/C Area, 340 meters (1,115 feet) west of the 105-C Reactor Building, between the 183-C Sedimentation Basins and the four 183-C Clearwell Tank Pads.

Related Sites/Structures: The 183-C Filter Building /Pump room Facility Foundation is associated with the yellow stained soil documented in 100-C-7:1.

Process: The 183 Filter Building/Pump Room Facility received water from the 183-C Sedimentation Basins and sent treated water to the 183-C Clearwells where it was stored for the 190-C Process Pump House.

One of the purposes of the 183-C Pump room was to treat the cooling water with sodium dichromate, a rust inhibitor, prior to storage in the four exterior 1.89E+07-liter (5E+06-gallon) tanks (183-C Clearwells). Water was drawn from the 183-C Filter Building clearwells and injected with sodium dichromate in the pump room prior to being pumped to the four, large tanks for storage. During past practices, the sodium dichromate was stored, mixed, and spilled in various locations throughout the building.

Waste Type: Chemicals
Waste Description: An underground asbestos wrapped steam line was encountered during the foundation demolition along the north clearwell. Due to the length and location of the steam line, the small area uncovered during the excavation work was not remediated. The pipe was wrapped in plastic, marked with "DANGER ASBESTOS HAZARD" tape, and covered again with soil.

Waste Type: Chemicals
Waste Description: The 183-C Filter Building foundation and clearwells were filled with demolition and inert waste materials and leveled to grade.

Waste Type: Chemicals
Waste Description: The concrete foundation located in the 183-C Pumproom is contaminated with sodium dichromate. Characterization data showed the contamination at the worst location to be 20
centimeters (8 inches) deep, half the thickness of the floor. Therefore, assuming the contamination averaged a depth of 15 centimeters (6 inches) throughout and covered a total area of 93 square meters (1000 square feet), a quantity of 14 cubic meters (500 cubic feet) was calculated.

**Closure Info:**

Note: The contaminated concrete and 66,387 BCM of contaminated soil has been removed. The 100-C-7 waste site Reclassification status was updated when the 100-C-7 Subsite 1 remediation was completed. The Reclassification form for 100-C-7 Subsite 1 was approved on 3/11/2014.

During a previous 1996 remediation activity, the 183-C Filter Building Pump Room Facility was demolished. The remediation phase included the removal of asbestos lagged pipes located throughout the facility, hazardous materials, pumping equipment, valves, transit siding and roofing, and the structural steel. Demolition of the concrete structures below grade occurred during the steel removal activities. Once the complex was cleared of all the structural steel, the remaining concrete slab contaminated with sodium dichromate was removed and disposed of offsite. All foundations and below-grade structures were demolished to a minimum of 1 meter (3 feet) below grade and backfilled. Structures deeper than 1 meter (3 feet), including those contaminated with sodium dichromate and an asbestos steam line remained in place. The amount of contaminated concrete was significantly more than what was originally estimated. Characterization data showed sodium dichromate contamination penetrating up to 20 cm (8 in.) into the concrete floor. As efforts were initiated on chiseling up the concrete, it became evident that there was no simple method to control the depth of concrete removal. The contaminated concrete was stabilized with a plastic barrier and a soil layer.

In 2004, the excavation of the concrete and contaminated soil beneath the concrete was completed to a depth of 4.6 meters (15 ft). In-process sampling indicated residual chromium contamination. Remedial activities were discontinued when yellow stained soil, due to sodium dichromate contamination, was observed beneath a north-south trending steam line. A test pit was excavated and sampled to a depth of 10 meters (33 ft). Total chromium contamination of 1,230 mg/kg and hexavalent chromium of 1620 mg/kg were present at the 33 foot level and extended beyond the waste site boundary. In 2007, a borehole (C4947) was drilled to evaluate the vertical extent of the contamination. Analytical results from the borehole showed a maximum concentration of 310 mg/kg total chromium at a depth of 10.7 meters (35 ft) below ground surface. It was determined that the contamination below 4.6 meters (15 ft) needed to be remediated to protect the 100-B/C Area groundwater. This contamination will be addressed in 100-C-7:1.

Demolition of reinforced concrete substructures associated with the 183-C Headhouse, 183-C Sedimentation Basins, 183-C Filter Building, and 183-C Clearwell pads began on June 8, 2010. Demolition of concrete foundations included shearing pipes and rebar and staging concrete rubble to the designated staging areas. Following subsurface concrete demolition, remedial activities to remove contaminated soil and portions of an inactive pipeline resumed on January 27, 2011. The 100-C-7 excavation was extended to a depth of approximately 17 meters (55 ft) bgs, and in-process sampling was performed. In-process sample results identified hexavalent chromium above cleanup levels at this depth. On June 20, 2011, a pothole was excavated to a depth of 22 meters (72 ft) bgs. Visual observations of discolored soil, elevated x-ray fluorescence (XRF) readings for total chromium and in-process sample results showed hexavalent chromium at concentrations exceeding cleanup criteria. The excavation continued until groundwater was encountered at a depth of approximately 26 meters (85.3 ft) bgs. The remedial design was revised to encompass additional remediation of the 100-C-7 waste site to the north, based on the presence of chromium contamination at a depth of 22 meters (72 ft) that appeared to be trending to the northeast.

The 100-C-7 site remediation was completed on December 13, 2011. Approximately 73,780 bank cubic meters (BCM) (96,501 bank cubic yards [BCY]) of concrete and building slab...
rubble was transported to U-Canyon, located in the 200 West Area. Approximately 66,387 BCM (86,831 BCY) of contaminated soil was excavated for disposal to Environmental Restoration Disposal Facility (ERDF). 285,660 BCM (373,629 BCY) of overburden/layback soil was stockpiled at the 100-C-7 waste site for use as backfill material.

Description: The subsite has been remediated and Interim Closed Out. It was the 183-C area of stained soil. It was a large area (approximately 6600 sq meters) of soil that was mostly free of vegetation. The yellow stained soil was located between the railroad tracks on the west side of 183-C. The stained soil was observed in early April 2002. Discussions with project personnel concerning the past use of this area indicate that the appearance of the stain is consistent with sodium dichromate. It is unclear how the Sodium Dichromate was transferred from the Head House, located west of the sedimentation basins, to the Pump Room Facility, located east of the basins. The stained area may be a result of this transfer process.

Location: The stained soil was located adjacent to the northwest corner of the 183-C Sedimentation Basins. The 183-C head house is located 557 meters (1,828 feet) west of the 105-C Reactor Building.

Process Description: It is believed that a railroad spur was used to deliver water treatment supplies to the 183-C Head House. One of these chemicals was sodium dichromate, a corrosion inhibitor, used to treat the reactor cooling water. The Final Decommissioning Report for the 183-C Filter Building/Pump Room Facility (BHI-01005) states that the sodium dichromate was stored, mixed and spilled in various locations throughout the 183-C Pump Room Facility where it was then pumped into the four large exterior tanks and stored for the 190-C Process Pump House.

Waste Type: Process Effluent

Waste Description: The waste is contaminated concrete and stained soils.

Closure Info: The 183-C Filter building and pump room were demolished in 1996. Characterization data showed sodium dichromate contamination penetrating up to 20 cm (8 in.) into the concrete floor. As efforts were initiated on chiseling up the concrete, it became evident that there was no simple method to control the depth of concrete removal. It was determined that continued removal of the sodium dichromate-contaminated concrete was not cost efficient using the available resources and additional removal would occur during remediation of 100-B/C waste sites. In order to stabilize the remaining contaminated concrete (known as the monolith) in a manner that would not hinder future cleanup activities, the contaminated concrete was covered with a plastic barrier and then a soil layer. In 2002, an area of yellow soil was observed and added as a subsite (100-C-7:1) to the 100-C-7 waste site. A sample analyzed in 2003 found total chrome and hexavalent chrome present.

Remedial action at the 100-C-7:1 subsite was initiated in December 2004 with excavation of the stained soil area located north of the 183-C Head House to a depth of approximately 3.5 meters.
Excavation adjacent to the north side of the 183-C Head House, where the outdoor chemical storage tanks were once located, proceeded to a depth of 4.6 meters (15 ft) where in-process sampling indicated residual chromium contamination exceeding cleanup criteria. Chromium staining was also observed on the outside foundation wall of the 183-C Sedimentation Basins exposed in the east sidewall of the excavation. Following initial remediation of the 100-C-7 waste site, it was determined that total chromium and hexavalent chromium were present in the subsurface soil beyond the boundaries of the remediation excavations at both the 100-C-7:1 and 100-C-7 monolith waste sites at concentrations exceeding the remedial action objectives and goals. Several potholes and boreholes were excavated at 100-C-7:1 to evaluate the distribution of sodium dichromate contamination. The initial pothole in April 2005 showed residual soil contamination present at 10 meters (33 ft) below ground surface (bgs). In 2009, it was determined that the hexavalent chromium in the vadose zone below 4.6 meters (15 ft) would need to be remediated in order to protect groundwater in the 100-B/C Area.

Demolition of reinforced concrete substructures associated with the 183-C Head House, 183-C Sedimentation Basins, 183-C Filter Building, and 183-C Clearwell pads in the vicinity of the 100-C-7 and 100-C-7:1 waste sites began on June 8, 2010. Demolition of concrete foundations included shearing pipes and rebar and staging concrete rubble to the designated staging areas. Following subsurface concrete demolition, remedial activities to remove contaminated soil and portions of inactive pipeline resumed on January 27, 2011. Remediation of the 100-C-7:1 subsite included removal and disposal of the inactive section of the relocated export water line, a segment of fire water piping, and the segment of 7.6-cm (3 inch) sodium dichromate pipeline from beneath the export water line crossing.

Approximately 45,000 bank cubic meters (BCM) (58,858 bank cubic yards [BCY]) of concrete and building slab rubble was transported to the U Canyon (in the 200 West Area) to be used as fill. By March 2012, approximately 261,414 BCM (341,917 BCY) of contaminated soil was excavated for disposal to the Environmental Restoration Disposal Facility (ERDF) and 373,403 BCM (488,393 BCY) of overburden/layback soil was excavated and stockpiled at the 100-C-7:1 waste site for use as backfill material. No anomalies were encountered. There are no radiological constituents associated with this site.

**The SubSite is Part Of:**

**Code:** 100-C-7

**Names:** 100-C-7; 183-C Filter Building /Pumproom Facility Foundation and Demolition Waste; 183-C Monolith

**Code:** 100-C-9

**Names:** 100-C-9; 100-C Area Process and Sanitary Sewer Underground Piping

**Type:** Process Sewer

**Status:** Inactive

**Description:** This site was divided into four subsites. All of the subsites have been reclassified to Interim Closed Out or No Action. Therefore, the parent site is considered Interim Closed Out. It consisted of approximately 3,000 meters (9,842.5 feet) of miscellaneous underground pipelines in 100-C Area. Subsite 1 is the main process sewers associated with the 105-C Reactor operations, Subsite 2 is the sanitary sewer feeder pipelines to four septic systems (1607-B8, 1607-B9, 1607-B10), Subsite 3 is the 183-C Clearwell pipelines, and Subsite 4 is the 100-C cooling water transfer lines and tunnels.

**Location:** The pipelines came from the 183-C Head House, Sedimentation/Filter Building, and...
Clearwells, the 190-C Pump House, and joined to form the 2,143-meter (7,032-foot) long concrete flume. The flume contained two side-by-side 4 foot by 6 foot (1.2 meter by 1.8 meter) process sewers that eventually drained at the 132-C-2 Outfall Structure.

Related Sites/Structures: The buildings that discharged to the process and septic sewers are the 183-C Facilities and 190-C Pump House discharged to 1607-B8; the 105-C Reactor discharged to the 1607-B9 Septic system pipeline, and the 190-C Pump House connected to the 105-C Reactor through the treated cooling water pipelines.

Process Description: These pipelines carried a variety of non-radioactive waste fluids, treated cooling water (pre-reactor), and septage. This site did not include the clean water pipelines, pipelines otherwise identified with septic systems, or the main reactor effluent pipelines (100-C-6).

Waste Type: Water
Waste Description: The subsite consisted of the non-radioactively contaminated process and septic sewer pipelines associated with the 105-C Reactor operations. The 1607-B9 septic system serviced the 105-C Reactor and thus may be radioactively contaminated. Any contamination associated with these pipelines was expected to be in residual amounts. Chemical additives to the reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, the free chlorine residual was approximately 0.2 milligrams/liter, and sodium dichromate was added at a rate of about 2 milligrams/liter. (Note: Reference: WHC-SD-EN-TI-169 is for 100-F, and applies equally to 100-C).

This Site has the Following SubSites:

Code: 100-C-9:1
Names: 100-C-9:1; 100-C Main Process Sewer Collection Line
Type: Process Sewer
Status: Inactive
Description: The subsite has been remediated and Interim Closed Out. It included pipelines from the 183-C and 190-C facilities that fed into the main process sewer which consisted of a dual 1.2-meter by 1.8-meter (48-inch by 72-inch)-reinforced concrete box sewer that shared a central dividing wall. The duel reinforced concrete box sewers were often referred to as the twin box culvert. The deep zone portion of the southern twin box culvert was left in place. Given the construction sequence, leaks from the cold joints could have developed at any point along the length of the structure between the floor and walls.

Location: The main process sewer began down-gradient from the 183-C sedimentation basins and was oriented east-west, running to the north of the 100-C Area water treatment and pump house facilities. Multiple feeder pipes of various sizes from the 183-C and 190-C facilities discharged...
into the twin box culvert. The intended purpose of these pipelines was to handle diluted, nonhazardous process wastes and storm water. Sanitary wastes were handled separately via multiple septic systems. North of the 105-C Reactor Building, the twin box culvert changed orientation to approximately north-south and ran north to the former 132-C-2 outfall.

**Waste Type:** Oil  
**Waste Description:** Potentially contaminated pipeline (and contents), concrete, and underlying/associated soils.  
**Closure Info:** Remedial action was divided into a northern and a southern section due to the length of the required excavation of approximately 1875 meters (6150 feet).

The entire northern section along with a minimum of 0.3 meters (1 foot) of underlying soil was excavated between November 22, 2004, and February 2005. Approximately 14,639 metric tons (16,137 U.S. tons) of contaminated soil and concrete were disposed at the Environmental Restoration Disposal Facility. Verification sampling of the northern excavation was performed on August 23, 2005.

The southern portion consisted of a deep zone [i.e., more than 4.6 meters (15 feet) deep] section of the twin box culvert and a shallow zone which included a section of the twin box culvert and the feeder lines from the 100-C water treatment facilities. Remediation of the southern portion shallow zone began in December 2004, and was completed on April 19, 2006. Approximately 5,851 metric tons (6,450 U.S. tons) of contaminated soil and concrete were removed for disposal at ERDF. The deep zone portion of the southern twin box culvert was left in place.

**The SubSite is Part Of:**

**Type:** Sanitary Sewer  
**Status:** Inactive  
**Description:** The subsite has been remediated and Interim Closed Out. It consisted of the feeder pipelines for the former 1607-B8, 1607-B9, 1607-B 10, and 1607-B 11 septic systems (septic tank and drain field). All four of the septic systems and underlying contaminated soils were removed between March and May 2003, leaving the feeder pipelines in place.

**Location:** Theses pipelines came from the 183-C, 190-C, and west side (pre-process side) of the 105-C Reactor buildings.

**Waste Type:** Vegetation  
**Waste Description:** Potentially contaminated pipeline (and contents), concrete, and underlying/associated soils.  
**Closure Info:** Remedial action associated with each of the four feeder pipelines began in early 2005 and concluded on September 29, 2006. A total of approximately 3,701 metric tons (4,080 U.S. tons) of contaminated material was disposed at ERDF. Statistical and focused sampling to verify the completeness of remediation was performed, and analytical results were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. A summary of the remediation for each of the four septic system pipelines follows:
The pipeline from the 1607-B8 septic system was removed between March 23, 2005 and April 13, 2005. The site was excavated 2 meters (6.6 feet) below grade. A total of 266 metric tons (293 U.S. tons) of contaminated material was disposed at ERDF. The resulting trench was approximately 9 meters (29.5 feet) in length by 3.5 meters (11.5 feet) wide.

Remediation of the 1607-B9 pipeline began on May 23, 2005 through July 11, 2005. The site was excavated to 3.5 meters (11.5 feet) below grade, removing a total of 2,626 metric tons (2,895 U.S. tons) of contaminated material that was disposed at ERDF. An additional 310 metric tons (342 U.S. tons) was removed on September 29, 2006, following detection of strontium-90 above the cleanup criterion in one verification sample.

During excavation of the pipeline on May 25, 2005, an anomaly consisting of reddish-brown material was discovered after a concrete structure was removed. Radiological readings were all at background levels. A sample (J03701) of the material was collected and analyzed for total metals, leachable metals (toxicity characteristic leaching procedure [TCLP]), and semivolatile organic compounds (SVOCs) to support waste characterization and disposal. There were no significant metal or SVOC concentrations associated with this anomaly. The COPCs for the pipeline were identified through process knowledge and analogous site data and consisted of inductively coupled plasma (ICP) metals, hexavalent chromium, pesticides, polychlorinated biphenyls (PCBs), and semivolatile organic compounds. Radiological screening was also performed using gross alpha, gross beta, and gamma energy analyses.

The 1607-B10 pipeline was removed by March 2005. A total of approximately 9 meters (29.5 feet) of sanitary sewer pipeline and an estimated 45 metric tons (50 U.S. tons) of contaminated material was removed and sent to ERDF. The resulting trench was approximately 9 meters (29.5 feet) in length by 3.5 meters (11.5 feet) wide.

The 1607-B11 pipeline was co-located and remediated with the subsite 100-C-9:1, (100-C main process sewer collection pipelines). The 100-C-9:1 process sewer pipeline was excavated to at least 4 meters (13 feet) below grade, which concurrently removed the 1607-B11 sanitary sewer pipeline that was approximately 1.2 meters (4 feet) below grade. The remediation activities were completed by April 2006, removing approximately 40 meters (131 feet) of the sanitary sewer pipeline and an estimated 454 metric tons (500 U.S. tons) of contaminated material was removed and sent to ERDF.

Soil cleanup levels were established in the Remaining Sites ROD based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels was made for the site contaminants of concern (COC), contaminants of potential concern (COPC), and other constituents. Ecological screening levels were exceeded for antimony, boron, cadmium, total chromium, copper, lead, mercury, vanadium, and zinc. Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. Residual concentrations of antimony, cadmium, total chromium, copper, lead, mercury, vanadium, and zinc were within the range of Hanford Site background levels, and boron concentrations were consistent with those seen elsewhere at the Hanford Site (no established background value is available). Concentrations of chromium, copper, lead, mercury, and zinc were within the range of Hanford Site background levels. All exceedances of screening values at the subsite will be evaluated in the context of additional lines of evidence for ecological effects following a baseline risk assessment for the river corridor portion of the Hanford Site, which will include a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decision for the 100-C-9 site.

The SubSite is Part Of:

Code: 100-C-9
Names: 100-C-9; 100-C Area Process and Sanitary Sewer Underground Pipelines
**Code:** 100-C-9:3  
**Classification:** Accepted  

**Names:** 100-C-9:3; 183-C Clearwell Pipelines  
**Reclassification:** Interim No Action (6/3/2004)  

**Type:** Process Sewer  
**Status:** Inactive  

**Description:** This subsite was evaluated and reclassified to No Action. It consisted of the process sewer pipelines that surrounded and drained from the 183-C Clearwells. The clearwell drains ran from circular aboveground steel tanks and connected to cast-iron process sewers surrounding the tanks. The cast-iron process sewers eventually drained to the main twin box process sewers that connected to the 190-C Facility. The basis for separating this site from the other 100-C-9 sites is that these process sewer lines were isolated from facilities known to be potential sources of radioactive and chemical contaminants. The clearwells were used to store treated cooling water for the 105-C reactor. Chromium was added to the treated water at concentrations between 2-4 ppm (parts per million) as a corrosion inhibitor. The primary contaminant of concern was hexavalent chromium.

**Location:** This subsite was located west of the 105-C Reactor building.

**Waste Type:** Equipment  
**Waste Description:** Potentially contaminated pipeline (and contents), concrete, and underlying/associated soils.

**Closure Info:** The No Action decision for the 100-C-9:3 site (a deep zone site) is supported based on reviews of site history, field observations, and characterization results. The maximum detected results from pipe scale and underlying/surrounding soil samples collected at locations suspected of having the greatest potential for residual contamination levels were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

**The SubSite is Part Of:**

**Code:** 100-C-9  
**Names:** 100-C-9; 100-C Area Process and Sanitary Sewer Underground Pipelines
The waste is the feedwater pipelines and their contents.

The scope of the confirmatory sampling effort consisted of the cooling water pipes and tunnels to the reactor. Sampling efforts were conducted only on the pipes. Previous sampling and survey data associated with decontamination and decommissioning (D & D) activities at the 105-C cooling water pipe tunnels was used to evaluate the tunnels and soil. This data, as well as a focused sampling approach at the analogous 100-B-14:4 site, were used to confirm current site conditions. The analogous, focused sampling data, previous tunnel sampling and survey data, and previous soil sampling beneath the tunnels was used to make decisions for reclassifying the site in accordance with the TPA-MP-14 (RL-TPA-90-0001) process. The confirmatory sampling results for pipe scale at an analogous site, previous sampling and surveying data associated with the concrete floor of the tunnels, and previous soil sampling from beneath the tunnels, support a no action reclassification of the 100-C-9:4 site.

The confirmatory sampling results for pipe scale at an analogous site, previous sampling and surveying data associated with the concrete floor of the tunnels, and previous soil sampling from beneath the tunnels, support a No Action reclassification of the 100-C-9:4 site.

The western end of the tunnels was removed from the 190-C Pump House to within approximately 18 meters (60 ft) of the tunnel ventilation structures during pump house demolition activities in 1996 and 1997. All of the water pipes in the remaining tunnel structures were cut and capped, and the western tunnel end was sealed with wood beams, railroad ties, angle iron, and foam sealant. During the 1996 through 1998 105-C Reactor interim safe storage activities, the eastern-most end of the tunnels was removed from the reactor building to approximately 3 meters (10 ft) from the west edge of the reactor building and backfilled with clean soil. Approximately 121 meters (400 ft) of open tunnel and piping remain in place.

The no action decision for the 100-C-9:4 site is supported based on reviews of site history, field observations and characterization results from an analogous site, and previous investigations performed at the site during D&D activities. The maximum detected results from pipe scale at analogous locations suspected of having the greatest potential for residual contamination levels were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. It should be noted, however, that given the demonstrated maximum residual concentration of hexavalent chromium in the feedwater pipes, institutional controls are required to prevent an inhalation exposure pathway.

The SubSite is Part Of:

| Code: 100-C-9 |
| Names: 100-C-9; 100-C Area Process and Sanitary Sewer Underground Pipelines |

| Code: 116-C-2A |
| Classification: Accepted |
| Reclassification: Interim Closed Out (3/15/2000) |
| Names: 116-C-2A; 105-C Crib; 105-C Pluto Crib; 116-C-2 |
| Type: Crib |
| Start Date: 1/1/1952 |
| End Date: 1/1/1969 |
| Status: Inactive |
| Description: This site has been remediated and Interim Closed Out. The crib was covered over by concrete roof slabs. A 20-centimeter (8-inch) well casing extended through the crib and extended 36 meters (118 feet) below grade. |
| Location: The crib was located 275 feet east of the northeast corner of the 105-C Building. |
Process Description: The pluto crib was constructed of concrete ties that were notched and stacked in a log cabin formation. Walls of concrete ties were constructed to divide the crib into twelve sections. Spaces between the ties were filled with sand. It measured 6.8 meters (22 ft) by 4.7 meters (15 ft) and was 5.1 meters (17 ft) deep.

The pluto crib was used for disposal for reactor cooling water after fuel cladding failures. This was the largest of the 100 Area Pluto Cribs and was unique in that effluents passed through a settling tank and sand filter before being discharged to the crib. A 20-centimeter (8-inch) schedule 40 stainless steel pipe ran from the 105-C Reactor Building to the 116-C-2B Pump Station. From the pump station, waste flowed through a 10-centimeter (4-inch) clay vitrified pipe that led to the 116-C-2C Sand Filter. The pipe was around 1.2 meters (4 feet) below grade at its junction with the pump station and 0.9 meters (3 feet) below grade at its junction with the sand filter. A 20-centimeter (8-inch) clay vitrified pipe, located approximately 6.1 meters (20 feet) below grade, similarly led from the sand filter to the Pluto crib. The sand filter and Pluto Crib were 12.6 meters (41.5 feet) apart. Wastes were drained by gravity from the sand filter to the Pluto Crib. After decommissioning, the crib and a surrounding depression were filled to grade with gravel and sand.

Waste Type: Construction Debris

Waste Description: This unit was initially used for the disposal of reactor cooling effluent after fuel cladding failures. Unknown additional quantities of contaminated wastes included wash water from the decontamination of dummy fuel elements on the 105-C wash pad, contaminated water received from the 105-C Metal Examination Facility, and liquid wastes received from the 105-C Reactor rear face. Potential contaminants of concern include americium-241, plutonium-238/239/240, cobalt-60, cesium-137 and strontium-90. Reports vary as to the amounts of different chemicals disposed of at the Pluto Crib site. Two reports state that the crib contained 500 kilograms (1,100 pounds) of sodium dichromate, 1,000 kilograms (2,200 pounds) of sodium oxalate, and 1,000 kilograms (2,200 pounds) of sodium sulfamate. Another report, states that the crib contained 990 kilograms (2,180 pounds) of sodium dichromate, 2,100 kilograms (4,630 pounds) of sodium oxalate, and 6,600 kilograms (14,550 pounds) of sodium sulfamate. Sodium hydroxide and nitric acid were also believed to be disposed at the site. The total waste volume is listed as 7.5E+06 liters (1.98E+06 gallons).

Closure Info: The cleanup verification package (CVP-99-00019) for the 116-C-2A Pluto Crib, 116-C-2B Pump Station and 116-C-2C Sand Filter were combined into a single remediation area and collectively referred to as the 116-C-2ABC site. The overburden was removed from the 116-C-2ABC, 116-B-2, 116-B-3, 116-B-4, 116-B-9 and 116-B-12 waste sites located in the 100-BC-1 and 100-BC-2 Operable units. Excavation of the 116-C-2ABC site began on March 3, 1999, by removing the overburden materials, contaminated structures, and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated have been disposed of at ERDF. On May 7, 1999, the excavation had reached the design limit at El. 141.36 meters (464 ft), a depth of 9.15 meters (30 feet). Cleanup verification sampling began on May 17, 1999, and was finished on July 1, 1999.

At the completion of the remedial action, the area of the excavation was approximately 2,516 square meters (27,728 square feet) at a maximum depth of approximately 9.15 meters (30 feet). Approximately 15,939 metric tons (17,570 tons) of material were disposed of at ERDF. Approximately 2,000 cubic meters (70,629 cubic feet) of overburden was set aside from the 116-C-2ABC site as potentially clean. The excavation will be backfilled with clean fill materials to the reference grade of El. 150.5 meters (494 feet).

The posted URMA at 100 B/C Area, located south of B Ave, was removed in 2014. The waste sites in this area were released under an approved interim or final Record of Decision. (CCN 176577)
### 116-C-2B Pump Station

**Classification:** Accepted  
**Reclassification:** Interim Closed Out (3/15/2000)

**Start Date:** 1/1/1952  
**End Date:** 1/1/1969

**Description:** This site has been remediated and Interim Closed Out. It was a rectangular shaped, concrete sump. A diamond-plate steel access hole cover was located in the northwest corner, and a vent was located at the east end. The site included all underground pipelines between the 105-C Reactor and the 116-C-2C Sand Filter.

**Location:** The site was located northwest of the 116-C-2C Sand Filter.

**Related Sites/Structures:** The associated structures were the 116-C-2A Pluto Crib, 116-C-2C Sand Filter, and the 105-C Reactor.

**Waste Type:** Chemicals

**Waste Description:** The unit received waste from the 105-C Reactor and pumped it into the 116-C-2C (105-C Pluto Crib Sand Filter).

**Closure Info:** The cleanup verification package (CVP-99-00019) for the 116-C-2A Pluto Crib, 116-C-2B Pump Station and 116-C-2C Sand Filter were combined into a single remediation area and collectively referred to as the 116-C-2ABC site. The overburden was removed from the 116-C-2ABC, 116-B-2, 116-B-3, 116-B-4, 116-B-9 and 116-B-12 waste sites located in the 100-BC-1 and 100-BC-2 Operable units. Excavation of the 116-C-2ABC site began on March 3, 1999, by removing the overburden materials, contaminated structures, and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated have been disposed of at ERDF. On May 7, 1999, the excavation had reached the design limit at El. 141.36 meters (464 ft), a depth of 9.15 meters (30 feet). Cleanup verification sampling began on May 17, 1999, and was finished on July 1, 1999.

At the completion of the remedial action, the area of the excavation was approximately 2,516 square meters (27,728 square feet) at a maximum depth of approximately 9.15 meters (30 feet). ### 116-C-2C Sand Filter

**Classification:** Accepted  
**Reclassification:** Interim Closed Out (3/15/2000)

**Start Date:** 1/1/1952  
**End Date:** 1/1/1969

**Description:** This site has been remediated and Interim Closed Out. The structure was an open-bottom concrete box placed in a sand and gravel pit. It was covered with concrete shielding slabs. The
site included the underground pipelines from the 105-C Pluto Crib Sand Filter to the 116-C-2A Pluto Crib.

**Location:**
The site is located west of the 116-C-2A (105-C Pluto Crib). The crib was located 275 feet east of the northeast corner of the 105-C Building.

**Related Sites/Structures:**
This unit was associated with 116-C-2A (105-C Pluto Crib) and 116-C-2B (105-C Pluto Crib Pump Station).

**Process Description:**
Contaminated water was spread over the surface of the sand filter media by distribution trays. The effluent passed through this filter prior to being discharged to the soil column of the 116-C-2 Crib.

**Waste Type:**
Batteries

**Waste Description:**
The 105-C Pluto crib sand filter was sampled and surveyed between 2/6/76 and 4/5/76. Based on sample results, the sand filter contains an estimated radioactive inventory of 260 curies (Table 3.4-9, page 3-30, UNI-946) in 90,000 cubic feet of soil (about 6,100,000 Kg). Beta-gamma concentrations in the sand filter averaged 42,000 pCi/g with a maximum value reported of 7,300,000 pCi/g in a sample taken from an inlet distribution tray. Radioactivity in this sample was primarily due to cobalt-60 although high levels of strontium-90 (29,000 pCi/g) and cesium-137 (140,000 pCi/g) were present as well. This sample also contained 1,500 pCi/g plutonium-239/240. The average concentration of plutonium-239/40 in the sand filter was reported to be about 20 pCi/g for the entire mass of potentially contaminated soil column. Sample analyses for the sand filter are presented in Table 3.4-7 (page 3-28, UNI-946) by Dorian and Richards. The site may have received contaminated wastes from the decontamination of dummy fuel elements on the wash pad. Americium-241 is another potential contaminant of concern.

**Closure Info:**
The cleanup verification package (CVP-99-00019) for the 116-C-2A Pluto Crib, 116-C-2B Pump Station and 116-C-2C Sand Filter were combined into a single remediation area and collectively referred to as the 116-C-2ABC site. The overburden was removed from the 116-C-2ABC, 116-B-2, 116-B-3, 116-B-4, 116-B-9 and 116-B-12 waste sites located in the 100-BC-1 and 100-BC-2 Operable units. Excavation of the 116-C-2ABC site began on March 3, 1999, by removing the overburden materials, contaminated structures, and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated have been disposed of at ERDF. On May 7, 1999, the excavation had reached the design limit at El. 141.36 meters (464 ft), a depth of 9.15 meters (30 feet). **Code:**
116-C-3

**Names:**
116-C-3; 105-C Chemical Waste Tanks

**Type:**
Storage Tank

**Classification:**
Accepted

**Reclassification:**
Interim Closed Out (1/31/2008)

**Start Date:**
1/1/1964
**Status:** Inactive  
**End Date:** 1/1/1969  
**Description:** The site has been remediated and Interim Closed Out. It has been backfilled, and revegetated. Before remediation the site consisted of two below-grade chemical waste storage tanks, designed to receive and store chemical waste from the 105-C Reactor Metals Examination Facility (MEF) de-jacketing process. Each of the waste tanks was approximately 3.5 meters (11.5 ft) in diameter and approximately 10.9 meters (36 ft) in length, with a nominal capacity of 102,200 L (27,000 gal). The long axis of each tank was oriented east-west on a horizontal plane, with one tank located north of the other. The crests of the tanks were located approximately 3.4 meters (11 ft) below existing grade, with centerlines spaced approximately 6.2 meters (20 ft) apart.

**Location:** The site was located approximately 100 meters (330 ft) northeast of the 105-C Reactor safe storage enclosure, just outside the exclusion area fence.

**Related Sites/Structures:** The site is associated with the 105-C Reactor Building and pipeline site 100-C-6:1.

**Process Description:** The tanks were originally installed to receive liquid wastes from the 105-C Metal Examination Facility (MEF), which was part of the 105-C Reactor Building, and was used to examine and test irradiated fuel elements. Examination included chemical de-jacketing of the fuel slugs. The process consisted of two cycles of immersing the fuel slugs in a 50% sodium hydroxide solution, draining the resulting solution, and rinsing the de-jacketed slugs with water. The slugs were then cleaned with a 10% nitric acid solution, followed with multiple water rinses.

Waste was discharged to the tanks from the 105-C MEF via a 5-cm (2-in.) stainless-steel pipeline connected to top-feed distribution piping at the tanks. This discharge line was included in the 100-C-6:1 subsite (known as Pipeline 31). The pipeline was removed up to a point immediately upstream of the discharge to the southern 116-C-3 tank. Multiple additional small-diameter pipelines were also connected to the tops of the tanks, including vent risers, overflow lines, and conduits for the cathodic protection system used for corrosion control.

**Closure Info:** The chemical tanks were installed in 1955. Conflicting reports describe their usage. One report indicated the tanks were potentially unused. However, remediation of the influent pipeline and confirmatory evaluation of the waste site in 2003 confirmed that the site had received radiological waste. Subsequent additional characterization was done in 2004 that indicated that the southern tank was approximately one-third full of mixed waste consistent with the 105-C Reactor Metals Examination Facility (MEF) de-jacketing process. The north tank was found to contain only a small volume of suspect condensate or residual water from pressure testing. No significant radiological activity or metals concentrations were detected in the north tank.

Remediation of the waste site was performed from February through December 2007. The overburden and surrounding soils were removed to provide a sub-grade staging and operations area for waste treatment activities. During excavation, a small volume of radiologically contaminated soil was encountered beneath the influent pipelines near the southern tank, and staged onsite in the waste staging pile area before disposal at the Environmental Restoration Disposal Facility (ERDF). A concrete pad, unrelated to the 116-C-3 waste site, was also partially demolished and removed from the northeastern corner of the operations area. Systematic global positioning system environmental radiological surveys (GPERS) were performed across each 1 meter (3 ft) lift of stockpiled overburden soil. No significant radiological activity was detected.

Site remediation consisted of the removal and stockpiling of overburden material, followed by a proof-of-principle demonstration of the empty northern tank. A treatment and remediation process was planned for the southern tank. Subsequently, the contents if the southern tank was treated using chemical treatment to address the corrosivity characteristic of the waste and
reduce hexavalent chromium to trivalent chromium. A physical treatment using in situ grout stabilization was applied to the southern tank. Verification sampling indicated that requirements had been met, and the treated tank was demolished and removed, along with approximately 1.5 meters (5 ft) of underlying soil.

Treated material, demolition rubble, and approximately 1 meters (3 ft) of soil underlying the tank was removed for disposal at ERDF. Initial soil samples from the tank footprint indicated residual hexavalent chromium concentrations above soil remedial action goals (RAGs) and elevated residual radiological activity. Therefore, an additional 0.7 meters (2 ft) of soil was removed from the southern tank footprint and disposed at ERDF. Excavation at the site extended to a maximum depth of approximately 8.5 meters (28 ft) below ground surface (bgs). The footprints of the remediated waste tanks were entirely in the deep zone (greater than 4.6 m [15 ft] bgs). Approximately 3,767 metric tons (4,152 U.S. tons) of treated waste, debris, and soil was removed from the site and disposed at ERDF. Following verification of attainment of cleanup criteria, the site was backfilled and revegetated.

---

**Classification:**

Interim Closed Out (12/8/2003)

**Names:**

116-C-6; 105-C Fuel Storage Basin Cleanout Percolation Pit; 105-C Pond

**Type:**

Process Pit

**Status:**

Inactive

**Start Date:**

1/1/1984

**End Date:**

1/1/1985

**Description:**

The site has been evaluated and determined to meet remedial action objectives and supports reclassification to interim closed out. The site was an unlined, L-shaped open excavated pit. Soil was excavated from the center and used as a berm around its perimeter.

**Location:**

The site was located east of the 105-C Reactor Building, east of the reactor exclusion fence.

**Related Sites/Structures:**

The site was related to the 105-C Fuel Storage Basin.

**Process Description:**

The pit was constructed to receive liquid from the clean out of the 105-C Fuel Storage Basin. The radiologically contaminated shielding water in the basin was processed through an ion exchange column and filter system. After being sampled to determine if the radioactivity was below release criteria, the water was discharged to the pit. Chemical analysis for hazardous substances was not a standard practice and there was no evidence that it was performed. The water percolated into the soil as fast as it was discharged to the site.

**Waste Type:**

Chemicals

**Waste Description:**

This unit received water from the 105-C Fuel Storage Basin cleanout. Before being discharged to the pit, the radiologically contaminated shielding water in the basin was processed through ion exchange columns. Composite samples were taken to ensure that radionuclide concentrations were below release criteria in Table II of DOE Order 5480.1. No known hazardous substances were present in the water; however chemical analysis during that period was not a standard practice, and there is no evidence that any chemical analyses were performed.

**Closure Info:**

In 2003 the waste site evaluation 0100B-CA-V0121, Rev. 4 demonstrated that information (which included previous sample results, a 2003 field walkdown (site evaluation), and historical data) supported reclassification to "interim closed out" of the 116-C-6 site. The site soil conditions have achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL 2002) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2,
Cleanup verification samples collected, from four test pits in March 2003. The samples were analyzed by offsite contract laboratories using U.S. Environmental Protection Agency approved analytical methods. Sample results from test pit #3 had elevated levels of cesium-137. Per agreement with the EPA, the area of the hot spot was excavated and contaminated soil removed and disposed of at the Environmental Restoration Disposal Facility. After remediation, a confirmatory sample was collected to verify cleanup levels had been met.

Residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario and pose no threat to groundwater or the Columbia River.

**Code:** 118-C-1  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (7/19/2007)  
**Names:** 118-C-1; 118-C-1 Burial Ground; 105-C Burial Ground; 105-C Solid Waste Burial Ground  
**Type:** Burial Ground  
**Start Date:** 1/1/1953  
**End Date:** 1/1/1969  
**Description:** The site has been remediated and Interim Closed Out. It was a burial ground that contained six small engineered disposal structures (rectangular pits with reinforced side walls) and several trenches running north and south. A total of ten trenches were identified during remediation. The site boundaries were permanently marked with concrete posts numbered C-70-1 through C-70-20.

**Location:** The site was located approximately 152 meters (500 feet) southeast of the 105-C Building.

**Process Description:** This site was the primary burial ground for general wastes from the operation of the 105-C Reactor. It received radioactively contaminated process tubes, aluminum fuel spacers, control rods, reactor hardware, and soft wastes. Some Spent Nuclear Fuel was found during remediation.

**Waste Type:** Chemicals  
**Waste Description:** The unit was used for miscellaneous solid waste from 105-C Building that included process tubes, aluminum spacers, control rods, soft waste, and reactor hardware. The C Area Land Burial log (1962-1965) identified waste as trash, poison splines, dummies, hot laundry, fan filters, irradiated boron balls, ceramic samples, thimbles, gun barrels, and hoses. The Burial Ground ROD reported that an estimate of the waste was 86 metric tons (94.8 tons) of boron, 1.1 metric tons (1.2 tons) of graphite, 0.51 metric tons (0.56 tons) of lead, 21.6 metric tons (23.8 tons) of lead/cadmium, and 96 metric tons (105.9 tons) of other materials. Potential contaminants include: Ag-108m, C-14, Co-60, Cs-137, Eu-152, Eu-154, Eu-155, H-3, Ni-59, Ni-63, Sr-90, Ba-133, Ca-41, cadmium, Cr+6, lead, boron, mercury, PCBs, SVOAs, TPH, and VOAs.

**Closure Info:** Remedial action began on February 2, 2004 and was completed on May 27, 2006. Excavation of the ten trenches, (eight oriented in a north-south direction and the other two oriented east to west) involved removing the uncontaminated overburden, the buried contaminated debris, and the underlying contaminated soil. Visual observations of the buried waste confirmed that the following items had been disposed in the Burial Ground during its operation: several thousand perforated and non-perforated spacers, piping and tubing, vertical control rods, sheet metal, boron balls, boron ball vacuums, bismuth, paint, high-dose piping, wax, casks, tar, tar paper, miscellaneous metal, mercury tubes, lead items, reactor parts and hardware, Spent Nuclear Fuel (SNF), hydraulic hoses and parts, degraded drums, glassware, concrete, electrical components, and other miscellaneous debris.
During remedial excavation and sorting, Spent Nuclear Fuel (SNF) was discovered on September 27, 2004. All remedial activities were suspended until the Authorization Basis could be properly assessed and revised to include the SNF. Load-out operations were re-established on April 11, 2005, for previously sorted and segregated material. All remedial activities (excavation, sorting, and load-out) resumed on October 25, 2005 and were completed on May 27, 2006. Over 75,300 metric tons (83,000 tons) of waste and contaminated soil from the Burial Ground was disposed at the Environmental Restoration Disposal Facility (ERDF). The Spent Nuclear Fuel was transferred to the 100-K Basins for interim storage prior to final packaging and disposal. ERDF and approximately 9,300 bank cubic meters (BCM) of overburden soil was removed for subsequent backfill. At the conclusion of excavation activities, the elevation at the deepest part of the remedial excavation was 146 meters (480 feet) above sea level. The remediation excavation footprint was approximately 20,500 square meters (220,600 square feet) in area with a maximum depth of approximately 5 meters (17 feet).

Description: The site has been remediated and interim closed out. The waste site had been an underground storage tank.

Location: The site was located approximately 6 meters (20 feet) directly north of the northeast corner of the 105-C Reactor Building (original footprint).

Process Description: Operation of this waste site began in 1969, coinciding with the Ball 3X Project work. The project operation ended that same year. During Ball 3X Project work with a prototype-contaminated ball sorter, the tank received highly radioactive, irradiated, nickel-plated boron-steel and carbon-steel balls. The tank served as temporary storage until the balls decayed radiologically before being transferred to a solid waste burial ground. The storage box had a slope with vents at each end. One vent was used to put the balls into the tank and the other was used to remove them, following a decay period. Approximately 9,070 kilograms (20,000 pounds) of highly radioactive balls remained in the storage tank. Approximately 70% of the balls remaining are boron-steel and 30% are carbon-steel.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: During Ball 3X project work with a prototype contaminated ball sorter, the tank received highly radioactive, irradiated, nickel-plated boron steel and carbon steel balls for temporary storage so that they would decay radiologically before burial. Approximately 9,070 kilograms (20,000 pounds) of highly activated balls remain in the storage tank. Seventy percent of the balls remaining are boron steel, and thirty percent are carbon steel. A 1987 evaluation of the tank waste estimated that 80 curies of cobalt-60 and 1.6 curies of nickel-63 are present. Potential contaminants include: Co-60, Ni-63, Sr-90, Cs-137, Eu-152, Eu-154, U-238, Pu-238, Pu-239/240, chromium, lead, mercury.

Closure Info: Remedial action began on November 10, 2003. Excavation of the site involved removing the overburden materials, debris, and underlying contaminated soil. Both the collection tank and loose boron balls exposed during the excavation were removed. The tank was a light gage stainless steel tank installed about two feet below grade, about 8 feet long x 8 feet deep and 4 feet wide (long rectangular box) with two 4 inch diameter riser pipes in the top of the tank that were about 4 feet apart and protruded 2 feet above ground. The box tank was installed at a
slight slope, possibly to allow the 1-centimeter (0.39 inch) diameter nickel-plated 1 weight %
borated stainless steel balls to roll to one end. The field staff reported that the light gage
stainless steel box tank was about half full of the 3/8-inch diameter metal balls. The tank was
flattened, crumpled up and hauled off with the soil waste to ERDF. There was no external
piping to or from the tank. There was no exposed piping removed during the excavation. All
contaminated materials were disposed of at the ERDF.

At the completion of remedial action on December 3, 2002, the site excavation was
approximately 123.8 square meters (1,333 square feet) in area, while the former staging pile
area was approximately 166.1 square meters (1,787 square feet). The excavation had an average
depth of approximately 3.1 meters (10.3 feet). Approximately 420 metric tons (463 tons) of
material, including soil and debris, were removed from the 118-C-2 Burial Ground site and
transferred to ERDF for disposal. Both the collection tank and loose boron balls exposed during
the excavation were removed and transferred to ERDF. There was no piping associated with
this remediation.

---

**Code:** 118-C-4

**Names:** 118-C-4; 105-C Horizontal Control Rod Storage Cave

**Type:** Storage

**Status:** Inactive

**Description:** The site has been remediated and interim closed out. The site consisted of two steel-plate
tunnels covered with 1.2-meters (4-foot) of soil, gravel and asphalt emulsion. The two tunnels
were grouted onto a concrete floor that had three equally spaced 0.6-meter (2-foot) diameter by
0.6-meter (2-feet) deep french drains beneath the centerline of the long axis of the structure.
The french drains removed water runoff that could collect between the tunnels in the earth
shielding.

**Location:** The site was located south of the 105-C Reactor Building, within the 105-C exclusion area
fence.

**Related Sites/Structures:** The site was associated with the operation of the 105-C Reactor.

**Process Description:** The tunnels were used for temporary storage of control rods, and possibly miscellaneous
equipment, to allow radioactive decay prior to disposal. Three french drains were located along
the center of the structure floor for the removal of precipitation runoff that could potentially
percolate and collect between the tunnels.

**Waste Type:** Chemicals

**Waste Description:** Some miscellaneous components are currently in the rod cave. The radiation reading at the
entrance to the tunnel with the door open was once documented to be 5 millirads/hour.

**Closure Info:** The rod cave was demolished as part of decontamination and decommissioning activities in
March 2003. The cleanup verification package (CVP) documents completion of remedial action
for the soil beneath the former 118-C-4 Horizontal Control Rod Cave. The 118-C-4 waste site
consisted of the soils underlying the former 118-C-4, 105-C Horizontal Control Rod Cave (rod
cave) building.

Field screening was used to guide the excavation to quickly assess the presence and level of
contamination. Field screening for the 118-C-4 site included using a radiological data mapping
system survey. The radiological mapping survey was performed over more than 50% of the site.
excavation surface area. Final cleanup verification samples were collected following variance sampling. Cleanup verification sampling was conducted on May 15, 2003. Each verification sample was a composite formed by combining soil collected at four randomly selected nodes within each sampling area. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the Sampling and Analysis Plan (SAP) (DOE/RL-96-22). The sample design methodology and sample location figure is presented in the calculation briefs for variance analysis and sample design.

Remedial action objectives and goals from the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA, 1995) are used for the 118-C-4 site. Although the 118-C-4 site is not identified in the ROD, the remedial action objectives and goals documented in the ROD, and in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17), are designated for the 118-C-4 site in the Approved Action Memorandum for the 100 B/C Area Ancillary Facilities and the 108-F Building Removal Action (EPA, 1997 CCN 042276). The remedial action goals and objectives were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology.

The selected remedial action for the 118-C-4 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility near the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and nonradionuclide contaminants of concern (COCs) and contaminants of potential concern (COPCs).

Site excavation and waste disposal are complete, and the exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 122 square meters (1,310 square feet) in area with an approximate depth of 0.85 meters (2.8 feet). Approximately 453 metric tons (500 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

Results of the sampling, laboratory analyses, and data evaluations for the 118-C-4 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

CVP-2003-00015 demonstrates that remedial action at the 118-C-4 site has achieved the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils at the 118-C-4 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 118-C-4 site containing Contaminates of Concerns at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site are protective of groundwater and the Columbia River. The 118-C-4 site is verified to be remediated in accordance with the RAOs and RAGs of the ROD and may be backfilled.

---

**Code:** 128-C-1  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (8/10/2005)  
**Start Date:**  
**End Date:**

**Names:** 128-C-1; 100-C Burning Pit  
**Type:** Burn Pit  
**Status:** Inactive  
**Description:** The site has been remediated and Interim Closed Out. It was a vegetation and ash-covered field
strewn with pieces of green, clear, and bright blue glass; small glass bottles, rusted cans, auto
parts, assorted scrap metal, chunks of concrete and pieces of asbestos transite.

**Location:**
The site was located east of the 105-C Reactor Building and west of the eastern leg of the 100-
B/C perimeter road. It was bounded on the north by an export water line and on the east by the
export water line soil berm.

**Waste Type:** Chemicals
**Waste Description:** The burning pit received combustible materials such as office wastes, paint wastes, vegetation,
and chemical solvents. Large metal items such as hardware, machinery, and other
noncontaminated equipment were also deposited at the site.

**Closure Info:** Remedial action at the 128-C-1 site was initiated on September 16, 2004, and completed on
November 9, 2004. Approximately 8,750 bank cubic meters (11,440 bank cubic yards) were
excavated for disposal, including contaminated ash and soil, concrete, tar, mastic, and asbestos
containing material (e.g., transite). All excavated material was disposed of at the Environmental
Restoration Disposal Facility. A yellow-brown suspect soil material containing chromium and
lead was identified and removed during excavation as well as a suspect garnet material
contaminated with chromium and likely used for abrasive decontamination activities. No
residual anomalous features were noted during a post remediation site inspection performed on

Based on the Work Instruction for Verification Sampling of the Waste Site 128-C-1, Burn Pit
Waste Site, statistical sampling was required for this site because the spatial distribution of
potential residual soil contamination over the study area (site) was uncertain. The results of
verification sampling show that residual contaminant concentrations do not preclude any future
uses (as bounded by the rural residential scenario) and allow for unrestricted use of shallow
zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrate that residual
contaminant concentrations are protective of groundwater and the Columbia River. This site
does not have a deep zone.

**Code:** 132-C-1
**Classification:** Accepted
**Reclassification:** Interim No Action (9/11/2003)
**Names:** 132-C-1; 105-C Reactor Stack Site; 116-C
Reactor Exhaust Stack Site
**Type:** Burial Ground
**Start Date:** 1/1/1952
**Status:** Inactive
**End Date:** 1/1/1969
**Description:** The site has been evaluated and reclassified to "No Action". The stack was demolished with
explosives in September 1983. The rubble was pushed into a trench. This waste site is the area
that contains the buried rubble from the 105-C Reactor Stack. The stack was 5.1 meters (16.6
feet) in diameter and 61 meters (200 feet) high. It operated from 1952 through 1969, exhausting
confinement air from the work areas in the reactor. The area currently appears as a vegetation-
free, cobble-covered field adjacent to the 100-C Reactor. It is no longer marked or posted.

**Related Sites/Structures:** Air was exhausted from the 105-C Reactor Building and the 117-C Filter Building.

**Process Description:** Exhaust air flowed through concrete ducts from the 105-C Building directly out the exhaust
stack. Following completion of the confinement project in the 1950's, the air was diverted via
underground, reinforced concrete ducts to the 117-C Filter Building. After flowing through the
filters, the air went through below-grade and above-grade concrete ducts into the exhaust stack.

**Waste Type:** Process Effluent
Waste Description: Sampling of the stack inlet was performed in 1976, using standard smear techniques. Low-level beta and gamma radiation was detected in the stack. It was estimated that the interior of the unit contained approximately 2.8 millicuries of radioactive materials. At the time of demolition (1983), the interior of the reactor stack contained approximately 2 millicuries of radioactive materials.

Closure Info: Reclassification form 2003-26 and attached supporting information document the site reclassification to No Action.

The stack and foundation were demolished with explosives in September 1983. Rubble from the stack foundation was pushed into the trench using heavy equipment. The remainder of the stack was buried in place. The trench containing the stack rubble and the foundation base were covered with clean fill to a depth of at least 1 meter (3.3 ft). The area was graded to conform with the natural area topography. Five concrete core samples were collected from the stack to establish the radionuclide inventory and depth of contaminant penetration. Core samples were collected at elevations above, below, and approximately equal to the inlet duct. The contamination in the concrete was only in a thin layer of the concrete.

It was determined that excavating the trench for more information presented a greater risk than No Action.

An evaluation of the historical data and RESRAD models supports no action interim closure of the 132-C-1 site.

</tr>
<tr>
<td>Waste Description:</td>
<td>Total radionuclide inventory in this unit is estimated to be 0.84 millicuries. The radionuclides comprising this inventory are tritium, carbon-14, cobalt-60, cesium-137, strontium-90, europium-154, plutonium-152, and plutonium-239/240. Of these radionuclides, strontium-90 is the most restrictive in the Allowable Residual Contamination Level (ARCL) calculations.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The 117-C Filter Building and associated below-grade ductwork were decommissioned and demolished in two phases. Phase I decommissioning work was completed in 1984, including</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
extensive radiological characterization, removal of contaminated equipment, and decontamination. Low-level radioactive waste (e.g., HEPA filters, pumps, frames) removed from the facility was packaged and shipped to the 200 West Area burial grounds for disposal. No asbestos, mercury, or any other nonradioactive hazardous materials were found in the 117-C Facility. Following equipment removal, decontamination consisted mainly of using Masslin cloth to wipe down the vinyl-based coating on the exposed surfaces and, in some cases, by application of a sweeping compound and vacuum cleaner. As part of Phase I activities, a calculation methodology known as "allowable residual contamination level" (ARCL) was used to evaluate the potential radiological dose to a hypothetical, maximally exposed site resident if the site was released for unrestricted use after the demolition and burial in situ of the facility. The ARCL calculation results indicated that the facility was ready for Phase II (demolition) activities. Demolition and site grading were performed in October and November 1988 using conventional heavy equipment. The rubble was buried under at least 1 meter (3 ft) of clean fill, except for rubble from the seal pits, which was buried beneath clean fill at a minimum of 5 meters (16.4 ft) deep.

Using the greatest activities from the pre-demolition characterization data to represent residual contamination levels over 100% of the inner surface area of the former facility, RESidual RADioactivity (RESRAD) modeling was performed in 2003 to support the previous decision to demolish and bury the facility in place. The RESRAD modeling accounts for radioactive decay from 1988 (the year of building demolition) to 2003, and conservatively predicts that the site achieves the dose limits and risk objectives for rural residential land use, groundwater protection, and river protection.

<td>The site is associated with the 1904-D Outfall Structure and the 116-D-7 Retention Basins.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The Patrol Road south of the site shows evidence of an area of pavement which was removed and replaced at one time, suggesting that the site may have been used for drainage for the low area south of the Patrol Road. Drawing H-1-8548-DR shows a 30.5-centimeter (12-inch) drain pipe in this location. On the west side of the junction box, a 23-centimeter (9-inch) pipe runs toward the 1904-D Outfall Structure. Site evaluation concluded that the junction box collected runoff and spillage from a culvert under Patrol Road and the Patrol Road ditch, and discharged the collected liquid to a drainage pipe. The drainage pipe led from the junction box to the river, according to the 100-D Area Technical Baseline Report (WHC-SD-EN-TI-181). Operational dates for this site were unknown, but the associated drainage system appeared to have been at least partially removed or abandoned. Leaks were known to have been common from the nearby 116-D-7 (107-D) and 116-DR-9 (107-DR) retention basins, likely resulting in contaminant introduction to the 100-D-1 Contaminated Storm Drain.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Misc. Trash and Debris</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>Leakage of the nearby retention basins and effluent discharge lines may have accumulated in a low area located between the 107-D Retention Basin (116-D-7) and the Patrol Road. The area was drained through a culvert which ran under the Patrol Road to this junction box and then through a 23-centimeter (9-inch) pipe to the 1904-D Outfall. Potential contaminants include Co-60, Cs-174, Cs-137, Eu-152, Eu-154, Eu-155, H-3, Pu-238, 239 and 241, Am-241, Sr-90, U-238, arsenic, chromium, cadmium, lead and sulfates.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Remedial action was performed on April 15, 2009, to remove the diversion box located at the eastern end of the waste site. Remedial action resumed on January 5, 2010 and continued through January 11, 2010 to remove the associated pipelines. Remediation removed all pipes that were associated with the junction box; however, the portion of pipe that was removed did not extend to the river. Process history indicates a portion of the pipe was previously removed; the portion of the pipe that was there appears to lead to the 100-D-65 site, a spillway that does lead to the river shoreline. The two sites were not connected and the potential association could not be confirmed. A section of pipeline associated with 100-D-65 waste site was uncovered during remediation of the 100-D-1 waste site. The 100-D-65 pipeline was left in place and is</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
located at the western end of the 100-D-1 waste site excavation. It has been assigned to the 100-D-105 waste site.

A total of approximately 495 bank cubic meters (647 bank cubic yards) of soil and debris were removed and directly loaded for disposal at Environmental Restoration Disposal Facility (ERDF).

<td>Description:</td>
<td>The waste site has been remediayed and Interim Closed Out. The site appeared as a small lead sheet covering a concrete pad. It was not marked or posted.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The unit was located southwest of the 185-D Building about 16 meters (52 feet) north of an east/west roadway and 16 meters (52 feet) west of the access road to the west side of the 185 Building.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The history of this site is unknown. The 100-D Area Technical Baseline Report refers to this site as an undocumented solid waste site, lead sheeting. The report indicates that the purpose could not be determined by documentation. A review of aerial photographs, of the 100-D Area from 1943 through 19766, show that the 151-D electrical substation and the overhead steam lines were in the vicinity of the 100-D-2 waste site. According to a 1944 drawing of temporary construction facilities in 100-D Area (HEW 1944), a temporary railroad was also located near this site. However, nothing conclusive was found to indicate the purpose of the lead sheet covering the concrete. Lead sheets previously encountered at other areas of the Hanford Site were used as shielding for penetrating radiation or for corrosion protection (i.e., as barriers below sulfuric acid tanks and pumps).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Soil</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>Remediation of the waste site was performed on April 12, 2007. The lead sheet, which was approximately 0.64 centimeters (0.25 inches) thick, was removed and placed in a drum for later treatment and disposal to the Environmental Restoration Disposal Facility (ERDF). The soil surrounding the concrete pad was moved aside to expose the concrete pad for inspection. The concrete was determined to be solid to at least a depth of 0.6 meters (2 feet).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The 100 Area Remedial Action Sampling and Analysis Plan (SAP) specified lead as the contaminant of potential concern (COPC) for the site. Although not COPCs, the expanded list of inductively coupled plasma metals was analyzed and included arsenic, antimony, barium, beryllium, boron, cadmium, total chromium, cobalt, copper, manganese, molybdenum, nickel, phosphorous, selenium, silver, strontium, tin, uranium, vanadium, and zinc. Due to the potential of handling sulfuric acid, mercury and soil pH were also analyzed. Hexavalent chromium was included as a COPC for verification sampling because of its presence as a contaminant in groundwater and the proximity of the site to historical sodium dichromate handling facilities in the 100-D Area.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Verification soil sampling was performed on October 8, 2007, with one soil sample collected adjacent to each side of the concrete pad. Each sample consisted of 20 aliquots of soil distributed across the surface (0 to 0.15 meters [0 to 6 inches]) below the existing ground</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
surface, combined into one sample representative of each of the four sides. The analytical results indicated the presence of lead up to 578 milligrams/kilogram, exceeding the direct exposure cleanup criteria. Additionally, a sample chipped from the surface of the concrete exhibited lead at a concentration of 32,900 milligrams/kilogram. Therefore, additional excavation to remove the concrete pad and surrounding soil was performed on October 15, 2007. Approximately a total of 216 metric tons (239 US tons) of soil and concrete were excavated and disposed of at ERDF.

Following the October 15th excavation, a second set of verification samples were collected on October 17, 2007, to determine if the remedial action was adequate to support site closure. The analytical results of this sampling indicated that the waste removal action achieved compliance with the RAOs and RAGs. The results of the verification sampling were used to make reclassification decisions in accordance with the TPA-MP-14 procedure in the Tri-Party Agreement Handbook Management Procedures.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River.

<tr>
<td>Description:</td>
<td>The site has been reclassified to No Action. It was a suspected burial trench that would have received contaminated silica gel from the drying towers in the 115-D/DR building. The site has been surface stabilized and resembles a gravel parking lot.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The site is located east/northeast of the south end of the 115-D/DR Building site.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The site was used to contain contaminated silica gel removed from the drying towers in 115-D. Inert gas (helium and/or carbon dioxide) was circulated through the 105-D Reactor for the purpose of removing moisture. The gas circulation system was housed in the 115-D Building and consisted of blowers, silica gel drying towers, and filters. Silica gel is a granular material made from sodium silicate. It was used as a desiccant to reduce the humidity of the reactor gas and was regenerated by condensing the moisture. The moisture-absorbing efficiency of the silica gel was reduced as the material aged and eventually required removal from the gas circulation system.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Soil</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>The site contains contaminated silica gel removed from drying towers in the 115-D/DR Building.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The supporting information attached to Reclassification form 2008-017 states the exact location of the waste site was not clear. Three locations characteristic of disturbed soil were identified in the vicinity of the reported silica gel burial ground. The suspected primary location for the silica gel burial ground was excavated during remediation of the 116-D-2/116-D-2A waste site. The presence or absence of the silica gel at this location would have been difficult to discern, because the physical characteristics of the silica gel waste resemble soil (dark brown silicate material) and the silica gel will have been expected to have decomposed after more than 40 years in contact with soil moisture.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Two alternative locations based on geophysical survey data were excavated. Excavation of the two potential locations for the 100-D-3 waste site was completed on October 9, 2007. Both sites were excavated to approximately 4.5 meters (15 ft) below ground surface. No evidence of waste was encountered at either location. The sites were backfilled a few days later to eliminate the safety hazard of an open excavation. Neither location contained evidence of silica gel. Soil samples collected within the excavation did not detect carbon-14 or tritium above the minimum detectable activity (MDA).

Two test pits were excavated on November 5, 2008 to collect verification samples based on consultation with the Washington Department of Ecology. No radiological contamination was detected during field excavation. Soil samples were collected at four different depths from the center of each of the two potential locations and analyzed for carbon-14 and tritium. Carbon-14 and tritium were not detected above the MDA in any of the soil samples. Therefore, this site has been reclassified to No Action.

**Description:** The site has been remediated. The 100-D-4 site was constructed in 1953. This pit and two other identified sludge pits were associated with maintenance cleanout of the 116-DR-9 Liquid Effluent Retention Basin, which was constructed in the late 1940s. The 116-DR-9 Liquid Effluent Retention Basin was used to hold reactor effluent water for a brief period of time, allowing radioactive decay and thermal cooling to occur before the water was discharged to the Columbia River. The sludge pits were built for disposal of sludge removed from the bottom of the effluent retention basin to enable periodic maintenance and repairs to the basin during operation of the 100-D and 100-DR Reactors. There is no indication from available records that this sludge pit directly received any regular and/or high-volume liquid effluent wastes.

The sludge pit consisted of an unlined excavation approximately 630 square meter (6,779 square feet) bottom dimension with moderately sloped side walls. This pit extended to a depth of about 3 meters (10 ft) below grade, and was surrounded by native sandy gravel soils at the base and side walls of the excavation. After shutdown of the 100-D and 100-DR Reactors in the 1970s, subsequent decommissioning of the effluent retention basin and associated sludge pits (as part of the Radiation Area Remedial Action Program) included placement of approximately 2 meters (6 ft) of materials inside the sludge pit. The materials consisted primarily of soil with some miscellaneous debris from the effluent basin and surrounding area. This sequence of material placement was followed by placement of approximately 1 meter (3 ft) of clean soil cover for interim radiological, health, and safety protection purposes. The materials previously placed over the engineered pit structure (original pit excavation) are identified collectively as overburden materials.

**Location:** The site is located on the east side of the 107-DR Retention Basin, at the southeast corner.

**Process Description:** In the Spring of 1953, sludge was removed from the bottom of the 107-DR Retention Basin (116-DR-9) to facilitate repairs. The sludge was deposited in this and other nearby excavated trenches.

**Waste Type:** Soil
**Waste Description:** The site received radioactively contaminated sludge from the bottom of the 107-DR Retention Basin. From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP include the following (DOE-RL 1998a): Americium-241, Cobalt-60, Cesium-137, Europium-152, Europium-154, Europium-155, Plutonium-238, Plutonium-239/240, Strontium-90, Hexavalent chromium, and Polychlorinated biphenyls (PCBs).

**Closure Info:** Excavation of the 100-D-4 site began on March 18, 1997, by removing the overburden materials and underlying contaminated soil. Based on field screening, overburden materials that were identified as potentially clean were placed in stockpiles for potential use as backfill. Soil and overburden material that were found to be contaminated were disposed of at the ERDF. On March 27, 1997, the excavation had reached the design limits at the base of the engineered structure (El. 135.0 m [443 ft]) and closeout sampling was initiated.

At the completion of the remedial action, the excavation area was approximately 630 square meters (6,779 square feet) at a depth of 2.9 m (9.5 ft), and approximately 1,678 metric tons (1,850 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 135 m (443 ft). Clean backfill will be taken from overburden and Borrow Pit 21, which is located due south of the 100-D-4 site. The material in the borrow pit has been surveyed in accordance with the SAP (DOE-RL 1998a) and is appropriate for use as backfill. The overburden soil is also appropriate for use as backfill.

<tr>
<td>Closure Info:</td>
<td>Remediation at the 100-D-7 waste site was performed between December 22, 2009 and March 6, 2010. Because the 100-D-7 site was a debris site, the excavation focused on the areas identified by geophysics; however, the excavation extent was conducted as necessary to remove waste and debris and remove contaminated soil. The drawings, visual observations radiological surveys, and collection of in process soil samples guided the extent of excavation during remediation. Approximately 24,120 bank cubic meters (31,548 bank cubic yards) of contaminated soil and debris were removed from the 100-D-7 waste site. The soil and debris were staged in a staging pile to the southeast of the 100-D-7 waste site before being loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). The staging area includes a smaller area where topsoil from the waste sites was placed for use on top of the backfill to support successful revegetation as required by the ecological review for the 128-D-2 and 100-D-7 waste sites. All staged waste has been disposed to the ERDF. The staging area was then scraped to remove surface contaminated soil, which was disposed to the ERDF. Only a portion of the 100-D-7 waste site within the WIDS boundary required remediation. An agreement with the Washington State Department of Ecology (Ecology) that the areas within the WIDS boundary where remediation was not performed would become a separate decision unit subject to additional sampling for closeout of the site (WCH 2009c). Eight anomalies were initially identified during the remediation at the 100-D-7 waste site. These consisted of three 3.8-L (1-gal) bottles containing liquid (anomalies 100D-AN-10-001, 100D-AN-10-002, and 100D-AN-10-010); three areas of uncontained solid material: white powder (anomaly 100D-AN-09-082), a pink solid (anomaly 100D-AN-10-003), and a yellow/brown solid (anomaly 100D-AN-10-004). The remaining two anomalies are identified as grease and a metal cylinder (anomalies 100D-AN-10-006 and 100D-AN-10-008). The solid materials were sampled and characterized prior to removal and shipment to ERDF. Anomaly 100D-AN-09-082 was determined by the project engineer to be the same material as anomaly 100D-AN-09-065, so no sample was required for characterization. Anomalies 100D-AN-10-001, 100D-AN-10-002, 100D-AN-10-003, 100D-AN-10-004, 100D-AN-10-006, and 100D-AN-10-008.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
010, and 100D-AN-10-008 were overpacked and transferred to the 118-D-3:2 waste site anomaly characterization area.

</tbody>
</table>

Description: The waste site has been remediated and Interim Closed Out. The outfall structure was demolished, leveled, and covered to blend with the riverbank appearance in 1978. The 100-D-8 waste site consists of two components: an upland segment located above the Columbia River ordinary high water mark (OHWM) and a shoreline segment located below the OHWM and above the ordinary low water mark (OLWM).

Location: The site was located upstream of the 181-D Pumphouse on the Columbia River bank.

Process Description: The outfall was constructed in 1949 as a spillway for an emergency discharge for the DR Reactor. It consisted of a 1.8-meter (72-inch) diameter, reinforced concrete pipe. The pipe discharged into a concrete box flume that spilled onto a grouted riprap surface and extended about 13.1 meters (43 feet) beyond the low-water level of the Columbia River. In 1950 it was modified to increase the discharge flow capacity. Historical records indicate the outfall ceased operation in 1968 and was idle until 1978, when it was demolished.

A previously unidentified pipeline encountered during the remedial action excavation was placed in sitecode 100-D-105 for dispositioning.

Waste Type: Process Effluent

Waste Description: The outfall was used to discharge waste water from the 183-DR and 190-DR Water Treatment Facilities. Effluents included filter backwash effluent, storm runoff, and chemical discharges resulting from spills or releases relating to water treatment facilities. There is a potential for radioactive contamination from the 100-D Area Cask Pad storm drains.

Closure Info: The 100-D-8 waste site consists of two components: an upland segment located above the Columbia River ordinary high water mark (OHWM) and a shoreline segment located below the OHWM and above the ordinary low water mark (OLWM). Confirmatory sampling of the 100-D-8 outfall was not practical due to its location on the embankment of the Columbia River.

Remediation of the upland segment of the 100-D-8 waste site was performed from September 29, 2010 through February 17, 2011. In late March 2011, additional soil was removed at the base of the excavation in the area where four in-process soil samples indicated residual contamination exceeding cleanup criteria. On May 18, 2011, high Columbia River flows resulted in river water entering the excavation and presenting a potential fish-stranding hazard to juvenile fish. With Ecology approval, fill material was temporarily placed into the low areas of the excavation until such time that river flows were sufficiently low to resume excavation. In early December 2011, this fill material was removed and the remediation completed.

Remediation of the upland segment of the 100-D-8 waste site was performed from September 29, 2010 through February 17, 2011. In late March 2011, additional soil was removed at the base of the excavation in the area where four in-process soil samples indicated residual contamination exceeding cleanup criteria. On May 18, 2011, high Columbia River flows resulted in river water entering the excavation and presenting a potential fish-stranding hazard to juvenile fish. With Ecology approval, fill material was temporarily placed into the low areas of the excavation until such time that river flows were sufficiently low to resume excavation. In early December 2011, this fill material was removed and the remediation completed.

Approximately 118,440 metric tons (52,253 bank cubic meters) of material was excavated,
stockpiled. Approximately 80% was used as backfill material. 21,625 metric tons was disposed at the Environmental Restoration Disposal Facility (ERDF). Approximately 741 metric tons (1,680 bank cubic meters) of material was removed from the shoreline area and disposed at ERDF.

During excavation, one anomaly, a metal box, was discovered at Washington State Plane coordinates N 151596.7, E 572626.3. The anomaly was moved out of the excavation to an area reserved for characterization of the anomaly.

**Code:** 100-D-9  
**Classification:** Accepted

**Names:** 100-D-9; 184DA; 184-DA Boiler Oil Tank  
**Reclassification:** Interim Closed Out (8/10/2006)

**Type:** Storage Tank  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site has been remediated and Interim Closed Out. A test trench, measuring approximately 10 meters (23.8 feet) long and up to approximately 3.7 meters (12.1 feet) deep (to native soil), was excavated through the former fuel oil tank location. The excavation confirms that the tank was previously removed. The waste site consisted of an underground fuel storage tank that was believed to have been removed during general demolition efforts of the 100-D/DR area during 1985 and 1986. It now appears as a cobbled-covered field with vegetation on the surface. The elevation at the top of the tank was 141 meters (464.0 feet) and was covered by at least 0.6 meters (2 feet) of overburden.

**Location:** The tank was located in the 100-D Area, west of the northwest corner of the 184-DA Boiler House site, 55 meters (180 feet) south of Palouse Street and 165 meters (540 feet) east of Puget Avenue.

**Process Description:** The tank held fuel oil for the 184-DA Boiler House. It had a capacity of 94,600 liters (25,000 gallons). The fuel tank was installed in 1967 or 1968 to hold oil that fueled the boilers in the 184-DA Steam Generating Building (Boiler House).

**Waste Type:** Soil

**Waste Description:**

**Closure Info:** A test trench, measuring approximately 10 meters (23.8 feet) long and up to approximately 3.7 meters (12.1 feet) deep (to native soil), was excavated through the former fuel oil tank location. Concrete, metal and wood debris was encountered while digging. The excavation confirms that the tank was previously removed in 1994. Six soil gas probes had been installed around the tank in 1991. No COC/COPCs were detected above the RAGs during confirmatory sampling.

A geophysical survey was performed at the site in October 2005. Ground-penetrating radar, EM31 electromagnetic surveys, and magnetic gradiometer surveys were performed over an extended area surrounding the former tank location. Several linear anomalies were interpreted within the survey area, all trending roughly east-west. The former tank location appeared to be in the "disturbed" area that was near the center of the survey area. Small, relatively subtle geophysical anomalies were noted within this disturbed area, more typical of small debris or metal, but there was clearly no evidence of a tank of the documented size [94,600 Liters (25,000 gallons)].

Radionuclides were not COPCs for this site. However, the possible presence of radiological contaminants was evaluated using field radiological survey instrumentation (capable of detecting alpha, beta, and gamma radiation) during excavation. Although not specifically
COPCs, antimony, beryllium, boron, cobalt, copper, manganese, molybdenum, nickel, silver, vanadium, zinc, and mercury levels were also evaluated for the site.

Confirmatory sample results have been stored in the Environmental Restoration project-specific database prior to archiving in the Hanford Environmental Information System. A summary of the samples collected and laboratory analyses performed is provided in Table 1 of the RSVP-2006-030.

The waste site has been evaluated and remediated in accordance with the Remaining Sites ROD, the RDR/RAWP, and the requirements for underground storage tanks specified in WAC 173-360, "Underground Storage Tank Regulations." Focused sampling was performed and the analytical results were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the confirmatory sampling results support a reclassification of the waste site to interim closed out.

The results also demonstrated that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

| Closure Info: | Excavation of the site involved removing the overburden materials, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials found to be contaminated were disposed of at Environmental Restoration Disposal Facility (ERDF). Remedial action at this site began on September 8, 1997 and ended on December 3, 1998 when the excavation reached the design limit at El. 127.8 meters (420.3 feet). During that time, the shallow zone sidewalls were lost to other nearby remedial activities, leaving only the floor of the excavation for the site. At the completion of remedial action, the excavation area was approximately 344.3 square meters (3,706 square feet) with a maximum depth of approximately 6.6 meters (21.7 feet). Approximately 8,700 metric tons (9,592 tons) of material from the site
were disposed of at ERDF. Clean backfill was taken from the clean stockpile and from other sources of clean material that have been surveyed in accordance with the SAP and that are appropriate for use as backfill.

<tr>
<td>Closure Info:</td>
<td>Waste sites 100-D-48:1, 100-D-49:1, 100-D-19 and UPR-100-D-4 were co-located and remediated together. The CVP document referred to the four, combined waste sites as the 100-D-48:1/49:1 Pipeline site. Remedial action at the 100-D-48:1/49:1 Pipelines site began on December 28, 1998. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation reached the design limit. Because remediation of the 100-D-48:1/49:1 Pipelines site required moving an active overhead power line, site remedial action and sampling were conducted in two phases. These separate phases are reflected by the long time period between the start and finish dates for excavation. The excavation design depth generally corresponded with the invert elevation of the pipelines. At the completion of remedial action and removal of the engineered structure, the excavation was approximately 15,504 square meters (166,800 square feet) in area with a maximum depth of approximately 6.0 meters (20 feet) below ground surface. Approximately 107,266 metric tons (118,241 tons) of material from the D Area pipelines site have been disposed of at the ERDF through July 2000. Cleanup verification sampling began on April 3, 2000, and was finished on August 8, 2000. The ground surface in the vicinity of the site varies with an average elevation of approximately 134.4 meters (441 feet).</td>

Description: This site has been remediated and interim closed out.

The 100-D-20 Sludge Pit was constructed in 1953. This pit and two other identified sludge pits were associated with maintenance clean out of the 116-D-7 Retention Basin, which was constructed in the late 1940s. The 116-D-7 Retention Basin was used to hold reactor effluent water for a brief period of time, allowing radioactive decay and thermal cooling to occur before the water discharged to the Columbia River. The sludge pits were built for disposal of sludge removed from the bottom of the effluent retention basin to enable periodic maintenance and repairs to the basin during operation of the 100-D and 100-DR Reactors. There is no indication from available records that this sludge pit directly received any regular and/or high-volume liquid effluent wastes.

The sludge pit consisted of an approximate 575 square meter (6,189 square feet) unlined excavation (bottom dimension) with moderately sloped side walls, extended to a depth of about 2.1 meters (7 feet) below grade, and the pit was surrounded by native sandy gravel soils at the base and side walls of the excavation. After shutdown of the 100-D and 100-DR Reactors in the 1970s, subsequent decommissioning of the effluent retention basin and associated sludge pits (as part of the Radiation Area Remedial Action Program) included placement of approximately 2 meters (7 feet) of material within the sludge pit, which consisted primarily of soil with some miscellaneous debris material from the effluent basin and surrounding area. This sequence of material placement was followed by placement of approximately 1 meter (3 feet) of clean soil cover for interim radiological, health, and safety protection purposes. The materials previously placed over the engineered pit structure (original pit excavation) are identified collectively as overburden materials. A Geophysical Survey was done in 1996 that identified this trench as a disturbed zone that may also contain buried construction debris.

Location: The trench was outside of the south perimeter of 107-D. Refer to Hanford Drawing H-1-4046.

Process Description: In the Spring of 1953 sludge was removed from the bottom of the 107-D Retention Basin (116-D-7) to facilitate repairs. The sludge was deposited in this and other nearby trenches.

Waste Type: Demolition and Inert Waste

Waste Description: The site received radioactively contaminated sludge from the bottom of the 107-D Retention Basin. From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP include the following: americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, hexavalent chromium, and polychlorinated biphenyls.

Closure Info: Excavation of the 100-D-20 (107-D3) Sludge Pit began on July 30, 1997, by removing the overburden materials and underlying contaminated soil. Based on field screening, all overburden materials were found to be contaminated and were disposed of at the Environmental Restoration Disposal Facility (ERDF). On August 1, 1997, the excavation had reached the design limits at the base of the engineered structure (El. 132.3 meters [434 feet]) and closeout sampling was initiated.

At the completion of the remedial action, the excavation area was approximately 575 square meters (6,189 square feet) at a depth of 2.1 meters (7 feet). Approximately 9,710 metric tons (10,700 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 134.4 meters (441 feet). Clean backfill will be taken from Borrow Pit 21, which is located due south of the 100-D-20 site. The material in the borrow pit has been surveyed in accordance with the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL -96-22) and is appropriate for use as backfill.
### Description:

This waste site has been remediated. The 100-D-21 Sludge Pit was constructed in 1953. This pit and two other identified sludge pits were associated with maintenance cleanout of the 116-D-7 Retention Basin, which was constructed in the late 1940s. The 116-D-7 Retention Basin was used to hold reactor effluent water for a brief period of time, allowing radioactive decay and thermal cooling to occur before the water was discharged to the Columbia River. The sludge pits were excavated for disposal of sludge removed from the bottom of the effluent retention basin to enable periodic maintenance and repairs to the basin during operation of the 100-D and 100-DR Reactors. There is no indication from available records that this sludge pit directly received waste on a regular basis or receive a large volume liquid effluent waste.

The sludge pit consisted of an approximate 891 square meter (9,591 square foot) unlined excavation (bottom dimension), with moderately sloped side walls extending to a depth of about 3 meters (10 feet) below grade. The pit was surrounded by native sandy gravel soils at the base and side walls of the excavation. After shutdown of the 100-D and 100-DR Reactors in the 1970s, subsequent decommissioning of the effluent retention basin and associated sludge pits (as part of the Radiation Area Remedial Action Program) included placement of approximately 2 meters (7 feet) of material inside the sludge pit. The materials consisted primarily of soil with some miscellaneous debris material obtained from the effluent basin and surrounding area. After the material was placed into the trench, of approximately 1 meters (3 feet) of clean soil cover was added for interim radiological, health, and safety protection purposes. The waste was later covered with about 1.8 meters (6 feet) of clean fill and marked with an above-ground concrete marker. The soil and material previously placed over the engineered pit structure (original pit excavation) are identified collectively as overburden materials.

### Location:

The waste site was north of the 100-D reactors, outside the west perimeter of the 107-DR Basin (116-DR-9).

### Process Description:

In the Spring of 1953 sludge was removed from the bottom of the 107-DR Retention Basin (116-DR-9) to facilitate repairs. The sludge was deposited in this and other nearby trenches.

### Waste Type:

Asbestos (friable)

### Waste Description:

The site received radioactively contaminated sludge from the 107-DR Retention Basin. From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP include the following (DOE/RL-96-22): Americium-241, Cobalt-60, Cesium-137, Europium-152, Europium-154, Europium-155, Plutonium-238, Plutonium-239/240, Strontium-90, Hexavalent chromium, and Polychlorinated biphenyls (PCBs).

### Closure Info:

Excavation of the 100-D-21 Sludge Pit (elevation 135.0 meters [443 feet]) began on December 31, 1997, by removing the overburden materials and contaminated soil. Based on field screening, all overburden materials were found to be contaminated and were disposed of at the Environmental Restoration Disposal Facility (ERDF). On January 8, 1998, the excavation had reached the design limits at the base of the engineered structure (El. 131.9 meters [433 feet]) and closeout sampling was initiated. Elevated levels of PCBs were found at this elevation (El. 131.9 meters [433 feet]) and excavation was continued. On March 17, 1998, the final excavation was completed at El. 130.5 meters (428 feet). For the exposed surface excavation, initial confirmation sampling and testing using GEA began on April 29, 1998, to determine the number of final verification samples at the base of the engineered structure. Verification sampling and testing were completed on May 21, 1998 (El. 130.5 meters [14.8 feet]).

---

**Hanford Site Waste Management Units Report**

February 2015

132
At the completion of the remedial action, the excavation area was approximately 891 square meters (9,591 square feet) at a depth of 4.5 meters (14.8 feet). Approximately 9,943 metric tons (10,957 tons) of contaminated soil were disposed at the ERDF. The excavation will be backfilled to the reference grade of El. 135 meters (443 feet). Clean backfill was taken from Borrow Pit 21. The material in the borrow pit was surveyed in accordance with the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22) and determined to be appropriate for use as backfill.

Description: The site has been remediated and interim closed out.

Location: The site is outside the east perimeter of the 107-DR Basin.

Related Sites/Structures: The site was associated with the 116-DR-9 Basin.

Process Description: The 100-D-22 Sludge Pit was constructed in 1953. This pit and two other identified sludge pits were associated with maintenance cleanout of the 116-DR-9 Retention Basin, which was constructed in the late 1940s. The 116-DR-9 Retention Basin was used to hold reactor effluent water for a brief period of time, allowing radioactive decay and thermal cooling to occur before the water was discharged to the Columbia River. The sludge pits were excavated for disposal of sludge removed from the bottom of the effluent retention basin to enable periodic maintenance and repairs to the basin during operation of the 100-D and 100-DR Reactors. There is no indication from available records that this sludge pit directly received any regular discharge or high volumes of liquid effluent wastes.

The sludge pit consisted of an approximate 340 square meter (3,658 square feet) unlined excavation (bottom dimension) with moderately sloped side walls, extended to a depth of about 3 meters (10 feet) below grade, and the pit was surrounded by native sandy gravel soils at the base and side walls of the excavation. After shutdown of the 100-D and 100-DR Reactors in the 1970s, subsequent decommissioning of the effluent retention basin and associated sludge pits (as part of the Radiation Area Remedial Action Program) included placement of approximately 2 meters (7 feet) of material inside the sludge pit, which consisted primarily of soil with some miscellaneous debris materials from the effluent basin and surrounding area. The material was covered with approximately 1 meter (3 feet) of clean soil cover for interim radiological, health, and safety protection purposes. The materials previously placed over the engineered pit structure (original pit excavation) are identified collectively as overburden materials.

The site is outside the east perimeter of the 107-DR Basin. Sludge was removed from the bottom of the 107-DR Basin in the spring of 1953 and buried in a nearby trench. The waste was later covered with about 1.8 meters (6 feet) of clean fill and marked with an above-ground concrete marker. The Technical Baseline Report (Carpenter, 1993) says more than one sludge trench was placed in this area. Refer to Hanford Drawing H-1-4046. A Geophysical Survey was done in 1996 that identified the trench as a disturbed zone and contains what appears to be construction debris.

Waste Type: Demolition and Inert Waste
DOE/RL-88-30
Rev. 24

**Waste Description:** The site received radioactively contaminated sludge from the 107-DR Retention Basin. From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP include the following: Americium-241, Cobalt-60, Cesium-137, Europium-152, Europium-154, Europium-155, Plutonium-238, Plutonium-239/240, Strontium-90, Hexavalent chromium, and Polychlorinated biphenyls (PCBs). A small volume of debris containing lead was encountered during remedial action, which was subsequently transported, treated, and disposed of at the ERDF. Because of the presence of lead-containing debris, lead was included as a COC per regulator request.

**Closure Info:** Excavation of the 100-D-22 Sludge Pit began on March 14, 1997, by removing the overburden materials and underlying contaminated soil. Based on field screening, all overburden materials were found to be contaminated and were disposed of at the Environmental Restoration Disposal Facility (ERDF). On March 25, 1997, the excavation had reached the design limits at the base of the engineered structure [elevation 132.4 meters (434 feet)], and closeout sampling was initiated. Because of the presence of polychlorinated biphenyls (PCBs) at that depth, the excavation was extended to 4.8 meters (16 feet) below grade [elevation 130.2 meters (427 feet)] on November 11, 1997, to remove residual PCB contamination. Closeout sampling for PCBs was initiated at this depth.

Waste materials that were excavated, loaded into shipping containers, and disposed of at the ERDF consisted of soils not meeting direct exposure Remedial Action Goals (RAGs) based on field screening results. This included overburden material removed from the southeast portion of the excavation (to construct an equipment access ramp). For the exposed surface of the excavation, initial confirmation sampling and testing using GEA began on June 25, 1997, to determine the number of final verification samples at the base of the engineered structure [elevation 132.4 meters (434 feet)].

At the completion of the remedial action, the bottom of the excavation was approximately 340 square meters (3,658 square feet) at a depth of 4.8 meters (16 feet), and approximately 9,710 metric tons (4,960 loose cubic meters) of material from the site were disposed of at the ERDF. Upon regulatory approval, the excavation will be backfilled with clean fill materials to the reference grade of elevation 135 meters (443 feet). Clean backfill will be taken from Borrow Pit 21 (Gravel Pit 21). The material in the borrow pit was surveyed in accordance with the Sampling and Analysis Plan (SAP) (DOE/RL-96-22) and determined to be appropriate for use as backfill.

**Code:** 100-D-24  
**Classification:** Accepted

**Names:** 100-D-24; 119-D Sample Building Drywell  
**Reclassification:** Interim No Action (9/19/2006)

**Type:** French Drain  
**Start Date:** 1/1/1959

**Status:** Inactive  
**End Date:**

**Description:** The site has been evaluated and determined to require No Action. It consisted of a drywell that received drainage from a floor drain in the 119-D Sample Building. The sample building has been demolished and the surrounding area has been graded.

**Location:** The drywell was located south of the 119-D Sample Building, between the intake and exhaust ducts for the 117-D Filter Building.

**Related Sites/Structures:** The drywell was associated with the 119-D Sample Building.

**Process Description:** The 119-D Sample Building was situated over the intake and exhaust ducts to the 117-D Filter Building and was used to sample effluent gases and particulates. The drywell was connected to the 119-D Sample Building by a 5-centimeter (2-inch) drainage pipe buried at least 0.9 meters deep.
(3 feet) below grade. A 1.9-centimeter (3/4-inch) drain line from the building's evaporative cooler connected into the 5-centimeter (2-inch) drain line near the southern edge of the building.

Waste Type: Equipment

Waste Description: The drywell received effluent from the building's evaporative cooler. It was likely that the floor drain also received sample waste and janitorial waste since the building had no other drains or connections to the process sewer system.

Closure Info: Per discussion with the Washington Department of Ecology and review of historical drawings, the coordinates for the drywell were determined to be incorrect. Accordingly, one test pit was excavated at the drywell location shown on historic drawings. The drywell was not identified in the test pit area. The excavation proceeded to 3 meters (10 feet) below ground surface (bgs), at the suspected location of the former base of the drywell. One soil grab sample was collected at 2.4 meters (8 feet) bgs, and another grab sample was collected at 3 meters (10 feet) bgs. The drywell could not be located, so soil samples were collected at the location of the former drywell. It was presumed the dry well had been removed at the time of 119-D building decommissioning and demolition activities.

Code: 100-D-25
Names: 100-D-25; Unplanned Release - 116-DR-9 (107-DR) Retention Basin Leaks
Type: Unplanned Release
Status: Inactive

Description: This unplanned release site was remediated with the 116-DR-9 Retention Basin and Interim Closed Out. It was done under the provisions of the Interim Action Record of Decision for "proximity sites." Leakage from the 107-DR Basin was confined at the south end and beneath the basin. The contamination could not be separately distinguished in the gravel retention basin area.

Location: The release was located in the soil beneath the 107-DR Retention Basin.

Release Description: The release involved leakage from the 107-DR Basin.

Related Sites/Structures: The leak was associated with 116-DR-9 (the 107-DR Retention Basin).

Process Description: The basin had a history of leaking and underwent repairs in 1951. Waste site 100-D-25 documents leakage beneath the basin and outside the south end of the basin where the neoprene seals in the concrete floor failed and the pipes pulled away from the basin walls at the retention basin inlet. The contamination could not be distinguished from other contaminated soil.

Waste Type: Equipment

Waste Description: Radioactively contaminated effluent was released to the site.

Closure Info: The 116-DR-9 retention basin received cooling water effluent from the 105-DR Reactor from 1950 until 1965. After the 105-D Reactor was deactivated in 1965, the basin remained active until 1967 as part of the 105-D Reactor effluent system. Leakage occurred as unplanned releases in 1951 beneath the basin and outside the south end of the basin when seals in the concrete floor of the basin failed and the pipes pulled away from the basin walls at the retention basin inlet. The basin had a history of leaking and underwent repairs in 1951. Waste site 100-D-25 documents leakage beneath the basin and outside the south end of the basin where the effluent was released.
neoprene seals in the concrete floor failed and the pipes pulled away from the basin walls at the retention basin inlet. The contamination could not be distinguished from other contaminated soil. It was remediated with the 116-DR-9 Retention Basin under the provisions for "proximity sites."

Excavation began on October 21, 1997, by removing the overburden materials and underlying contaminated soil. Overburden materials, which were contaminated, were disposed at the ERDF. On December 28, 1998, the excavation had reached the design limits below the base of the engineered structure (El. 130.25 m [427.35 ft]) and cleanup verification sampling was initiated. At the completion of the remedial action, the excavation area floor was approximately 16,352 square meters (176,013 sq ft) at a depth of 4.75 meters (15.6 ft), and approximately 201,519 metric tons (222,122 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 135.0 meters (443 ft).

Contaminated soil associated with the process effluent pipelines was not removed completely, but deferred for final remediation with the pipeline waste sites. The 116-DR-9 sidewall areas that are adjacent to future pipeline excavation areas were not sampled as part of the basin cleanup verification effort. These areas will be sampled and verified clean as part of the effluent pipeline remediation efforts.

Code: 100-D-29  Classification: Accepted
Names: 100-D-29; Effluent Line Leak #2  Reclassification: Interim Closed Out (3/25/2010)
Type: Unplanned Release  Start Date: 1/1/1951
Status: Inactive  End Date:
Description: The waste site is a release from the 107-DR Retention Basin. It is possible that the location of the 100-D-29 waste site in documented in WIDS and SIS may not be the actual trench location. The location description was developed using historical sketches and a 1954 photograph. Contamination associated with the release shown in this photograph may have had some portion removed during remediation of the 107-DR Retention Basin (CVP-99-00006). As a result of this new information, a discovery site, 100-D-102, was created in WIDS.

In 1952, the trench was covered by about 1.2 meters (4 ft) of clean fill material upon completion of the basin repair. A portion of the contaminated soils from this leak was used as fill around the pipeline anchor blocks south of the basin. All contaminated soil was then covered by 0.61 meters (2 ft) of soil. Contaminated soil associated with the pipeline anchor blocks would have been removed with the 100-D-49, 100-DR Effluent Cooling Water Pipelines.

Location: The site was located southwest of the 107-DR Retention Basin and southeast of the 107-D Retention Basin. The site is centered at Washington State Plane coordinates, E573832.364, N152132.5.

Release Description:
In 1951, extensive leakage of effluent water was detected above ground about 46 meters (105 feet) southeast of the 107-D Basin. A maximum dose rate of 50 millirads/hour was observed at the surface. Two excavations were made to investigate the leakage, but the effluent continued to seep to the surface. In the fall of 1952, there was extensive leakage of effluent water at the inlet end of the 107-DR retention basin (116-DR-9) that was caused by the pipes pulling loose from the basin wall from thermal expansion and contraction of the steel pipelines and the concrete basin wall. In order to repair the leak, a trench was dug to receive the leaked effluent so that repairs could be made. This trench formed a "dogleg" adjacent to the southwest corner of the basin towards the southeast end of the 107-D Retention Basin. (UNI-946).

Related Sites/Structures: The site was related to the 107-DR Retention Basin and 100-D-102.
Process Description: The site was a planned release to allow for the repair of the 107-DR Retention Basin.

Waste Type: Misc. Trash and Debris

Waste Description: Contaminants of potential concern (COPCs) include: Co-60, Cs-134, Cs-137, Eu-152, Eu-154, Eu-155, H-3. The waste is contaminated soil from a temporarily constructed drainage trench. In the fall of 1952, readings up to 100 mrad/hr were detected at the surface of the mud leaking from the retention basin. The source is radioactive process effluent from the 107-D Retention Basin.

Closure Info: Remedial activities at the 100-D-29 waste site began on March 7, 2008, and were completed on March 28, 2008. The excavation was approximately 4.6 meters (15 ft) deep and 30 meters (100 ft) long with variable width. Approximately 5,200 bank cubic meters (BCM) (6,800 bank cubic yards [BCY]) of soil was excavated and stockpiled adjacent to the site. Historical information indicated that residual radiological contamination associated with the 100-D-29 waste site would be expected to be encountered at approximately 1.2 meters (4 feet) below ground surface (bgs) because the trench that formed the site had been backfilled with 1.2 meters (4 feet) of soil. However, no field detectable contamination was encountered during excavation to this depth. The excavation was extended to a depth of 4.6 meters (15 feet), but still no radiological contamination was detected. A limited amount of concrete and pipe debris was encountered during excavation; this was loaded directly into a container for disposal at the ERDF. The concrete and pipeline were likely remnants of a north-south fire protection pipeline and associated valve box in the area. Historic drawings show north-south and east-west 15.20-cm (6-in.) fire protection pipelines (included in the 100-D-63 waste site) in the area.

Based on field observations, in combination with hand-held radiological surveys that indicate the absence of detectable contamination associated with a retention basin leak, it is suspected that the contaminated soil associated with the 100-D-29 site was removed in the fall of 1952 and used as backfill for the anchor blocks at the 107-DR Retention Basin inlet.

Code: 100-D-30

Classification: Accepted

Reclassification: None

Names: 100-D-30; 185-D; 185-D Sodium Dichromate Trench & Sump; 189-D Decontamination & Demolition Project; 190-D Sodium Dichromate Soil Contamination

Type: Unplanned Release

Start Date: 1/1/1945

End Date: 1/1/1967

Status: Inactive

Description: The site is sodium dichromate contaminated soil. The site was discovered during the 185-D/189-D Subgrade Decontamination and Demolition Project. Sodium dichromate contamination was discovered in the soil along the entire length of the sodium dichromate trench of 185-D. The contamination was visually identified on concrete surfaces and on large cobbles in the soil by the yellow film on the surface. Photographs were taken during demolition of the subgrade structures and show the contaminated soil and structures.

Location: The site is located in 100-D Area, between the 105-D Building and the 183-D Building.

Release Description: Sodium dichromate solutions were released from cracks or expansion joints in the "chromate trench" which extended the length of the 185-D Building.

Related Sites/Structures: The site was related to the 190-D, 185-D, 189-D and 105-D process piping.
Process Description: The process water flowed from the 185-D Building into the refrigeration room of the 189-D Building where it was chilled and pumped into either or both of the two center storage tanks in the 190-D Building. Four large 6.62E+06-liter (1.75E+06-gallon) steel storage tanks were provided in the 190-D High Bay to supply water to the coolant pumps for the reactor. The water in the tanks was treated with sodium dichromate to inhibit corrosion in the reactor process tubes. The 185-D Building contained sodium dichromate mixing tanks and a pipe trench to convey sodium dichromate solutions to be added to the large 190-D Storage Tanks.

Waste Type: Oil
Waste Description: Sodium dichromate contamination is in the soil.

Description: The waste site encompasses the underground pipelines that transported pre-reactor, non radioactive cooling water and process sewer waste streams from water treatment, reactor, and laboratory facilities. The waste site was divided into twelve subsites. All of these underground pipelines are pre-reactor (pre-irradiation) disposal and supply lines, except for the septic sewer lines that fed the 1607-D2 septic tank. All the underground process sewer and drainage piping from water treatment facilities to the 116-D-5 Outfall Structure are part of this site. The site also includes the feed pipelines from the 117-DR Filter Building and the 105-DR Reactor to the 100-D-13 septic System.

Excluded from this site are the process sewer system that was constructed specifically for the 100-DR Reactor facilities, chemical supply, or underground effluent pipelines designed to dispose of radionuclide contaminated effluents and pipelines within buildings. These systems are addressed as separate WIDS sites. This site does not include the 120-D-1 Ponds, used for process sewer discharge from 1977 to 1994 or the 116-D-5 Outfall Structure and river pipelines. This site also does not include raw river water, potable water, or fire system water pipelines, or the sodium dichromate underground supply pipelines (100-D-56).

Location: The pipelines are located in the 100-D Area. The system is a network of underground piping that extends from water treatment facilities, the 184-D Powerhouse, 1700-D Series Buildings, and 105-D Reactor to the 116-D-5 Outfall and septic tank 1607-D2. These pipelines run from the 182-D Reservoir, the 183-D Basins, Filters and Clearwells, the 185-D, 183-DR, and 189-D/190-D Complex, the 105-D Reactor and the 1700-D Series Buildings. The individual subsites contain the pipeline descriptions and associated structures.

Related Sites/Structures: The process sewer received effluent from the following facilities: 182-D, 183-D, 183-DR, 184-D, 185-D 186-D, 189-D, 190-D, 105-D, and 107-D. All associated facilities have been demolished except for 181-D, 182-D, 183-D, and 105-D.

Process Description: Water was taken from the Columbia River and treated extensively to purify it prior to use as reactor cooling water. The cooling water was used in a single pass operation and once through the reactor cores became irradiated reactor effluent. The non-radioactive overflows, process cooling waste streams, filter backwashes, and floor drains in non-radioactive areas became process sewer wastes. The 107-D Retention Basin discharged to the process sewer pipeline just prior to the 116-D-5 Outfall Structure.
Waste Type: Water

Waste Description: The waste consists of steel piping, concrete, and soil (if contaminants are present). The water supply and process sewer drain pipelines at the 100-D Area provided for the supply and disposal of non-radioactive streams generated in water treatment and water treatment laboratories facilities and powerhouse operations. Known chemical additions to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained near 7.5, free chlorine residual at about 0.2 milligrams per liter, and sodium dichromate was added at a rate of about 2 milligrams per liter. The sodium dichromate product pipelines would have much greater concentrations. Sodium chloride was also used to regenerate water softeners in both water treatment and powerhouse operations. The process sewer system connected to the 116-D-5 (1904-D Outfall) at the Columbia River shoreline. (The outfall and the pipelines that carried the process sewer and reactor effluent to the center bottom of the river are addressed by separate Waste Information Data System [WIDS] entries.) Specific chemicals and potential radionuclide content is currently unknown. However, minor amounts of radionuclide, chemical, and mercury contamination may be present in process sewer lines from the 185-D and 189-D/190-D complex as a result of laboratories once located in these now demolished facilities.

This Site has the Following SubSites:

Code: 100-D-31:1  
Names: 100-D-31:1; 1607-D2 Septic Sewer Pipeline

Code: 100-D-31:2  
Names: 100-D-31:2; 1700-D Series Buildings Septic Sewer Pipelines

Code: 100-D-31:3

Code: 100-D-31:12  
Names: 100-D-31:12; 183-D West Process Sewer Pipelines

Code: 100-D-31:1  
Classification: Accepted
Subsite one has been remediated. It consisted of approximately 390 meters (1,280 ft) long, 8 inch diameter segment of vitrified clay pipe (VCP) and was located to the northwest of the 105-D Reactor. The pipelines fed into the 1607-D2:3 portion of the 1607-D2 sanitary sewer system, which was the main sanitary sewer servicing the 100-D Area. It transported sewage from manhole S-21D north to manhole S-25D. This system of sewers was active from 1944 to 1994 and received effluent from the 1700-D, 1704-D, 1707-D, 1707-DA, 1708-D, 1713-D, 1716-D, 1717-D, 1718-D, 1719-D, 1722-D, 182-D, 183-D, 184-D, 185-D, 186-D, 189-D, 190-D, and 108-D Buildings.

Several miscellaneous pipelines crossing over the subsites were encountered during excavation, however, none were connected. All of these pipelines will be addressed separately.

The 100-D-31:1, 1607-D2 septic sewer pipeline subsite is located northwest of the 105-D Reactor in the 100 DR-1 Operable Unit. The 100-D-31:1 waste site addresses a portion of the 1607-D2 septic sewer pipeline that transported sewage from manhole S-21D north to manhole S-25D.

The 100-D-31:1 waste site addresses a portion of the 1607-D2 septic sewer pipeline that transported sewage from manhole S-21D north to manhole S-25D. The 1607-D2 septic system received waste from the 1700-D, 1704-D, 1707-D, 1707-DA, 1708-D, 1713-D, 1716-D, 1717-D, 1718-D, 1719-D, 1722-D, 182-D, 183-D, 184-D, 185-D, 186-D, 189-D, 190-D, and 108-D buildings. The 100-D-31:1 pipeline transported sewage from all these buildings.

The waste consists of steel piping, concrete, and soil.

Remedial action was performed between June 18, 2007 and July 17, 2008. The final excavation depths for 100-D-31:1 and 100-D-31:2 were approximately 5 meters (16 ft) and 3 meters (9 ft), respectively. The excavation resulted in approximately 2,512 bank cubic meters (BCM) (3,287 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility, including 756 m (2,480 ft) of pipe.

Analytical results show that residual contaminant concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Several miscellaneous pipes crossing over the 100-D-31:1 and 100-D-31:2 pipelines were encountered during excavation. None of the crossing pipelines were connected to the 100-D-31:1 or 100-D-31:2 pipelines. Most of these pipelines are associated with the 100-D-63 clean water pipelines and will be addressed with that site. Four pipelines were not previously identified. These four pipelines were added into 100-D-105 for dispositioning.
Subsite two has been remediated. It consisted of multiple segments of 8 in. diameter VCP, totaling approximately 365 m (1,200 ft) in length. This pipeline segment was located between manholes S-19D and S-21D, where it connected with the 100-D-31:1 pipeline. The pipelines from the following 1700-D Buildings were connected to the 100-D-31:2 pipelines: 1704-D, 1707-D, 1707-DA, 1713-DD, 1717-D, 1719-D, and 1722-D. Another portion of the pipeline was located east of manhole S-21D and serviced the 108-D Building.

For specific remedial information see subsite 1.

The 100-D-3 1:2 waste site is the 1700-D Series Buildings septic sewer pipelines. This pipeline segment is located between manholes S-19D and S-21D, where it connected with the 100-D-31:1 pipeline. The 1700-D Series Buildings were non-radiological offices, shops, change rooms, and equipment storage. The septic sewer pipelines from the following 1700-D Buildings were connected to the 100-D-31:2 pipeline: 1704-D, 1707-D, 1707-DA, 1713-DD, 1717-D, 1719-D, and 1722-D. Another portion of the 100-D-31:2 septic sewer pipeline was located east of manhole S-21D and serviced the 108-D Building.

The waste consists of steel piping, concrete, and soil.

Remedial action was performed between June 18, 2007 and July 17, 2008. The final excavation depths for 100-D-31:1 and 100-D-31:2 were approximately 5 meters (16 ft) and 3 meters (9 ft), respectively. The excavation resulted in approximately 2,512 bank cubic meters (BCM) (3,287 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility, including 756 m (2,480 ft) of pipe.

Analytical results show that residual contaminant concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Several miscellaneous pipes crossing over the 100-D-31:1 and 100-D-31:2 pipelines were encountered during excavation. None of the crossing pipelines were connected to the 100-D-31:1 or 100-D-31:2 pipelines. Most of these pipelines are associated with the 100-D-63 clean water pipelines and will be addressed with that site. Four pipelines were not previously identified. These four pipelines were added into 100-D-105 for dispositioning.
Description: This subsite has been remediated and Interim Closed Out. It included three process and septic sewer lines, one from the northwest corner and the other from the west side of the 105-D Reactor building. The pipelines ran west and northwest respectively to a 91.44 cm (36 in) line which led in to the 205.74 cm (6 ft 9 in) square line that connected to the 116-D-5 outfall. Also included were the vitrified clay sewer lines from the 108-D and 1728-D facilities that joined with the 20 cm (8 in) vitrified clay sewer pipe that is part of 100-D-31:1.

Location: The 105-D sewer pipelines transported waste from the 105-D Reactor north to manhole S-21D. The subsite also included pipelines that transported waste east from manhole S-13D toward the 1607-D2 septic tank. The 100-D-31:3 subsite includes the septic sewer pipelines exiting the northwest and east sides of the 108-D Building, and the septic sewer pipeline under the 1728-D Building.

Process Description: The 100-D-31:3 and 100-D-31:4 process sewer pipelines actively transported process and septic sewer waste beginning in 1944 and continuing through 1994. During reactor operations from 1944 through 1967, the nonradioactive overflows, process cooling waste streams, filter backwashes, and floor drainage in nonradioactive areas became process sewer wastes that flowed through these pipelines.

Waste Type: Equipment

Waste Description: The waste consists of steel piping, concrete, and soil.

Closure Info: Remedial action at the 100-D-31:3 pipeline subsite was performed between May 19 and December 30, 2008. Excavation continued until all debris and contamination associated with the pipeline structure had been removed. The site was excavated to depths ranging from approximately 2.8 to 3.5 meters (9.1 to 11.3 ft), resulting in approximately 7,687 bank cubic meters (10,070 bank cubic yards [BCY]) of soil and piping/debris being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). In addition, approximately 785 linear meters (2,576 linear ft) of pipe were removed. This piping was sorted within the excavation and direct loaded for disposal at ERDF.

In July 2008, during the 100-D-31:3 remedial excavation, a 55 gallon metal drum was uncovered. The drum was confirmed to be empty and managed as non-hazardous waste.

Several pipelines not previously identified were found during the excavation. They were added to 100-D-105 for dispositioning.

</tbody>
</table>
20 cm (8 in) VCP (W-71477).

186-D - A 30.48 cm (12 in) process sewer line exited the northeast corner, heading east to the 205.74 cm (6 ft 9 in) line to the 116-D-5 outfall. Also, a 15 cm (6 in) vitrified clay pipe (VCP) sewer exited the north side and joined with an east-west 20 cm (8 in) VCP.

189-D - A 137 cm (54 in) process sewer line exited the north side and joined with an east-west 205.74 cm (6 ft 9 in) line to the 116-D-5 outfall (W-71477).

190-D High Bay - A 45.7 cm (18 in) process sewer line exited the north side and joined with an east-west 205.74 cm (6 ft 9 in) line to the 116-D-5 outfall, and a 76.2 cm (30 in) process sewer line exited the north side to a 91.4 cm (36 in) line, which headed west to the 205.74 cm (6 ft 9 in) line to the 116-D-5 Outfall. Three other lines exited the east side of the 190-D Building, a 10 cm (4 in) cast iron, a 15 cm (6 in) cast iron, and a 15 cm (6 in) VCP, which all joined into a 15 cm (6 in) VCP that headed north to the west side of the 1728D Building location (M-1904-D, Sheet 5, W-71477).

Location: The pipelines were located on the north side of the 105-D Reactor. The 190-D sewer pipelines are bound by manholes S-13D and P-9D to the east and manholes S-11D and P-13D to the west. The pipelines included in this subsite transported process sewer waste from the northeast corner of the 186-D Building and the north side of the 190-D Building toward the 116-D-5 outfall. The pipelines also transported the septic sewer waste from the 185-D, 186-D, and 190-D Buildings.

Related Sites/Structures: The 100-D-31:4 subsite pipelines also intersect with pipelines from 100-D-31:8 and 100-D-31:9 at junction box P-13D and manhole S-11D, respectively.

Process Description: The 100-D-31:3 and 100-D-31:4 process sewer pipelines actively transported process and septic sewer waste beginning in 1944 and continuing through 1994. During reactor operations from 1944 through 1967, the nonradioactive overflows, process cooling waste streams, filter backwashes, and floor drainage in nonradioactive areas became process sewer wastes that flowed through these pipelines.

Waste Type: Equipment

Waste Description: The waste consists of steel piping, concrete, and soil.

Closure Info: Remedial action at the 100-D-31:4 pipeline subsite was performed between September 26, 2008 and December 10, 2009. Excavation continued until all debris and contamination associated with the pipeline structure had been removed. The site was excavated to depths ranging from approximately 3.8 to 4.8 meters (13 to 16 ft), resulting in approximately 9,883 BCM (12,926 BCY) of soil and piping/debris being removed for disposal at ERDF. In addition, approximately 636 linear meters (2,087 linear ft) of pipe were removed. This piping was sorted within the excavation and direct loaded for disposal at ERDF.

During the remediation of the 100-D-31:4 pipeline subsite, it was determined that construction of a land bridge spanning a portion of the open excavated waste site trench was needed to support both existing and future pump-and-treat lines prior to cleanup verification statistical sampling. Three focused samples were collected within 1 meter (3.3 ft) of either side of the pipeline along the center line of the bottom of the 100-D-31:4 excavation. No results from focused sampling within the area of the then proposed land bridge were above shallow zone remedial action goals (RAGs). The Washington State Department of Ecology approved construction of the land bridge in a regulatory agreement titled "Soil Bridges at 100-D-31:4 and 100-D-31:8" (Ecology 2009). The 100-D-31:4 land bridge was constructed on November 16, 2009.

Waste Description: The waste consists of steel piping, concrete, and soil.

Closure Info: Remedial action at the subsite was performed between November 1, 2007 and March 5, 2008. The site was excavated between 1.5 meters (5 ft) and 3.3 meters (7.5 ft) below grade resulting in approximately 371 bank cubic meters (BCM) (485 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility, including approximately 329 meters (1,079 ft) of vitreous clay pipe encased in concrete and 30 meters (98 ft) of steel pipe. Approximately 2,440 BCM (3,192 BCY) of soil (overburden) was removed and stockpiled for evaluation as clean backfill. No anomalies or stained soil were discovered during remediation; however, coal ash and asphalt is present throughout the site. Several miscellaneous pipes crossing over the 100-D-31:6 pipeline were encountered during excavation.

The SubSite is Part Of:
Code: 100-D-31
Names: 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

Code: 100-D-31:7
Names: 100-D-31:7; 116-D-5 and D-Pond Sewer Pipeline
Type: Process Sewer
Status: Inactive

Description: This subsite has been remediated and Interim Closed Out. Subsite 7 consisted of pipelines that transported process and septic sewer waste from 1944 to 1994. This subsite is a 2-meter (6-foot, 9-inch) square pipeline that collected sewer wastes from smaller pipelines and fed into the 116-D-5 Outfall. The pipeline was approximately 480 meters (1,574.9 feet) long. The 116-D-5 and D-Pond sewer pipeline transported process waste from junction box P-13D north to the 116-D-5 outfall. It also includes the vitrified clay pipe transporting septic sewer waste from manhole S-19D to manhole S-18D.

Location: The 100-D-31:7 was a north-south oriented pipeline located north-northwest of the 105-D Reactor.

Waste Type: Process Effluent
Waste Description: The waste consists of steel piping, concrete, and soil.

Closure Info: Remedial action at the subsite began on November 5, 2007, and continued through December 9, 2009. The site was excavated to depths between 12 meters (40 ft) and 16 meters (53 ft) below grade, resulting in approximately 17,684 bank cubic meters (BCM) (23,130 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility, including approximately 480 meters (1,574.9 ft) of pipe.

An intact 946.3-L (250-gal) motor oil storage tank was found within the layback of the subsite approximately 12 meters (36 ft) west of the demolished 1716-D Building. The tank was identified as being associated with the 130-D-1, 1716 Gasoline Storage Tank waste site. While relocating the tank from the excavation layback, approximately 95 L (25 gal) of oily fluid spilled onto a polyethylene-lined containment area set up adjacent to the tank. No oily fluid was released to the soil. The oily fluid was sampled for waste designation, and the remaining fluid was absorbed using soil from the surrounding area. The soil underneath the tank was inspected and it was determined that no leaks had occurred from the pipe that was previously attached to the tank. All piping associated with the 130-D-1 waste site that was present within the 100-D-31:7 excavation was removed. The remaining soil will be assessed during remediation and...
closeout verification of the 130-D-1 waste site.

**The SubSite is Part Of:**

- **Code:** 100-D-31
- **Names:** 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

**Names:** 100-D-31:8; 183-D and 186-D Northern Sewer Pipelines

**Type:** Process Sewer

**Status:** Inactive

**Description:** The 100-D-31:8 subsite has been remediated and Interim Closed Out. The pipeline subsite is made up of piping from two different sewer systems (sanitary and process sewers).

The following segment is part of the process sewer:

A 121.94 cm (48 in) reinforced concrete process sewer line exited the north side of the 183-D filter Plant connecting to a 144.2 cm (4 ft 9 in) concrete box pipe, connecting to a 167.54 cm (5 ft 6 in) concrete box pipeline, to the 205.74 cm (6 ft 9 in) line (100-D-31:7) to the 116-D-5 outfall (W-72688).

The following segment is part of the sanitary sewer:

A 20 cm (8 in) vitrified clay pipeline north of the 183-D filter plant and extending to above the northwest side of the 186-D Building and connecting to the 100-D-31:4 pipeline (W-72688).

**Location:** The 183-D and 186-D northern sewer pipelines were vitrified clay pipelines and reinforced concrete pipelines exiting the north side of the 183-D Building, as well as an east-west trending reinforced concrete pipeline segment from junction box P-3D to junction box P-13D.

**Process Description:** The process sewer received raw water drained from the 182-D and 183-D Buildings (also see 100-D-31:11). It also received waste water (backwash) and overflow from the 183-D Filter Building. The sanitary sewer received septic waste from the lavatories in the 182-D Pump House and 183-D Headhouse. The 100-D-31:8 pipelines received waste water from the north side of the 182-D and 183-D Buildings via the 100-D-31:11 pipelines at junction box P-3D and at a second connection along the same pipeline approximately 23 meters (75 ft) to the south. The 100-D-31:8 pipelines also received waste water from the 186-D Building where it connected to the 100-D-31:9 pipelines at manhole S-10D and at a second connection approximately 18 meters (59 ft) to the east along the same pipeline. The waste water was then transferred to the 100-D-31:4 and 100-D-31:7 pipeline segments at junction box P-13D and manhole S-11D.

**Waste Type:** Chemicals

**Waste Description:** The waste consists of steel piping, concrete, and soil.

**Closure Info:** Remedial action at the 100-D-31:8 subsite was performed between August 27, 2009, and May 19, 2010. The final excavation depth for 100-D-31:8 was approximately 9 meters (30 ft). The excavation resulted in approximately 5,732 bank cubic meters (BCM) (7,509 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Additionally, approximately 535 meters (1,755 ft) of pipe were removed and disposed at the ERDF. Approximately 61,330 BCM (80,432 BCY) of soil (overburden) was removed.
and stockpiled for evaluation for use as clean backfill. It was determined that construction of a land bridge spanning a portion of the open excavated waste site trench was needed to support both existing and future pump-and-treat lines prior to conducting cleanup verification sampling. Demolition of the 1902-D water tank in January 2010 resulted in a rust stained area outside the north end of the 100-D-31:8 waste site footprint. This area was sampled (J19KJ9) for characterization and the impacted surface soils were disposed of at ERDF.

Remedial action at the 100-D-31:9 subsite was performed between July 15, 2009, and April 21, 2010. The final excavation depth for 100-D-31:9 was approximately 7 meters (23 ft). The excavation resulted in approximately 11,485 BCM (15,045 BCY) of material removed for disposal at the ERDF. Additionally, approximately 705 meters (2,313 ft) of pipe were removed and disposed of at the ERDF. Approximately 44,310 BCM (57,957 BCY) of soil (overburden) was removed and stockpiled for evaluation for use as clean backfill.

Remedial action at the 100-D-31:10 subsite was performed between December 29, 2009, and January 27, 2010. The final excavation depth for 100-D-31:10 was approximately 3 meters (10 ft). The excavation resulted in approximately 208 BCM (272 BCY) of material removed for disposal at the ERDF. Additionally, approximately 128 meters (420 ft) of pipe were removed and disposed of at the ERDF. Approximately 1,544 BCM (2,019 BCY) of soil (overburden) was removed and stockpiled for evaluation for use as clean backfill. A section of the 100-D-31:10 pipeline subsite is located adjacent to the active 199-D5-33 groundwater monitoring well. To maintain structural integrity of the well, a section of the 100-D-31:10 pipeline subsite was left in place, resulting in a small land bridge measuring 11 meters (36 ft) wide across the pipeline excavation.

On February 22, 2010, confirmatory sampling was being conducted at 100-D-63, test pit 16. While backfilling the test pit, a piece of concrete fell out of the backhoe bucket and struck one of the two pipes in the bottom of the excavation, causing it to leak water. Approximately 37,854 liters (10,000 gal) of raw water was released due to this pipeline not being properly valved off from the export water line. It was unclear whether the leaking water was contaminated. Therefore, Ecology agreed to allow the released raw water to be pumped to the 100-D-31:9 open excavation. In the course of isolating and draining the export water pipeline to repair the leak, and waiting for approval to pump the water into the 182-D Reservoir, approximately 7,571 liters (2,000 gal) of water was pumped from the export water line to the 100-D-31:8 subsite. On March 2, 2010, in-process samples were collected from inside the water release footprints within the 100-D-31:8 and 100-D-31:9 open excavations. On March 4, 2010, an in-process soil sample (J19L76) was collected from outside the water release footprint in 100-D-31:9. Based on results of these in-process samples, the soil from within the water release footprints was placed in the associated overburden stockpiles. These in-process sample results were not used for determining the interim closure.

**Type:** Process Sewer  
**Status:** Inactive  
**Description:** The 100-D-31:9 subsite has been remediated and Interim Closed Out. The pipeline subsite is made up of piping from two different sewer systems (sanitary and process sewers).
The segments following are part of the process sewer:

A 106.7 cm (42 in) process sewer line exiting the east side of the 183-D Building to junction P-6D, connecting to a 114.3 cm (3 ft 9 in) pipe (100-D-31:8) that runs north to a 167.54 cm (5 ft 6 in) line, east to the 205.74 cm (6 ft 9 in) line (100-D-31:7) to the 116-D-5 outfall (W-72883, W-72688, W-72689). Two concrete process sewer pipes running north-south between the 183-D and 186-D buildings, joining together to a 114 cm (45 in) reinforced concrete box pipe between the buildings (M-1904-D, Sheet 5).

The following segments are part of the sanitary sewer:

A 20 cm (8 in) vitrified clay pipeline that exited the east side of the 183-D building and turned north to connect to the 100-D-31:8 pipeline (W-72883). Two 15 cm (6 in) vitrified clay pipelines that exited the west side of the 186-D Building and connected to the 20 cm (8 in) main sanitary sewer trunkline (W-71788).

**Location:**

The 183-D and 186-D process sewer pipelines extend from the intersection with the reinforced concrete pipe (RCP) exiting the east side of the 183-D Building to manhole S-10D, and comprise the vitrified clay pipe and RCP pipelines from the east side of the 183-D Building and the west side of the 186-D Building.

**Process Description:**

The process sewer received waste water from floor drains and sumps in the 183-D Pump House and drainage from the 186-D Waste Acid Reservoir (120-D-2). A portion of the process sewer was the main trunk line that was downstream from the 100-D-50:7 pipeline. The sanitary sewer received septic waste from the lavatories in the 183-D Pump House and 186-D Demineralization Plant. The 100-D-31:9 pipelines consist of the 183-D and 186-D Buildings process sewer. These pipelines exit the buildings at various locations, including a 24 inch diameter vitrified clay pipe (VCP) and a 54 inch diameter concrete pipe, which are continuations of the 100-D-50:7, 183DR Head House Floor Drain and Catch Basins Pipelines, and connect to the 100-D-31:8 pipelines at manhole S-10D and a second connection approximately 18 meters (59 ft) to the east along the same pipeline.

**Waste Type:** Process Effluent

**Waste Description:** The waste consists of steel piping, concrete, and soil.

**Closure Info:**

Remedial action at the 100-D-31:8 subsite was performed between August 27, 2009, and May 19, 2010. The final excavation depth for 100-D-31:8 was approximately 9 meters (30 ft). The excavation resulted in approximately 5,732 bank cubic meters (BCM) (7,509 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Additionally, approximately 535 meters (1,755 ft) of pipe were removed and disposed at the ERDF. Approximately 61,330 BCM (80,432 BCY) of soil (overburden) was removed and stockpiled for evaluation for use as clean backfill. It was determined that construction of a land bridge spanning a portion of the open excavated waste site trench was needed to support both existing and future pump-and-treat lines prior to conducting cleanup verification sampling. Demolition of the 1902-D water tank in January 2010 resulted in a rust stained area outside the north end of the 100-D-31:8 waste site footprint. This area was sampled (J19KJ9) for characterization and the impacted surface soils were disposed of at ERDF.

Remedial action at the 100-D-31:9 subsite was performed between July 15, 2009, and April 21, 2010. The final excavation depth for 100-D-31:9 was approximately 7 meters (23 ft). The excavation resulted in approximately 11,485 BCM (15,045 BCY) of material removed for disposal at the ERDF. Additionally, approximately 705 meters (2,313 ft) of pipe were removed and disposed of at the ERDF. Approximately 44,310 BCM (57,957 BCY) of soil (overburden)
was removed and stockpiled for evaluation for use as clean backfill.

Remedial action at the 100-D-31:10 subsite was performed between December 29, 2009, and January 27, 2010. The final excavation depth for 100-D-31:10 was approximately 3 meters (10 ft). The excavation resulted in approximately 208 BCM (272 BCY) of material removed for disposal at the ERDF. Additionally, approximately 128 meters (420 ft) of pipe were removed and disposed of at the ERDF. Approximately 1,544 BCM (2,019 BCY) of soil (overburden) was removed and stockpiled for evaluation for use as clean backfill. A section of the 100-D-31:10 pipeline subsite is located adjacent to the active 199-D5-33 groundwater monitoring well. To maintain structural integrity of the well, a section of the 100-D-31:10 pipeline subsite was left in place, resulting in a small land bridge measuring 11 meters (36 ft) wide across the pipeline excavation.

On February 22, 2010, confirmatory sampling was being conducted at 100-D-63, test pit 16. While backfilling the test pit, a piece of concrete fell out of the backhoe bucket and struck one of the two pipes in the bottom of the excavation, causing it to leak water. Approximately 37,854 liters (10,000 gal) of raw water was released due to this pipeline not being properly valved off from the export water line. It was unclear whether the leaking water was contaminated. Therefore, Ecology agreed to allow the released raw water to be pumped to the 100-D-31:9 open excavation. In the course of isolating and draining the export water pipeline to repair the leak, and waiting for approval to pump the water into the 182-D Reservoir, approximately 7,571 liters (2,000 gal) of water was pumped from the export water line to the 100-D-31:8 subsite. On March 2, 2010, in-process samples were collected from inside the water release footprints within the 100-D-31:8 and 100-D-31:9 open excavations. On March 4, 2010, an in-process soil sample (J19L76) was collected from outside the water release footprint in 100-D-31:9. Based on results of these in-process samples, the soil from within the water release footprints was placed in the associated overburden stockpiles. These in-process sample results were not used for determining the interim closure.

<td>Description:</td>
<td>The 100-D-31:11 pipeline subsite is made up of piping from two different sewer systems (sanitary and process sewers). The subsite includes short sections of the pipes where they exited the 182-D and 183-D facilities, but were left in place because of difficulty in excavating too close to the foundation walls. The process sewer segments added to this subsite include: A 91.4 cm (36 in) line exits northeast side of the 182-D Reservoir, east to the 121.9 cm (48 in) process sewer line, ending up at the 116-D-5 outfall (W-71520). A 106.7 cm (42 in) process sewer line exits the east corner of the building to the 121.9 cm (48 in) line heading to the 116-D-5 outfall (W-72845). A 20 cm (8 in) vitrified clay sewer pipe exits the northeast corner of the 182-D building and connects to the 91.4 cm (36 in) line mentioned above (W-72835). A 45.5 cm (18 in) vitrified clay pipe exited the west side of 183-D and connected to the 121.9 cm (48 in) north-south concrete pipe between the 182-D and 183-D Buildings. Note: During remedial actions at the 100-D-31:8, :9, and :10 pipeline subsites, short sections of the pipes where they exited facilities were left in place because of difficulty in excavating too close to the foundation walls. These short segments have been added to the 100-D-31:11 subsite. The sanitary sewer segments added to this subsite include: A 15 cm (6 in) vitrified clay sewer pipe exits the east side of the 182-D building and joins with the 20 cm (8 in) vitrified clay pipe traveling north between the 182-D and 183-D buildings (H-1-26378).</td>

</table>
Subsite 12 is the 183-D west process sewer pipelines that transported treated cooling water from eight process sewer pipelines exiting the west side of the 183-D Building. The pipeline subsite is bounded on the north end by junction box P-2D.

Location: Between the west side of the 183-D Building and the junction box P-2D to the north.

Description: The waste consists of steel piping, concrete, and soil.

The SubSite is Part Of:

The site has been remediated and reclassified to Interim Closed Out. It consisted of a small 3.0-meter (10-foot) by 3.0-meter (10-foot) burial ground. Only a small amount of concrete debris was unearthed in the northwest corner of the site.

Location: The site was approximately 150 meters (500 feet) southeast of the 105-D Reactor Building and 25 meters (82 feet) north of the railroad tracks (north of 118-D-3 Burial Ground).

Process Description: The trench was excavated in the Fall of 1956. HW-46715 states the site will be used for disposal of contaminated material and equipment. It has been assumed that the site was used as planned.

Waste Description: The burial ground was excavated to receive contaminated reactor and effluent system equipment. Potential contaminants include: Co-60, Ni-63, No-59, Sm-151, Pd-107, Sr-90, Ag-108, Am-241, Ba-133, C-14, H-3, Cs-137, Eu-152 and 154, Pu-238, 239 and 241, Ca-41, Cd-113, Kr-85, U-238, Tc-99, Zr-93, chromium, lead and mercury.

Closure Info: Remedial action began on August 28, 2007, with the removal of 375 bank cubic meters (BCM) (490 bank cubic yards [BCY]) of overburden material. The overburden was stockpiled east of the burial ground. Excavation continued through September 5, 2007, to a remedial design depth of approximately 3 meters (10 ft), resulting in approximately 600 BCM (785 BCY) of material removed for disposal at ERDF. Only a small amount of concrete debris was unearthed in the northwest corner of the site.

Because only a small amount of concrete debris was encountered during excavation, the floor of the excavation had not reached beyond the limit of disturbed soil, and the uncertainty of the depth of the burial ground, an additional exploratory excavation was completed on July 31,
The burial ground excavation was expanded to verify that no waste was present below the 3 meter (10 ft) remedial design limit. The exploratory excavation was performed to a depth of 6 meters (20 ft), with native soil encountered at a depth of approximately 5 meters (17 ft) below surface grade. An additional 525 BCM (687 BCY) of soil was removed from the side slopes and excavation floor and placed on the overburden stockpile.

During remedial excavation only a minor amount of concrete debris was unearthed in the northwest corner of the 100-D-32 Burial Ground. No spent nuclear fuel, anomalous material (containers, stained soils, or other waste forms), or other waste indicative of the disposal of contaminated material or equipment were discovered. It is likely that the 100-D-32 Burial Ground was never used (as reported in Heid, 1956). It may have been excavated and discussed in the context of potential future use (i.e., "will be used").

A previously unidentified pipeline encountered during the remedial action excavation that was added into site 100-D-105 for dispositioning.

---

**Code:** 100-D-42  
**Names:** 100-D-42; Buried VSR Thimble Site  
**Type:** Burial Ground  
**Status:** Inactive  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (5/13/2010)

**Start Date:** 1/1/1955  
**End Date:** 1/1/1955

**Description:** The waste site has been remediated and Interim Closed Out. It was a solid waste burial ground. The 100-D-42, 100-D-43, and 100-D-45 waste sites were located in the same area and were remediated as one decision unit. The burial ground was in very close proximity to the (exhumed) 152-centimeter (60-inch) effluent lines. Following remediation activities, the project was authorized to remove radiological postings.

**Location:** The site is located east of the 100-D Reactor Building, outside the reactor security fence and south of the railroad spur that services 100-D.

**Waste Type:** Water  
**Waste Description:** The waste is a buried Vertical Safety Rod (VSR) thimble. The VSR thimbles were made of aluminum similar to that used in the process tubes and should contain similar isotopic composition. Sampling of process tubes was conducted in March 1967. The radionuclide levels, when decay corrected by Dorian and Richards to March 1977, were 5.9E+03 picocuries of manganese-54 per gram of aluminum and 2.5E+07 picocuries of cobalt-60 per gram of aluminum. When buried, the thimble's exterior surfaces would also have been contaminated with activated graphite products and potassium borate.

**Closure Info:** The 100-D-42, 100-D-43, and 100-D-45 waste sites were located in the same area and were remediated as one decision unit. Remedial action at the sites began on September 6, 2007, and was completed on April 22, 2008. Contaminated soil and debris were excavated and removed from the burial grounds for shipment to ERDF. Field observations during excavation indicated the presence of VSR thimbles in two of the three burial grounds. Only concrete debris and plastic sheeting were found to be present in the 100-D-42 Burial Ground. The 100-D-43 Burial Ground contained VSR thimbles and other reactor hardware. Mastic, aluminum pipe, VSR thimbles, reactor hardware, and a drum containing rags were found in the 100-D-45 Burial Ground. Due to the close proximity to each other and the type of debris encountered during excavation, the three sites were included in one CVP and interim closed out as one decision unit.

Remedial action at the 100-D-45 Burial Ground began on September 6, 2007, with the removal of 930 bank cubic meters (BCM) (1,216 bank cubic yards [BCY]) of overburden material. Excavation began on September 11, 2007 and continued through July 23, 2008 to a depth of...
approximately 7 meters (23 ft) resulting in approximately 2,605 BCM (3,407 BCY) of contaminated soil and debris removed for disposal at ERDF. Remedial action at the 100-D-43 Burial Ground began on September 10, 2007, with the removal of 165 BCM (216 BCY) of overburden material. Excavation began on September 25, 2007 and continued through October 10, 2007, to a depth of approximately 5 meters (16 ft), resulting in approximately 803 BCM (1,050 BCY) of contaminated soil and debris removed for disposal at ERDF. Remedial action at the 100-D-42 Burial Ground began on April 22, 2008, with the removal of 495 BCM (647 BCY) of overburden material. Excavation of the burial ground was initiated on April 25, 2008 and continued through May 13, 2008, to a depth of approximately 5 meters (16 ft), resulting in approximately 530 BCM (693 BCY) of contaminated soil and debris removed for disposal at ERDF.

A geophysical survey was conducted in June 2004 at the 100-D-42, 100-D-43, and 100-D-45 Burial Ground locations, and an additional survey was conducted at the 100-D-45 Burial Ground location in September 2004. No notable features with the characteristics of an excavated area or buried debris were detected at the documented location of the 100-D-42 site. Immediately to the south of the 100-D-42 Burial Ground was an area with distinct excavation boundaries and notable concentrations of anomalies with the characteristics of buried debris. This area correlates more closely with the documented locations of the 100-D-43 and 100-D-45 Burial Grounds. One anomaly was encountered in the 100-D-43 Burial Ground. A 57 liter (15 gal) metal container partially filled with liquid was found during excavation. The container was found to have been breached and the contained liquid is suspected to have been water used for dust suppression during excavation activities. No suspect spent nuclear fuel was present in the burial grounds.

The excavation area has a maximum depth of approximately 7 meters (23 ft). However, the entire excavation area is considered one decision unit and meets the more restrictive shallow zone cleanup criteria.

</tbody>
</table>
Closure Info: The 100-D-42, 100-D-43, and 100-D-45 waste sites were located in the same area and were remediated as one decision unit. Remedial action at the sites began on September 6, 2007, and was completed on April 22, 2008. Contaminated soil and debris were excavated and removed from the burial grounds for shipment to ERDF. Field observations during excavation indicated the presence of VSR thimbles in two of the three burial grounds. Only concrete debris and plastic sheeting were found to be present in the 100-D-42 Burial Ground. The 100-D-43 Burial Ground contained VSR thimbles and other reactor hardware. Mastic, aluminum pipe, VSR thimbles, reactor hardware, and a drum containing rags were found in the 100-D-45 Burial Ground. Due to the close proximity to each other and the type of debris encountered during excavation, the three sites were included in one CVP and interim closed out as one decision unit.

Remedial action at the 100-D-45 Burial Ground began on September 6, 2007, with the removal of 930 bank cubic meters (BCM) (1,216 bank cubic yards [BCY]) of overburden material. Excavation began on September 11, 2007 and continued through July 23, 2008 to a depth of approximately 7 meters (23 ft) resulting in approximately 2,605 BCM (3,407 BCY) of contaminated soil and debris removed for disposal at ERDF. Remedial action at the 100-D-43 Burial Ground began on September 10, 2007, with the removal of 165 BCM (216 BCY) of overburden material. Excavation began on September 25, 2007 and continued through October 10, 2007, to a depth of approximately 5 meters (16 ft), resulting in approximately 803 BCM (1,050 BCY) of contaminated soil and debris removed for disposal at ERDF. Remedial action at the 100-D-42 Burial Ground began on April 22, 2008, with the removal of 495 BCM (647 BCY) of overburden material. Excavation of the burial ground was initiated on April 25, 2008 and continued through May 13, 2008, to a depth of approximately 5 meters (16 ft), resulting in approximately 530 BCM (693 BCY) of contaminated soil and debris removed for disposal at ERDF.

A geophysical survey was conducted in June 2004 at the 100-D-42, 100-D-43, and 100-D-45 Burial Ground locations, and an additional survey was conducted at the 100-D-45 Burial Ground location in September 2004. No notable features with the characteristics of an excavated area or buried debris were detected at the documented location of the 100-D-42 site. Immediately to the south of the 100-D-42 Burial Ground was an area with distinct excavation boundaries and notable concentrations of anomalies with the characteristics of buried debris. This area correlates more closely with the documented locations of the 100-D-43 and 100-D-45 Burial Grounds. One anomaly was encountered in the 100-D-43 Burial Ground. A 57 liter (15 gal) metal container partially filled with liquid was found during excavation. The container was found to have been breached and the contained liquid is suspected to have been water used for dust suppression during excavation activities. No suspect spent nuclear fuel was present in the burial grounds.

The excavation area has a maximum depth of approximately 7 meters (23 ft). However, the entire excavation area is considered one decision unit and meets the more restrictive shallow zone cleanup criteria.

</table>

The 100-D-48 site includes those underground pipelines that transported radioactive treated and...
untreated waste water from the 105-D Reactor Building to the 116-D-7 (107-D) Retention Basin and the 116-D-5 Outfall. The included pipeline components are listed below.

There are many small drain pipelines that leave from the east and south sides of the 105-D Reactor Building and terminate at the 132-D-3 (1608-D) Building site. The pipelines that ran from the 105-D Reactor and the 132-D-3 (1608-D) Building to either the 116-D-1A Trench or 116-D-1B Trench or connected to the main cooling water effluent pipelines are part of this waste site.

The main cooling water effluent pipeline is a large 1.5-meter (60-inch) diameter reinforced concrete pipeline that exited the 105-D Reactor Building on the north side and continued north to the 116-D-7 (107-D) Retention Basin. A map in the Dorian and Richards document, UNI-946, indicates that some sections of the pipeline were replaced at least once (as does M-1904-D Sheet 8). The second (replacement) pipeline began at a junction box south of the 116-D-7 (107-D) Retention Basin and ran parallel to the original pipeline up to the 116-D-7 (107-D) Retention Basin. A portion of the steel replacement pipeline remained in place, above grade, at the retention basin, covered with a soil berm, visually indicating the location of the pipeline.

This pipeline system also included a 1.5-meter (60-inch) diameter by 1.3-centimeter (0.5-inch) thick wall, carbon steel cross-tie pipeline to the 105-DR Reactor effluent pipelines that were adjacent to the 103-D Building and connected at a junction box to the west 100-DR Reactor Cooling Water Effluent Pipeline (SiteCode 100-D-49).

This site includes a single pipeline that runs from the west end of the 116-D-7 (107-D) Retention Basin to the 116-DR-1 Trench and 116-DR-2 Trench and two pipelines from the west end of the 116-D-7 (107-D) Retention Basin to the 116-D-5 Outfall.

Because of their length, these pipelines have been broken into four subsites: 100-D-48:1, the pipelines from 116-D-7 to the outfalls; 100-D-48:2, the pipelines from D Avenue to 116-D-7; 100-D-48:3, the pipelines from D Avenue to the 105-D Reactor; and 100-D-48:4, the small cooling water effluent pipelines at the 105-D Reactor.

The site does not include the facilities where the pipelines terminate, or the pipelines (100-D-60) from the 116-D-5 Outfall to the bottom center of the Columbia River. The pipelines associated with (100-D-49) 100-DR Reactor Cooling Water Effluent Underground Pipelines or (100-D-50) 100-DR Reactor Process Sewer Underground Pipelines [pipelines that transported nonradioactive treated and untreated waste water from the 183-DR, 183-DR Clearwell area and the 105-DR Reactor Buildings to the 100-D-8 (1907-DR) Outfall] are not included in this site.

**Location:**

The underground pipelines ran in a north-south direction north of the 105-D Reactor, to the 116-D-7 Retention Basin, terminating at the 116-D-5 Outfall. Pipeline descriptions for this waste site and associated structures are as follows.

105-D Reactor:

- a 20 centimeter (8 inch) vent pipe exits the north side and extends to a junction box in the cross-tie pipeline
- a 15 centimeter (6 inch) line and a 20.32 centimeter (8 inch) line exit the northeast corner to a 76 centimeter (30 inch) pipe, to a diversion box for the 116-D-1A trench
- a 30 centimeter (12 inch) effluent line exits the northeast corner and runs to the 152.4 centimeter (60 inch) DR effluent mainline to 116-DR-9
- a 41 centimeter (16 inch) effluent pipe exits the east side and runs to a junction box, then to 116-D-1A
- a 66 centimeter (26 inch) effluent line exits the south side and runs to a 76.2 centimeter (30 inch) line
- a 152 centimeter (60 inch) main line runs to the 116-D-7 Retention Basin from the north side. A new main line was made just east of the original, crossing the original line approximately 160 meters (530 feet) south of the basin.
- a 152 centimeter (60 inch) cross-tie line connects the D and DR effluent lines, approximately 75 meters (250 feet) north of the 105-D Reactor.

1608-D Waste Water Pump House:

- a 15 centimeter (6 inch) waste pipe exits the south side and proceeds east to the 116-D-1A Trench.
- a 61 centimeter (24 inch) pipe exits the east side, then runs north to the new 168 centimeter (66 inch) effluent line to 116-D-7.
- a 66 centimeter (26 inch) line exits the east side and continues to the southeast corner of the 105-D Reactor.

107-D Retention Basin:

- a 107 centimeter (42 inch) bypass line flows from the north west corner east to the 116-DR-1&2 Trench.
- a 107 centimeter (42 inch) line flows out the west end to the 116-D-5 Outfall.
- a 152 centimeter (60 inch) bypasses the before-mentioned 107 centimeter (42 inch) line, and flows northwest intersecting the 152 centimeter (60 inch) line coming from the DR retention basin.

Related Sites/Structures:
The associated structures are the 105-D Reactor Building, 132-D-3 (1608-D), the 116-D-7 Retention Basin and the 116-D-5 Outfall. Other related sites are the 116-D-1A, 116-D-1B Trenches, and 116-DR-1, 116-DR-2 Trenches, 100-D-85 (105D Reactor Effluent Pipelines), 100-D-49 (100-DR Reactor Cooling Water Effluent Underground Pipelines).

Process Description:
The pipelines were used to dispose of radioactive cooling and waste water from the reactor facility. One large main effluent pipelines drained cooling water from the 105-D Reactor. The small effluent pipelines that drained process waste from the sides (east and south) of the 105-D were joined into a single pipeline that ran to the 1608-D Building (Waste Water Pumping Station or Process Lift Station). The 1608-D Building was a rectangular shaped, two-story, reinforced concrete structure that was half below grade elevation. The purpose of this facility was to pump process effluent to the main effluent pipeline.

Waste Type: Sanitary Sewage

Waste Description:
The waste is contaminated steel piping, concrete, and soil. Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, diatomaceous earth (a scouring agent), and sodium dichromate. Water pH was maintained at about 7.5, and free chlorine residual was about 0.2 milligrams per liter. Radionuclides discovered at the retention basin during sampling by Dorian and Richards (1978) included the following: plutonium-238, cesium-134, plutonium 239/240, cesium-137, strontium-90, hydrogen-3, uranium, europium-152, europium-154, europium-155, nickel-63, cobalt-60, and carbon-14.

This Site has the Following SubSites:

Code: 100-D-48:1
Names: 100-D-48:1; North Pipelines from 116-D-7 to the Outfalls

Code: 100-D-48:2
Names: 100-D-48:2; West Pipelines from D Avenue to 116-D-7
### Code: 100-D-48:3
Names: 100-D-48:3; Effluent Pipelines from D Avenue to 105-D Reactor

### Code: 100-D-48:4
Names: 100-D-48:4; Small Cooling Water Effluent Pipelines at 105-D Reactor

### Code: 100-D-48:1
Classification: Accepted
Reclassification: Interim Closed Out (3/19/2001)

### Type: Radioactive Process Sewer
Status: Inactive

### Description:
This subsite has been remediated and Interim Closed Out. The 100-D-48:1 pipeline sections were located north of the 116-D-7 Retention Basin and went to the 116-D-7 (1904-D Outfall). Pipeline components consisted of a 106.7 cm (42 in) reinforced concrete pipeline (RCP) from the retention basin to the outfall structure, a 106.7 cm (42 in) bypass pipeline, a 152.4 cm (60 in) steel pipeline, and a crosstie pipeline from the 106.7 cm (42 in) Reinforced Concrete Pipe to the 152.4 cm (60 in) steel pipeline. These pipelines have been removed.

### Location:
Generally, the underground pipelines ran in a north-south direction north of the 105-D Reactor, went to the 116-D-7 Retention Basin, and ended at the 116-D-5 Outfall. Pipeline descriptions include:

**107-D Retention Basin:**
- a 107 centimeter (42 inch) bypass line flows from the north west corner east to the 116-DR-1&2 Trench
- a 107 centimeter (42 inch) line flows out the west end to the 116-D-5 Outfall
- a 152 centimeter (60 inch) bypasses the before-mentioned 107 centimeter (42 inch) line, and flows northwest intersecting the 152 centimeter (60 inch) line coming from the DR retention basin.

### Waste Type: Sanitary Sewage
### Waste Description:
The waste was contaminated steel piping, concrete, and soil.

### Closure Info:
Waste sites 100-D-48:1, 100-D-49:1, 100-D-19 and UPR-100-D-4 were co-located and remediated together. The CVP document referred to the four, combined waste sites as the 100-D-48:1/49:1 Pipeline site. Remedial action at the 100-D-48:1/49:1 Pipelines site began on December 28, 1998. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation reached the design limit. Because remediation of the 100-D-48:1/49:1 Pipelines site required moving an active overhead power line, site remedial action and sampling were conducted in two phases. These separate phases are reflected by the long time period between the start and finish dates for excavation.

The excavation design depth generally corresponded with the invert elevation of the pipelines. At the completion of remedial action and removal of the engineered structure, the excavation was approximately 15,504 square meters (166,800 square feet) in area with a maximum depth of approximately 6.0 meters (20 feet) below ground surface. Approximately 107,266 metric tons (118,241 tons) of material from the D Area pipelines site have been disposed of at the Hanford Site Waste Management Units Report
February 2015

158
ERDF through July 2000. Cleanup verification sampling began on April 3, 2000, and was finished on August 8, 2000. The ground surface in the vicinity of the site varies with an average elevation of approximately 134.4 meters (441 feet).

The SubSite is Part Of:

**Code:** 100-D-48

**Names:** 100-D-48; 100-D Reactor Cooling Water Effluent Underground Pipelines

**Type:** Radioactive Process Sewer

**Status:** Inactive

**Description:** This subsite of pipelines has been remediated and Interim Closed Out. It consisted of two parallel pipelines that ran from D Avenue to the 116-D-7 Retention Basin. The most western pipeline was a 152.4 cm (60 in) reinforced concrete pipeline (RCP). The other pipeline was a 152.4 cm (60 in) steel pipeline that connected to a junction box (approximately 237 meters (777 ft) south of the 116-D-7 Retention Basin). Inside the junction box, a new 152.4 cm (60 in) pipeline was added. This pipeline continued north to the 116-D-7 Retention Basin.

**Location:** This segment ran north from D Avenue to the 116-D-7 Retention Basin.

**Waste Type:** Equipment

**Waste Description:** The waste was contaminated steel piping, concrete, and soil.

**Closure Info:** Remediation at the 100-D-48:2 and 100-D-49:2 pipelines and the associated releases UPR-100-D-2 and UPR-100-D-3 were remediated together. Remedial activities began in July 1997. Excavation of the waste sites involved removing the overburden material, contaminated structures, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Excavated material found to be contaminated was disposed of at the ERDF. In August 1999, the excavation reached the design limit. The excavation design depth generally corresponded with the invert elevation of the pipelines. Because of the length of the pipeline site, the top-of-excavation elevation ranges from 138 meters (453 feet) near the retention basins to 143 meters (469 feet) near D Avenue.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 20,475 square meters (220,280 square feet) in area with a maximum depth of approximately 6 meters (20 feet) below ground surface. During the time of excavation and waste disposal (December 1998 through September 1999) approximately 57,106 metric tons (62,960 tons) of material from 100-DR-1 Operable Unit pipelines were disposed of at the ERDF.

**Reclassification:** Interim Closed Out (4/23/2001)
**Type:** Radioactive Process Sewer  
**Status:** Inactive

**Description:** This subsite has been remediated and Interim Closed Out. The subsite is the section of the 105-D Reactor cooling water effluent pipelines, extending south from D Avenue to about 1.5 meters (5 feet) from the wall of the reactor foundation. The subsite includes a 1.5 meter (60 inch) diameter reinforced concrete pipeline extending south from D Avenue to about 1.5 meters (5 feet) from the wall of the reactor foundation, a parallel 2 meter (66 inch) steel pipe that extends south from D Avenue to an east-west trending cross-tie line to 100-D-49:3, a 1.5 meter (60 inch) steel east-west trending cross-tie line connecting these subsite pipelines to 100-D-49:3 and two 20 centimeter (8 inch) steel lines ending south from the cross-tie to about 1.5 meters (5 feet) from the wall of the reactor foundation. The Decontamination and Decommissioning project is responsible for the remaining stub as part of the foundation removal.

**Location:** These pipelines extend south from D Avenue to about 1.5 meters (5 feet) from the wall of the reactor foundation. The site is located near the center of the 100-D/DR Area and is approximately 750 meters (2,461 feet) from the Columbia River at the nearest location.

**Process Description:** The pipelines were used to dispose of large quantities of radioactive cooling and waste water from the 105-D Reactor facility to the 116-D-7 (107-D) Retention Basin.

**Waste Type:** Process Effluent

**Waste Description:** The waste was contaminated steel piping, concrete, and soil.

**Closure Info:** The 100-D-48:3, 100-D-49:3, 100-D-5 and 100-D-6 waste sites were remediated together. The CVP document refers to the group of waste sites as the 100-D-48:3/49:3 pipelines site. Remedial action began on October 28, 1999. Excavation of the sites involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation was completed. The excavation design depth generally corresponded with the invert elevation of the pipelines.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 24,574 square meters (264,517 square feet) in area with a maximum depth of approximately 5.7 meters (18.7 feet). Approximately 55,561 metric tons (61,245 tons) of material from the 100-D-48:4 and 100-D-48:3/49:3 pipeline sites disposed of at ERDF. The excavation was backfilled with appropriate materials to match the surrounding surface grade (average elevation of 143.7 meters [471 feet]).

**The SubSite is Part Of:**

**Code:** 100-D-48  
**Names:** 100-D-48; 100-D Reactor Cooling Water Effluent Underground Pipelines

---

**Code:** 100-D-48:4  
**Names:** 100-D-48:4; Small Cooling Water Effluent Pipelines at 105-D Reactor  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (4/23/2001)

**Type:** Radioactive Process Sewer  
**Status:** Inactive

**Description:** This subsite has been remediated and reclassified to Interim Closed Out. It included multiple small drain pipelines that exit from the east and south sides of the 105-D Reactor Building and...
terminate at the 132-D-3 (1608-D) Building site. The pipelines that ran from the 105-D Reactor and the 132-D-3 (1608-D) Building to either the 116-D-1A Trench and 116-D-1B Trench or connected to the main cooling water effluent pipelines are also part of this subsite. The pipelines were removed up to 4.9 meters (16 ft) from the 105-D and 1608-D Building exterior walls.

**Location:** These pipelines are on the north, east, and south sides of the 105-D Reactor.

**Process Description:** The pipelines were used to dispose of radioactive cooling and waste water from the reactor facility. One large main effluent pipeline drained cooling water from the 105-D Reactor. The small effluent pipelines that drained process waste from the sides (east and south) of the 105-D Reactor were joined into a single pipeline that ran to the 1608-D Building (Waste Water Pumping Station or Process Lift Station). The 1608-D Building was a rectangular-shaped, two-story reinforced concrete structure that was half below grade. The purpose of the 1608-D facility was to pump process effluent to the main effluent pipeline. The pipelines were removed up to 4.9 meters (16 ft) from the 105-D and 1608-D Building exterior walls.

**Waste Type:** Process Effluent

**Waste Description:** The waste was contaminated steel piping, concrete, and soil.

**Closure Info:** Remedial action at the 100-D-48:4 site began on October 28, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation reached the design limit at El. 136 meters (446 feet).

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 3,291 square meters (35,420 square feet) in area with a maximum depth of approximately 7 meters (23 feet). Approximately 27,738 metric tons (30,576 tons) of material from the site were disposed of at ERDF. Cleanup verification sampling began on September 11, 2000, and was completed on October 18, 2000. The excavation is to be backfilled with appropriate materials to the reference grade of El. 143 meters (469 feet).

Part of the 100-D-48:4 pipeline beneath reactor room 210 was deferred for remedial action with the 118-D-6:4 subsite (105-D Fuel Storage Basin Side Slopes - see CVP-2005-00003).

**The SubSite is Part Of:**

**Code:** 100-D-48

**Names:** 100-D-48; 100-D Reactor Cooling Water Effluent Underground Pipelines

**Code:** 100-D-49

**Names:** 100-D-49; 100-DR Reactor Cooling Water Effluent Underground Pipelines

**Classification:** Accepted

**Reclassification:** Interim Closed Out (1/15/2004)
Type: Radioactive Process Sewer  
Start Date: 1/1/1950

Status: Inactive  
End Date: 1/1/1967

Description: The four subsites associated with this site have been remediated and Interim Closed Out. The total waste site included the underground pipelines that transported radioactive, treated and untreated, waste water from the 105-DR Reactor Building, and the 132-DR-1 (1608-DR) Building to the 116-DR-9 (107-DR) (107-DR) Retention Basin and both of the 116-D-5 and 116-DR-5 Outfalls. The pipeline components included in this waste site are listed below.

There are many small drain pipelines that originated on the east side of the 105-DR Reactor Building and terminated at the 132-DR-1 (1608-DR) Building site. The drain pipelines that ran from the 132-DR-1 (1608-DR) to either the 116-DR-6 Trench or connected to the main cooling water effluent pipelines are part of this waste site.

The main cooling water effluent pipelines were two large 1.5-meter (60-inch) diameter by 1.3-centimeter (0.5-inch) thick wall carbon steel pipelines. The east pipeline exited the 105-DR Reactor Building on the south side and ran due east and then turned northeast to a point 75 meters (210 feet) east of the original exclusion fence. The pipeline then ran north to the 116-DR-9 (107-DR) Retention Basin. The west pipeline exited the 105-DR Reactor Building on the north side and turned northeast to a point 55 meters (154 feet) east of the original exclusion fence. The pipeline then turned north to the 116-DR-9 (107-DR) Retention Basin. The pipelines ran parallel to each other and were approximately 25 meters (70 feet) apart.

This site also includes the discharge pipelines from the 116-DR-9 (107-DR) Retention Basin to the 116-DR-1 and 116-DR-2 Trench and both 116-D-5 and 116-DR-5 Outfalls. At the outlet of the 116-DR-9 (107-DR) Retention Basin, two 1.5-meter (60-inch) carbon steel pipelines are combined into a single 1.5-meter (60-inch) pipeline at a junction box. This pipeline then runs to the outfall structure. The outfall discharge pipeline is a 1.7-meter (66-inch) carbon steel pipeline that continues to the center of the Columbia River.

Because of its length, this site has been broken into four subsites: 100-D-49:1, the pipelines from 116-DR-9 to the Outfalls; 100-D-49:2, the pipelines from D Avenue to 116-DR-9; 100-D-49:3, the pipelines from D Avenue to the 105-D Reactor; and 100-D-49:4 the effluent pipelines within 60 meters of the reactor.

The facilities where these pipelines terminate are not included as part of this site.

The following pipelines are not included as part of this site (included as part of 100-D-48): Opposite the 105-D Reactor Building, the west 105-DR Reactor effluent pipeline is cross-tied to the 105-D Reactor 1.5-meter (60-inch) effluent pipeline by a 1.5-meter (60-inch) diameter by 1.3-centimeter (0.5-inch) thick wall, carbon steel pipeline. The underground pipelines (100-D-50) that transported nonradioactive treated and untreated waste water from the 183-DR, 183-DR Clearwell area, and the 105-DR Reactor Buildings to the 100-D-8 (1907-DR) outfall are not included in this site.

Location: The pipelines ran in a north-south direction east of the 100-D Reactors. Several expansion boxes are apparent at the ground surface along the length of the pipelines. Pipeline descriptions and associated structures are as follows.

105-DR Reactor:
- a 20.32 centimeter (8 inch) effluent line exits the south side and runs to the east side of 1608-DR
- a 45.72 centimeter (18 inch) effluent line exits the south side and also runs to the east side of 1608-DR
- two 152.4 centimeter (60 inch) effluent pipe exit the northeast side and run to the 116-DR-9 Retention Basin

116-DR-9 Retention Basin:

- two 152.4 centimeter (60 inch) lines exit the north end and flow, parallel, west to the 116-D-5 Outfall.
- a 152.4 centimeter (60 inch) bypass line intersects the southern DR basin to the outfall effluent line, and flows north to the 116-DR-5 Outfall.
- a 10.16 centimeter (4 inch) line exits the south end and flows into the 100-D-4 Trench.
- two 30.48 centimeter (12 inch) lines flow east from the north end into the 116-DR-1&2 Trench.

Related Sites/Structures:
The associated structures are the 105-DR Building, the 132-DR-1 (1608-DR), the 116-DR-9 (107-DR) Retention Basin, the 116-D-5 Outfall and 116-DR-5 Outfall. Other related sites are the 116-DR-1, 116-DR-2 and 116-DR-6 Trenches, 100-D-85 (105D Reactor Effluent Pipelines) and 100-D-48 (100-D Reactor Cooling Water Effluent Underground Pipelines). 

Process Description:
The pipelines were used to dispose of radioactive cooling and waste water from the reactor facility. Two large main effluent pipelines drained cooling water from the 105-DR Reactor. The small effluent pipelines that drained process waste from the sides (east and south) of the 105-DR were joined into a single pipeline that ran to the 132-DR-1 ([1608-DR Building] Waste Water Pumping Station or Process Lift Station). The 132-DR-1 (1608-DR) Building was a rectangular shaped, two-story, reinforced concrete structure that was half below grade elevation. The purpose of this facility was to pump process effluent to the main effluent pipeline.

Waste Type: Process Effluent

Waste Description: The waste is contaminated steel piping, concrete, and soil. Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, diatomaceous earth (a scouring agent), and sodium dichromate. Water pH was maintained at about 7.5, and free chlorine residual was about 0.2 milligrams per liter. Radioelements discovered at the retention basin during sampling by Dorian and Richards (1978) for UNI-946, included: plutonium-238, cesium-134, plutonium-239/240, cesium-137, strontium-90, hydrogen-3, uranium, europium-152, europium-154, europium-155, nickel-63, cobalt-60, and carbon-14.

This Site has the Following SubSites:

Code: 100-D-49:1
Names: 100-D-49:1; North Pipelines from 116-DR-9 to the Outfalls

Type: Radioactive Process Sewer

Classification: Accepted

Reclassification: Interim Closed Out (3/26/2001)

Start Date:
Inactive

Status: Inactive

Description: This subsite has been remediated and Interim Closed Out. The 100-D-49:1 pipeline sections were located north of the 116-D-7 Retention Basin and went to the 116-D-5 (1904-D Outfall). Pipeline components consisted of a 1.5 meter (60 inch) steel pipeline, part of another 1.5 meter (60 inch) steel pipeline coming from the 116-DR-9 Retention Basin, up to its connection with the 1.5 meter (60 inch) steel pipeline associated with the 116-D-7 Retention Basin, and part of a 1.1 meter (42 inch) bypass pipeline (up to the northeast end of 116-D-7).

Location: These pipelines were north of the 107-D and 107-DR Retention Basins, extending to the 1904-D and 1904-DR Outfalls.

Process Description: These pipelines drained radioactive cooling water from the retention basins to the 1904-D and 1904-DR Outfalls structures.

Waste Type: Process Effluent

Waste Description: The waste was contaminated steel piping, concrete, and soil.

Closure Info: Waste sites 100-D-48:1, 100-D-49:1, 100-D-19 and UPR-100-D-4 were co-located and remediated together. The CVP document referred to the four, combined waste sites as the 100-D-48:1/49:1 Pipeline site. Remedial action at the 100-D-48:1/49:1 Pipelines site began on December 28, 1998. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation reached the design limit. Because remediation of the 100-D-48:1/49:1 Pipelines site required moving an active overhead power line, site remedial action and sampling were conducted in two phases. These separate phases are reflected by the long time period between the start and finish dates for excavation.

The excavation design depth generally corresponded with the invert elevation of the pipelines. At the completion of remedial action and removal of the engineered structure, the excavation was approximately 15,504 square meters (166,800 square feet) in area with a maximum depth of approximately 6.0 meters (20 feet) below ground surface. Approximately 107,266 metric tons (118,241 tons) of material from the D Area pipelines site have been disposed of at the ERDF through July 2000. Cleanup verification sampling began on April 3, 2000, and was finished on August 8, 2000. The ground surface in the vicinity of the site varies with an average elevation of approximately 134.4 meters (441 feet).

The SubSite is Part Of:

Code: 100-D-49

Names: 100-D-49; 100-DR Reactor Cooling Water Effluent Underground Pipelines

Code: 100-D-49:2

Names: 100-D-49:2; East Pipelines from D Avenue to 116-DR-9

Type: Radioactive Process Sewer

Status: Inactive

Description: This subsite has been remediated and Interim Closed Out. It consisted of a section of two parallel pipelines that ran from D Avenue to 116-DR-9 Retention Basin. The two pipelines were constructed of 1.5 meter (5 ft) diameter by 1.3 cm (0.5 in.) thick carbon steel with welded joints. The two parallel pipelines were about 25 meters (66 ft) apart.
This section of two parallel pipelines ran from D Avenue to the 116-DR-9 Retention Basin. The waste was contaminated steel piping, concrete, and soil.

**Location:**

**Waste Type:** Process Effluent

**Waste Description:** Remediation at the 100-D-48:2 and 100-D-49:2 pipelines and the associated releases UPR-100-D-2 and UPR-100-D-3 were remediated together. Remedial activities began in July 1997. Excavation of the waste sites involved removing the overburden material, contaminated structures, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Excavated material found to be contaminated was disposed of at the ERDF. In August 1999, the excavation reached the design limit. The excavation design depth generally corresponded with the invert elevation of the pipelines. Because of the length of the pipeline site, the top-of-excavation elevation ranges from 138 meters (453 feet) near the retention basins to 143 meters (469 feet) near D Avenue.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 20,475 square meters (220,280 square feet) in area with a maximum depth of approximately 6 meters (20 feet) below ground surface. During the time of excavation and waste disposal (December 1998 through September 1999) approximately 57,106 metric tons (62,960 tons) of material from 100-DR-1 Operable Unit pipelines were disposed of at the ERDF.

**Type:** Radioactive Process Sewer

**Status:** Inactive

**Description:** This subsite has been remediaded and Interim Closed Out. It extends south from D Avenue to about 60 meters (200 feet) from the wall of the reactor foundation. The east lines are longer and the west lines are shorter. The two parallel pipelines were constructed of 1.5 meter (5 ft) diameter carbon steel with welded joints. The Decontamination and Decommissioning project is responsible for the remaining pipelines as part of the foundation removal.

**Location:** These pipelines run from the 105-DR Reactor to D Avenue.

**Waste Type:** Process Effluent

**Waste Description:**

**Closure Info:** The 100-D-48:3, 100-D-49:3, 100-D-5 and 100-D-6 waste sites were remediaded together. The CVP document refers to the group of waste sites as the 100-D-48:3/49:3 pipelines site. Remedial action began on October 28, 1999. Excavation of the sites involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at...
ERDF. On July 24, 2000, the excavation was completed. The excavation design depth generally corresponded with the invert elevation of the pipelines.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 24,574 square meters (264,517 square feet) in area with a maximum depth of approximately 5.7 meters (18.7 feet). Approximately 55,561 metric tons (61,245 tons) of material from the 100-D-48:4 and 100-D-48:3/49:3 pipeline sites disposed of at ERDF. The excavation was backfilled with appropriate materials to match the surrounding surface grade (average elevation of 143.7 meters [471 feet]).

Type: Radioactive Process Sewer  
Status: Inactive

Description: This subsite has been remediated and Interim Closed Out. The sections of the effluent pipelines were transferred from the Remedial Action (RA) group to Decontamination and Decommissioning (D&D) to allow D&D to continue their stabilization work on the DR Reactor. The subsite includes the smaller effluent pipelines near the 132-DR-1 Pumping Station and the large 1.5 meter (60 inch) main effluent steel pipelines (two adjacent pipes) extending from the reactor. The eastern main effluent pipe section is about 67 meters (220 feet) long. The northern section is about 35 meters (115 feet) long.

Location: These pipelines are on the north, northeast and east sides of the 105-DR Reactor.

Process Description: The effluent pipelines were used to dispose of large quantities of radioactive cooling and waste water from the 105-DR Reactor facility to the 116-DR-9 (107-DR) Retention Basin.

Waste Type: Process Effluent
Waste Description: The waste was contaminated steel piping, concrete, and soil.

Closure Info: The Cleanup verification package CVP-2003-00016 documents completion of removal action for 118-DR-2:2 Below Grade Structures and Underlying soils and the 100-D-49:4 pipeline in support of the 105-DR Reactor Interim Safe Storage Project. The 100-D-49:4 region consisted of the north effluent pipe tunnel, which had been removed. The soil beneath the floor and the side slopes were sampled for cleanup verification purposes. A portion of the 100-D-49:3 pipelines, located adjacent to the 105-D building, were also part of this remedial activity. The remedial activity was divided into five Zones, the north effluent pipeline and three decontamination areas. The three decontamination areas were also part of this remediation.

Removal and disposal activities at the 105-DR site began in September 1998 and concluded through September 2001. Excavation of the site involved removing the overburden materials, building structure, debris, and underlying contaminated soil. The 105-DR D&D activities resulted in removal of above-grade structures and below-grade structures outside of the 105-DR Reactor core shield walls, to 1 meter (3 ft) below surrounding grade, with the exception of the Fuel Storage Basin (FSB). The FSB structure was removed to 4.6 meters (15 ft) below the surrounding grade.
Sample results from the northwest and south decontamination areas resulted in additional excavation of these areas.

An individual calculation of contaminated material removed for cleanup of the pipeline area was not provided in the CVP. A total of approximately 7,220 cubic meters (25,500 cubic feet) of contaminated materials were disposed at the ERDF. The results of this effort indicated that the materials from the site containing COCs at concentrations exceeding RAGs have been excavated and disposed at the ERDF.

| Description:   | The waste site is the underground pipelines associated with the pre-reactor cooling water, process waste water and sanitary water. The waste site was divided into ten subsites. The pipelines transported nonradioactive treated and untreated waste water from the 183-DR, 183-DR Clearwell area, and the 105-DR Reactor Buildings to the 100-D-8 (1907-DR) Outfall. Subsite descriptions are as follows:

Subsite 1 - Emergency Discharge Pipelines
Subsite 2 - Reactor Cooling Water Pipelines
Subsite 3 - Reactor Cooling Water Pipelines
Subsite 4 - Gas Recirculation Pipelines
Subsite 5 - 183-DR Sedimentation Basin Drain Pipelines
Subsite 6 - 183-DR Clearwell Drain Pipelines
Subsite 7 - 183-DR Head House Floor Drain and Catch Basin Pipelines
Subsite 8 - 117-DR Condensate Drain Lines
Subsite 9 - 1607-DR3 Sanitary Sewer Pipelines
Subsite 10 - Construction Camp Potable Water Supply Drain Lines

Location: The pipelines run in an east-west direction with north-south lines connecting to the individual facilities. Several manhole access points are located along the length of the system.

Related Sites/Structures: The site is associated with the 116-D-8 Cask Storage Pad, 183-DR, the 183-DR Clearwell Area, the 105-DR Reactor Buildings, and the 1907-DR Outfall (100-D-8).

Process Description: This site was used to dispose of nonradioactive waste water from water treatment facilities associated with the 100-DR Reactor. These pipelines discharged to the 100-D-8 (1907-DR) Outfall just upstream of the 181-D Building. The 100-D-8 (1907-DR) Outfall and the facilities connected to this system are not addressed by this site, nor are the 100-D-56 sodium dichromate pipelines.

Waste Type: Water

Waste Description: The waste is steel pipelines, concrete, and soil (if contaminants are present). Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at
about 7.5, free chlorine residual was about 0.2 milligrams/liter, and sodium dichromate was added at a rate of about 2 milligrams per liter. Water and chemical storage tank overflows and other drains discharged to this disposal system. Drawings indicate that it also received storm drainage from the 183-DR Tank Clearwell Basin. Sodium dichromate was used to treat reactor cooling water to assist in the control of process tube corrosion. Sodium dichromate storage tanks may have discharged to this system and potentially act as a source of elevated chromium found in the 100-D groundwater. However, unless there was a deliberate discharge of sodium dichromate to the system, only very dilute discharges would have occurred.

<tr>
<td>Description: The 100-D-50:1 subsite has been remediated and Interim Closed Out. It encompassed the process and storm sewer collection main for the southern portion of the 100-D/DR Area. It was also intended to serve as an emergency discharge pipeline for the 105-DR reactor. The 100-D-50:1 pipeline included approximately 1,550 meters (5,100 ft) of reinforced concrete pipeline. The line began as a 1.07 meter (42 in) pipeline in the 105-DR Reactor Building footprint. It transitioned to a 1.37 meter (54 in) pipeline upstream of the 183-DR clearwell process sewer (100-D-50:6 subsite) influent manhole (MH T-2a). It increased to a 1.83 meter (72-in.) pipeline upstream of the 183-DR sedimentation basin process sewer (100-D-50:5 subsite) influent manhole (MH T-3). The pipeline terminated at the 100-D-8 outfall. The 100-D-8, 105-DR Process Sewer Outfall Site was remediated in 2011, and the waste site was reclassified to Interim Closed Out on August 2, 2012.</td>
<td></td>
</tr>
</tbody>
</table>
The 100-D-50:1 Emergency Discharge Pipeline traveled from the west side of the 105-DR Reactor, south of the 183-DR Clearwells, and ultimately ended at the 100-D-8 Outfall. The pipeline invert was located 7 to 9.5 meters (23 to 31 ft) below grade, sloping down towards the point of discharge.

The pipeline was associated with 105-DR and the 100-D-8 outfall structure.

In addition to servicing the 105-DR Reactor Building, the 100-D-50:1 pipeline received discharges from the process and storm sewers associated with the 100-DR water treatment facilities (addressed as the 100-D-50:5 and 100-D-50:6 subsites). These facilities used physical and chemical treatment to condition raw water for reactor use. Chemical addition included sulfuric acid, lime, chlorine, commercial coagulants containing primarily ferrous sulfate or alum, sodium silicate, and sodium dichromate. Discharges to the process sewers presumably consisted primarily of stormwater runoff, backwash water, and underflow drainage from the water treatment units. However, discharges of concentrated chemical products to these sewers likely also occurred.

The waste was contaminated steel piping, concrete, and soil.

Confirmatory sampling at the 100-D-50:1 subsite was performed in four test pits from December 2005 to January 2006, and again in April 2006, to collect data to support a determination if remedial action would be required at the subsite. The test pits were adjacent to manholes MH T-6, T-2a, T-3 and T-1. Based on the confirmatory sampling, it was recommended that the pipeline be remediated downgradient from manhole MH T-2a (aka Service Area 2).

Remediation of Service Area 2 of the 100-D-50:1 emergency discharge pipeline was performed from February 14 through March 6, 2012. The excavation extended to a depth of 7.5 meters (25 ft) below ground surface along the length of the pipeline. Approximately 17,000 bank cubic meters (22,000 bank cubic yards) of overburden material was placed in five stockpiles. Approximately 1,350 BCM (1,800 BCY) of potentially contaminated soil, concrete, and piping was excavated and stockpiled in one Spoil Pile Area (SPA) east of the excavation and one SPA to the south of the excavation and later disposed at the Environmental Restoration Disposal Facility. No anomalous materials were encountered during the excavation.
demolition of the 190-DR Pumphouse and from the points of discharge from the 190-DR valve houses to the boundaries of interim safe storage activities at the 105-DR Reactor Building. The pipelines formerly connecting these two groups have been removed as part of decommissioning and demolition of the 190-DR facility. Residual supply piping within the boundaries of the interim safe storage project has been encased in concrete.

The process lines upstream of the former 190-DR Pumphouse consist of four 0.61-m (24-in.) subsurface steel pipelines. Downstream of the 190-DR facility, these pipelines are housed in two separate tunnels that converge upstream of the 105-DR Reactor Building. Several small diameter water lines are also located in the pipe tunnels, including raw water, filtered water, fire protection water, and potential dichromate-treated process water piping. Raw water, fire protection water piping, and filtered water piping are expected to be part of the 100-D/DR clean water/service water pipelines (100-D-63 waste site). This functional pipeline group has been rejected from consideration as a WIDS site based on process knowledge at other production reactor areas (100-B-7, 100-C-5, 100-H-35, and 100-K-59), but potential process water lines (i.e., the lines labeled "SOUTH RISER," "NORTH RISER," "SOUTH PROCESS WATER," and "NORTH PROCESS WATER") will be considered as part of the 100-D-50:2 subsite.

Waste Type: Soil
Waste Description: The waste is any potentially contaminated pipelines.

**The SubSite is Part Of:**
**Code:** 100-D-50

</tbody>
</table>

**Description:** This subsite has been evaluated and reclassified to Rejected on form 2012-067. It consists of steel piping, within a subsurface concrete pipe tunnel, designed to deliver treated cooling water from the 190-D High Bay to the 105-DR Reactor. The pipelines were used only during startup testing between May and July 1950. The pipeline tunnels provide habitat for maternal colonies of bats. There is also evidence of pigeon roosting and nesting.

**Location:** These pipelines extend southeast from the 190-D Building Annex to the 105-DR Reactor.

**Process Description:** These pipeline were designed to carry clean, treated (with sodium dichromate) water from the 190-D pump house to the 105-DR Reactor. The pipelines were used only during startup testing between May and July 1950 (HW-17971, HW-18473).
The waste site has been remediated and Interim Closed Out. The subsite consisted of the steel piping inside the subsurface tunnel between the former 115-D Gas Recirculation Facility and the 105-DR Reactor. The 100-D-50:4 subsite was composed of two 0.41 meter (16 in.) diameter, steel pipelines with a combined length of approximately 270 meter (900 ft). These pipelines presently exist within the collapsed subsurface tunnel between the former 115-D/DR Gas Recirculation Facility and the 105-DR Reactor. Characterization of analogous pipelines in the gas recirculation wing of the 105-H Reactor revealed the accumulation of oil sludge containing multiple radionuclides at levels above remedial action goals (RAGS).

In a 4/19/2005 Remove, Treat, and Dispose Report, based on a review of historical site information and analogous analytical data, it was cited that this subsite contained hazardous constituents at levels in exceedance of RAGs. Remedial action was recommended for this site in accordance with the ROD (EPA, 1999).

**Location:** The 100-D-50:4 subsite is south of the former 115-D/DR facility, between the 105-D and 105-DR Reactors.

**Process Description:** Operational use of the 105-DR Reactor equipment and 100-D-50:4 pipelines began in 1950 and ceased in 1964. The 115-D/DR facility was decommissioned in 1985 and 1986. The 100-D-50:4 pipelines were buried in situ (with a portion of the demolition rubble from the 115-D/DR facility) when the pipeline tunnel roofs were collapsed into the tunnels.

**Waste Type:** Chemicals

**Waste Description:** The waste is the pipelines and any contaminated soil associated with this site.

**Closure Info:** Remediation of the 100-D-50:4 gas recirculation pipelines and tunnels was performed from May 5, 2011, through July 12, 2011. The excavation extended to a depth of 3.5 meters (11.5 ft) below ground surface. Approximately 370 cubic meters (13,000 cu. ft.) of contaminated soil, concrete, and piping was excavated and loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). The excavation was approximately 3.5 meters (11.5 feet) deep. No anomalous materials were encountered during the excavation. Waste material was stockpiled in a staging pile area east of the excavation prior to disposal at ERDF. No overburden material was associated with the subsite.

The SubSite is Part Of:

| Code: | 100-D-50 |
| Names: | 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines |

---

**The SubSite is Part Of:**

| Code: | 100-D-50:5 |
| Names: | 100-D-50:5; 183-DR Sedimentation Basin Drain Pipelines |

**Type:** Process Sewer

**Status:** Inactive

**Description:** The subsite has been evaluated and determined to require No Action. It encompassed the
southern process sewers for the 183-DR coagulation and sedimentation basins, The subsite consisted of approximately 200 meters (650 feet) of pipeline: three 0.15-meters (6-inches) drain lines immediately south of the former 183-DR coagulation and sedimentation basins, which discharged to a 0.30-meter (12-inch) reinforced concrete collection line, trending generally north-south. A 0.30-meter (12-inch) feeder line also connected a runoff collection drain (catch basin U) to the collection line.

Located on the southern side of the 183-DR facility, these sewers were designed to provide underflow drainage for the 183-DR coagulation and sedimentation basins and possibly overflow drainage as well. Several surface runoff collection drains for the area south of the 183-DR facility also discharged to this sewer. The subsite process sewers discharged to the 100-D-50:1 process sewer collection line, which ultimately discharged to the Columbia River at the 100-D-8 outfall. Additional drainage for the 183-DR basins was also provided by higher capacity process sewers on the northern side of the 183-DR facility (100-D-50:7 subsite).

**Location:** The 100-D-50:5 process sewers are on the south side of the 183-DR facility.

**Process Description:** As part of the coolant water treatment facilities for the 105-DR Reactor, the 183-DR coagulation and sedimentation basins used physical and chemical treatment to condition raw river water for reactor use. The chemicals added at the 183-DR coagulation basins or at the upstream 183-DR Headhouse included: sulfuric acid, lime, chlorine, and commercial coagulants containing primarily ferrous sulfate or alum. Sodium dichromate was also added to cooling water as a corrosion inhibitor, but was injected downstream of the sedimentation basins.

**Waste Type:** Water

**Waste Description:** The waste is the pipelines, pipeline sediments, and any contaminated soil associated with this site.

**Closure Info:** Confirmatory samples were collected from test pits in November and December 2005. The analytical results from the subsite pipe sediment and underlying soil samples were shown to meet the remedial action objectives for direct exposure, groundwater protection, and river protection.

**The SubSite is Part Of:**

**Code:** 100-D-50

**Names:** 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines

</thead>
<tbody>
<tr>
<td>100-D-50:6</td>
<td>Accepted</td>
<td>Interim Closed Out (6/11/2013)</td>
</tr>
</tbody>
</table>

**Type:** Process Sewer

**Status:** Inactive

**Description:** This subsite has been remediated and Interim Closed Out. The site included three functional groups of piping at the 183-DR Clearwells: (1) process sewers that provided underflow and overflow drainage for the 183-DR Clearwells and drainage for proximate runoff catch basins, (2) process supply lines from the 183-DR Filter Building, and (3) drainage lines for the 190-DR Pumphouse tunnel floor drains. The 100-D-50:6 subsite and remedial action recommendation was expanded to include the circular, concrete clearwell pads.

**Location:** This site is directly east of the 183-DR Water Treatment Facility (demolished) and west of 190-DR. It is southwest of the 105-DR Reactor Building.

**Process Description:** The 183-DR Clearwells were part of the coolant water treatment facilities. The function of these facilities was to provide storage and chemical contact time for river water conditioned for use in
reactor cooling. The chemicals added upstream of the clearwells included sulfuric acid, lime, chlorine, and commercial coagulants including ferrous sulfate, alum, or polymeric flocculants to coagulate suspended solids in the water before filtration.

**Waste Type:** Process Effluent

**Waste Description:** The waste includes piping, concrete pads and surrounding contaminated soils.

**Closure Info:** Remediation of the 100-D-50:6 subsite was performed from March 11, 2011, through May 28, 2012, to a depth of approximately 9 meters (30 ft). Approximately 49,975 bank cubic meters (BCM) (65,365 bank cubic yards [BCY]) of contaminated soil, concrete, and piping was excavated for disposal at the Environmental Restoration Disposal Facility (ERDF). A majority of the waste was direct loaded for shipment to Environmental Restoration Disposal Facility (ERDF). However, a portion of the waste was stockpiled separately, prior to shipment and disposal at ERDF. Approximately 31,400 BCM (41,070 BCY) of soil (overburden) was removed and stockpiled for evaluation for use as clean backfill.

Additional remediation was conducted from January 21 through 24, 2013. Approximately 180 BCM (235 BCY) of additional soil was removed from the Pipe 4 location within the excavation area on January 21 and 22, 2013, and disposed at ERDF. Approximately 100 BCM (131 BCY) of contaminated soil was removed from the Staging Pile Area (SPA) 8 location on January 24, 2013, and placed into the deep zone of the 100-D-50:6 excavation with regulatory concurrence. The removal of extra material from these two locations did not change the original boundary for either decision unit and the original sample locations were utilized. A sample in the overburden decision unit (OB-8) also exceeded RAGs for PAH, but soil from this location was placed in the deep zone at least 4.6 meters (15 ft) below ground surface within the 100-D-50:6 excavation during site backfill and therefore does not require additional remediation. The vadose zone underlying the excavation is approximately 15 meters (50 ft).

Additionally, approximately 58,674 liters (15,500 gal) of water from inside the pipelines was removed and disposed at the Effluent Treatment Facility (ETF) in 200 East Area.

**Code:** 100-D-50:7

**Names:** 100-D-50:7; 183-DR Head House Floor Drain and Catch Basins Pipelines

**Type:** Process Sewer

**Status:** Inactive

**Description:** The subsite was remediated and Interim Closed Out. It included the pipelines that provided drainage for the 183-DR Coagulation Basins, floor drains and catch basins at the 183-DR Head House, and mixing tanks in the vicinity of the 186-D Waste Acid Reservoir. These pipelines ultimately discharged to the 100-D Area process sewer systems.

The sewers for the 183-DR Head House floor drains, 183-DR Coagulation and Sedimentation Basins, and nearby catch basins included 82 meters (269 ft) of 0.20 meter (8 in.) vitrified clay pipe (VCP), 40 meters (131 ft) of 0.25 meter (10 in.) VCP, 36 meters (118 ft) of 0.51-m (20-in.) cast iron pipe, 158 meters (518 ft) of 0.69 meter (27 in.) reinforced concrete pipe (RCP), 332 meters (1,089 ft) of 1.37 meter (54 in.) reinforced concrete pipe (RCP). The piping for the 186-D Mixing Tank process sewer included 90 meters (295 ft) of 0.61 meter (24 in.) VCP.
Location: These pipelines extend from the 183-DR Head House northward to the 186-D Building.

Waste Type: Misc. Trash and Debris

Waste Description: The waste is any potentially contaminated pipelines.

Closure Info: Confirmatory sampling of the 100-D-50:7 subsite was performed from November 9 to December 28, 2005.

The 100-D-50:7 excavation boundary had an excavation depth of approximately 7 meters (23 ft). During remediation of the 100-D-50:7 subsite, all of the pipeline was remediated except for the portion of Service Area 3 in which a 7 meters (23 ft) section of pipe was left in place beneath the 183-DR foundation. Clean overburden was removed and stockpiled. The stockpiles consisted of mixed cobble and fine- to coarse-grained soils. Also observed was a large amount of coarse-grained black soils. Between August 8, 2011, and April 25, 2013, approximately 5,700 BCM of soil was excavated and sent to the ERDF and 5,300 BCM of overburden soil was excavated from the 100-D-50:7 subsite to the 100-D-50:7 stockpiles to be used as clean backfill material. No anomalies were found during this time.

Three other excavations overlapped the 100-D-50:7 subsite excavation. The north 27 meters (89 ft) of the 100-D-50:7 subsite was removed during the 100-D-31:9 subsite excavation. All verification samples taken in this area attained remedial action objectives (RAOs) per the 100-D-31:9 Remaining Sites Verification Package (RSVP). The southern end of 100-D-50:7 subsite pipeline was remediated during the excavation of 100-D-62, 100-D-77, and 100-D-83:1. A majority of the 100-D-50:7 subsite pipeline and underlying soil was within the 100-D-100 waste site boundary and was removed with the 100-D-100 excavation. Seven meters (23 ft) of pipe was left in place beneath the 183-DR foundation.

| Description: | The 100-D-50:8 subsite has been remediated and Interim Closed Out. It was a 10 centimeter (4 in) diameter, nonfriable asbestos cement distribution pipe that connected the 117-DR Filter Building to the 116-DR-8 Seal Pit Crib. The distribution pipe had a total length of 83 meters (272 ft) and operated independently from all other pipelines. The distribution pipe received radioactive process effluent from the 117-DR HEPA Filter Building. |

| Location: | The 117-DR Filter Building was located south of the 105-DR Reactor Building. The pipeline and crib are located south of 117-DR Filter Building. |

| Process Description: | Although the 100-D-50 pipelines generally did not transport radioactive liquids, this distribution pipe received radioactive process effluent from the 117-DR HEPA Filter Building. The 117-DR HEPA Filter Building, which was later used for the 105-DR Large Sodium Fire Facility (LSFF), was demolished in 2004, and the 116-DR-8 Seal Pit Crib was filled with gravel and covered with clean soil. The distribution pipe was used from 1960 to 1964 in support of reactor operations. It transferred water that collected in the seal pits as part of the exhaust filter system at the 117-DR HEPA Filter Building to the 116-DR-8 Crib. The distribution pipe was |
then used from 1972 through 1986 in support of the 105-DR LSFF. The LSFF was subject to the regulatory requirements for the storage and treatment of dangerous waste and was included in the Hanford Facility Dangerous Waste Part A Permit Application (DOE-RL 1998). The LSFF was divided into seven areas according to use and deposition of reaction by-products for closure evaluation as described in the 105-DR Large Sodium Fire Facility Closure Plan. Area 6 consisted of the 116-DR-8 Crib and the connecting distribution pipe. In 1996, the Washington State Department of Ecology (Ecology) identified that Area 6 was believed not to have received dangerous waste and was considered closed for the purposes of WAC 173-303.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The waste is potentially contaminated piping and soil.

**Closure Info:** Geophysical survey results, process knowledge, historical drawings, and site visit information were used to develop confirmatory sampling designs for the 100-D-50:8 and 116-DR-8 waste sites.

The sample designs included collection of samples from the pipeline at the point of discharge to the crib and at an upstream bend and collection of soil samples from beneath the pipeline and crib. Excavation at the bend in the 100-D-50:8 pipeline located a concrete thrust block and the intact pipeline at approximately 0.9 meters (3.5 ft) below ground surface (bgs). The pipeline was breached at the downstream side of the thrust block, and minimal visible scale was noted in the lower third of the pipeline.

Remediation of the 100-D-50:8 waste subsite was performed on April 11 and 12, 2012. The excavation extended to a depth of 3.3 meters (10 ft) bgs. Approximately 720 bank cubic meters (BCM) (941.7 bank cubic yards [BCY]) of contaminated soil, concrete, and piping was excavated and staged in a stockpile area before disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 70 meters (230 ft) of pipe was also removed during remediation and disposed at the ERDF. The remaining portion of the 100-D-50:8 pipeline (approximately 13 meters [42 ft]) was removed during remediation activities of the 116-DR-8 waste site. During the 100-D-50:8 excavation, two additional pipeline segments from the 100-D-63, 100-D/DR Service Water Pipeline were discovered. One of the two segments was removed, because it was impeding the 100-D-50:8 remediation campaign, and one segment was left in place. A post-excavation civil survey was completed on April 24, 2012. In June and July 2008, a portion of the 100-D-50:8 pipelines was removed during the 116-DR-8 excavation. This area underwent verification sampling as part of the 116-DR-8 waste site.

**The SubSite is Part Of:**

**Code:** 100-D-50

**Names:** 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines

**Code:** 100-D-50:9

**Classification:** Accepted

**Names:** 100-D-50:9; 1607-DR3 Sanitary Sewer Pipelines

**Reclassification:** Interim Closed Out (1/17/2013)

**Type:** Process Sewer

**Start Date:**

**Status:** Inactive

**End Date:**

**Description:** The 100-D-50:9 site has been remediated and Interim Closed Out. It encompassed two functional pipeline groups: (1) the overflow drain line and (2) the residual sanitary sewer lines. The overflow drain line began north of the 105-DR Reactor Building, traveled south along the western side of the building, and turned west to join the sanitary sewage system. The sanitary sewer cut across the southeast corner of the 116-D-8 cask storage pad and was accessible through a manhole set in the concrete pad. For remediation purposes, the subsite was divided...
into two Service Areas. Confirmatory sample results determined Service Area 1 met the remedial action objectives. Confirmatory sample results determined Service Area 2 required remediation.

The Hanford Site Waste Management Units Report (DOE/RL-88-30) stated the pad was designed with a drain to facilitate pad decontamination and rain runoff, and the drain discharged into the 105-DR sewer (100-D-50:9). The residual sanitary sewer lines are located south and southeast of the 105-DR Reactor Building. Both pipeline functional groups discharged into the 100-D-13 septic tank. Although sections of the former sewer system have been removed under past Group 3 remedial efforts for coexistent sites (the 116-DR-6 Liquid Disposal Trench and the 100-D-48 Reactor Cooling Water Effluent Underground Pipelines), excavations for confirmatory sampling established that portions of the 100-D-50:9 pipelines still remain.

During remediation of 118-D-5 Burial Ground (CVP-2009-00008) a concrete junction vault located in the southern portion of the burial ground was opened prior to the start of the burial ground excavation and found to contain a breached 15-cm (6-in.) vitrified clay pipe. The pipeline was part of the 100-D-50:9, 1607-DR-3 Sanitary Sewer. The concrete junction vault and pipe located within the excavation were removed for disposal to ERDF.

Location: The overflow drain line (1) was located north of the 105-DR Reactor Building and ran south along the western side of the building, and then turned west to join the sanitary sewage system. The residual sanitary sewer lines (2) were located in the south and southeast sides of the 105-DR Reactor Building.

Process Description: 100-D-50:9 encompassed two functional pipeline groups: (1) the overflow drain line and (2) the residual sanitary sewer lines. Both functional groups discharged to the 100-D-13 septic tank.

Waste Type: Misc. Trash and Debris

Waste Description: The waste is the pipelines, pipeline sediments, and any contaminated soil associated with this site.

Closure Info: A stratified sampling strategy was employed to address the 100-D-50:9 subsite as two Service Areas. These Service Areas were determined based on the principles of hydraulics and the potential impact of different waste loading across the system. Service Area 1 was the piping near the 105-DR reactor building. Service Area 2 was located east and southeast of 105-DR reactor. The confirmatory sample design included the excavation of three test pits along the 100-D-50:9 pipelines in order to access the pipe sediment and underlying soil. Two of the test pits were located within Service Area 2. Each test pit was excavated at an unlabeled manhole associated with the pipelines. Confirmatory samples were collected on November 7, 2005. Excavations within the two Service Areas confirmed that portions of the former construction camp sewer lines and elevated water tank drain line still remain. The results of the confirmatory sampling determined that Service Area 1 did not require remedial action because it achieved the established remedial action objectives. The confirmatory samples collected in Service Area 2 exceeded the remedial action levels for mercury and hexavalent chromium, pesticides, SVOCs, aroclor-1260, and cesium-137. A remedial action was planned for Service Area 2.

The 100-D-50:9 subsite (Service Area 2), was remediated between January 25 and March 30, 2011. Approximately 1,800 bank cubic meters (BCM) (2,354 bank cubic yards (BCY)) of overburden material was stockpiled and sampled for use as clean backfill material. Approximately 287 linear meters (942 linear feet) of pipeline was removed from the 100-D-50:9 subsite, resulting in approximately 565 BCM (739 BCY) of soil and piping removed and staged in a staging pile area for subsequent disposal at the Environmental Restoration Disposal Facility. Final loadout of material was completed in June 2011. The deepest part of the excavation extended to approximately 4 meters (13 ft) below ground surface. No anomalous
materials were encountered during the remedial action activities.

<tr>
<td>Description:</td>
<td>This subsite has been evaluated and determined to require No Action. It consists of the residual cast iron pipelines used to supply potable water to the temporary construction camp southeast of the 105-DR Reactor. The exact operational period of the subsite is uncertain, but is believed to be limited to 1947 to 1949 when the construction camp was in use. The system was supplied with water via the fire protection loop piping, which in turn was supplied by the 100-D Area water treatment train at a point prior to any chemical treatment. The subsite is composed of approximately 680 meters (2,220 ft) of 0.15-meter (6-in.) cast iron pipe around the northern, eastern, and southeastern sides of the 105-DR Reactor. Portions of the former supply system were removed under past Group 3 remedial efforts for coexistent sites (the 116-DR-6 Liquid Disposal Trench and the 100-D-48 Reactor Cooling Water Effluent Underground Pipelines). No evidence has been located to suggest that operation of these sites impacted the 100-D-50:10 pipelines beyond the boundaries of previous remedial efforts.</td>
</tr>
<tr>
<td>Location:</td>
<td>These pipelines are on the north, east, and south sides of the 105-DR Reactor.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The pipelines provided potable water to the temporary construction camp, located southeast of the 105-DR reactor. The 100 Area Remedial Action Sampling and Analysis Plan identifies contaminants of potential concern (COCs) for the 100-D-50 pipelines, but they were not applicable to this subsite due to the operational history of the pipelines. Process knowledge provides no basis for the introduction of any hazardous or dangerous wastes to these pipelines. Therefore, no further evaluation or confirmatory sampling was necessary for this subsite.</td>

<tr>
<td>Description:</td>
<td>This site has been remediated and Interim Closed Out. The waste site consisted of a french drain (dry well). The 1 meter (3 foot) diameter dry well was filled with 2.2 meters (5 feet) of 2.5 to 5-centimeter (1 to 2-inch) gravel from the bottom at 6.9 meters (22 feet) below grade to the top at 5.2 meters (17 feet) below grade. The dry well was fed by a 10.2-centimeter (4-inch) steel drain pipe from Room 38A that entered the dry well at 5.8 meters (19 feet) below grade. The drain line discharged into the annulus between a vertical 25.4-centimeter (10-inch) diameter distributor pipe and vertical 10.2-centimeter (4-inch) diameter radiation monitor</td>
</tr>
</tbody>
</table>
housing pipe in the center of the dry well. The monitor was used to ensure detection of radiation in the water (condensate or cooling water leakage) from Room 38A. (Room 38A of the 105-D Building is the concrete enclosure for the 105-D Downcomer.) The concentric distributor pipe and radiation monitoring housing pipe ended 30 centimeters (1 foot) above the bottom of the dry well. The radiation monitor pipe extended about 0.6 meters (2 feet) above grade with a valve on the upper end.

Location: The site was located next to the 105-D Reactor Building at Washington Coordinate System (WCS83S) Easting 573797.076, Northing 151625.344.

Related Sites/Structures: The site was related to 105-D Reactor Building Room 38A.

Process Description: This drywell was installed in 1955 to drain non-contaminated condensate water and contaminated cooling water from the space between the 100-D Reactor process effluent downcomer and the reactor wall. The contaminated cooling water resulted from potential leakage from the downcomer (a metal baffled structure through which collected reactor cooling water cascaded prior to entry into the effluent discharge line). This site also contained a pipe providing access for radiation monitoring that extended from the bottom of the drywell to just above grade.

Waste Type: Batteries

Waste Description: No record could be found that indicated any radiological or chemical contamination data. Based on available information it was assumed that contamination would be limited to those radionuclides found in reactor effluent water that potentially leaked from the metal downcomer and collected nonradioactive condensate water. The COPCs for the remedial action were developed in the Sampling and Analysis Plan.

Closure Info: Remedial action began on January 4, 2000. The excavation involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Contaminated materials were disposed at ERDF. On February 25, 2000, the excavation reached the design limit at elevation 134.9 meters (443 feet).

At the completion of remedial action the excavation was approximately 415 square meters (4,467 square feet) in area with a maximum depth of approximately 7.6 meters (25 feet). Approximately 199 metric tons (219 tons) of material from the site were disposed at ERDF. The excavation will be backfilled with appropriate materials to the reference grade of elevation 142.5 meters (468 feet).

Code: 100-D-56
Names: 100-D-56; 100-D Area Sodium Dichromate Underground Supply Lines
Type: Product Piping
Status: Inactive
Description: Both subsites have been Interim Closed Out, so 100-D-56 is also Interim Closed Out. The site consisted of two abandoned 7.6-centimeter (3-inch) underground sodium dichromate supply lines that transported concentrated liquid sodium dichromate between the 108-D, 185-D, 189-D, 190-D, 183-DR, and the 100-D Sodium Dichromate Transfer Station. The sodium dichromate and sodium silicate supply lines exited the 185-D/190-D Building complex running parallel to each other. One set (100-D-56:1) traveled north and east to the 108-D Building, and one set (100-D-56:2) traveled south and west to the vicinity of the 100-D-12 Sodium Dichromate Pumping Station. The 100-D-56:2 chemical supply lines continued west from the vicinity of the 100-D-12 Sodium Dichromate Pumping Station and then turn south to the 183-
Location: The underground lines run between the former 108-D, 185-D, 189-D, 190-D, 183-DR Buildings, and the 100-D Sodium Dichromate Transfer Station. The north pipeline exited the north side the 190-D Pump Room and flowed to the west side of 108-D. 183-D Filter Plant - 7.62 centimeter (3 inch) line exits west side and flows south to near the 100-D-12 pump station 183-DR - Two 7.62 centimeter (3 inch) lines exit the west side of 183-DR Head House and flow east to 185-D.

Related Sites/Structures: Portions of these lines are co-located with the lines in the 100-D-92 encasement.

Process Description: The heat generated during reactor operation was removed by pumping cooling water continuously through the reactors. Cooling water was pumped from the Columbia River at the 181-D River Pump House. The water was purified and treated in the 182-D Reservoir and Pump House and in the 183-D Filter Building, deaerated in the 185-D Plant, and then cooled in the 189-D Refrigeration Building. Water then flowed into the 190-D Process Pump House and was delivered to the front risers of the reactor building. Water treatment chemicals were added to prevent excessive corrosion of the slugs or process tubes, excessive film formation on the slugs and tubes, and excessive effluent water radioactivity. Aluminum sulfate, ferric sulfate, sodium silicate, sulfuric acid, chlorine, lime, sodium dichromate, and diatomaceous earth were stored, mixed, and used in the water treatment process.

The 100-D-56 supply lines transported sodium silicate and sodium dichromate solutions. Sodium silicate was used as a coagulation aid to increase the rate of flocculent formulation and to produce a flocculent with stronger filtering characteristics. Sodium silicate was also used to minimize the radionuclides reaching the Columbia River in the reactor effluent water. Sodium dichromate was commonly used as a corrosion inhibitor in reactor coolant solutions. The chemicals were unloaded from railcars in either bags or barrels. Sodium dichromate was received in crystalline form, dissolved in water, and diluted to a 10% to 15% dichromate solution then transferred to feed tanks in the 105-D and 185-D Buildings. Sufficient sodium dichromate was added to reactor cooling water so that the instantaneous concentration was 2.0 ppm as required by the reactor cooling water specifications. Sodium dichromate was pumped from the 108-D Building through two different pipelines. One 7.6 cm (3 in.) diameter overhead pipeline connected to the 105-D Reactor. The other sodium dichromate pipeline was a below grade 7.6 cm (3 in.) diameter pipeline that exited the 108-D Building on the west side in combination with a parallel 7.6 cm (3 in.) diameter pipeline that transferred sodium silicate to the north side of the 185-D Building. These mixed solutions were injected into the process water systems at the 105-D Reactor and 185-D Building.

When the transfer of the sodium dichromate system from the 108-D Building to the 185-D Building was completed, the use of dry material handling was replaced with use of concentrated liquid sodium dichromate that was delivered by railcar and truck to an unloading facility/pumping station (100-D-12). The sodium dichromate pumping station was located south of the 183-D Building, next to the railroad tracks. A 7.6 cm (3 inch) diameter underground line provided the means to pump stock solution to storage tanks in the 185-D Building.

Waste Type: Process Effluent

Waste Description: The waste is abandoned 7.6-centimeter (3-inch) pipe contaminated with sodium dichromate.

This Site has the Following SubSites:

Code: 100-D-56:1

Names: 100-D-56:1; North Portion of the 100-D Area Sodium Dichromate Underground Supply Lines
Names: 100-D-56:2; South Portion of the 100-D Area Sodium Dichromate Underground Supply Lines

Code: 100-D-56:2

Reclassification: 100-D-56:1; North Portion of the 100-D Area Sodium Dichromate Underground Supply Lines

Type: Product Piping

Status: Inactive

Classification: Accepted

Description: This subsite has been reclassified to Interim Closed Out. The 100-D-56 site consisted of two abandoned 7.6 cm (3 in) underground pipelines that transported sodium silicate and sodium dichromate liquids between the 108-D, 190-D, 185-D, and 189-D facilities; the 100-D-12 Sodium Dichromate Pumping Station; and the 183-DR Building. The sodium dichromate and sodium silicate supply lines exited the 185-D/190-D Building complex running parallel to each other. One set (100-D-56:1) traveled north and east to the 108-D Building, and one set (100-D-56:2) traveled south and west to the vicinity of the 100-D-12 Sodium Dichromate Pumping Station. The 100-D-56:2 chemical supply lines continued west from the vicinity of the 100-D-12 Sodium Dichromate Pumping Station and then turn south to the 183-DR Building.

Location: The northern portion of the 100-D-56 pipeline ran from the 108-D Building to the 185-D Building. The 108-D Building was located north of the 105-D Reactor and east of the 1709-D Building. The 185-D Building was located west of the 105-D Reactor.

Process Description: The 100-D-56 supply lines transported sodium silicate and sodium dichromate solutions. Sodium silicate was used as a coagulation aid to increase the rate of flocculent formulation and to produce a flocculent with stronger filtering characteristics. Sodium silicate was also used to minimize the radionuclides reaching the Columbia River in the reactor effluent water. Sodium dichromate was commonly used as a corrosion inhibitor in reactor coolant solutions. The chemicals were unloaded from railcars in either bags or barrels. Sodium dichromate was received in crystalline form, dissolved in water, and diluted to a 10% to 15% dichromate solution then transferred to feed tanks in the 105-D and 185-D Buildings. Sufficient sodium dichromate was added to reactor cooling water so that the instantaneous concentration was 2.0 ppm as required by the reactor cooling water specifications. Sodium dichromate was pumped from the 108-D Building through two different pipelines. One 7.6 cm (3 in.) diameter overhead pipeline connected to the 105-D Reactor. The other sodium dichromate pipeline was a below grade 7.6 cm (3 in.) diameter pipeline that exited the 108-D Building on the west side in combination with a parallel 7.6 cm (3 in.) diameter pipeline that transferred sodium silicate to the north side of the 185-D Building. These mixed solutions were injected into the process water systems at the 105-D Reactor and 185-D Building.

Waste Type: Process Effluent

Waste Description: The waste is potentially contaminated equipment (pipelines) and any contaminated soil associated with the pipeline.

Closure Info: Remediation of the 100-D-56 waste site was initiated in June 2006. Remediation activities consisted of removal and stockpiling of overburden soil to expose the pipelines; tapping, draining, and collection of the pipeline contents; removal and size reduction of the pipelines; and excavation and removal of approximately 0.3 meters (1 ft) of soil directly below the pipelines, including stained and contaminated soil that was identified during remediation. Field portable x-ray fluorescence (XRF) instrumentation was used to evaluate residual soil.

Hanford Site Waste Management Units Report
February 2015
contamination and guide the excavation. Areas of discolored soil were sampled as necessary to support waste characterization, supplement field XRF measurements, and assist in guiding the excavation. The laboratory results for these samples are provided in Appendix B. Stained soil and suspect contaminated soil was staged on plastic until transported to the Environmental Restoration Disposal Facility (ERDF) for disposal. In addition, an approximate 0.3 meters (1 ft) layer of soil below the pipeline was removed for disposal. The low points of the pipes were tapped. The high points were raised to allow draining and collection of pipe contents and the process was repeated with drained pipeline segments cut and removed until the low points in the pipelines were reached.

Excavation of the north portion of the 100-D-56 pipelines (100-D-56:1) was initiated on December 18, 2006 and completed on January 10, 2007. Approximately 1,885 bank cubic meters (BCM) of soil and pipeline debris was excavated and disposed of at ERDF. Approximately 1,500 L (400 gal) of liquid were drained and collected from the northern pipelines for disposition at the Effluent Treatment Facility. Stained soil and suspect contaminated soil was placed on plastic until it could be shipped to ERDF. In addition, an approximate 0.3 meters (1 ft) layer of soil below the pipeline was removed for disposal. Overburden soil removed from above the pipelines was placed in stockpiles and was sampled to verify its acceptance for use as clean backfill.

The north 100-D-56 pipelines did not contain sodium dichromate as was found for the south pipelines. However, sodium silicate liquids were present in the north pipes. The pipes were observed to have significant buildup of interior scale and the exterior was highly corroded in some locations. The differences observed between the south pipelines and the north pipelines likely relate to activities associated with the transfer of the sodium dichromate system from the 108-D Building to the 185-D Building when the use of dry sodium dichromate was replaced with the use of liquid sodium dichromate. It is also probable that the northern lines were completely flushed and not used after the aforementioned change in the sodium dichromate mixing process.

The SubSite is Part Of:

Code: 100-D-56
Names: 100-D-56; 100-D Area Sodium Dichromate Underground Supply Lines

Code: 100-D-56:2
Names: 100-D-56:2; South Portion of the 100-D Area Sodium Dichromate Underground Supply Lines
Type: Product Piping
Status: Inactive
Classification: Accepted
Reclassification: Interim Closed Out (1/23/2012)
Start Date: 
End Date: 
Description: The 100-D-56:2 subsite has been remediated and interim Closed out. It consisted of two abandoned 7.6 cm (3 in) underground pipelines that transported sodium silicate and sodium dichromate liquids between the 108-D, 190-D, 185-D, and 189-D facilities, the 100-D-12 Sodium Dichromate Pumping Station and the 183-DR Building. 100-D-56:2 extended south and west to the vicinity of the 100-D-12 Sodium Dichromate Pumping Station. The 100-D-56:2 chemical supply lines continued west from the vicinity of the 100-D-12 Sodium Dichromate Pumping Station and then turned south to the 183-DR Building.

100-D-56:2 subsite addressed the southern portion of the pipeline. The pipelines exited the south side of the 185-D Building to 100-D-12 and continued to the 183-DR building. This pipeline continued to be used after the transition to concentrated liquid sodium dichromate. The pipeline measured a total of 788 meters (2,585 feet).

Location: The southern portion of the 100-D-56 pipeline ran from the 185-D Building to the 183-DR
Head House. The 185-D Building was located west of the 105-D Reactor. The 183-DR Head House is located west of the 190-DR Building.

**Related Sites/Structures:** A 20 meter (65.6 ft) section of the 100-D-56:2 pipelines, located at the entrance into the 183-DR Head House, and the 183-DR Filter Building sample room were also remediated with 100-D-77. Loadout of waste material with subsequent disposal at ERDF was conducted between July 13 and October 18, 2011.

**Waste Type:** Process Effluent

**Waste Description:** The waste is abandoned 7.6 cm (3 in) pipe contaminated with sodium dichromate.

**Closure Info:** Remediation of the 100-D-56 waste site was initiated on June 13, 2006. Remediation activities consisted of removal and stockpiling of overburden soil to expose the pipelines; tapping, draining, and collection of the pipeline contents; and removal and size reduction of the pipelines, including stained soil and contaminated soil identified during remediation. Remediation of the south portion of the 100-D-56 pipelines (100-D-56:2) began on June 13, 2006, and was completed on February 7, 2007. The 100-D-56:2 excavation removed all the chemical supply piping and contaminated soil. However, a 20 meter (65.6-ft) section of concrete encasement that entered the demolished 183-DR Headhouse was left in place. The concrete encasement became part of the 183-DR Headhouse waste site (100-D-77). A 6.1 meter (20 ft) section of 100-D-56:2 was remediated with 100-D-77.

During excavation at the southernmost section of the south portion of the 100-D-56:2 pipelines, approximately 60 meters (197 ft) west of the 183-DR Headhouse, the pipelines were breached and released about 114 liters (30 gal) of a reddish brown liquid from one pipe and a pale green liquid from the other. A second pipeline breach occurred resulting in another release of liquids. It was presumed that the entire section of the 100-D-56 pipelines south of Paddock Street contained liquids, and remediation of the pipelines was suspended. The pipelines were tapped and drained. Samples of liquid from each pipeline were collected for laboratory analysis to support waste disposition. Approximately 3,123 liters (825 gal) of chromium-contaminated liquids were collected from the south pipelines and sent offsite for treatment and disposal.

Following site remediation, verification sampling of the overburden soil stockpiles and soil within the excavation footprint was conducted on March 9 through March 11, 2009. The overburden soil above the pipelines at this location had visible chromium staining. On June 15, 2011, additional soil was removed within Area F (where the second pipeline release occurred). Verification samples were recollected from that location.

Note: The use of dry material handling was replaced with use of concentrated liquid sodium dichromate that was delivered by railcar and truck to an unloading facility/pumping station (100-D-12). The sodium dichromate pumping station was located south of the 183-D Building, next to the railroad tracks. A 7.6 cm (3 inch) diameter underground line provided the means to pump stock solution to storage tanks in the 185-D Building. This pipeline is identified with the 100-D-56:2 pipelines in the south portion of the sodium dichromate pipelines and was removed as part of the 100-D-56:2 remediation and the 100-D-12 remediation.

*Hanford Site Waste Management Units Report*  
February 2015  
182
Type: Radioactive Process Sewer
Status: Inactive

Description: This site includes the river effluent pipelines (river lines) that extend from the two outfalls in the 100D/DR area into the main channel of the Columbia River.

Location: The river effluent pipelines extend from the discharge (river side) face of their respective outfall structure. The river lines are located in the Columbia River, adjacent to the 100-D/DR area. The lines extend northwest from two outfall structures located near the river shore, through D Island, into the main channel of the river.

Related Sites/Structures: The site is associated with the 116-D-5 (1904-D outfall), 100-D-65 Spillway, the 116-DR-5 (1904-DR outfall), 100-D-66 Spillway, 100-D-48 (the 100D process effluent lines), 100-D-49 (the 100DR process sewer lines), and the 100-D-31 (100D water treatment facilities underground pipelines).

Process Description: Reactor cooling water and process sewer wastes were collected and temporarily stored in the 107-D and 107-DR Retention Basins before being pumped to the river via the 116-D-5 and 116-DR-5 outfall structures and associated river effluent pipelines.

The river pipeline extends from the 116-D-5 (1904-D Outfall) via two buried 107-centimeter (42-inch) diameter reinforced concrete/steel pipes. The steel pipes have a 1.3-centimeter (1/2-inch) thick wall. The pipe extends approximately 400 meters (1300 feet) into the river, passing through D Island. The pipelines are buried along their entire run to a depth of 0.6 meters (2 feet) to 2.1 meters (7 feet). The outlets are not exposed on the river bed.

The river pipeline extends from the 116-DR-5 (1904-DR Outfall) via a buried 168-centimeter (66-inch) diameter carbon steel pipe with a 1.3-centimeter (1/2-inch) thick wall pipe. The line also extends approximately 400 meters (1300 feet) into the river, passing through D Island (100-D-67, D Island Contamination). The pipeline is buried along its entire run to a depth of 0.6 meters (2 feet) to 1.8 meters (6 feet). The DR outlet is exposed on the river bed.

Waste Type: Process Effluent
Waste Description: The waste includes the pipelines and the contaminated scale contained within them. The contaminants of potential concern are based on those for the outfalls themselves. The contaminants of concern for all D/DR river effluent pipelines include C-14, Cs-137, Sr-90, U-235, -238, and Pu-239/240.

Code: 100-D-61
Names: 100-D-61; Utility Pole and Fixture Debris Piles
Type: Dumping Area
Status: Inactive

Description: The site consisted of debris piles containing utility poles, lead-tipped bolts, railroad ties, light fixtures, scrap wire and cable, scrap construction wood, and other miscellaneous debris from tearing down electrical utility poles. The exact history of the site was unknown.

Location: The site was located northwest of the 105-D Reactor on the northern side of Palouse Street, occupying a surface area of approximately 500 square meters (5,400 sq. ft.). The coordinates as reported by Ron Del Mar are N152838, E573481, northeast of the 183-D Filter Plant.

Related Sites/Structures: Underlying the debris pile was a segment of 100-D-31:6 pipeline.
**Waste Type:** Water

**Waste Description:** The waste includes creosote-treated wood poles and cross beams, wood pallets, metal debris, lead-tipped bolts and other debris.

**Closure Info:** Initial remediation of the waste site was performed from November 12, 2007, through January 24, 2008. Approximately 270 metric tons (300 U.S. tons) of surface debris and soil was removed including utility poles, railroad ties, light fixtures, scrap wire and cable, scrap construction wood, and other miscellaneous debris. The soil within the waste site footprint was excavated to a depth of 0.3 meter (1 ft) below ground surface (bgs), resulting in 100 bank cubic meters (BCM) (130 bank cubic yards [BCY]) of soil being disposed at the Environmental Restoration Disposal Facility (ERDF). The analytical results indicated residual contamination exceeding cleanup criteria in the southern portion of the waste site. Further (Phase II) remediation was conducted at the location on October 13, 2008. The soil within the Phase II waste site footprint was excavated to a depth of 1 meter (3 ft) bgs. The resulting 50 BCM (65 BCY) of soil was disposed at ERDF.

A global positioning survey was used to delineate the boundaries of the excavation footprint for the purpose of the verification sampling design. The site footprint was located above a section of vitrified clay sewer pipeline associated with the 100-D-31:6 waste site. Subsequent to the initial 100-D-61 excavation, the 100-D-31:6 pipeline was removed. The area associated with the 100-D-31:6 remediation trench was excavated to a depth of 1.5 meters (5 ft) below grade.

**Names:** 100-D-63; 100-D/DR Clean Water Pipelines; 100-D/DR Service Water Pipelines

**Type:** Product Piping

**Status:** Active

**Description:** The waste site has been evaluated and determined to require No Action. It is comprised of the service water pipelines upstream of the 100-D and 100-DR reactors that were not treated with hexavalent chromium. The service water pipelines are those that were used to transport raw water (RW), filtered water (FW), sanitary water (SW), and condenser return water (CW). The 100-D-63 waste site also includes pipelines associated with the Plenum Filling Experiment (PFE) that were designed, but never built.

**Location:** These pipelines were located in the 100-D Area within 100-DR-1 and 100-DR-2 Operable Units.

**Related Sites/Structures:** The structures related to this site were the 184-D Boiler House, 182-D Pump House, 190-D and 190-D Annex Pump Houses, 190-DR and 190-DR Annex Pump Houses, 105-D and 105-DR Reactor Buildings, and the 187-D and 187-DR elevated water tanks adjacent to the Reactor Buildings. Related WIDS sites include: 100-D-63, 100-D/DR Service Water Pipelines, 100-D/DR Clean Water Pipelines, 100-D-31, 100-D Water Treatment Facilities Underground Pipelines (See Subsites), 100-D-77, DR Reactor Water Treatment Facility, Acid Facility, 183-DR Head House, 183-DR Filter Building, Sodium Dichromate Systems, 183-DR Flocculation Basins, 183-DR Sedimentation Basins.

**Process Description:** An enormous quantity of service water (i.e., 243 million gallons per day in June 1960) was required to support the 105-D/DR Reactors and the many supporting facilities in the 100-D/DR Area. Reactor cooling was the single largest use of the water accounting for more than 94% by volume. The majority of the remaining water use was allocated to the steam turbines as condenser water and filter backwash. Less than 1% of the water demand was used by the power house, fire and sanitary supply, and miscellaneous industrial operations.

*Hanford Site Waste Management Units Report*  
February 2015
Raw water originating from the Columbia River was pumped from the 181-D River Pump House to the 182-D Reservoir and Pump House and the 183-DR filter plant.

The pipelines were designed to supply raw river water from the 181-D River Pump House, treated and filtered at the 183-D Filter Plant to 100-D Area facilities, including the 184-D Boiler House, 182-D Pump House, 190-D and 190-D Annex Pump Houses, 190-DR and 190-DR Annex Pump Houses, 105-D and 105-DR Reactor Buildings, and the 187-D and 187-DR elevated water tanks adjacent to the 105-D and 105-DR Reactor Buildings. The 183-D and DR Filter Plants were used to remove suspended fine solids from river water using chemical flocculation and pH additives, sedimentation basins, and sand/coal bed filters for the physical and chemical treatment of river water to provide solids-free water suitable for reactor cooling, producing steam, and to supply the ancillary water uses within the 100-D and 100-DR Areas, e.g. water makeup, fire water, emergency cooling water (high towers), etc.

Prior to 1956 - 1957, the 182-D reservoir was used as the principal water supply source for the 183-D filter plants. Following implementation of Project CG-558, the purpose of the reservoir was to provide reserve (emergency) water for reactor cooling, condenser water for the steam condensers, and raw water (export water) to the 200 Areas. The 182-D Reservoir consists of a rectangular, sloped, reinforced concrete basin. The reservoir was divided into two sections by a 25.4 centimeters (10 inches) reinforced concrete wall running parallel to the short dimension of the structure. The inlet section of the reservoir, known as the reserve section, held 56.8 million liters (15 million gallons) of water, while the other, or working section, holds 37.9 million liters (10 million gallons).

The Columbia River water was filtered and chemically treated to prevent filming in the reactor process tubes. Alum, sulfuric acid and chlorine were proportioned in the 183-D Head House (component of the 183-D Filter Plant). Raw bauxite was stored in bunkers in the 183-D Filter Building Head House and flowed to a proportional dry chemical feeder which supplied bauxite at the required rate. From the conveyor belt of the proportional feeders, the bauxite fell into a lead-lined mixing chamber together with sulfuric acid and water.

The sulfuric acid was used to control the pH of the water. The reaction of the bauxite and diluted sulfuric acid formed a solution of alum and excess diluted sulfuric acid. Chlorine was added at this point for algae control in the settling basins. There were two flocculators in series for each settling basin in the 183-D Filter Plant. The purpose of the settling basins was to allow heavier particulate matter to settle out of the water before entering the filters. The filter media consisted of 0.31 meters (12 inches) of graded gravel, 0.15 meters (6 inches) of sand, and 0.61 meters (24 inches) of crushed and graded anthracite coal. Water entered the gullet from the influent flume through an influent valve and flowed to both halves of the filter through port openings. An organic polyelectrolyte filter aid to improve filter efficiency was added to the water in the gullet to improve water quality.

The filtered water collected in the false bottom below the filter and flowed through effluent piping to the effluent flumes. Valves controlled the amount of water passing through the effluent flumes and into the 183-D Clearwells (still within the 183-D Filter Building). The 183-D pump room was the primary supply point for filtered water for the entire production reactor plant. The eastern most clearwell provided the filtered water for power house water, fire and sanitary water (chlorinated before delivery), and for emergency filtered water. Separate pumps and clearwells provided water for the primary reactor cooling water.

Filter backwashing was supplied from the clearwells by backwash pumps located in the 183-D Filter Building Pump Room. Backwash water entered the filter collection area, flowed upward through the filter media into the gullet and through a waste valve into a sewer. The backwash water for the 183-DR filters was supplied from the 183-D Pump Room via a 0.76 meters (30
inches) cross-tie pipeline to the 183-DR Pipe Gallery. There was no equivalent to the 183-D Filter Plant Clearwells at 183-DR Filter Plant. This same pipeline was also used to supplement the 183-DR water requirements.

The 183-D and 183-DR Filter Plant Pump Rooms were the primary supply points for filtered water for each reactor area and the associated limited area (outside the reactor exclusion area). For the primary reactor cooling system, pumps were provided to transfer water to the 190-D and 190-DR Storage Tanks via 0.91 meter (36 inch) and 0.41 meter (16 inch) pipelines, backwash water for the filters and filtered water for the emergency high tanks. The pumps that supplied the four 1,135,624 Liter (300,000 gallon) high tanks (two at 105-D and two at 105-DR) also provided filtered water for cooling the primary coolant pumps and motors, filter controls and service, reactor thermal loop and control rod cooling. Pumps at 183-D Filter Plant were provided to supply the power house water, fire and sanitary water and for additional emergency filtered water. Four pumps at the 183-D Filter Plant were connected to the combined sanitary and fire protection system.

For the 184-D Power House, boiler feed water was provided from four sources of supply, the first three from the 183-D Filter Plant Pump Room and a last ditch source of raw water from the 182-D Reservoir. At the 184-D Power House, three Zeolite water softeners were used to soften the filtered water. In the 184-D, boiler water treatment chemicals, sodium sulfite and tri-sodium phosphate, were used to reduce scale. In the event of total failure of the electric power to the Hanford Site, a secondary power source was available. It was independent of the electrical or primary source, and was capable of providing adequate cooling water to the reactor until the primary system could be re-established.

---

**Waste Type:** Water

**Waste Description:** The pipelines were associated with the raw water, filtered water, sanitary water, and fire water systems in the 100-D Area. Chemical treatment included pH adjustment (with sulfuric acid or lime), chlorination for algae control, the addition of flocculants, (primarily alum prepared at the 183-D Filter Plant (Head House component) with bauxite and sulfuric acid), and a commercial organic polymer flocculation/filtration aid. This site also includes the potable and fire water pipelines that was delivered to the 1700 (site service buildings) series buildings. Contaminants of potential concern include potential radiological contaminants.

**Closure Info:** Confirmatory sampling was initiated on January 26, 2010 and completed on March 15, 2010. The samples were collected from the soil in test pits and from inside the exposed pipes. Eighteen test pits were planned for excavation and sampling. However, due to field constraints, one test pit was not excavated. Two test pits (TP1 and TP2) were excavated, but not sampled. They were connected to active water lines.

**Code:** 100-D-65  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (1/9/2013)  
**Type:** Outfall  
**Status:** Inactive  
**Start Date:**  
**End Date:**  
**Description:** The waste site has been remediated and Interim Closed Out. It consisted of a concrete spillway (a.k.a. flume) that served as an alternate discharge point for the 1904-D Outfall Structure. The 100-D-65 spillway waste site consisted of two components; an upland segment located above the Columbia River ordinary high water mark (OHWM) and a shoreline segment located below the OHWM and above the ordinary low water mark (OLWM).

**Location:** The site was located northwest of 116-D-7 (the 107-D Retention Basin) and upstream of 116-
The waste site was an alternate discharge point for the 1904-D Outfall Structure. It was planned to be used only if the 100-D-60 river effluent pipelines were blocked, damaged, or undergoing maintenance. Due to the presence of beta/gamma radioactivity discovered during confirmatory sampling collected in January 2005, it is believed the spillway had been previously used.

The site is associated with 100-D-60 (the 100-D River Effluent Pipelines) and 116-D-5 (the 1904-D Outfall Structure).

The spillway was an alternate discharge point for the 1904-D Outfall Structure. It was planned to be used only if the 100-D-60 river effluent pipelines were blocked, damaged, or undergoing maintenance. Due to the presence of beta/gamma radioactivity discovered during confirmatory sampling collected in January 2005, it is believed the spillway had been previously used.

No evidence has been found that the spillway was ever put into service, the COPCs for the 100-D-65 spillway would be the same as those for the 116-D-5 outfall structure. The contaminants of concern include carbon-14, cesium-137, strontium-90, uranium-235/238, and plutonium-239/240.

Because the 100-D-65 spillway extended into the Columbia River, the waste site consisted of two components: an upland segment located above the Columbia River ordinary high water mark (OHWM) and a shoreline segment located below the OHWM and above the ordinary low water mark (OLWM). Remediation of the upland segment of the outfall was performed September 1 through September 15, 2011. Approximately 468 bulk cubic meters of material was excavated, stockpiled, and later disposed at the Environmental Restoration Disposal Facility (ERDF). Remediation, verification sampling, and backfill of the below OHWM segment of the waste site was performed November 11 through November 13, 2011, during low river flow. Approximately 336 bulk cubic meters of material was removed from the shoreline area and disposed at ERDF. The portion of the concrete spillway remaining below water on the day of excavation was left in place. A sample of concrete exposed just above the water was collected.

A post-excavation Global Positioning Environmental Radiological Surveyor (GPERS) survey of the excavation was conducted on September 27, 2011. A hand-held sodium iodide survey was performed on December 20, 2011, for a portion of the remediation that was not surveyed using GPERS.

The waste site has been remediated and Interim Closed Out. It consisted of a concrete spillway (also referred to as a flume). The majority of the spillway was demolished in 1978. It consisted of two components: an upland segment located above the Columbia River ordinary high water mark (OHWM) and a shoreline segment located below the OHWM and above the ordinary low water mark (OLWM).

The site is located northwest of 116-D-7 (the 107-D Retention Basin) and downstream of 116-D-5 (the 1904-D Outfall Structure).
Process Description: The spillway was an alternate discharge point for the 116-DR-5 Outfall Structure. It was planned to be used only if the 100-D-60 river effluent pipelines were blocked, damaged, or undergoing maintenance. Due to the presence of beta/gamma-emitting radionuclides discovered during confirmatory sampling in January 2006, it is believed that the spillway had been used previously. Originally the spillway exited the east side of the 116-DR-5 outfall structure, made a rounding 90-degree turn, and continued to the river shoreline.

Waste Type: Process Effluent

Waste Description: No evidence has been found that the spillway was ever put into service, the COPCs for the 100-D-66 spillway would be the same as those for the 116-DR-5 outfall structure. The contaminants of concern include carbon-14, cesium-137, strontium-90, uranium-235/238, and plutonium-239/240.

Closure Info: Because the 100-D-66 spillway extended into the Columbia River, the waste site consisted of two components: an upland segment located above the Columbia River ordinary high water mark (OHWM) and a shoreline segment located below the OHWM and above the ordinary low water mark (OLWM).

Remediation of the upland segment of the spillway was initiated on June 15, 2011 and completed on May 1, 2012. Remediation of the portion of the 100-D-66 waste site located below the OHWM, was performed November 18 through November 20, 2011, during low Columbia River flows. Approximately 3,400 bulk cubic meters of material was removed for disposal at the Environmental Restoration Disposal Facility (ERDF).

A post-excavation Global Positioning Environmental Radiological Surveyor (GPERS) survey of the excavation was conducted on May 2, 2012.

Code: 100-D-67  Classification: Accepted
Names: 100-D-67; D Island; D Island Contamination  Reclassification: Interim No Action (4/1/2014)
Type: Unplanned Release  Start Date: 
Status: Inactive  End Date:
Description: The site has been evaluated and determined to require No Action. It consists of contamination spreading from vent risers attached to the buried river effluent pipelines (100-D-60).

Location: D Island is a tapered, 213 meter (700 foot) wide island, located approximately 183 meters (600 feet) from the shoreline, directly across from the D and DR outfalls.

Related Sites/Structures: This site is associated with 100D River Effluent Pipelines (100-D-60), 100-DR Outfall Structure, (116-DR-5) and the 1904-D Outfall Structure (116-D-5).

Process Description: The island received contamination from the 116-D-5 and 116-DR-5 Outfall Structures via vented river effluent pipelines during operation of 100D/DR Area.

Closure Info: A 1978 radiological survey identified specks of Cobalt-60 on the surface of D Island. In 1982 and 1990, aerial radiological surveys found the contamination levels were steadily decreasing. In 1992, a radiological survey using the Ultrasonic Ranging Data System (USRADS) found 67,000 data points representing elevated readings. Some specks were removed. In 1994, 40 vent pipe risers were cut off and sealed. In 1994, the Washington State Department of Health concluded the risk related to the specks did not justify further activity to locate and remove the specks.

The Cobalt-60 has gone through almost 4 half-lives of decay since this evaluation in 1992, decaying to approximately 8% of its 1992 activity in the year 2011.
The results of the evaluation indicate that the residual concentrations of radionuclide contaminants of concern/contaminants of potential concern at this waste site do not preclude any futures land uses (as bounded by a recreational scenario). The 100-D-67 nonradionuclide concentrations are within the determined value ranges for the Columbia River riparian zone and do not represent contamination of riparian zone soils. Additionally, the dose rate and carcinogenic risk of radionuclide contaminants for the 100-D-67 waste site are less than the human-health risk criteria. This evaluation supports a reclassification of the 100-D-67 waste site to No Action.

The 100-D-67 waste site is not included in any decision document (record of decision or explanation of significant differences). This waste site will be dispositioned as a plug-in site in accordance with the Explanation of Significant Differences for the 100 Area Remaining Sites Interim Remedial Action Record of Decision, Hanford Site, Benton County, Washington (ESD) (EPA 2009). Per the ESD (EPA 2009), plug-in sites will be documented in the Administrative Record, and an annual fact sheet will be published by the U.S. Department of Energy identifying sites that have been added to the Remaining Sites ROD.

### 100-D-69; Sodium Dichromate Found Near Pacific Avenue and Paddock Street
- **Type:** Unplanned Release
- **Status:** Inactive
- **Classification:** Accepted
- **Reclassification:** None

**Description:** The site consists of a stained concrete foundation and potentially contaminated soil.

**Location:** The site is located in a parking lot southwest of the intersection of Pacific Avenue and Paddock Street (the "T" intersection southwest of 105-D Reactor and northeast of the 151-D Substation). The center of the site is estimated at E573695.26, N151358.74.

**Related Sites/Structures:** The site may have been related to the decommissioning of the 190-D Complex in 1996.

**Process Description:** During early 100-D water plant demolition activities, concrete debris was crushed and spread in-lieu of gravel fill. Adjacent areas have been covered with gravel as part of field remediation's parking lot construction activities. Likely, the material has been there for approximately 10 years. Gravel covered areas are not characterized.

**Waste Type:** Chemicals

**Waste Description:** The waste is sodium dichromate contaminated concrete. Sodium dichromate was the only contaminant of potential concern.

### 100-D-70; 184-DA Steam Generating Plant Dry Well
- **Type:** French Drain
- **Status:** Inactive
- **Classification:** Accepted
- **Reclassification:** Interim No Action (7/7/2011)

**Description:** The waste site consists of a 122 centimeter (48 inches) diameter drywell located on the south side of the 184-DA Building. It received steam separator discharge from equipment within the former 184-DA (demolished) Building. The pipeline from the building to the dry well is part of
site 100-D-88. Confirmatory sampling results supported a reclassification of the 100-D-70 waste site to No Action.

Location: The drywell is on the south west side of the former 184DA Building. The 184DA building was located just south of the 1719D First Aid Station, southeast of the 1716D Gas Station, and north of the 189D building.

Related Sites/Structures: The site was associated with the 184-DA Building and 100-D-88.

Process Description: The 184DA Building was a metal building constructed in 1968 and was designed as a steam generating facility. The facility contained a steam generator, fuel oil storage tank, fuel oil pump, deaerator, water softener, chemical treatment, fuel tank, steam separator, heater, diesel generator, liquid level gauges, and steam flow meter. One fuel tank (100-D-9) was located near the northwest corner of the building and has been removed. The other fuel tank was located near the southeast corner of the building. GPR was conducted in the southeast corner of the building and could not confirm if the tank was present.

Closure Info: Confirmatory sampling results supported a reclassification of the 100-D-70 waste site to No Action. Based on confirmatory sampling at the 100-D-70 waste site, remedial action was determined to be unnecessary, and the confirmatory sampling data has been used to document this waste site for reclassification as a No Action site. This site was not remediated.

### 100-D-71; Vertical Safety Rod Tower Components

**Code:** 100-D-71  
**Classification:** Accepted  
**Names:** 100-D-71; Vertical Safety Rod Tower Components  
**Reclassification:** Interim Closed Out (9/3/2013)  
**Start Date:** 1/1/1957  
**End Date:** 1/1/1985  
**Description:** The waste site has been remediated and Interim Closed Out. The waste site consisted of the remaining components of the 195-D vertical safety rod tower, that was demolished in 1995. The remaining components included a 1.2 meter (4 foot) diameter by 2.2 meter (7 foot) deep concrete drywell, a below grade pit that is approximately 30.5 centimeters (12 inches) square, a 7.6 centimeter (3 inch) diameter underground cast iron process waste pipe, originating at the bottom of the tower's elevator shaft, and any potentially contaminated soil. The cast iron pipe extended underground from the pit, to the west, about 12 meters (39 feet) to the drywell. Wastes generated in the tower collected in the floor of the pit located at the bottom of the tower's elevator and which drained to the drywell.

**Location:** The site was approximately 23 meters (75 feet) southwest of the 189-D building. The french drain was centered at coordinates E573542.5, N151538.6. The pit was centered at coordinates E573558.9, N151541.4.

**Related Sites/Structures:*** This site relates to the 195-D VSR Tower. The tower was a stand-alone test facility. The remediation was associated with 100-D-104.

**Process Description:** Constructed in 1957 (Project CA-548), the structure (195-D) was a steel tower built in 100-D to replace the original wooden VSR at White Bluffs. It was constructed of corrugated steel wall over steel framing and sat on a 1 meter (3 feet) thick underground octagonal shaped concrete base. Its construction coincided with major upgrades and expansions of the pumping and piping systems of the Hanford reactors to allow increased power levels. At the time these power level increases were proposed, an intensive review was performed of all of the safety and control equipment associated with the eight reactors.

During fiscal year 1957, 5.33 million dollars was allocated for vertical safety rod (VSR)
improvements on existing reactors. These improvements were directed specifically towards decreasing the insertion time of the VSRs in order to eliminate the possibility of the slug jacket melting on loss of cooling water with existing power levels and VSRs. One major hurdle before the improved safety rods could be used was the effect of accelerating a rod into a graphite channel filled with 3X balls. Tests with an unaccelerated VSR falling on a column of balls showed extensive damage to the graphite. Accelerated rods would have up to four times the energy of a free falling rod indicating that even more extensive graphite damage might result.

A second major development problem was graphite growth in the 100-B, D, and F reactors that distorted some safety rod channels to the point where flexible rods were required. A method had to be found for accelerating rods into these distorted channels before the design of new safety rods could be completed. The only adequate method of obtaining the required information was building a full-scale mock-up of a VSR test facility. Thus, Project CA-548, was created to replace the old VSR tower located at White Bluffs.

The Ball 3X systems were investigated in 1959 and in-pile ball removal equipment was designed and tested in the 195-D building. By the late 1960s, the N Reactor was experiencing multiple problems with the Ball 3X system. During N Reactor's next 15 years of operation, tests were conducted to evaluate various aspects of ball mechanics and operation and of the issues and difficulties raised by graphite distortion effects on the ball channels. The testing in this tower helped establish criteria for the ball system upgrade that actually occurred in 1984. Following these tests, very little work was done in the building.

| Waste Type: | Animal Waste |
| Waste Description: | Potential contaminants of concern (COPCs) would include oils and PCBs. No testing with radiological materials was known to have occurred in the tower. A transformer bearing PCB oil was located inside the tower on the ground floor. Industrial chemicals and lubricating oils were used in the building. It is not known what, if any, dangerous or hazardous chemical wastes may have been discharged to the dry well. |
| Closure Info: | The 195-D VSR facility was removed to a depth of approximately 1 meters (3 ft) by the D&D Project in 1995. The remaining components of the facility (the drywell, pipeline, and elevator pit) define the 100-D-71 waste site. The remaining components were located inside the 100-D-104 excavation. They were removed with the Tier II remediation of the 100-D-104, Unplanned Release Near 185-D Sodium Dichromate Storage Tanks and Acid Neutralization French Drain waste site. Upon completion of the 100-D-104 waste site remediation, approximately 7 meters (23 ft) of soil below the base of the lowest elevation for the 100-D-71 waste site will have been removed. No evidence of soil staining related to the 100-D-71 waste site location was observed within the footprint of the 100-D-104 waste site excavation, indicating that adequate remediation has been performed for the 100-D-71 waste site. The basis for interim closure of the 100-D-71 waste site is supported by historical operational information, field observations, and the excavation depth. The 100-D-71 waste site has been remediated as part of the remediation of the 100-D-104 waste site. The site does not pose a risk to human health or the environment and will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario. |
| Code: | 100-D-72 |
| Classification: | Accepted |
| Names: | 100-D-72; 183D Acid Facility |
| Reclassification: | None |
| Type: | Process Unit/Plant |
| Start Date: | |
| Status: | Inactive |
| End Date: | |
| Description: | The waste site is comprised of the 183-D acid addition facility. It includes a concrete trench that |
protected the service piping (air, steam, filtered water, lime slurry, sulfuric acid) and drained acid waste to the neutralization pit. The underground piping contained in the trench are part of this waste site, with the exception of the filtered water line which is assigned to 100-D-63. The site also includes a dry well, two sumps (exterior to the trench), two storm drains, a storm sewer and an acid/silica supply line.

**Location:**
The site is south of the 183-D Head House, east of the railroad car spot and on the west side of the flocculation basins.

**Release Description:**
All activities associated with this waste site are related to the unloading, storage and use of acid to support water treatment in the 183-D Head House.

**Related Sites/Structures:**
The site was associated with the 183-D Head House, flocculation basins and 100-D-31 water treatment facilities underground pipelines.

**Process Description:**
All components were associated with the storage and flow of sulfuric acid to the 183-D Head House where it was added for water treatment. The 183-D Head House was designed to treat raw river water before it entered the reactor. Chemicals were added to the river water in the head house. The head house was used for the storage, preparation, and addition of alum, sulfuric acid, and chlorine for water treatment. Alum was used as a flocculating agent and the excess sulfuric acid was used to control the acidity of the water. Bauxite was stored in bunkers on the third floor and used at a required rate. Chlorine was added to control algae. Concentrated sulfuric acid was received by railroad car and stored in the outside acid storage tanks. It was pumped from the storage tank to the head tank through black iron pipelines. The building also contained a laboratory, restrooms, janitor's room, electrical switchgear room, and locker room. As of August 2006, the 183-D Head House is inactive, but still intact.

**Waste Type:** Equipment

**Waste Description:** Contaminants of potential concern (COPCs) include lead and mercury. Sulfuric acid used at the head house may have contaminated impurities, such as lead and mercury. The trench exits the south side of the 183-D Head House and continues toward the two sulfuric acid storage tanks. The trench is 0.76 m (2 ft 6 in) wide and depending on the location contains different piping. From the south side of the 183-D Building to the sulfuric acid pumps, the trench contains a 2.5 cm (1 in) steam line, a 5 cm (2 in) filtered water line, a 5 cm (2 in) lime slurry line and a 1.9 cm (0.75 in) air line. From the sulfuric acid pumps to the two sulfuric acid storage tanks, the trench contains 1 steam line, a 5 cm (2 in) lime slurry line, a 5 cm (2 in) sulfuric acid line that goes to the storage tank, a 5 cm (2 in) sulfuric acid line that goes to the head tank, and 2-5 cm (2 in) PVC storage tank drains in the bottom of the trench.

**Code:** 100-D-73

**Classification:** Accepted

**Reclassification:** Interim Closed Out (1/28/2013)

**Type:** Process Unit/Plant

**Status:** Inactive

**Description:** The site has been remediated and Interim Closed Out. It was the soil and possibly the demolition debris under the former 108-D Building. It was identified as part of the Orphan research for sodium dichromate investigation conducted for the D/DR Reactor area. The 108-D Building was demolished in 1987 and the rubble disposed in the 126-D-2 (184-D) coal pit, inert landfill.

**Location:** The 108-D Building was located north of the 105-D Reactor and east of the 1709-D Building.

**Release Description:** A mixing tank may have discharged high concentrations of sodium dichromate into the soil. It was reported that "several sodium dichromate storage tanks associated with the water treatment facilities overflowed or drained into the process sewer and outfall. Monitoring wells near the..."
108-D Building indicate that up gradient well 199-D5-15 contained chromium concentrations higher than the down gradient well 199-D5-14. Suggesting sodium dichromate may have originated from this area.

Related Sites/Structures: A total of eight pipelines were associated with the 108-D Building. The 108-D Building was associated with the two sodium dichromate lines (100-D-56) that exited the west side of the facility and extended to the 185-D Building. It is also associated with a 7.6 centimeter (3 inches) diameter overhead sodium dichromate line that extended from the 108-D to the 105-D Reactor (removed). There are also two pipelines (100-D-63) that exit the northwest corner of the facility. Three pipelines are associated with 100-D-31. Structures associated with the sodium dichromate system included the 185-D, 190-D Pump Room and sodium dichromate tank and the 183-DR Head House.

Process Description: From about 1944 until 1950, the receiving, mixing, and transfer of sodium dichromate were conducted in the 108-D Building. The 108-D facility received, stored, and prepared various chemicals for the preparation of solution concentrations. Chemicals were unloaded from railcars at the weather-proof unloading railroad car spot in either bags or barrels (Spec. HW-2036). The method utilized for the mixing of sodium dichromate chemicals in the 108-D Building was referred to as the "batch method" that consisted of dichromate in crystalline form. The crystalline material was dissolved in water and diluted to a 10% to 15% dichromate solution, mixed, and transferred to feed tanks in the 105-D and 185-D Buildings. Although the total quantity of material used in the facility is unknown, some indication is available; for example, from January 29 through February 25, 1945, 8,960 kilograms (19,736 pounds) were mixed into solution (HW-7-1388 Del). Required additives were prepared in batches and emptied into the conical mix tank (HAN-10970). Water was added and a 10% concentration of sodium dichromate solution was prepared and pumped by two transfer pumps to one of two solution feed tanks located near the #1 deaerator on the mezzanine floor in the 185-D Building. Each tank in the 185-D Building had a 3,800 Liter (1,000 gallon) capacity and dimensions of 1.6 meters by 2.4 meters (5 feet 4 inches by 8 feet) (Spec. 2017). From the tanks, sodium dichromate was added to the process water at the exit side of the deaerators in the 190-D Building. The above grade structures of the 185-D and 190-D Buildings have been demolished. Mixed sodium dichromate was pumped from the 108-D Building through two different pipelines. One overhead pipeline connected to the 105-D Reactor and the other below grade to the 185-D Building (W-74552). Pumps in the 108-D Building transferred sodium dichromate to the 105-D Reactor through a 7.6 centimeter (3 inches) diameter overhead pipeline to the valve pit extension into a storage tank located in the acid mixing area (Spec. HW-2036 and W-73176). The second pipeline was a 7.6-centimeter (3 inches) diameter sodium dichromate pipeline (100-D-56) that extended from the west side of the 108-D Building to the north side of the 185-D Building. Mixed solutions were injected into the process water systems in the 105-D and 185-D Buildings (Spec. HW-2036). These pipelines were active until about 1950 when the mixing facility was relocated to the 185-D Building as part of Project C-396 (H-1-2901). Research suggests that the mixing of sodium dichromate into solution in the 108-D Building and associated pipelines was discontinued in 1950. Previous investigations stated that sodium dichromate storage tanks were located on the west side of the 108-D Building. Historical research indicates that no sodium dichromate storage tanks ever existed outside the west side of the 108-D Building. The only tanks located on the west sides of the facility were two sulfuric acid tanks and two sodium silicate tanks.

Waste Type: Soil

Waste Description: The waste is potentially contaminated soil because of the releases from the 108-D Building. There is a potential for sodium dichromate, oxalic acid, sodium silicate, and radionuclides under the existing below grade footprint of the 108-D Building. Soil samples collected in 1994 indicate the presence of radionuclide contamination that may include Carbon-14, Potassium K-40, radium Ra-226, Thorium-228, and Thorium-232 (DOE/RL-93-29). The possibility also exists for sodium dichromate. It is not known what would cause the presence of radionuclide contamination.
Closure Info: 100-D-76 confirmatory sampling was done in September 2008. A layer of red gravel was found 1.2 meters (4 ft) below the surface. Total chromium was detected in the samples.

The 100-D-73 and 100-D-76 waste sites were remediated between June 8 and 16, 2011. The maximum excavation depth at the 100-D-76 french drain location extended to approximately 5.5 meters (18.0 ft) below ground surface. Approximately 2,171 bank cubic meters (2,840 bank cubic yards) and 182 bank cubic meters (238 bank cubic yards) of soil and debris were excavated from the 100-D-73 and 100-D-76 waste sites, respectively. Debris included concrete chunks, rebar, lumber, miscellaneous metal wire, and ropes. The total resulted in 2,353 bank cubic meters (3,078 bank cubic yards) of excavated materials removed and staged for disposal at the Environmental Restoration Disposal Facility.

Code: 100-D-74  Classification: Accepted
Names: 100-D-74; Drywell Well  Reclassification: Interim No Action (6/15/2011)
Type: French Drain  Start Date:
Status: Inactive  End Date:

Description: The site is a drywell.
Location: The drywell is located north of the northwest side of original 105D Reactor footprint. The coordinates of the dry well are E 573744.2, N 151316.3.
Related Sites/Structures: The site is associated with the 105-DR Reactor.
Process Description: Drawing H-1-8522-DR, indicates the purpose of the dry well was to receive steam condensate from the heaters inside the 105-DR Building. In conjunction with the dry well is a flash tank (flash steam to condensate) and a 5.1 cm (2 in) line to the dry well. Although the drawing is not clear, it also appears that some floor drains were connected also. Steam heating is a non-contact system isolated from radiological contaminated portions of the facility. The entire building was a negative draft system vented through the 117-D Filter Building eliminating the possibility of radiological contamination in this part of the building.
Waste Type: Process Effluent
Waste Description: The site received steam condensate from the heating units inside the 105-DR Reactor.

Code: 100-D-75  Classification: Accepted
Names: 100-D-75; 151-D Primary Electrical Substation; 152-C1-D & 152-E1-D Secondary Electrical Substations  Reclassification: None
Type: Electrical Substation  Start Date:
Status: Inactive  End Date:

Description: The waste site contains of three components; the area within the fence at the 151-D Primary Substation, and two Secondary Electrical Substations (152-C1-D and 152-E1-D). Electrical substations are automatically categorized as New Discovery Sites because historically leaks and spills of PCBs from the electrical transformers, circuit breakers, and transfer systems during the early years of operation went unreported. An analogous site, the 151-H Primary Substation (100-H-24) was remediated in 2000, by removing and disposing of more than 21,000 tons of PCB-contaminated material. All three substations are inactive (not providing any electrical
power to D Area), although live 230KV power lines will be routed across the 151-D switchyard for the foreseeable future. The site has been divided into three subsites as follows:

100-D-75:1, 151-D Primary Electrical Substation
100-D-75:2, 152-E1-D Secondary Electrical Substation, Substation C4-S1. This subsite was determined to require No Action.
100-D-75:3, 152-C1-D Secondary Electrical Substation. This subsite was determined to require No Action.

Location: The 151-D Building and associated switchyard are located approximately 350 meters (107 ft) southwest of the 105-D Reactor building and 235 meters (72 ft) northwest of the 105-DR Reactor building, with the center point of the yard at coordinates N151328 E573542.

The 152-C1-D Secondary Electrical Substation, centered at coordinates N151584 E573369, is near the 183-D Filter Building.

The 152-E1-D Secondary Electrical Substation, centered at coordinates N151692.84 E572833.69, is near the 181-D Pump House.

Release Description: The only significant reported release of transformer oil was in 1995 in the 151-D switchyard. The site was remediated, and reclassified to Closed Out. See WIDS General Summary Report 100-D-27 for details.

Related Sites/Structures: The 151-D Primary Substation distributed 13.8KV power to transformers located at the 181-D River Pump House, 182 Head Houses, 183 Filter Houses, 184-D Power House, 186-D Water Treatment Plant, 190 Pump Houses, and 105-D/DR Reactors, which in turn distributed power to associated facilities. The 151-D Switch House is essentially a one-story building, having a sub-level cable pit equipped with a sump pump. All duct lines originate/terminate at the Switch House. The cable pit is a completely enclosed reinforced concrete pit with floor slab, varying from 0.3 to 0.4 meters (1 to 1.5 feet) in thickness, and with 0.3 meters (1 foot) thick walls. Switchgear is located on the main floor directly above the cable pit. The overall dimensions of the Switch House are 25 meters by 9.3 meters by 8.7 meters (83 feet by 30.5 feet by 28.5 feet.)

Process Description: The Midway Station fed 230KV power to the 31,250 KVA transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D/DR Area. Circuit breakers were also in service to support the switchyard operations. PCB-containing oil was transferred, as needed, from a rail tanker on the railroad spur through over ground hoses and piping to transformers and oil circuit breakers in the yard. The smaller transformers at the secondary and distribution substations were also filled via over ground hoses from oil trucks.

Waste Type: Soil

Waste Description: PCB contamination of the soil surrounding the transformer and circuit breaker pads is the primary waste concern. PCB-contaminated soil could also exist along the railroad spur.

Names: 100-D-75:1; 151-D Primary Electrical Substation
Reclassification: None
Type: Electrical Substation
Status: Inactive

Description: The substation consists of a fenced, gravel-bed yard, measuring approximately 165 meters (541 ft) on each side, with the 151-D Switch House on the northern fence line. A railroad spur enters the yard from the east and parallels the northern fence line. Concrete pads of various sizes protrude from the crushed gravel bed throughout the yard that support a variety of electrical equipment, including transformers, circuit breakers, and power line towers and stands.

The 31,250 KVA transformers were originally located at N151338/E573515; and N151338/E573556. Sometime after 1956, a third very large ground transformer was added at N151374/E573516. The circuit breakers were located at N51300/E573494; N151300/E573536; and N151300/E573576.

Location: The 151-D Building and associated switchyard are located approximately 350 meters (107 ft) southwest of the 105-D Reactor building and 235 m (72 ft) northwest of the 105-DR Reactor building, with the center point of the yard at coordinates N151328 E573542.

Related Sites/Structures: The 151-D Primary Substation distributed 13.8KV power to transformers located at the 151-D Switch House, 181-D River Pump House, 182 Head Houses, 183 Filter Houses, 184-D Power House, 186-D Water Treatment Plant, 190 Pump Houses, and 105-D/DR Reactors, which in turn distributed power to associated facilities.

Process Description: The Midway Station fed 230KV power to the 31,250 KVA transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D/DR Area. Circuit breakers were also in service to support the switchyard operations. PCB-containing oil was transferred, as needed, from a rail tanker on the railroad spur through over ground hoses and piping to transformers and oil circuit breakers in the yard.

An oil spill from one of the 151-D switchyard transformers was remediated in 1995 (100-D-27). This may not have been the extent of transformer leaks and spills, because such events were not consistently recorded before about 1985. There is some information from power operators that transformer spills and leaks were not uncommon. Therefore, any transformer or circuit breaker pad and surrounding soil may have PCB contamination. Most of the equipment within the substation has already been drained of oil.

According to the Hanford Electrical Utilities craft supervisor, the equipment in the 151D yard is inactive. The only thing energized is the overhead lines going through the yard. Because there is a section of energized 230kV buswork that runs through the substation yard, the yard is off-limits to all, except for qualified system workers.

There are circuit breakers stored in the northeast corner of the switchyard that have been disconnected and drained. These circuit breakers could not have been in use at this location. When in service, the circuit breakers would have to be put on a concrete pad and bolted to the overhead bus. Two smaller transformers were placed in the switchyard from the old, 181D yard (100-D-75:2). Both PCB contaminated transformers were drained on 7/12/2005. This action stopped the 5-year TSCA time requirement. Based on the available aerial photography, it is evident that the two smaller transformers were added to the switchyard sometime between April 2008 and August 2009.

The switch house was used to control the switchyard. There were no processes that indicate any type of contamination to be associated with this structure.
Waste Type: Equipment

There may be PCB contaminated soil at these substation sites.

The SubSite is Part Of:
Code: 100-D-75
Names: 100-D-75; 151-D Primary Electrical Substation; 152-C1-D & 152-E1-D Secondary Electrical Substations

Code: 100-D-75:2
Names: 100-D-75:2; 152-E1-D Secondary Electrical Substation; Substation C4-S1
Type: Electrical Substation
Status: Inactive
Description: The subsite has been evaluated and determined to require No Action. It is a secondary substation that consists of a small fenced area measuring 25 meters (80 ft) by 8 meters (25 ft), with concrete pads for the former transformers and inactive electrical components.

Process Description: Based on the historical photograph (P-4479), two transformers originally existed behind the power poles. According to the 100-D Area National Code Inspector, two concrete pads are currently located at this secondary substation and suspected to have housed two smaller transformers to provide power for 181D Pump House. The transformers were drained of PCB-containing oil on 7/12/2005. This action stopped the 5-year TSCA time requirement. The transformers have since been removed, but the concrete pads remain. The transformers were moved to the 151-D switchyard (100-D-75:1). Based on the available aerial photography, it appears the two smaller transformers were moved to between April 2008 and August 2009.

Location: The 152-E1-D Secondary Electrical Substation (centered at N151692.84/E572833.69) is located near the 181-D Pump House and the Columbia River.

The 152-E1-D Secondary Electrical Substation is rectangular shaped fenced area.

Waste Type: Soil

There may be contaminated soil at these substation sites.

Closure Info: Confirmatory sampling was performed at the 100-D-75:2 subsite on May 8, 2014. Confirmatory sampling of the 100-D-75:2 subsite was performed to support evaluation of the site against the RAGs specified in the Remaining Sites ROD (EPA 1999). The analytical results were evaluated against the cleanup criteria specified in the RDR/RAWP (DOE-RL 2009b) to support a No Action or Remedial Action decision.

Based on the historical photograph (P-4479), the two transformers were originally located behind the power poles that remain today. Surface sample SS 1 and SS 2 were collected at this location. No transformer pads were observed at these sample locations. According to the 100-D Area National Code Inspector, two concrete pads that are currently located at this secondary substation.
substation are suspected to have housed two smaller transformers. Surface sample locations SS 3 and SS 4 were collected at this location. The transformers have since been removed, but the two concrete pads remain. Two samples of concrete were (CS 5 and CS 6) were scabbled from these pads.

**The SubSite is Part Of:**

**Code:** 100-D-75

**Names:** 100-D-75; 151-D Primary Electrical Substation; 152-C1-D & 152-E1-D Secondary Electrical Substations

**Code:** 100-D-75:3

**Names:** 100-D-75:3; 152-C1-D Secondary Electrical Substation

**Type:** Electrical Substation

**Status:** Inactive

**Description:** The subsite has been evaluated and determined to require No Action. Three secondary transformers were located at this substation, but have since been removed; leaving the three concrete pads that supported the transformers.

**Location:**

The 152-C1-D Secondary Electrical Substation, centered at coordinates N151584 E573369, is near the 183-D Filter Building and the Columbia River.

The 152-C1-D Secondary Electrical Substation has a rectangular perimeter of 42.3 meters (138.8 ft). Length 8.60 meters (28.22 ft), width 13.6 meters (44.62 ft).

**Process Description:**

The Midway Station fed 230 KV power to the 31,250 KVA transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D/DR Area. The smaller transformers at the secondary and distribution substations were filled with PCB-containing oil via over ground hoses from oil trucks.

A portion of the 100-D-31:9 pipeline was located directly beneath the 152-C1-D Secondary Electrical Substation. During the remediation of the 100-D-31:9 waste site the three concrete pads at the 152-C1-D Secondary Electrical Substation and portions of the surrounding soil were removed and disposed of at the Environmental Restoration Disposal Facility (ERDF).

Additional surrounding soil was collected as part of the overburden for the 100-D-31:9 waste site. The 152-C1-D secondary substation will be addressed using the sample results associated with the 100-D-31:9 closeout sampling.

**Waste Type:** Equipment

**Waste Description:** There may be PCB contaminated soil and concrete at these substation sites.

**Closure Info:** This site was determined to require No Action and was not remediated.

The 100-D-75:3 subsite contained three transformers that had been previously removed. A portion of the 100-D-31:9 pipeline was located directly beneath the 100-D-75:3, Secondary Electrical Substation. During the remediation of the 100-D-31:9 subsite, the three remaining concrete pads at the 100-D-75:3 subsite and portions of the surrounding soil were removed and disposed of at the Environmental Restoration Disposal Facility.

<td>Crib</td>
</tr>
<tr>
<td>Status:</td>
<td>Inactive</td>
</tr>
<tr>
<td>Description:</td>
<td>The site has been remediated and Interim Closed Out. It was a potential crib, located near the former 108D building. It was identified during a 2008 geophysical investigation as either a French drain or crib. 100-D-76 was determined, thorough historical research, to be the crib formerly known as 116-D-3.</td>
</tr>
<tr>
<td>Location:</td>
<td>The site is located just off the edge of southeast corner of the former 108D building.</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The crib is associated with the 108-D Building, 100-D-73 and a vitrified clay pipe known as 100-D-31:3 that crosses this waste site in a north/south direction. It is also associated with 116-D-3.</td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Equipment</td>
</tr>
<tr>
<td>Waste Description:</td>
<td>Due to the confusion of the location of the crib, the same historical documentation may apply to waste sites 116-D-3 and 116-D-4. Historical information suggests the crib may have received low level fission product wastes from the contaminated maintenance shop and cask decontamination pad in the 108-D Building. The crib received 0.08180 curies of Cs-134 and 30,000 liters (7,920 gallons) of liquids. The contaminants of potential concern are assumed to be the same for 116-D-4 that were uranium-238 and hexavalent chromium.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>100-D-76 confirmatory sampling was done in September 2008. A layer of red gravel was found 1.2 meters (4 ft) below the surface. Total chromium was detected in the samples. The 100-D-73 and 100-D-76 waste sites were remediated between June 8 and 16, 2011. The maximum excavation depth at the 100-D-76 French drain location extended to approximately 5.5 meters (18.0 ft) below ground surface. Approximately 2,171 bank cubic meters (2,840 bank cubic yards) and 182 bank cubic meters (238 bank cubic yards) of soil and debris were excavated from the 100-D-73 and 100-D-76 waste sites, respectively. Debris included concrete chunks, rebar, lumber, miscellaneous metal wire, and ropes. The total resulted in 2,353 bank cubic meters (3,078 bank cubic yards) of excavated materials removed and staged for disposal at the Environmental Restoration Disposal Facility.</td>

<tr>
<td>Description:</td>
<td>The site has been remediated and Interim Closed Out. It consisted of four locations of contaminated soil between the 183-D and 186-D structures. The stained soil was yellow in color, with some white crusty material.</td>
</tr>
<tr>
<td>Location:</td>
<td>The four patches of yellow-stained soil were located in the area between the 183-D and 186-D structures. Stain Areas one and two were associated with the acid-proof brick trench that was</td>
</tr>
</tbody>
</table>
parallel to the entire length of the west wall of the 186-D Building. Stain Area three was at the southwest corner of the 120-D-2, Waste Acid Reservoir. Stain Area four was located west of Stain Area three, near the southwest corner of the 120-D-2 Waste Acid Reservoir.

**Related Sites/Structures:**
- Related structures included: the 186-D Waste Acid Reservoir waste site 120-D-2, 183-D and the 186-D Buildings.

**Process Description:**
- The potentially contaminated soil may have originated from activities associated with the 186-D Building, which was initially constructed as a demineralization plant to remove dissolved calcium, magnesium, and salts through sulfonated coal. However, the building was not used for this purpose. Historical information is very limited for this facility. Although the exact historic use of the facility is unknown, it is believed that it was used for a period of time for storage. The overall dimensions of the building were 204 by 39 by 27 meters (670 feet by 128 feet by 87 feet).

- The demineralization plant was a two story structure with a reinforced concrete foundation, reinforced concrete slab floor, steel framework, concrete block superstructure and built-up roofing over precast concrete tile slabs. The ground floor contained two banks of twelve wood mixing tanks located on the east side of the facility. Between the mixing tanks were four wood acid reclaiming tanks and two steel soda reclaiming tanks. Two steel soda dissolving tanks were located at the southern end of the facility. The second floor contained 24 wood tanks along the east wall. The building contained acid tanks, pumps, clearwells and associated equipment. The clearwells were mostly below grade and were located along the east side of the facility with dimensions of 166 by 17 by 9 meters (545 feet by 55 feet by 30 feet). The clearwells and pump building adjoined the 185-D Building. Adjacent to and east of the center portion of the clearwells was a pump house that contained seven stainless steel water pumps.

- Along the west wall is an acid-proof brick trench approximately 1.2 meter by 1.8 meters (4 feet deep by 6 feet wide), that extends almost the entire length of the building. The trench empties into the 186-D Waste Acid Reservoir (120-D-2). Approximately 3 meters (10 feet) west of the plant at the south end of the building were six, outside, horizontal sulphuric acid steel tanks.

- West of the 186-D Building was the Waste Acid Reservoir (120-D-2) used for the disposal of waste acid from the facility. The Waste Acid Reservoir was constructed of acid proof brick with a 3 ply water proof membrane. Drain pipes were connected to the D-Area process sewer system. It was demolished in 1979 and buried in place.

**Waste Type:**
- Soil

**Waste Description:**
- The 186-D Waste Acid Reservoir has been identified as a site requiring remediation as stated in the interim ROD for the 100-DR-1, 100-DR-2 Operable Units, so the waste is potentially contaminated soil. Contaminants of Potential Concern indicated by sample data are asbestos, ICP metals, mercury, PCB, herbicide, pesticide, and hexavalent chromium were present.

**Closure Info:**
- Confirmatory sampling was done in test pits September 2008. Stained areas two and three were partially removed during the remediation of the 120-D-2 waste site.

- The above-ground portions of the 186-D Building had been previously removed. Remediation of the 100-D-78 waste site was conducted between April 2 and April 26, 2012, and extended to a depth of 2 meters (6.6 ft) below ground surface. The remove, treat, and dispose (RTD) of stained soil areas one and two consisted of removal of the entire length of the brick acid trench and the entire length of subsurface structure along what had been the west wall of the 186-D Building. Approximately 4.823 BCM of soil, building debris, and acid brick from the acid trench were removed, stockpiled, and then disposed at the Environmental Restoration Disposal Facility (ERDF). The intent of the RTD action was to remove the contents of the acid trench and any impacted underlying soils. The acid brick trench and the west wall of 186-D structure...
were removed. However, some remnants of the 186-D structural concrete that was part the outside wall remained. A small volume of ion-exchange resin found in the acid brick trench was also removed and stockpiled for later disposal at ERDF.

<tr>
<td>Description:</td>
<td>100-D-80:1 has been evaluated and determined to require No Action. The subsite consisted of three areas identified during the 2006 100-D Area Orphan Site Evaluation (OSR-2006-0001). These areas were designated as Area 1, Area 2, and Area 3. In 2006, Area 1 was described as a single broken light bulb with a metal base, a glass cover and two internal fluorescent-type bulbs located approximately 100 meters (328 ft) south of the 118-D-1 waste site. A site visit on November 4, 2009 found no evidence of the glass debris was found at this location. In 2006, Area 2 was described as tar-like material with a fiber matrix that appeared to have been dumped (Orphan Site ID# D49). Area 2 was located within the 118-D-3 Burial Ground remedial action sorting cells. In 2009, the material was no longer at this location. In 2006, Area 3 was described as a tar-and oil-stained area (Orphan Site ID# D65), located approximately 50 m (164 ft) south of the southwest corner of the 182-D Reservoir. In 2009, the location of Area 3 was vegetated with native grasses. Confirmatory sampling was performed on</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
this portion of the waste site in August 2010.

**Location:**
Area 1 is located approximately 100 m (328 ft) south of the 118-D-1 waste site. Area 1 is centered at coordinates E 573068.8, N 151491.248.

Area 2 is located approximately 260 m (853 ft) southeast of the 100-DR Reactor and 110 m (387 ft) northwest of the 100-D-17 waste site. Area 2 is centered at coordinates E 574022.38, N 151103.16.

Area 3 is located approximately 50 m (164 ft) south of the southwest corner of the 182-D Reservoir. Area 3 is centered at coordinates E 573757.9, N 150857.4.

**Waste Type:** Stormwater Runoff
**Waste Description:** The waste is any potentially contaminated soil.

**Closure Info:** Three of the four items discovered in 2006 became 100-D-80:1 and designated as Area 1, Area 2 and Area 3. Remedial investigations were done in 2009.

In 2006, Area 1 was described as a single broken light bulb, a glass cover and two fluorescent type bulbs. In 2009, no glass or light bulbs were found and no samples were collected at this location.

In 2006, Area 2 was described as tar-like material with a fiber matrix. Because this location was within the area used as the 118-D-3 burial ground sorting cell, remnants of the tar-like material were removed during the 118-D-3 remediation activities. No samples were collected at Area 2.

In 2006, Area 3 was described as a tar and oil stained area that measured approximately 1 meter by 2 meters (3 by 7 feet). One shallow soil sample and one duplicate soil sample were collected from Area 3 in 2006. No radiological activity or volatile organic compounds (VOCs) were detected during confirmatory sampling. In 2009, Area 3 was covered by vegetation and no tar or oil staining was visible. In August 2009, additional confirmatory sampling was done at Area 3. The results indicated that environmental contamination was not present, and remedial action was not necessary. The confirmatory sampling data has been used for a No Action determination.

**The SubSite is Part Of:**

</table>

**Type:** Dumping Area
**Status:** Inactive

**Description:** Subsite 2 has been removed and Interim Closed Out. It was a structure believed to be a valve box cover. It was a small wooden structure that contained piping (Orphan Site ID# D76). The valve box cover possibly prevented pipes from freezing during the winter months. A raw water pipeline was known to have existed in the area. The proximity of the valve box to the 91 centimeter (36 in) raw water pipeline would suggest that it is associated with the 100-D-63 pipelines.
**Location:** This subsite was located south of the 182-D Reservoir and northwest of the 183-DR Head House. Area 4 is centered at coordinates E573111.347, N151295.8. The area dimensions are 1 meter (3 ft) by 1 meter (3 ft).

**Waste Type:** Equipment

**Waste Description:** The waste is potential asbestos containing materials that have been abandoned.

**Closure Info:** The 100-D-80:2 waste site was remediated on January 24, 2013. The wooden structure and contents were removed and disposed at the Environmental Restoration Disposal Facility. The insulation inside of the wooden structure was observed as "fiberglass" insulation rather than friable asbestos. No anomalies were found. Approximately 1.5 bank cubic meters (2.0 bank cubic yards) of soil was removed with the wooden structure resulting in an excavated area measuring approximately 3 by 3 meters (10 by 10 ft) and approximately 0.18 meters (6 in.) deep.

**Names:** 100-D-80; 100D Tar Stained Soils & Miscellaneous Debris

**Code:** 100-D-81

**Names:** 100-D-81; 100D Burn Areas and Other Stained Areas

**Type:** Dumping Area

**Status:** Inactive

**Description:** During the 4/26/06 Orphans Sites field walk down a total of eight soil areas were identified as either stained soil or a burn area.

**Location:** The burned and stained areas are scattered throughout the 100D area.

**Code:** 100-D-82

**Names:** 100-D-82; 100D Garnet Sand Sites

**Type:** Dumping Area

**Status:** Inactive

**Description:** The waste site has been evaluated and determined to require No Action. It includes three areas of garnet sand discovered during the WCH Orphan Site's Evaluation field investigation during 2007.

**Location:** Area 1 is located southeast of the 105-DR Reactor. The site is centered at coordinates E 573909.37, N 151021.07. Area 2 is located just west of the 1716-D Building. It is centered at coordinates E 573516.8, N 151794.9. Area 3 is located northwest of the 105-D Reactor and northeast of the 190-D Building. It is centered at E 573695.229, N 151676.929.

**Related Sites/Structures:** Area 1 was associated with 105-DR (Reactor). Area 2 was associated with 1717-D (Maintenance Shop) and 184-D (Power House). Area 3 was associated with 105-D (Reactor) and 190-D (Main Pump House). Also with waste sites 100-D-31:1, 31:2, and 31:7.

**Process Description:** Garnet sand was recorded as waste sites due to their potential to contain contaminants. Garnet grit was commonly used in sandblasting operations to remove rust, paint, and other
contaminants from the surface of metal components. The garnet sand itself is not hazardous.

**Waste Type:** Process Effluent

**Waste Description:** Garnet grit was commonly used in grit-blasting operations to clean rust, paint, or contamination from the surface of metal components. The garnet material is not a hazardous substance, but there was a potential for contamination from the surface material that was removed by grit blasting. Contaminants of potential concern include lead, mercury and polychlorinated biphenyls (PCBs).

**Closure Info:** A site visit was performed in October 2009. Areas 2 and 3 were observed to have been removed as a part of the 100-D-31:1, 100-D-31:2 and 100-D-31:7 pipelines remediation. Area 1 of 100-D-82 was readily identifiable. It was flat terrain and could be readily accessed for confirmatory sampling. Only Area 1 was addressed by the confirmatory for this waste site.

Confirmatory samples found no radioactivity or volatile organic compounds. Based on the sample results, no remedial action was required.

**Code:** 100-D-83

**Names:** 100-D-83; 100D Treated Water Pipelines

**Reclassification:** None

**Type:** Product Piping

**Start Date:**

**Status:** Inactive

**End Date:**

**Description:** The site includes 56 additional treated water pipe segments that were not previously identified within an existing waste site. The pipelines supported the pre-reactor non-radioactive cooling water processing facilities. The pipelines were used to transfer chemical products to the water treatment building and treated cooling water to the reactor and laboratory facilities. The additional pipeline segments also include any associated manholes (with associated drains), catch basins, junction boxes, valve control systems or any other below surface related feature. The site has been divided into five subsites as follows:

- 100-D-83:1 - 183-DR Acid Addition Pipelines has been Interim Closed Out
- 100-D-83:2 - 183-DR Filter Backwash Connection has been Interim Closed Out
- 100-D-83:3 - 108-D Acid Addition Facility Pipelines
- 100-D-83:4 - Additional Treated Water Pipelines (which has been determined to require No Action)
- 100-D-83:5 - 186-D Acid Neutralizing System Pipelines

**Location:** The treated water pipelines are located adjacent to related facilities (108D, 183D, 186D, 190D, 183DR, and 187-DR).

**Related Sites/Structures:** The 108D, 183D, 185D, 186D, 189D, 190D, 183DR, 190DR, annexes, pipe tunnels and associated rail/car unloading spots are associated with this pipeline classification. Associated waste sites include: 100-D-31, 100-D-56, 100-D-77, DR Reactor Water Treatment Facility, Acid Facility, 183-DR Head House, 183-DR Filter Building, Sodium Dichromate Systems, 183-DR Flocculation Basins, 183-DR Sedimentation Basins, 100-D-73.

**Process Description:** The 2009 WCH 100-D Area Orphan Site Evaluation identified a number of treated water pipe segments that were not accounted for in other waste sites. Some of the pipe segments connect to (or are extensions of) other waste sites. In some cases the pipe segments have been previously removed by remediation of co-located waste sites. See individual subsites for detailed process descriptions.

**This Site has the Following SubSites:**

<td>Description:</td>
<td>The subsite has been remediated and Interim Closed Out. It consisted of thirty five pipeline segments associated with the 100-D-77 (183-DR Acid Facility). It included the low pressure steam, sulfuric acid, and lime slurry lines. The majority of the segments were located within the 100-D-77 acid pipe trench.</td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The facility was located on the north side of the 183-DR Head House. The majority of the pipeline segments were contained in the acid pipe trench.</td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>Sulfuric acid was received by railroad car and stored in two outside aboveground acid storage tanks. The acid was fed by gravity to the 183-DR Head House by maintaining the supply in the Acid Head Tank. The piping between the head tank and the 183-DR Head House was all above grade. Sulfuric Acid was added to the raw water supply before coagulation and filtration to reduce the pH below 7.5 and to aid in the suspension of solids. After filtration, lime was added to the water to raise the pH to between 7.5 and 7.8. Lime slurry was returned to the acid trench for neutralization of the waste acid. The sulfuric acid was reportedly purchased from a mining company and contained mercury and lead.</td>

<tr>
<td>Waste Description:</td>
<td>The waste is the pipelines and any contaminated soil associated with leaks from the pipelines.</td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Remedial action at the 100-D-62 waste site was conducted on May 2 and 3, 2011. A reinforced concrete septic tank, associated concrete piping, and soil were removed as part of the remediation and staged at the Spoil Pile Areas. Approximately 793 bank cubic meters (BCM) (1,037 bank cubic yards [BCY]) of soil and debris was loaded on July 12 and 13, 2011, for disposal at the Environmental Restoration Disposal Facility (ERDF). Remedial action at the 100-D-77 waste site began on May 3, 2011, and continued through July 13, 2011. The 100-D-83:1 subsite consisted of the pipeline segments associated with the 183-DR Acid Facility. Most of the pipelines were within the 100-D-77 acid trench and were removed during the 100-D-77 waste site remediation.Remediation continued to a depth of approximately 4.5 meters (15 ft) below ground surface (bgs) resulting in approximately 7,103 BCM (9,290 BCY) of contaminated soil and debris that was removed and staged at the staging pile areas (SPAs) prior to loadout and disposal.</td>
<td></td>
</tr>
</tbody>
</table>
The 100-D-83:1 waste site was inside the 100-D-77 site and was fully removed with the 100-D-77 excavation. Verification samples were collected from these three locations on May 29, 2013.

A 20 meter (65.6 ft) section of the 100-D-56:2 pipelines, located at the entrance into the 183-DR Head House, and the 183-DR Filter Building sample room were also remediated with 100-D-77. Loadout of waste material with subsequent disposal at ERDF was conducted between July 13 and October 18, 2011.

At the completion of the remediation, in-process soil samples were collected on July 6 and July 11, 2011, to determine if additional remediation of the waste site was necessary. Mercury was measured above the direct exposure remedial action goals (RAGs) in the in-process sample data. Based on these results, a second tier (Tier 2) of excavation was designed.

The Tier 2 remediation began on December 8, 2011, and continued through January 16, 2012. Approximately 7,126 BCM (9,320 BCY) of contaminated soil and debris were removed from the excavation and moved to the SPAs for loadout and disposal at ERDF. The excavation depth extended a maximum of 9.5 meters (31 ft) bgs. Loadout of the Tier 2 waste material began on December 14, 2011.

The presence of elevated PAH within the excavation area was attributed to cross-contamination of asphalt. Additional remediation of benzo(a)pyrene at location EXC-3 was a result of cross-contamination with asphalt. Additional soil was removed at and around the sample location (EXC-4) with elevated mercury on March 15, 2013. An additional 76 BCM (100 BCY) of contaminated soil and debris were removed from the excavation and staged prior to disposal at ERDF. The area in which additional removal was performed included the FS-1 sample location. Replacement verification samples were collected at the EXC-4 and FS-1 locations on March 15, 2013.

Contaminated soil, concrete, and rebar from previously demolished buildings, piping, and a brick-lined concrete acid trap were among the types of material removed from the excavation. All materials removed from the 100-D-62, 100-D-77, and 100-D-83:1 excavation were staged at five SPAs prior to loadout and disposal at ERDF.

<tr>
<td>Release Description:</td>
<td>100-D-83:2 was remediated with 100-D-100.</td>
</tr>
<tr>
<td>Process Description:</td>
<td>The backwash water for the 183-DR filters was supplied from the 183-D Pump Room via a 76.2 cm (30 in) carbon steel cross-tie line (100-D-63) to the 183-DR pipe gallery. This line is</td>
</tr>
</tbody>
</table>
also used to supplement the 183-DR water requirements including make-up water for the DR Reactor cooling water system (HW-74094, Vol.3). A redundant supply of filtered water was provided via a 40.6 cm (16 in) pipeline (100-D-63) from the 105-D filtered water supply. The two lines, laid parallel to each other, were joined in the water reducing valve pit. The water reducing valve pit had two drain lines (H-1-9660-DR). One was connected to the cross-tie between the backwash and filtered water lines. It received intermittent discharges during pressure surges between the lines. The other drain line collected water in the bottom of the valve pit from leaking valves or pipe repairs. Both drain lines discharged to the process sewer (100-D-50:7).

Waste Type: Demolition and Inert Waste
Waste Description: The waste is the pipeline segments, the valve pit, and any contaminated soil associated with leaks from the pipelines.
Closure Info: Hanford construction drawing H-1-9660-DR indicates the base of the valve pit was approximately 15 feet below ground surface. The 100-D-83:2 valve pit was located within the Excavation boundary of the 100-D-100 Stained Soil waste site.

The 100-D-83:2 waste site, including the associated piping and valve pit, were removed during the Tier III remediation of the 100-D-100 waste site. Approximately 16 meters (52.5 ft) of soil was removed during the 100-D-100 waste site Tier III remediation. Since a significant amount of soil has been removed to a depth well into the deep zone, (more than 4.6 meters (15 ft) below surface grade), there are no direct exposure pathways for the waste site. Field observations during Tier III remediation did not identify any stained soil or other evidence of contamination at the location associated with the 100-83:2 waste site. Therefore, no verification samples are required and the 100-D-83:2 waste site is reclassified as Interim Closed Out.

Type: Product Piping
Status: Inactive

Description: The subsite consists of the pipeline segments associated with the 108-D Acid Addition Facility (100-D-101) and includes the sulfuric acid pipeline and a process sewer.

Location: The facility (100-D-101) was located approximately 10 meters (32.8 ft) west of the 108-D Chemical Pump House.

Process Description: Sulfuric acid was added to the cooling water upstream of the reactor to lower the pH. The acid was received by railroad tank cars and stored in two above ground storage tanks just west of 108-D. The acid was fed to the 105-D building through a 5.08 cm (2 in) steel pipeline by gravity. The acid neutralization pit was used to balance the pH of the waste acid. The pit drained to the process sewer (100-D-31:3) through a 15.24 cm (6 in) vitrified clay pipe.

Waste Type: Construction Debris
Waste Description: The waste is the pipeline segments, the process sewer, and any contaminated soil associated with leaks from the pipelines.

<tr>
<td>Description:</td>
<td>This subsite was evaluated and determined to require No Action. It consists of the remaining treated water pipeline segments that were not addressed by 100-D-83:1, 100-D-83:2, 100-D-83:3 and 100-D-83:5. They include piping associated with the sulfuric acid and sodium silicate supply lines, reused water return lines at the 190-D building and an elevated storage tank drain line south of the 105-DR Reactor Building. Originally, 100-D-83:4 consisted of four areas of pipelines that were used for treated water and chemical transfer. However, Area 1 will now be addressed with the 100 D 83:5, 186-D Acid Neutralizing System Pipelines. Area 1 consisted of the 18 pipeline segments located west of the 186-D building that are associated with the acid and lime slurry transfer from tanks to the 120 D-2, 186-D Waste Acid Reservoir. A portion of these pipelines, entering the reservoir, were removed during 120-D-2 remediation activities. During confirmatory sampling of the 100 D 83:4 subsite, the pipe tunnels were encountered. It was determined that these segments would be sent to remove, treat, and dispose (RTD). Areas 2, 3, and 4 of the 100 D 83:4 subsite were reclassified to &quot;No Action&quot; on the reclassification form and Remaining Sites Verification package. Area 2 consisted of 19 pipeline segments located southwest of the 190-D Building that were associated with acid and reused water transfer from the 185-D Deaerating Plant to the underwater test facility. It was known prior to confirmatory sampling that many of these pipelines were removed with previous 100-D-30 remediation activities. As confirmatory sampling was conducted, it became apparent that all of these pipelines had been previously removed. The above ground portion of the 100-D-83:4 pipeline that went south from this location had also been previously removed. Area 3 consisted of the pipeline segment located at the 187-DR elevated water tank that was associated with transporting untreated emergency cooling water to the 105-DR Reactor in the event that normal flow of cooling water was disrupted. An additional area of pipelines, which included segments in both the 100-D-83:3 and 100-D-83:4 subsites, was located west of the 108-D Building. It is associated with the sulfuric acid and sodium silicate tanks. Area 4 of the 100 D 83:4 subsite consisted of the pipeline sections that ran from the 108-D tanks towards the 105 D Reactor, but will not be recommended for RTD along with the north-trending 100-D-83:3 pipeline sections, because the pipeline was not located during confirmatory sampling, and is believed to have been removed with the 100-D-31:3 remedial activities. Location: The sulfuric acid and sodium silicate supply tanks are located just outside the southwest corner of the 190-D Building. Another sulfuric acid line runs between the 108-D Acid Storage Tanks and the 105-D Reactor. The reused water return lines are on the south side of the 190-D Building. The 187-DR elevated storage tank is located on the southeast side of the 105-DR Reactor.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Process Description:

190-D Sulfuric Acid Supply
Sulfuric acid was added to lower the pH of reactor coolant and to prepare activated silica from sodium silicate (HW-34095). The original facility included two acid storage tanks outside the southwest corner of building 190-D that were supplied by piping from a rail car. The acid was later supplied by truck (HW-29542, HW-34095). An acid trench ran from under the two storage tanks to building 185-D where it continued the length of the building. The acid trench has also been referred to as the sodium dichromate trench and was assigned to the 100-D-30 waste site. The original two sulfuric acid storage tanks were relocated to building 183-D in January 1957 (HW-35606, HW-48046). The piping inside the trench was removed during remediation of 100-D-30. A new acid storage tank was installed outside the 185-D building in 1962 as part of the half-reactor test. A 7.6 cm (3 in) acid pipeline was installed between the storage tank and an acid unloading station off the railroad spur just north of the electrical substation 151-D. The test (IP-442-A) which began on January 30, 1963 fed sulfuric acid to lower the pH of the process water for one-half of D Reactor (HW-76398). Two pumps were added to the sulfuric acid storage tank a few months later to permit pH adjustment on the other half of the reactor.

190-D Sodium Silicate Supply
A sodium silicate storage tank was installed in November 1964 south of the 190-D Building not far from the acid storage tanks. The sodium silicate tank was used for another half-reactor test conducted between January 15, 1965 and March 11, 1966 (RL-REA-472 and DUN-1293). Sodium silicate was added to inhibit the formation of film on slug and tube surfaces in the reactor.

190-D Reused Water Return
Filtered water was deaerated before going to the 190-D process water storage tanks or to the refrigeration units (189-D) to remove dissolved oxygen and carbon dioxide (while 186-D was in operation). Steam ejectors exhausted the gases from the deaerators to barometric condensers. The barometric condensers discharged the gases to the atmosphere. Raw water was used to operate the barometric condensers. The raw water (condenser water) was heated in the barometric condensers and emptied into the hotwells below. The condenser water overflowed the condenser hot wells into the reuse water reservoir through a 61 cm (24 in) reused water return line (TNX-PG-4). Hot condenser water was also returned to the storage reservoir (182-D) during the winter through a 50.8 cm (20 in) cast iron pipeline (100-D-63).

108-D Acid Supply Line
Sulfuric acid was added to the cooling water upstream of the reactor to lower the pH. The acid was received by railroad tank cars and stored in two above ground storage tanks just west of 108-D. The acid was fed to the 105-D building through a 5.08 cm (2 in) steel pipeline by gravity. The northern portion of this pipeline is assigned to 100-D-83:3.

105-DR Elevated Storage Tank Drain Line
Two elevated storage tanks (187-DR) with a capacity of 1.14 ML (300,000 G) each were erected to serve 105-DR. Both tanks were located in the vicinity of, and on opposite sides of the 105-DR Building. With the exception of the tank supports, which were cylindrical columns, these installations were the same as the 187-D elevated tanks (HW-24800-34). Both tanks had 7.62 cm (3 in) drain lines that emptied a sump in the floor of the valve pit (W-72733). The tank on the northwest side of 105-DR drained to the process sewer (100-D-50:9). The tank on the southeast side drained to the process sewer (100-D-85:2) on the east side of the reactor. It is this second drain line that has been assigned to 100-D-83:4.

Waste Type: Construction Debris
Waste Description: The waste is the contaminated piping, concrete, and soil.
Closure Info: Confirmatory sampling of the 100-D-83:4 subsite was performed in August 2010. Based on the...
Rev. 24

DOE/RL-88-30

results, remedial action was determined to be unnecessary. The confirmatory sampling data has
been used for reclassification of this site to No Action. The results indicated that the waste site
achieved compliance with the remedial action objectives (RAOs) and remedial action goals
(RAGs) for subsite, and remediation was not necessary.

The SubSite is Part Of:

</tr>
<tr>
<td>Waste Description:</td>
<td>The waste is the pipelines and any contaminated soil associated with leaks from the pipelines.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The western segments of 100-D-83:5 were originally part of 100-D-83:4. Therefore the confirmatory samples were collected from 100-D-83:4 Test Pit 1 in August 2010 and determined the Remove, Treat, Dispose (RTD) option would be required. The eastern segment was recommended for RTD without confirmatory samples. Remedial action at the 100-D-83:5 waste site began on April 24, 2013 and continued through June 10, 2013. The waste from the site included residual pipe debris, concrete, soil and debris (including asphalt), building materials, and miscellaneous reactor hardware (unirradiated spacers and perfs). Lead sheeting material was removed from the acid neutralization tanks area. The remnants of the bases of two acid neutralization tanks and one lime storage silo and hopper associated with the demolished 186-D Facility at the south end of the 100-D-83:5 pipeline (western portion) were also removed and disposed. Remediation at the western portion of the 100-D-83:5 waste site at the 186-D acid neutralizing system pipelines extended from 3.5 meters (11.5 ft) bgs to a maximum depth of 8.0 meters (26 ft) bgs. The majority of the pipelines had been previously removed during remediation of adjacent waste sites 100-D-50:7 and 100-D-31:9.</td>
</tr>
</tbody>
</table>

Hanford Site Waste Management Units Report
February 2015

210
The western pipelines section also included short segments of pipeline located at the northwest corner and east side of 120-D-2. Within the northwest portion of 120-D-2, a segment of 100-D-83:5 extended approximately 8 meters (26 ft) to the south and a second section extended approximately 3 meters (10 ft) north. Post-exavcation drawings for the 120-D-2 and 100-D-31:9 waste sites indicated that these pipeline segments had been previously removed. Therefore, no verification sampling was required for the pipe segments in the northwest portion of 120-D-2. Previous removal of the pipeline segments on the east side of 120-D-2 could not be confirmed. Therefore, a test pit was excavated on September 6, 2013, to determine if the pipes had been removed. A concrete structure was present in the area of the test pit at a depth of approximately 3 meters (10 ft) bgs. This structure had served as a pipe cradle but the pipe had been removed. A test pit was excavated at coordinates N151558.6/E573447.5 to a depth of 3 meters (10 ft) bgs. No pipes were found. A sample (J1I0K9) was collected at the base of the test pit. Per agreement with the Washington State Department of Ecology, no further verification sampling was required for the pipe segments on the east side of 120-D-2.

Remediation at the eastern portion of the 100-D-83:5 waste site between 190-D and 105-D extended to a maximum depth of 6.5 meters (21 ft) bgs. The top of the concrete tunnels had previously been demolished and the tunnels were filled with debris, including pipe debris. The majority of the remaining concrete tunnel structures that contained the 100-D-83:5 pipelines were also removed during remediation. However, a section of one of the tunnels remains due to being located near overhead power lines. Additional safety considerations, including potentially de-energizing the power lines, would have been required for removal of the tunnel. With concurrence with the Washington State Department of Ecology, this section of concrete tunnel was left in place. Portions of the eastern pipelines excavation were within the adjacent 100-D-30 excavation boundary. No indications of contamination were present in the tunnel.

Approximately 1,800 bank cubic meters (BCM) (2,350 bank cubic yards [BCY]) of clean overburden was removed and stockpiled. In total, approximately 12,800 BCM (16,740 BCY) of contaminated soil and debris was removed and placed at the staging pile area (SPA) pending loadout and disposal.

Description: The site consist of numerous sanitary sewer pipe segments discovered during the Orphan Site Evaluation process that were not previously identified or addressed within WIDS site database. The entire site includes underground sanitary sewer connections including associated manholes (and associated drains), catch basins, junction boxes and valve control systems or any other below surface associated feature not previously identified. The sanitary sewer pipelines are service connections supporting ancillary and temporary construction facilities and discharge to associated septic systems. The site has been divided into two subsites as follows:

- 100-D-84:1, Sanitary Sewer Pipelines - Areas 1 and 2
- 100-D-84:2, Sanitary Sewer Pipelines - Areas 3 and 4

Location: The pipeline segments were observed in various locations throughout the 100-D Area.
**Related Sites/Structures:**
Ancillary support and temporary construction facilities

**Process Description:**
The pipelines carried non-radioactive liquid sanitary sewage waste.

**Waste Type:** Abandoned Chemicals

**Waste Description:**
The waste consists of pipelines and any contaminated soil associated with leaks from the pipelines. The contaminants of potential concern (COPCs) are unknown.

**Description:** This subsite consists of piping from two areas (Areas 1 and 2) as defined in the Confirmatory Work Instruction (0100D-WI-G0092). Area 1 includes 23 pipeline segments south of the 105-DR Reactor Building. Area 2 includes seven pipeline segments northwest of the 105-D Reactor Building.

**Location:** Area 1 is located approximately 121 m (400 ft) southeast of the 105-DR Reactor. Area 2 is located approximately 150 m (500 ft) northwest of the 105-D Reactor.

**Related Sites/Structures:**
The site was related to ancillary support and temporary construction facilities.

**Process Description:**
The pipelines in Area 1 were the result of temporary construction that was put into place to support 1947 modification of 100-D Area Buildings and facilities and provide a water supply for the existing 105-D Pile Building (water supply unrelated to 100-D-84:1) (per HW-24800-34). At the completion of the construction program, all temporary construction was removed with the exception of the Atkinson-Jones and G.E. Warehouses, a sewage disposal system, and the Atkinson-Jones (A.J.) Superintendent's Building. It is believed that all the Area 1 piping drained to the 100-D-50:9 piping system. Confirmatory sampling was conducted at this area in August 2010.

The pipelines in Area 2 were service lines that carried waste from various buildings north of the 105-D reactor to the sanitary sewer main. These buildings included 190-D, 1703-D, 1717-D, 1725-D, 1726-D, 1727-D, 1728-D, and 1729-D. A number of these pipelines were previously removed during remediation of 100-D-31:4 or have been recommended for remove, treat, and dispose (RTD) along with other portions of the 100-D-84:2 subsite. The service line for the 1725-D trailer ran parallel to the 100-D-63 pipelines, and underwent confirmatory sampling in August 2010.

**Waste Type:** Oil

**Waste Description:**
The waste is the pipelines, pipe contents, and any contaminated soil associated with leaks from the pipelines.

100-D-85:2 pipelines are located on the east side of the 105-DR reactor.
The pipelines were used to dispose of radioactive cooling and waste water from the reactor facility. Two large main effluent pipelines drained cooling water from the 105-DR Reactor. The small effluent pipelines that drained process waste from the sides (east and south) of the 105-DR were joined into a single pipeline that ran to the 132-DR-1 ([1608-DR Building] Waste Water Pumping Station or Process Lift Station). The building was a rectangular shaped, two-story, reinforced concrete structure that was half below grade elevation. The purpose of this facility was to pump process effluent to the main effluent pipeline. All but one of the pipeline segments are associated with the 105-DR Reactor discharge to the 1608-DR Lift Pump Station (100-D-85:2). The remaining segment (100-D-85:1) connects the two effluent lines (100-D-48:2 and 100-D-49:2) that empty into the 107-D and 107-DR Retention Basins. The reactor effluent pipelines were used to carry reactor cooling water effluent away from the 105-DR Reactor to the 107-DR Retention Basin (116-DR-9), and to the associated outfalls for final discharge to the Columbia River. Contaminated water from building drains in the reactor and piping at elevations below the elevation of the 107-DR Retention Basin flowed by gravity to the 1608-DR Building (132-DR-1) where it was pumped to the 107-DR Retention Basin.

The associated structures include the 105-DR Building, the 132-DR-1 (1608-DR), the 116-DR-9 (107-DR) Retention Basin, the 116-D-5 Outfall and 116-DR-5 Outfall. Other related sites include the 116-DR-1 and 116-DR-2 Trench, the 116-DR-6 Trench, 100-D-48, 100-D Reactor Cooling Water Effluent Underground Pipelines (See Subsites), and 100-D-49, 100-DR Reactor Cooling Water Effluent Underground Pipelines (See Subsites), and 100-D-60, 100D/DR River Effluent Pipelines, 100D River Lines.

Waste site contaminants of concern (COCs) identified through process knowledge were identified in the Sampling and Analysis Plan for the 105-F and 105-DR Phase III Below Grade Structures and Underlying Soils (SAP), (DOE/RL-99-35). The 105-DR SAP classified the different areas and structures into affected media that were similar in characteristics and contaminants. The COCs included: americium-241, barium-133, carbon-14, cobalt-60, cesium-137, europium-152, europium-154, europium-155, nickel-63, plutonium 238, plutonium-239/240, strontium-90, technitium-99, uranium-234, uranium-235, uranium-238, hexavalent chromium, lead, mercury and polychlorinated biphenyls. The waste consisted of contaminated steel piping, concrete, and soil. Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, diatomaceous earth (a scouring agent), and sodium dichromate. Water pH was maintained at about 7.5, and free chlorine residual was about 0.2 milligrams per liter. Radionuclides discovered at the retention basin during sampling by Dorian and Richards (UNI-946), included: plutonium-238, cesium-134, plutonium 239/240, cesium-137, strontium-90, 155, nickel-63, cobalt-60, and carbon-14. Post Reactor cooling water effluent had anti corrosive chemical additives including pH adjustment and was radioactive.

### This Site has the Following SubSites:

**Code:** 100-D-85:1  
**Names:** 100-D-85:1; Additional 107-DR Effluent Pipeline

**Code:** 100-D-85:2  
**Names:** 100-D-85:2; Additional 105-DR Reactor Effluent Pipelines

---

**Waste Type:** Chemical Release  
**Waste Description:** Waste site contaminants of concern (COCs) identified through process knowledge were identified in the Sampling and Analysis Plan for the 105-F and 105-DR Phase III Below Grade Structures and Underlying Soils (SAP), (DOE/RL-99-35). The 105-DR SAP classified the different areas and structures into affected media that were similar in characteristics and contaminants. The COCs included: americium-241, barium-133, carbon-14, cobalt-60, cesium-137, europium-152, europium-154, europium-155, nickel-63, plutonium 238, plutonium-239/240, strontium-90, technitium-99, uranium-234, uranium-235, uranium-238, hexavalent chromium, lead, mercury and polychlorinated biphenyls. The waste consisted of contaminated steel piping, concrete, and soil. Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, diatomaceous earth (a scouring agent), and sodium dichromate. Water pH was maintained at about 7.5, and free chlorine residual was about 0.2 milligrams per liter. Radionuclides discovered at the retention basin during sampling by Dorian and Richards (UNI-946), included: plutonium-238, cesium-134, plutonium 239/240, cesium-137, strontium-90, 155, nickel-63, cobalt-60, and carbon-14. Post Reactor cooling water effluent had anti corrosive chemical additives including pH adjustment and was radioactive.
Description: The subsite has been evaluated and determined to require No Action. It consisted of a single pipeline segment identified on one historical drawing, H-1-8348, (HEW 1948); however, it was unknown whether it was ever constructed. The pipeline was believed to be approximately 92 meters (300 ft) in length, buried at approximately 5 meters (16 ft) below ground surface (bgs). It was composed of unknown construction material. If constructed, it was anticipated that the pipe would not have been removed by any previous effluent sewer remedial actions. During excavation of the 100-D-29 waste site, which extended to approximately 4.6 meters (15 ft) bgs into this location, there was no indication of a pipeline.

Location: The pipeline is located adjacent to the southwest corner of the 107-DR retention basin.

Waste Type: Construction Debris

Waste Description: The waste is potentially contaminated soil.

Closure Info: Confirmatory sampling was performed in August 2010. Undisturbed native soil was encountered at approximately 3 meters (6 ft) bgs. Native black sand was encountered until the base of the test pit excavation ended at 4.9 meters (16 ft) bgs. No pipe was found. Based on field observations and the confirmatory sampling results, remedial action was determined to be unnecessary.

The SubSite is Part Of:
Code: 100-D-85
Names: 100-D-85; 100D Reactor Effluent Pipelines

Description: Subsite two consists of sixteen additional reactor effluent pipe segments that were identified during the WCH D Area Orphan Site Evaluation (OSE). The segments are associated with the 105-DR Reactor that discharged to the 1608-DR Waste Water Pump House. These segments have not been associated as part of an existing WIDS site. There was insufficient information to account for their removal during nearby remedial actions (i.e. 118-DR-2:2 and 100-D-49:4; see CVP-2003-00016).

The pipelines consists of various sizes of cast iron pipe and black steel pipe.

Location: They are located on the east side of the 105-DR reactor.

Process Description: The pipelines carried process water and steam condensate collected from sumps, floor drains, sinks and steam traps on the eastern half of the 105-DR building. The processes water drained by gravity to the 1608-DR Waste Water Pumping House (132-DR-1) where it was pumped to the main effluent pipeline (100-D-49:3). Many of the 100-D-85:2 pipelines were found to be leaking in 1958 (HW-56911 and HW-57840). Repairs were made and the steam condensate drains were disconnected from the sewers (100-D-85:2) on the north end of the building (HW-58360).

Waste Type: Water

Waste Description: The waste is contaminated steel piping, concrete, and soil.

<td>The site encompasses 32 additional process sewer pipelines that were not previously identified within an existing WIDS site. Pipelines that were presumed to have been removed in their entirety because they were located within an existing cleanup verification package (CVP) footprint were excluded. The entire site includes those underground pipelines that transported non-radioactive waste streams from water treatment, reactor, and laboratory facilities. The site includes any other below grade feature associated with the pipeline segment (i.e. manholes, catch basins, junction boxes and valve boxes) not already assigned to another waste site. The site has been divided into three subsites as follows: 100-D-86:1 - 105-D Gas Recirculation Pipelines 100-D-86:2 - Additional Process Sewer Pipelines (determined to require No Action) 100-D-86:3 - 105-DR Fan Room Sewer Pipelines</td>
</tr>
</tbody>
</table>

**Location:** Refer to the subsites for locations of the pipeline segments.

**Related Sites/Structures:** The process sewer received effluent from the following facilities: 182-D, 183-D, 183-DR, 184-D, 185-D 186-D, 189-D, 190-D, 105-D, 107-D, 183-DR, the 183-DR Clearwell Area, the 105-DR Reactor Buildings, and the 1907-DR Outfall (100-D-8).

**Process Description:** The 100-D Orphan Site Evaluation Report (OSR-2006-0001) identified a number of process sewer pipe segments that were not accounted for in another waste site. These pipe segments were upstream of the reactor effluent discharges and were presumed to carry non-radioactive waste streams from various 100-D/DR Area facilities including the 105-D, 105-DR, 190-D, and 190-DR buildings. The pipelines ultimately discharged to the Columbia River through one of the outfalls (1904-D, 1904-DR and 1907-DR).

**Waste Type:** Process Effluent

**Waste Description:** Minor amounts of radionuclide, chemical, and mercury contamination may be present in process sewer lines from the 185-D and 189-D/190-D complex as a result of laboratories once located in these now demolished facilities. The waste consists of steel piping, concrete, and soil (if contaminants are present). The water supply and process sewer drain pipelines at the 100-D and DR Areas provided for the supply and disposal of non-radioactive streams generated in water treatment and water treatment laboratories facilities and powerhouse operations. Known chemical additions to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained near 7.5, free chlorine residual at about 0.2 milligrams per liter, and sodium dichromate was added at a rate of about 2 milligrams per liter. Sodium chloride was also used to regenerate water softeners in both water treatment and powerhouse operations.

This Site has the Following SubSites:

**Code:** 100-D-86:1

**Names:** 100-D-86:1; 105-D Gas Recirculation Pipelines
Names: 100-D-86:2; Additional Process Sewer Pipelines

Description: This Subsite consists of the steel gas recirculation piping in the subsurface tunnel between the former 115-D Gas Recirculation Facility and the 105-D Reactor. Features of the subsite include a pipeline described as a 41 cm (16 in) steel pipe that carried reactor atmosphere to and from the 115-D/DR Gas Recirculation Facility. The second feature is a 320 square meter (3,444 sq ft) pipe tunnel between the 115-D/DR Gas Recirculation Facility and the 105-D Reactor. The tunnel was 2.0 meters (6.5 ft) tall, with the floor being 3.4 meters (11 ft) below the 1st floor of the 115-D/DR Building. It includes the vacuum and pressure seal pit, located north of the 1608-D Lift Station.

Startup of the 105-D Reactor occurred on December 17, 1944. The 105-D Reactor was provided with an inert, non-radioactive gas environment (reactor atmosphere) to remove moisture and foreign gases. The reactor atmosphere was a mixture of helium and carbon dioxide (HW-74094). The initial and make-up reactor atmosphere was supplied from storage tanks (110-D) located west of 115-D/DR Gas Recirculation Facility. The reactor atmosphere was purified in the 115-D/DR Building and returned to the 105-D Reactor. Parallel, 41 cm (16 in) steel pipes carried the reactor atmosphere to and from the 115-D/DR Building inside an underground reinforced concrete pipe tunnel (W-73950). Connected to, and considered part of the 105-D tunnel, was the vacuum and pressure seal pit. The pit contained two vacuum seal tanks filled with oil (UNI-4281, W-74375). The tunnel also formed part of the 1608-D Lift Station (132-D -3).

The 115-D/DR Recirculation Facility was also used to purify the reactor atmosphere for 105-DR between 1950 and 1964. The piping contained in the 105-DR pipe tunnel was assigned to the 100-D-50:4 waste site. The 115-D/DR Recirculation Facility and the underground pipe tunnels were no longer used after the 105-D Reactor was shut down on June 26, 1967. The 115-D/DR Gas Recirculation Facility and adjoining tunnels were decommissioned by UNC Nuclear Industries in 1985 and 1986 using the Allowable Residual Contamination Levels (ARCL) methodology in conjunction with the in situ decommissioning alternative. The vacuum and pressure seal tanks were removed and disposed of as radioactive waste. The tunnel piping and valves were not removed. The tunnel roof was collapsed from the 115-D/DR Building up to but not including the 1608-D Building. The void was filled with rubble and clean fill. Based on survey data and pre-demolition dose assessment, the tunnel piping/valves met in situ decommissioning criteria (UNI-4281).

Characterization of analogous pipelines in the gas recirculation wing of the 105-H Reactor revealed the accumulation of soil sludge containing multiple radionuclides at levels above remedial action goals (CCN 120410). Consequently the two 41 cm (16 in) circulation lines between the 115-D and 105-D buildings were added to the 100-D-86 waste site on October 19, 2008.

Location: The piping is located in the subsurface tunnel between the former 115-D Gas Recirculation Facility and the 105-D Reactor.
The waste consists of steel piping, concrete, and soil (if contaminants are present).

The SubSite is Part Of:

Names: 100-D-86; 100D Process Sewer Pipelines

Classification: Accepted

Description: Subsite 2 was evaluated and determined to require No Action. It consisted of an additional 13 process sewer pipelines identified on historical drawings during the 100-D Orphan Site Evaluation (OSE). They included piping associated with the 105-D and 190-DR buildings. The 105-DR LSFF pipelines were transferred from the 100-D-86:2 subsite to the 100-D-86:3 subsite, and were recommended for Remove, Treat, and Dispose (RTD).

Location: The pipelines are located adjacent to the related facilities (105-D, 105-DR and 190-DR).

Process Description: The 105-D Building housed a graphite-moderated, water-cooled reactor for the production of weapons grade plutonium. The reactor was located in the process area of the building. Other areas of the building included the control room, fan house, valve pit, work area, storage basin, various offices and equipment storage rooms. Drainage piping was provided throughout the building to carry water from floor drains, steam traps, sumps and trenches to the process sewer (W-71186, W-71617). The process sewer (100-D-31:3) on the west side of 105-D was rerouted when the 190-D Annex was constructed in 1956. A catch basin located outside the northeast corner of the 190-D Annex emptied into the process sewer (100-D-31:3).

190-DR Main Process Water Pump House The 190-DR Building housed pumps that supplied primary cooling water to the 105-DR Reactor (HW-74094 Vol.3).

At 190-DR there were two pump rooms with four pumps in each. The filtered water used for cooling was stored in four large steel storage tanks outside of the 190-DR building. The water was treated with sodium dichromate at the 183-DR Building following filtration prior to entering the storage tanks.

Waste Type: Process Effluent

Closure Info: Investigation at the 100-D-86:2 subsite was carried out on November 16 and 17, 2010. Test pits were excavated at six locations. The purpose of each test pit was to determine if process sewer segments associated with the 100-D-86:2 subsite were present in any location.

Test pit 1 (N151287/,E573725) was excavated to a total depth of 6 meters (19 ft) below ground surface (bgs) attempting to access a pipeline associated with the 105-DR Large Sodium Fire Facility (LSFF). Because no pipeline was found in this test pit, an additional test pit was excavated to 6 meters (19 ft) bgs at an alternate location (N151275/, E573725). Because a pipeline was found at the alternate test pit location, the entire Test Pit 1 area was sent to RTD, including the 36 meters (120 ft) of pipeline that extends from this location to the south.
Approximately 17 meters (55 ft) of pipeline in the area south of the test pit is in the shallow zone, at a depth of approximately 3 meters (9 ft). The Test Pit 1 area became part of the 100-D-86:3 subsite for RTD.

Test pit 2 (N151189/ E573551) was excavated to a total depth of 1.2 meters (4 ft) bgs, attempting to access the center of a north-south-trending pipeline shown approximately 15 meters (50 ft) to the east of the 190-DR pump house and west of the valve house test pits 1 and 2 on a temporary drawing. Because the pipeline segment was not found in this test pit, it is concluded that the segment was not present because the pipeline was identified on a temporary piping drawing as being located inside a shallow trench with only 45 cm (18 in.) of sediment covering.

Test pit 3 (N151127/E573543) was excavated to a total depth of 4.6 meters (15 ft) bgs to access the corner of a 20 to 61 cm (8 to 24 inch) steel discharge pipeline. No pipeline was found. It was concluded that the pipeline was removed with demolition of the 190-DR pump house.

Test pit 4 (N151622/E573697) was believed to be the location of a manhole connecting to the 100-D-31:3 subsite. It was planned to be excavated to a maximum depth of 4.6 meters (15 ft) bgs. However, the Test Pit 4 location was determined to be within the excavation boundary of the 100-D-31:4 subsite, which was at a depth of 5.4 meters (18 ft) bgs. Therefore, no excavation was necessary to determine that there was no manhole at this location.

Test pit 5 (N151592/E573698) was excavated to a maximum depth of 4.6 meters (15 ft) bgs, attempting to access a 91 cm (36 in.) diameter manhole associated with the 190-D building annex. Only miscellaneous debris was found during the excavation. The miscellaneous debris included rebar, pieces of concrete, a piece of sheet metal, and a section of conduit. Due to the non-hazardous nature of this debris, the material was backfilled into the test pit when excavation was completed. It was concluded that the manhole and associated piping had been previously removed during demolition of the 190-D building annex.

Test pit 6 (N151036/E573549) was excavated to a maximum depth of 4.6 meters (15 ft) bgs to access a 30 cm (12 in.) diameter drain shown on historical drawings, that ran north-south and connected with the 100-D-50:1 sewer pipelines. No pipeline was found. It was concluded that this pipeline was never constructed.

The SubSite is Part Of:
Code: 100-D-86

Description: The site consists of process sewer pipelines that received waste from the 105-DR Fan Room floor drains and condensate.

The 105-DR LSFF pipelines have been transferred from the 100-D-86:2 subsite to the 100-D-86:3 subsite, and are recommended for Remove, Treat, and Dispose (RTD).

Location: The pipelines are located on the west side of the 105-DR Fan Room.
**Process Description:** The 105-DR Building housed a graphite-modulated, water-cooled reactor for the production of weapons grade plutonium. The fan room housed the main blowers, heaters and air-filters (HAN-10970 Vol. 3). Air was supplied to the 105 Building by two separate supply systems. These supply systems conditioned the air and distributed it to a particular section of the building. The ventilation air supplied to the building spaces outside the confinement zone was exhausted to the atmosphere through roof ventilators. The ventilation air supplied to spaces in the confinement zone was collected by exhaust ducts which discharged into the exhaust tunnel (HW-74094 Vol. 3). The air in the exhaust tunnel flowed to the exhaust fans in the fan room. At the exhaust fans, the exhaust air became pressurized and was exhausted through an aboveground concrete duct which ran to the base of the 200-foot exhaust stack (116-DR). Originally the ventilation air was released directly to the 116-DR stack. In 1960, air filtering systems (117-DR) were added to minimize the release of radioactive matter (WHC-SD-EN-TI-181).

**Waste Type:** Water
**Waste Description:** The waste consists of steel piping, concrete, and soil (if contaminants are present).

**The SubSite is Part Of:**

**Code:** 100-D-86
**Names:** 100-D-86; 100D Process Sewer Pipelines

**Code:** 100-D-87
**Classification:** Accepted
**Reclassification:** Interim No Action (1/6/2011)
**Start Date:**
**End Date:**

**Type:** Dumping Area
**Status:** Inactive
**Description:** The waste site consists of a suspected unplanned release of liquid near the acid railroad tank car spot. When the spill was photographed in 1945, liquid was present on the surface of the ground north of the railroad car spot on track "B".

The only documentation identifying the spill were construction drawings H-1-281, W-74157 and W71800. The drawings indicate that a 45 centimeters (18 inches) tile is buried in the ground at the car spot. The car spot contained two transfer pumps and two 7.6 centimeters (3 inches) diameter pipelines. The pipelines transported acid to the acid tanks at the 186-D and 185-D Buildings. There were six acid tanks on the west side of the 186-D Building and two on the south side of the 185-D Building.

**Location:** The railroad car spot was located between the 186-D and 189-D Buildings.

**Related Sites/Structures:** The 186-D and 190-D Buildings and waste sites 100-D-63 (clean water pipelines) is about 20 m (65 ft) northeast of 100-D-2 (lead sheet covering a concrete pad).

**Process Description:** The car spot was used to unload acid that was transported through overhead lines to storage tanks at the 186-D and 190-D Buildings.

**Waste Type:** Oil
**Waste Description:** The spill was probably acid associated with the car spot unloading facility. The contaminant of potential concern was acid.

**Closure Info:** Confirmatory samples were collected from five test pits ranging in depth from 2 to 10 feet deep.

No staining, anomalies, tiles or linear features were encountered during confirmatory sampling.
Analysis was performed to evaluate if contamination associated with the potential spill was present. Field surveys for radiological contamination and volatile organic compounds were also conducted during sampling. Confirmatory sampling indicated that environmental contamination was not present at this waste site. Based on confirmatory sampling at the site, remedial action was determined to be unnecessary.

<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Focused samples from eight test pit locations were planned to be used to evaluate the 100-D-88 waste site. However, upon preparation for confirmatory sampling, it was determined that test pit 7 could not be excavated, due to the presence of an internet tower in this location. The tower, which includes a base in the location of the french drain, indicates that this drain no longer exists due to the presence of guy wires at approximately 2 to 2.5 m (6 to 8 ft) below ground surface. Therefore, sampling was not necessary to make a No Action decision for this portion of the 100-D-88 waste site. Test pits were excavated at the remaining seven locations of the Pipeline segments of the 100-D-88 waste site to collect samples or verify removal of the associated piping. These seven test pits are adequate to represent the 100-D-88 waste site, as the absence of a french drain at the test pit 7 location changes the condition of the waste site such that seven sampling locations, instead of eight, are adequate to evaluate the waste site. All radiological and volatile organic vapor readings in the field were less than detectable.</td>

<tr>
<td>Description:</td>
<td>The site has been evaluated and determined to require No Action. It consists of the soil located below two transformers sitting on railroad ties. The transformers were removed from service in 2003 and drained by the Fluor Electrical Utilities group in July 2005.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| Location:        | The transformers had been located 18 meters (60 feet) west of the 183-D Facility next to the paved two lane road. The transformers and railroad ties were removed and staged in the 200 Area laydown yard. Although the waste site had been originally described as an unplanned
release, it became apparent through further research that a known release had not occurred.

**Related Sites/Structures:** These transformers are possibly associated with the 190-DR Building. The transformers were removed from service in 2003 and drained by the Fluor Electrical Utilities group in July 2005.

**Process Description:** There is no process associated with this site. The site is only the staging area for two transformers which may have originated from the 190-DR facility.

**Waste Type:** Soil

**Waste Description:** The transformers contained oil with <499 ppm of PCBs (per Fluor Electrical Utilities). The site has the potential to contain PCBs. However, there was no evidence of staining associated with this site, therefore, there are no contaminants of potential.

**Closure Info:** The soil exhibited no visible staining, and the transformers and railroad ties had been removed and staged in the 200 Area laydown yard. Although the waste site had been originally described as an unplanned release, it became apparent through further research that no release had occurred.

Because analytical documentation on the drained fluid from the transformers was not available, confirmatory sampling was performed in August 2010. The sample results indicated no remediation was required.

The transformers had been recorded in WIDS for tracking purposes. Thus, PCBs were determined to be the only COPC for the site, based on professional judgment and other transformer COPCs. PCBs were analyzed for this waste site using EPA Method 8082.

### Waste Site Characteristics

<td>Status: Inactive</td>
<td>End Date:</td>
</tr>
</tbody>
</table>

**Description:** The waste site consists of seven french drains and two dry wells. They have been assigned corresponding numbers FD-1 through FD-9 for identification purposes. All but one feature is believed to have received steam condensate from non-radioactive buildings. The source for the ninth feature was determined to be a pressure relief valve. The site was divided into two subsites on November 19, 2012 to accommodate closure of FD-4 separate from the other eight features. The drains in Subsite 1 were evaluated and determined to require No Action.

**Location:** The french drains were located throughout the 100-D/DR Area. Refer to the subsites for the locations of specific features.

**Process Description:** The features were identified during the 100-D Area Orphan Site Evaluation (OSE). The evaluation included reviewing construction drawings, aerial photographs, GIS utility layers, process knowledge and field observations (EL-1583-6). The conclusion of the OSE was that these features were used for the disposal of steam condensate.

Steam was typically used at all facilities for heating purposes. The 184-D Power House boiler facility supplied high pressure steam to all buildings through an above grade pipeline system. The boiler facility utilized clean filtered water from the 183-D filter building. The steam supply was used in a non-contact radial heating system. As a non-contact system the steam remained uncontaminated. The steam transport process utilized a high pressure supply line and a low pressure return or discharge line. It was necessary to bleed both the supply and return lines to prevent condensate build up. The condensate was typical blow off from the above grade piping system into a below grade covered french drain as a safety precaution as illustrated on
construction drawing H-1-9644-DR and H-1-15203. Construction drawings H-1-9640-DR thru H-1-9645-DR of the outside steam distribution system indicate steam trap locations (french drains) and typical construction. The size and construction of the french drains diameters varied depending on steam piping size, service capacity pounds per hour, and expected flow rate received.

This Site has the Following SubSites:

**Code:** 100-D-96:1  
**Names:** 100-D-96:1; 100-D/DR Additional French Drains Group 1

**Code:** 100-D-96:2

| Description: | The french drains in Subsite 1 were evaluated and determined to require No Action. The 100-D-96:1 subsite, includes six french drains, two dry wells, and the underlying soil. The following are the features associated with this subsite:

FD-1 site is a 0.6 meter (2 ft) concrete french drain that is 5 centimeters (2 in.) above grade. It is filled with cobbles.

FD-2 site is a 0.45 meter (1.5 ft) concrete french drain at grade level. It is cobbled filled.

FD-3 site is a 0.6 meter (2 ft) concrete french drain at grade level. It is covered with a steel plate with pipe inlet notch.

FD-5 site is a 0.9 meter (3-ft) vitrified clay pipe french drain that is 23 centimeters (9 in.) above grade. It is filled with cobbles.

DW-1 site was a 0.9 meter (3 ft) concrete dry well at grade level covered with a steel plate with pipe inlet notch. It was removed during remediation of the 100-D-31:9 Process Sewer Pipelines subsite in 2009 and 2010. According to drawing H-1-9644-DR, the depth of DW-1 was approximately 3.5 ft (1.1 m). Final depth for the 100-D-31:9 subsite excavation was approximately 7 meters (23 ft).

FD-6 french drain was not located during the discovery site investigation. The french drain was identified and excavated during the remediation of the 100-D-31:8, 183-D and 186-D Northern Sewer Pipelines subsite in 2009 and 2010. The final depth for the 100-D-31:8 subsite excavation was approximately 9 meters (30 ft).

FD-7 site is a 0.45 meter (1.5 ft) french drain. The FD-7 french drain was not located during the discovery site investigation, and it is unknown if the french drain was removed or was covered (DUN 1968, GE 1968).

DW-2 site is a 0.9 meter (3 ft) concrete dry well at grade level covered with a steel plate with a concrete rim. It was determined (H-1-26509 and H-1-9641-DR) to be consistent with the pressure relief valve (PRV) for the high pressure steam supply line to the 151-D annex building. Steam condensate was discharged to DW-2 drywell location.
**Location:**

FD-1 - South of the 151-D Switch Yard at Washington State Plane coordinates E573513.9 N151277.7.

FD-2 - East of the 151-D Switch Yard at Washington State Plane coordinates E573618.03 N151354.5.

FD-3 - Northeast of the 1716-D Maintenance Garage at Washington State Plane coordinates E573551.5 N151801.6.

FD-5 - East of the 181-D River Pump House at Washington State Plane coordinates E572813.3 N151736.1.

DW-1 - East of the 183-D Clear wells at Washington State Plane coordinates E573383.1 N151597.2.

FD-6 site is a 0.6 meters (2-ft) french drain located west of the 184-DA Building at Washington State Plane coordinates E573406.0 N151743.0.

FD-7 - Northwest of the 1716-D Maintenance Garage at Washington State Plane coordinates E573551.0 N151797.0

DW-2 (FD-9) - North of the 151-D Switch Yard at Washington State Plane coordinates E573520.5 N151396.2.

**Process Description:**

Steam was typically used at all facilities for heating purposes. The 184-D Power House boiler facility supplied high pressure steam to all buildings through an above grade pipeline system. The boiler facility utilized clean filtered water from the 183-D filter building. The steam supply was used in a non-contact radial heating system. As a non-contact system the steam remained uncontaminated.

**Closure Info:**

Confirmatory sampling of the 100-D-96 french drains was performed on June 6 and 7, 2012. The sample results indicated that french drain FD-4 exceeded the regulatory limit for benzo(a)pyrene. FD-4 became 100-D-96:2, to be addressed separately.

The 100-D-96:1 subsite includes six french drains, two dry wells and the underlying soil. Two of the drain features (FD-6 and DW-1) were removed with process sewer pipeline remediation activities.

**The SubSite is Part Of:**

**Code:** 100-D-96

**Names:** 100-D-96; 100-D/DR Additional French Drains

**Code:** 100-D-96:2

**Names:** 100-D-96:2; FD-4; 100-D/DR Additional French Drains Group 2

**Type:** French Drain

**Status:** Inactive

**Description:** The subsite is a 0.6 meters (24 inches) diameter French Drain. It was designated FD-4. It was constructed of concrete, cobble filled, and at grade level. It is believed to have received steam condensate from the non-radioactive 183-D filter building.

**Location:** FD-4 is located west of the 1902-D Water tank at Washington State Plane coordinates E573403.86 N151775.94.
Steam was typically used at all facilities for heating purposes. The 184-D Power House boiler facility supplied high pressure steam to all buildings through an above grade pipeline system. The boiler facility utilized clean filtered water from the 183-D filter building. The steam supply was used in a non-contact radial heating system. As a non-contact system the steam remained uncontaminated.

The UST was a 500 gallon fuel oil tank which supplied fuel to the 184-DA Steam Generating Facility. The 184-DA Building was a metal building constructed about 1968 and was designed as a steam generating facility. The facility contained a steam generator, fuel oil storage tank [94,600 Liters (25,000 gallons)], fuel oil pump, deaerator, water softener, chemical treatment, fuel tank, steam separator, heater, diesel generator, liquid level gauges, and steam flow meter. The 500 gallon fuel oil tank was located near the southeast corner of the 184-DA Building. The equipment number was K1-7-1 the tank had a 2 inch fill connection and a 2 inch sounding connection. Within the floor of the 184-DA Building were three trenches that contained pipelines used to transport fuel oil and vent lines associated with the fuel oil tanks. In 1973, the building was assigned to Atlantic Richfield Hanford Company (ARHCO), it contained a package boiler which was used to provide steam heat for the occupied facilities in 100-D Area. In case of electrical power outage, the boiler also provided steam for turbine driven pumps used to provide fire and service water to the 100-D facilities. The facility was required to remain in service as long as the area was occupied. It is assumed that the tank was removed during the demolition of the 184-DA Building.

The site consists of twenty-one electrical substations and underlying soil. Each of the
substations were surrounded by a fence that contained transformers at or near ground level, set on concrete pads (p. 17, WHC-MR-0425). The waste site does not include transformers mounted on electrical poles or the sides of a building. The 153-D, substation adjacent to 107-D, was excluded because it was made of up three small pole mounted transformers.

The site has been divided into three subsites - 100-D-98:1 is two Active 152D Substations. 100-D-98:2 is eighteen Inactive substations located at 152D and 153D. Subsite 2 was evaluated and determined to require No Action. 100-D-98:3 is only the 153-D-5 substation. The Subsite 3 concrete slab and underlying soil were remediated and the subsite was reclassified to Interim Closed Out.

During the Orphan Sites Evaluation (OSE) no staining or evidence of a substation was observed at the mapped locations of the nine former substations. They each had a primary voltage of 13.8 kV and a secondary voltage ranging from 110 V to 230 kV. Each was an open, wooden pole structure surrounded by a picket fence and contained transformers at or near ground level, set on concrete pads. Excluded from the site were an additional six distribution substations known to have been associated with buildings 107-D, 108-D, 115-D, 183-D, 1717-D, and 1720-D. These six could not be located during the OSE field investigation. Each was constructed identical to secondary substations. All had a primary voltage of 2.4 kV, and a secondary voltage ranging from 110 V to 480 V. Information on the exact location of these substations is extremely limited. There was no physical evidence of transformer pads or staining on the ground near the suspect locations. It is assumed that the distribution substations were removed during demolition of the buildings.

Location: The substations are located throughout the 100-D/DR Area. Specific locations are defined in the subsite text.

Related Sites/Structures: The 151-D Primary Substation distributed 13.8 kV power to transformers located at the 181-D River Pump House, 182-D Head House, 183-D Filter House, 184-D Power House, 186-D Water Treatment Plant, 190-D Pump House, and 105-D Reactor, which in turn distributed power to associated facilities.

Process Description: The Midway Station fed 230 kV power to the 31,250 kVA transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D Area. The substations had transformers that reduced the voltage to a value suitable for the local distribution system or facility. The transformers contained oil that cooled and insulated the windings. Polychlorinated biphenyls were once widely used in transformer oil due to their heat resistant properties. The transformers were filled with oil using hoses from oil trucks.

The Midway Station, located near the Vernita Bridge, fed 230 kV power to the 31,250 kVA transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D Area. Circuit breakers were also in service to support the switchyard operations. The 151-D Switch House is essentially a one-story building, having a sub-level cable pit equipped with a sump pump. All duct lines originated/terminated at the Switch House. The cable pit is a completely enclosed reinforced concrete pit with floor slab, varying from 0.30 to 0.45 meters (1 to 1.5 feet) in thickness, and with 0.30 meters (1 foot) thick walls. Switchgear is located on the main floor directly above the cable pit. The overall dimensions of the Switch House are 25 meters by 9.3 meters by 8.7 meters (83 feet by 30.5 feet by 28.5 feet). Beneath the switch yard, and throughout the D/DR area there is an extensive subsurface "highway" of electrical conduits, which may still contain lead and/or asbestos wrapped cable inside "Korduct" lining, all surrounded by reinforced concrete. Korduct is believed to be a transite-like material. These concrete monoliths are up to 1.8 meters by 1.8 meters (6 feet wide by 6 feet deep) and up to 152 meters (500 feet) long per segment, and are buried 0.9-1.5 meters (3-5 feet) below the surface. There are at least 20 major segments in the D/DR area. The segments are connected by...
mammoth concrete manholes, 2.4 meters by 2.4 meters by 2.4 meters (8 feet by 8 feet by 8 feet high). Each monolith contains up to 2 dozen conduits, each of which may contain 0.6-12.7 centimeters (2-5 inches) electrical cables.

PCB-containing oil was transferred, as needed, from a rail tanker on the railroad spur through over ground hoses and piping to transformers and oil circuit breakers in the yard. The smaller transformers at the secondary and distribution substations were also filled via over ground hoses from oil trucks.

**Waste Type:** Steam Condensate

**Waste Description:** The two active substations (C4S17 and 152-D1-D) will be evaluated upon termination of operations. There was no documented waste information found during the OSE historical evaluation. There were no contaminants of potential concern assigned to the sites discovered during historical evaluation.

**Type:** Electrical Substation

**Status:** Active

**Description:** This site consists of two active (C4-S17 and 152-D1-D) electrical substations and underlying soil.

**Location:** The C4-S17 Substation is located approximately 990 meters (3245 ft) west of the 105-D Reactor Building, adjacent to the south wall of the 181-D River Pump House (H-1-5100, Sheet 3, H-1-26611). The coordinates for the pads at the substation are N151725.34, E572791.61 and N151722.45 E572788.74.

The 152-D1-D Substation is located immediately east of the 182-D Reservoir and Pump House, approximately 565 meters (1850 ft) west of the 105-D Reactor Building (H-1-222). The coordinates for the substation are N151563.88, E573207.86.

**Process Description:** The Midway Station fed 230 kV power to the 31,250 KVA transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D Area. The substations had transformers that reduced the voltage to a value suitable for the local distribution system or facility. The transformers contained oil that cooled and insulated the windings. Polychlorinated biphenyls were once widely used in transformer oil due to their heat resistant properties. The transformers were filled with oil using hoses from oil trucks.

The C4-S17 Substation (152-E2-D) was constructed in 1957 and provided electricity to the 181-D Building. It contained two large transformers as well as additional electrical equipment. The transformers were connected to the 181-D Building switchgear through underground conduits.
It was a 13,800/2400 volt, 3750/4687 kV substation that was added to support the additional demand at the 181-D Building after the increase in pumping capacity (p. 29, HW-24800-104 and p. 31, HW-30401).

The 152-D1-D Substation was constructed in 1944 and provided electricity to the 182-D Building (H-1-26569). It was an open wooden pole structure surrounded by a picket fence and was constructed with one transformer set on a concrete pad (pp. 653, 716 and 717, HAN-10970, Volume 3). The transformer had a capacity of 3000 kV with a primary voltage of 13.8 kV and a secondary voltage of 2.3 kV (W-72007).

Description: This waste site has been evaluated and determined to require No Action. It consists of 19 inactive electrical substations (secondary and distribution) and underlying soil. Three substations were relocated. The original and the new locations are considered part of this waste site, making a total of 22 substation locations.

Most were an open, wooden pole structure surrounded by a picket fence and contained transformers at or near ground level, set on concrete pads. All substations and all but one concrete pads were removed and demolished with the associated building. Following excavations of these sites, clean soil, non-hazardous debris, and potential asbestos containing material (ACM) were backfilled. This potential ACM would have been buried deeper than 6 inches and covered with compacted non-asbestos containing material.

Substations Associated with 105-D - locations #9a and #9b are within the boundaries of the 118-D-6:4 and 118-D-6:5 waste sites, respectively.

Substations Associated with 108-D - location #10 is located a few feet from the 100-D-73 (108-D pump house) excavation. The 108-D Building was demolished in 1978 and the rubble was disposed of in the 126-D-2 coal pit, inert landfill. It is concluded that all concrete and possible contamination have been removed.

Substations Associated with 115-D - location #11 is located within the boundary of the 132-D-1 waste site.

Substations Associated with 183-D - #12 transformer pad is still visible. It is anticipated that this concrete slab and surrounding soil will be deferred to the Deactivation, Decontamination, Decommissioning, and Demolition (D4) Closure Project and the demolition of the 183-D Building.

Substations Associated with 184-D - The location #1 concrete structure was previously demolished to at least 1 meters (3 ft) below ground surface (bgs). All material was handled, packaged, and transported for disposal in the Hanford central landfill in 1988.

Substations Associated with 185-D - location #3 is located within the boundary of the 100-D-
31:9 waste site.

Substations Associated with 186-D - location #2 was part of the 186-D Building. The 186-D foundation, adjacent basins, and pits were demolished in 1979. The basin and pits were filled and the site leveled to blend with the adjacent area. The structural steel was salvaged and sold as excess material.

Substations Associated with 189-D - location #19 is clean with no visible staining. The 189-D Building would not have been demolished if any contamination or hazardous material was present in the area.

Substations Associated with 190-D - location #4 is within the 132-D-1 waste site boundary. Substation locations #6 and #7 are within the 100-D-31:4 waste site boundary. Associated substation locations #5, #8, and #15 are currently clean with no visible staining. The 190-D facility was demolished in 1995. The 190-D Building would not have been demolished if any contamination or hazardous material was present in the area.

Substations Associated with 1717-D - location #13 was removed with the 1717-D Building in 1980. The 1717-D Building and its concrete foundation were broken up, buried, and the site filled to blend in with the adjacent area. A review of historical and recent photographs shows no evidence of contaminated soil.

Substations Associated with 1720-D - location #14 was removed when the 1720-D Building was demolished in 1966.

Substations Associated with 105-DR - location #16 is currently clean with no visible staining. The main transformer was property of the Hanford Utility Group, which handled its disposal.

Substations Associated with 190-DR - locations #17a, #17b, #18a, and #18b are located within the boundary of the 100-D-28:1 waste site.

**Process Description:** The Midway Station fed 230 kV power to the 31,250 kV transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D Area. The substations had transformers that reduced the voltage to a value suitable for the local distribution system or facility. The transformers contained oil that cooled and insulated the windings. Polychlorinated biphenyls were once widely used in transformer oil due to their heat resistant properties. The transformers were filled with oil using hoses from oil trucks.

**Closure Info:** A site-specific sample design for the 100-D-98:2 subsite was developed using information provided from the OSE process, site walkdowns, and historical documentation.

The concrete transformer pad at location #12 still remains. Because of the proximity from the location #12 transformer pad to the 183-D Building was proposed that this pad be removed during demolition of the 183-D Building.

All the other concrete transformer pads and contaminated soils have been removed and no evidence of stained soil was reported. Eleven of the 22 substation locations (#3, #4, #6, #7, #9a, #9b, #11, #17a, #17b, #18a, and #18b) are within other waste site boundaries. These substation locations were either part of the associated waste site remediation during cleanup activities or beneath a staging pile area. Of the remaining 10 substation locations (#1, #2, #5, #8, #10, #13, #14, #15, #16, and #19), five were chosen for test pits. The five chosen substation locations had the least amount of historical documentation and the oldest transformers associated with them. These five substation locations include #1, #2, #5, #13, and #14.
One test pit was dug at each of the chosen locations to a depth of 10 feet.

**The SubSite is Part Of:**
**Code:** 100-D-98

<td>Description:</td>
<td>The subsite has been remediated and reclassified to Interim Closed Out. It was concrete slab of the former 153-D-5 electrical transformer. The slab was identified as a stewardship feature during the 100-D Area Orphan Site Evaluation (OSR-2006-0001).</td>
</tr>
<tr>
<td>Location:</td>
<td>The 153-D-5 Substation was located adjacent to the north side of the 183-D building, approximately 515 meters (1695 ft) west of the 105-D Reactor Building. The coordinates for the substation were N151625.10 E573254.7.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The 100-D-98:3 slab was located adjacent to the 183-D building. During the demolition of the 183-D Building in 2013, the 100-D-98:3 subsite concrete slab and underlying soil were excavated to a depth of 1.5 meters (5 ft) below ground surface. The material was disposed at the Environmental Restoration Disposal Facility. No soil staining was observed on the surface or during the removal of the concrete slab and underlying soil. Historical and visual documentation found no sign of stained soil within or around the substations. Confirmatory samples from the 183-D demolition were undetected or detected below Remedial Action Goals. The area was excavated to a depth greater than the concrete slab. No soil staining was identified before or during the excavation. The selected action involved (1) evaluating the site using available process information, (2) removing the concrete slab and underlying soil, and (3) proposing the site for reclassification to Interim Closed Out.</td>

During construction of the Hanford Engineer Works, temporary sewer lines and septic tanks were installed for the disposal of non-radioactive liquid sanitary sewage waste.

Waste Type: Water

Transfer of non-radioactive liquid sanitary sewage waste.

Process Description:

Code: 100-D-101
Classification: Accepted

Recategorization: Interim No Action (6/11/2013)

Names: 100-D-101; 108-D Acid Pit and Sump; 108-D Car Spot; 108-D Sodium Silicate Sump; 108-D Storage Tanks; Miscellaneous Structures

Type: Sump
Start Date:

Status: Inactive
End Date:

Description: The site has been evaluated and determined to require No Action. It consisted of two sulfuric acid storage tanks, two sodium silicate storage tanks, an acid neutralization pit and sump, a sodium silicate sump, two sets of pumps, and a railroad tank car spot. All of the components were located west of the 108-D Building.

Location: The site was located west of the 108-D building.

Related Sites/Structures: Waste sites in proximity to the 100-D-101 waste site include the 100-D-73, 100-D-76, 100-D-31:3, and 100-D-56:1 waste sites. The 100-D-73 waste site is the 108-D Building which housed the Sodium Dichromate System. The 100-D-76, former 116-D-3 waste site is a crib associated with the 108-D Building. The remedial excavation for these two waste sites is on the south and east sides of the 100-D-101 site. The 100-D-31:3, 105-D sewer pipelines subsite is a sewer pipeline that serviced the 105-D Building. The 100-D-56:1, north portion of 100-D-56 subsite consists of pipelines that conveyed water treatment chemical solutions from the 108-D Building to the 185???D Building. The 100-D-31:3 and 100-D-56:1 remedial excavations border the 100-D-101 waste site on the west.

Process Description:

Two elevated sulfuric acid storage tanks were located in the site footprint. Each measured 2.7 by 11.0 meters (9 by 36 ft) and was oriented horizontally, at a height of approximately 5 m off the ground (HAN-10970, HW-75014). A set of wooden stairs allowed workers to reach the top of the tanks (HW-74549). To fill the tanks, two self-priming unloading pumps were situated nearby in a protective shed. The capacity of each pump was 50 gpm and they were run by 440 V electric motors. These storage tanks were removed sometime prior to 1952. The two sulfuric acid tanks were located west of the 108-D building at (E573738.62886, N151772.25873) and (E573738.70631, N151768.65750). The separation between the two tanks was .9 meter (3 ft). The pumps for sulfuric acid were located at (E573744.09046, N151775.85017), off the northeast corner of the tanks.

The two chemicals stored near 108-D were sulfuric acid and sodium silicate. Each chemical had its own set of two large storage tanks. Additionally, each chemical had a set of two pumps for unloading solution out of railroad tank cars at the car spot. An acid neutralization pit/sump was located underneath the acid storage tanks, while another sump was located near the sodium silicate tanks. A car spot and railroad line passed through the site for delivering the solutions.

The sulfuric acid (68-70%), brought in by railroad tank cars, was delivered to the storage tanks. From the storage tanks, a gravity-flow line supplied the 105-D building with acid for controlling the pH of process water. In addition, equipment was set up in the 108-D building for diluting the sulfuric acid. Pumps with suction piping were used to transport acid from the tanks into the 108-D building. Historic photographs indicate that the sulfuric acid tanks were
The 108-D Acid Neutralization Pit and Sump was located underground beneath the sulfuric acid storage tanks on the west side of the 108-D building. The pit was covered with a removable 1.4 meters (4 ft, 8 in) wooden plank. A 10.1 cm (4 in) overflow pipe was attached to the south end of the pit, which connected to the water treatment process sewer. The northern portion of the pit was separated from the rest by a brick barrier and was used as a sump. Two 5.1 cm (2 in) inlet pipes inside an underground wooden box structure brought acidic solution into the sump. In addition, there were two 10.1 cm (4 in) drain pipes extending from the west ends of the acid tanks, with another 10.1 cm (4 in) drain line originating from the pump shed. Another overflow drain line connected from the center of the tanks. All of these overflow lines connected to the sump portion of the pit. All piping was above ground, except the 5.1 cm (2 in) inlet lines in the wooden box and the sewer drain line. The 108-D Acid Pit was located to the west of the 108-D building, directly underneath the elevated sulfuric acid tanks, at coordinates (E573736.72, N151770.62). It is also in the sidewall of 100-D-31.

A 108-D Acid Neutralization Pit and Sump was located underground beneath the sulfuric acid storage tanks on the west side of the 108-D Building. The pit was covered with a removable 1.4-m (4.6-ft) wooden plank. The Acid Pit consisted of two layers of acid-proof brick. The bottom layer was laid in asphalt, while the top layer was laid in Tegal Vitrabond. Joints were sealed with Vitrabond. The acid pit (excluding the sump portion) had an additional third layer, which was coated with 10.1 cm (4 in) of asphalt (HW-74807). The acid pit was used to safely neutralize acidic solutions. In particular, piping was in place to transfer acid that overflowed or leaked out of the tanks and pumps during the unloading process. Also, by using valves located both near the pumps and near the acid pit, acid could be released directly into the pit. According to drawing HW-74807, only sulfuric acid was supposed to be used in the acid pit.

Two elevated sodium silicate tanks were located just north of the sulfuric acid tanks. Each of these measured 6.1 m (20 ft) in diameter and 4.6 m (15 ft) in height, and had an internal steam heating coil system (HAN-10970, SPEC HW-2036). The tanks were removed prior to 1970 and most of the soil underneath them falls within the cleanup footprint for 100-D-56. According to HAN-10970, the pumps used for unloading sodium silicate from the car spot were identical to those used for the sulfuric acid (50 gpm flow rate). However, SPEC-HW-2036 states instead that there were two 100 gpm pumps. These pumps were also used to transfer sodium silicate into the 108-D building and were housed in a wooden shed with a radiator (SPEC-HW-2036, HW-74550). The tanks were located to the west of the 108-D building and north of the sulfuric acid tanks at (E573737.28065, N151780.51975) and (E573737.28309, N151787.92000). The two tanks were separated by 1.5 meters (5 ft). The sodium silicate pumps were located at (E573744.18968, N151787.46223), east of the northernmost storage tank. Both tanks are partially located in the sidewall of 100-D-56.

Sodium silicate was received in railroad tank cars and moved to the two storage tanks by using the nearby pumps. Those same pumps were then used to transfer the silicate into the 108-D building, where it was diluted with process water. This weaker solution was later transported to 185-D for process water treatment.

Sodium silicate was received in railroad tank cars and moved to the two storage tanks by using the nearby pumps. Those same pumps were then used to transfer the silicate into the 108-D Building, where it was diluted with process water. This weaker solution was later transported to the 185-D Building for process water treatment.

The 108-D Sodium Silicate Sump was built as part of the Alum-Activated Silica Water Treatment Facilities project in 1954. The purpose of the sump was to address the issue of potential spills during the unloading and transfer of sodium silicate solution. However, there is no indication of any drains extending to the sump from the sodium silicate tanks or pumps, so it
is not clear how the sump addressed the issue. The sump was located just north of the sodium silicate pumps and drained to the 100-D-31:3 process sewer via a 15 cm (6-in.) vitrified clay pipe. The sump was covered by a steel grating.

The 108-D Sodium Silicate Sump was just north of the sodium silicate pumps, at (E573743.77016, N151790.73936) between the sulfuric acid tanks and the sodium silicate tanks, and was used for unloading liquids. It included a platform for unloading chemicals, stairs to reach the top of railroad tank cars, flexible hoses to unload liquids, and a safety shower (HW-75250).

The 108-D Car Spot was used to unload liquid chemicals for the 108-D building and the nearby storage tanks. Using flexible connecting hoses, sodium silicate solution and sulfuric acid were pumped out of railcars and into the storage tanks. A second car spot, 100-D-73, was used to unload solids and move them into the 108-D building. Among the chemicals transported this way was sodium dichromate.

Waste Type: Animal Waste

Waste Description: Site contaminants of potential concern include mercury, lead, sodium silicate, and sodium dichromate. It is possible that contaminants leaked into the soil during the lifetime of the sulfuric acid storage tanks and the associated components, particularly prior to 1954 when there was no sump. Resulting in potentially high concentrations of heavy metals such as mercury and lead. In addition, during the process of filling the tanks or pumping it into the 108-D building, acid may have spilled into the soil elsewhere in the site footprint. Near the southern portion of the site boundary, sodium dichromate may have been released as it was being unloaded in the nearby car spot, which is included in the adjacent waste site 100-D-73.

Closure Info: Confirmatory sampling was performed in three test pits and two test trenches on May 31, June 4 and 5, 2012, and February 27, 2013.

Test Pit 1 (TP1) was excavated at the location of the neutralization pit. All of the piping connecting to the neutralization pit and sump, including the acid neutralization pit was removed with the 100-D-31:3 excavation. The pit structure had been removed during remediation of the adjacent 100-D-31:3 waste site, leaving the TP1 sample location on the side slope of the open excavation. In order to reach the target sample depth of 3 meters (10 ft) below the original grade, the side slope was excavated an additional 0.6 to 0.9 meters (2 to 3 ft) below the existing grade. Wood, brick, and concrete debris were present in the side slope. Yellow-brown stains were seen at sulfuric acid unloading and processing facilities and are characteristic of stains seen at sulfuric acid unloading and processing facilities elsewhere at the Hanford Site. The amount of staining suggested significant anomalous material was intermixed with the soil. The excavation was backfilled.

Test Pit 2 (TP2) was excavated at the suspected location of a silica pump. No structure was found. The excavation proceeded through clean fill material to an approximate depth of 2.4 meters (8 ft), where a few rotten boards were discovered. Below this level was black, gravelly sand that was considered to be undisturbed native soil. A sample (J1PPM8) was collected of this soil. The excavation was backfilled.

Test Pit 3 (TP3) was excavated to a depth of 0.9 meters (3 ft) below ground surface (bgs). No debris was found. A small amount of stained soil was observed. Since the staining was minimal and consistent with that sampled at TP1, no additional samples of the anomalous material were collected. A sample (J1PPM7) was collected of the soil from the bottom of the excavation and the hole was backfilled.

Test Trench 1 (TT1) was excavated in a former concrete pipe trench. The bottom and side walls of the trench were found largely intact. There was no piping or other debris in the soil material
that filled the trench. A sample (J1PPN6) was collected of the trench contents (fill material) near the west end. The excavation proceeded to the east inside the trench. Towards the center of the trench, the bottom was up to 1.2 meters (4 ft) bgs. The lower approximately 0.3 m (1 ft) of material in the trench was discolored from the fill material above it. The deeper soil appeared darker, possibly due to a higher organic content. White crystalline material was also mixed with this anomalously colored soil. Samples (J1PRP1 and J1PPT1) were collected of this anomalously colored soil. The excavation proceeded to the eastern end of the trench. A sample (J1PPN7) was collected of the soil fill near the bottom of the trench at the east end. The trench was then backfilled. The confirmatory work instruction called for excavating under the concrete trench and collecting three discrete samples from that location. However, the backhoe was unable to break through the bottom of the concrete trench. The physical constraints of the site did not allow for use of larger equipment. Therefore, a single pothole was excavated outside the trench to access the underlying soil. The pothole was excavated near the center of the north side of the trench to a depth of 2.1 meters (7 ft) bgs. The material appeared to be fill with a small amount of concrete debris and short conduit sections. A sample (J1PPN8) was collected of the soil from the bottom of the pothole. The pothole was backfilled.

Following a review of 100-D-101 waste site physical and procedural constraints and in consultation with Washington State Department of Ecology, it was determined that the two soil samples beneath the concrete trench could be obtained via access through adjacent excavations (100-D-31:3 to the west and 100-D-73/100-D-76 to the east). The samples could be collected by hand means, with shovel excavations from the east and west ends of the trench.

Sampling of the 100-D-101 waste site was resumed on February 27, 2013, when shovel excavations were made to access soil underlying the concrete trench that is located between the former sodium silicate tanks. Two soil samples were collected from the west (J1RFV0) and east (J1RFV1) end of the concrete trench, approximately 2.7 meters (9 ft) bgs, and 1.5-2 ft below the concrete trench.

Test Trench 2 (TT2) was excavated inside an abandoned railroad bed. The railroad ties were still in place at the surface when the excavation was started. These ties were removed and stacked near the excavation. The excavation then proceeded to an approximate depth of 0.3 meter (1 ft). A sample (J1PPP1) was collected from the bottom of the trench at the south end. A sample (J1PPP2) and duplicate (J1PPP3) were collected from the bottom near the north end. The site was left as a shallow excavation, roped, and posted as an exclusion zone pending analytical results.

<td>Description</td>
<td>The waste site was evaluated and determined to require No Action. The 100-D-102 waste site was identified as a dark area compared to the surrounding terrain in a 1962 aerial photograph. The dark area was suspected to be effluent that leaked to the ground outside of the 107-DR Basin. The feature on the photograph was an irregular shaped, dark feature visible in the aerial photograph (10974-PHOTO) adjacent to 116-DR-9. The surface of the site has been re-graded many times and is no longer discernible from the surrounding area.</td>
</tr>
<tr>
<td>Location</td>
<td>The site is located immediately to the southwest corner of 107-DR retention basin.</td>
</tr>
</tbody>
</table>
| Release       | The first known inventory of radioactive releases to the ground in the 100-D/DR area is contained in the January 29, 1953 report titled "Unconfined Underground Radioactive Waste
The 107-DR retention basin (116-DR-9) received cooling water effluent from the 105-DR Reactor, and reactor floor wastes from the 1608-DR Waste Water Pump House. The cooling water was held in the basin for as long as operating time would permit, allowing the water to thermally cool and for short-lived radionuclides to decay. The water was then discharged to the center of the river via the outfall structures and associated pipelines. The basin experienced several unplanned liquid releases during its lifetime.

Another inventory was made in October 1954 (HW-33305). The report listed those facilities that used for disposal of radioactive liquid wastes. It did not contain unplanned radioactive releases (as was done previously in HW-27337). The report listed just two locations (100-D-29 and 116-DR-1&2) near the 107-D/DR retention basins.

A comprehensive listing of underground radioactive contamination including planned and unplanned releases was issued again in November 1956 (HW-46715). It contained all of the waste sites mentioned previously but did not add any new ones in the vicinity of the 107-D/DR retention basins.

Hanford drawing (H-1-4046) which shows the underground radioactive waste sites in the 100-D/DR Area was revised in June 1964. It shows many (but not all) of the waste sites previously discussed. The drawing depicts two effluent leaks south of 107-DR. One of these is consistent with the location of 100-D-29. The shape and location was used for the remediation design of the 100-D-29 waste site. The other leak identified on the drawing did not correspond to any of the previously reported releases. This location was subsequently assigned to the UPR-100-D-5 waste site.

A report was issued in November 1967, following the deactivation of the 105-D/DR reactors (DUN-3063). This report mentioned the two retention basins and the sludge buried from 107-DR (100-D-22). It did not reveal any new information related to releases near the 107-D/DR retention basins.

The related sites/structures located near and associated with the retention basins include the following WIDS site codes:

- 100-D-4, Sludge Trench #5, 100-D-18, Sludge Trench #4, 100-D-19, Sludge Trench #6, 100-D-20, Sludge Trench #3, 100-D-21, Sludge Trench #2, 100-D-22, Sludge Trench #1, 100-D-29, Effluent Leak #2, 100-D-48, 100-D Reactor Cooling Water Effluent Underground Pipelines, 100-D-49, 100-D-63, 100-DR Reactor Cooling Water Effluent Underground Pipelines, 116-D-7, 107-D Retention Basin, 116-DR-1&2, 107-DR Liquid Waste Disposal Trench #1, 116-DR-9, 107-DR Retention Basin, UPR-100-D-2, Effluent Line Leak #1, UPR-100-D-3, Effluent Line Leak #3, UPR-100-D-4, 107-D Basin Leaks, UPR-100-D-5, Effluent Line Leak #4 and multiple pipeline sites.

The 107-DR retention basin (116-DR-9) received cooling water effluent from the 105-DR Reactor, and reactor floor wastes from the 1608-DR Waste Water Pump House. The cooling water was held in the basin for as long as operating time would permit, allowing the water to thermally cool and for short-lived radionuclides to decay. The water was then discharged to the center of the river via the outfall structures and associated pipelines. The basin experienced several unplanned liquid releases during its lifetime.

The irregular shaped feature visible in the 1962 aerial photograph (10974-PHOTO) is suspected to be an effluent leak. There are several planned and unplanned releases of cooling water effluent reported near the 107-D and 107-DR retention basins. A number of reports published during the operation of the 100-D/DR Area detail the releases. Previously identified releases...
have been documented as 100-D-4, Sludge Trench #5, 100-D-18, Sludge Trench #4, 100-D-19, Sludge Trench #6, 100-D-20, Sludge Trench #3, 100-D-21, Sludge Trench #2, 100-D-22, Sludge Trench #1, 100-D-29, Effluent Leak #2, 100-D-48, 100-D Reactor Cooling Water Effluent Underground Pipelines, 100-D-49, 100-DR Reactor Cooling Water Effluent Underground Pipelines, 116-D-7, 107-D Retention Basin, 116-DR-1&2, 107-DR Liquid Waste Disposal Trench #1, 116-DR-9, 107-DR Retention Basin, UPR-100-D-2, Effluent Line Leak #1, UPR-100-D-3, Effluent Line Leak #3, UPR-100-D-4, 107-D Basin Leaks, UPR-100-D-5, Effluent Line Leak #4 waste sites. The footprint of the waste site 100-D-102 falls outside the footprints of all the other waste sites previously identified. The original drawings which were used to define the boundary of the waste sites were imprecise. It is possible that the aerial photograph shows the actual footprint of a waste site that was previously identified and located using the less precise historical drawings.

Waste Type: Equipment

Waste Description: Contaminants of potential concern (COPCs) include: Co-60, Cs-134, Cs-137, Eu-152, Eu-154, Eu-155, H-3, Pu-238, Pu-239, Pu-241, Sr-90, U-238, Am-241, Sr-90, arsenic, chromium, lead, and zinc and should be the same as those for the 107-D/DR Retention Basins. The waste is contaminated soil from an unplanned release of process effluent.

Closure Info: Samples were collected from five test pits on May 30 and 31, 2012, and June 5, 2012. Test pits 1 and 2 were 4.6 meters (15 feet) deep. Test Pit 3 was 1.2 meters (4 feet) deep. Test Pit 4 was 1.8 meters (6 feet) deep. Test Pit 5 was 2 meters (7 feet) deep. Samples were collected from the backhoe bucket of material brought up from the bottom of the excavations. No elevated radiological readings were detected within the pits using field instruments. The excavations were backfilled.

Code: 100-D-103 Classification: Accepted
Names: 100-D-103; Suspected Trench and French Drain from 116-D-8 Cask Pad
Type: French Drain Reclassification: Interim No Action (7/18/2013)
Status: Inactive Start Date: End Date:
Description: The waste site was evaluated and determined to require No Action. The waste site was a suspect feature resembling a trench found on a December 1949 aerial photograph. It appeared to extend south from the 116-D-8 Cask Pad.
Location: The suspect feature is located at approximately E573698/N151250.

Closure Info: The December 1993 geophysical survey information was not helpful in identifying the location of the french drain, possibly due to the probable vitrified clay material used for construction of the french drain or due to the fact that french drain may have been removed from the identified location during the decommissioning process of the temporary airlock building or construction of the 100-D-50:2 pipeline tunnels.

Confirmatory samples of the 100-D-103 waste site were collected on February 22, 2013. A test pit was excavated at the suspected french drain location to investigate the presence of a french drain and to collect appropriate samples. The excavation extended to 3 meters (10 ft) below ground surface (bgs). No french drain or drain components were found. No pipelines or other debris was excavated at this test pit location. The excavation was backfilled with the excavated materials from the test pit.

A test trench was excavated at the location across the suspected trench location. The sloughing of the soils and unstable walls precluded the excavation from extending deeper than 3.7 to 4...
meters (12 to 13 ft) bgs. No pipelines, debris, or other anomalies were found within the test trench excavation. Due to the length of the trench, three samples were collected across the test trench floor, at 3.7 to 4 meters (12 to 13 ft) bgs. The excavation was backfilled with the excavated materials from the test trench.

No radioactivity was detected. Confirmatory sample results were evaluated and supported the No Action decision.

</tbody>
</table>
Closure Info: The 116-D-1A and 116-D-1B Storage Basin Trenches received contaminated water and sludge from the 118-D-6 Fuel Storage Basin. The 100-D-46 Burial Ground received solid waste and construction debris from modifications made to 105-D after 1967 and was co-located with the trenches. The three waste sites were remediated together, with the documentation presented in the same Cleanup Verification Package (CVP-2000-00010). The document referred to the collective three waste sites as the 116-D-1A/116-D-1B site.

The selected remedial action for the 116-D-1A/116-D-1B sites included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, RAGs were established to identify radionuclide and nonradionuclide contaminants of concern (COCs) and contaminants of potential concern (COPCs). Waste site COCs and COPCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22).

Remedial action at the 116-D-1A/116-D-1B site began on October 21, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 11, 2000, the excavation reached the design limit at El. 138.4 m (454 ft).

At the completion of the remedial action, the total excavation was approximately 2,648 square meters (28,470 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 10,987 metric tons (12,111 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

---

**Code:** 116-D-2  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (10/23/2000)  
**Names:** 116-D-2; 116-D-2A; 105-D Pluto Crib  
**Type:** Crib  
**Status:** Inactive  
**Start Date:** 1/1/1950  
**End Date:** 1/1/1956  
**Description:** This site has been remediated and Interim Closed Out. The crib was a 3 meter (10 feet) by 3 meter (10 feet) crib, 3 meters (10 feet) deep. The unit had been shored with railroad ties and filled with sand. The upper portion of the structure was above grade with a hatch opening that allowed a rubber hose to be inserted and discharge liquid to the crib.  
**Location:** The 116-D-2 site was located approximately 920 meters (3,018 feet) from the Columbia River and about 30.5 meters (100 feet) east of the 115-D/DR Gas Treatment Facility (132-D-1).  
**Process Description:** The 116-D-2 site was used to isolate coolant flow from process tubes containing ruptured fuel elements until the ruptured fuel could be discharged. A pluto valve was installed on the downstream end of the process tube, connecting the tube to a rubber hose. The coolant then flowed through the rubber hose into the crib. An estimated 4,000 liters (1,000 gallons) of liquid wastes were disposed at the 116-D-2 site, and the known hazardous chemical inventory included an estimated 0.004 kilograms (0.009 pounds) of sodium dichromate.  
**Waste Type:** Soil  
**Waste Description:** The site received effluent water from isolated tubes containing ruptured fuel elements.  
**Closure Info:** Remedial action at the 116-D-2 site began on November 1, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying
contaminated soil which were disposed at ERDF. On November 2, 1999, the excavation reached the design limit at El. 137.9 meters (452.4 feet).

At the completion of remedial action, the excavation was approximately 217.9 square meters (2,331.5 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 623.2 metric tons (687 tons) of material from the site were disposed of at ERDF. Cleanup verification sampling was conducted on January 3, 2000. The excavation will be backfilled in the near future with appropriate materials to the reference grade of El. 142.5 meters (467.5 feet).

Reclassification:

116-D-3; 108-D Crib #1

Crib

Inactive

Based on excavations, the review of site drawings, and ground penetrating radar, it has been determined that the 116-D-3 Crib is a duplicate number for site 116-D-4. Therefore, No Action was required. Historical research in 2008 found this site to be synonymous with 100-D-76.

This crib is actually a duplicate number for the 116-D-4 Crib.

See sitecodes 100-D-76 and 116-D-4 for additional information.

Crib 116-D-4/116-D-3 received low-level fission product wastes in contaminated wash water from the 108-D Shipping Cask Handling Facility.

Sanitary Sewage

The site (a duplicate number for the 116-D-4 Crib) is a crib containing contaminated soil and rock. The site received low-level fission product wastes in contaminated wash water from the 108-D Shipping Cask Handling Facility.

The 116-D-3 Crib is actually the same site as the 116-D-4 Crib. Remediation activities at 116-D-4 took place on October 20-21, 1999. Reference drawing H-1-3091 indicates that the 116-D-3 is co-located with 116-D-4 at coordinates N151757, E573832. The possibility of 116-D-3 being a separate site has been investigated through excavation at all historically reported locations. Initial excavation at the contract design coordinates (N151739, E573774) occurred on 10/20/99; however, the excavation showed no engineered structure or contamination (using field instruments). Excavation activities occurred on 11/4/99 at location coordinates N151757, E573768, which is also referenced as a possible location for 116-D-3. No evidence of a structure or contamination (using field instruments) was found. Excavation also occurred on 12/30/99 at coordinates N151725, E573807 and N151731, E573832. No structure or contamination (using field instruments) were found.

Reclassification form 2002-060 form amends a previous reclassification of this site. Originally the site was reclassified as "Rejected" in April 2000. Approval of form 2002-060 reclassified the site to "No Action" to align with remaining sites ROD.
Status: Inactive  
End Date: 1/1/1967  

**Description:** This waste site has been remediated and Interim Closed Out. The site was a 2.4 by 2.4-meter (8 by 8-foot) crib, 5 meters (16 feet) deep. This crib is often referred to as a french drain.

**Location:** The site is located 65.45 meters (281 feet) directly east of the demolished 108-D Shipping Cask Handling Facility. This location is the southeast corner of the 108-D Building and east of the 108-D wash pad.

**Related Sites/Structures:** The site is related to the 108-D Shipping Cask Handling Facility and to the maintenance shops and technical laboratory of that facility. 116-D-3 was determined to be a duplicate entry of 116-D-4.

**Process Description:** The site received low-level fission product wastes in contaminated wash water from the 108-D Shipping Cask Handling Facility maintenance shops and technical laboratory.

**Waste Type:** Equipment

**Waste Description:** The site was a crib containing contaminated soil and rock. The site received low-level fission product wastes from contaminated maintenance shops in the 108 buildings. Assuming that H-1-3091 represents the correct information, the crib received wash water from the 108-D Shipping Cask Handling Facility.

**Closure Info:** Remedial action began on October 20, 1999. Excavation involved removing the overburden, any engineered structure and the contaminated soil. Based on field screening, excavated materials identified as potentially clean were placed in stockpiles for potential use as backfill. On October, 21, 1999, the excavation reached the design limit at El. 140.7 meters (462 feet).

At the completion of remedial action, the excavation was approximately 137.8 square meters (1,482 square feet) in area with a maximum depth of approximately 2.8 meters (9 feet). The backfill reference grade is El. 143.5 m (471 feet). Backfill will be taken from the clean stockpile and/or from other sources of clean material surveyed in accordance with the SAP and that are appropriate for use as backfill.

---

**Code:** 116-D-5  
**Classification:** Accepted

**Names:** 116-D-5; 1904-D Outfall Structure  
**Reclassification:** Interim Closed Out (8/10/2011)

**Type:** Outfall  
**Start Date:** 1/1/1944  
**End Date:** 1/1/1975

**Description:** The outfall structure has been remediated and Interim Closed Out. It had been an open, reinforced, compartmentalized concrete outfall structure. The outfall structure was demolished, caved into itself and backfilled with soil in 1998. In the spring of 2009, the engineered structure, contaminated debris and soil was removed and disposed in the ERDF facility.

**Location:** The site is located at the top of river bank, northwest of 116-D-7 (107-D Retention Basin).

**Related Sites/Structures:** The site is associated with the 107-D Retention Basin (116-D-7), the 107-DR Retention Basin (116-D-9), 100D Reactor Cooling Water Effluent Lines (100-D-48), the 100DR Reactor Cooling Water Effluent Lines (100-D-49), the 100D River Effluent Lines (100-D-60) and Flumes (100-D-66).

**Process Description:** Process sewer wastes, and reactor cooling water collected and temporarily stored in the 116-D-7 and 116-DR-9 retention basins, were pumped to the river via the 116-D-5 outfall structure and associated 100-D-60 river effluent pipelines. The reactor cooling water discharged into the upper chamber of the concrete outfall structure, flowed through a bar grillwork and fell about 6.10 meters (20 feet) to the lower chamber of the outfall structure. Then it overflowed from the
lower chamber into the discharge pipe to the river. The discharge pipe to the river (100-D-60) was connected to the side wall of the lower chamber of the outfall structure. The inlet to the discharge pipe from the outfall structure was about 0.10 meters (4 inches) above the floor of the lower chamber. The Outfall Structure was open to the atmosphere which allowed rain and snow to collect in the bottom 4 inches of the lower chamber. Prior to the structure being demolished and caved into itself, the Outfall Structure was enclosed with a chain-link security fence and an aviary exclusion mesh cover.

**Waste Type:** Oil
**Waste Description:** This unit received reactor coolant water from the 107-D & 107-DR Retention Basins and waste water from the 100-D Water Support Facilities including 183-D and 190-D. The contaminants of concern include C-14, Cs-137, Sr-90, U-235, -238, and Pu-239/240.

**Closure Info:** Remedial action at the 116-D-5 waste site was performed between February 6 and April 1, 2009. Additional remediation was conducted on March 15, 2011 to remove residual contamination identified after the initial round of verification sampling. The site was originally excavated to a depth of approximately 5 meters (16 ft) on the northwestern side of the excavation and 10 meters (33 ft) on the southeastern side of the excavation. The depth of the excavation following additional remediation is approximately 6 meters (20 ft) on the northwestern side and 11 meters (36 ft) on the southeastern side of the excavation. The engineered structure was completely removed. The entire excavation resulted in approximately 2,275 bank cubic meters (2,976 bank cubic yards) of contaminated soil and debris being removed for disposal to the Environmental Restoration Disposal Facility (ERDF). Some of the material removed from the excavation was placed in a staging pile area prior to being loaded out for disposal at ERDF.

**Code:** 116-D-6  **Classification:** Accepted
**Names:** 116-D-6; 105-D Cushion Corridor French Drain  **Reclassification:** Interim Closed Out (11/8/2000)
**Type:** French Drain  **Start Date:** 1/1/1953
**Status:** Inactive  **End Date:** 1/1/1967
**Description:** This site has been remediated and Interim Closed Out. The waste site was a 1-meter (3.3-foot) diameter french drain, 1 meter (3.3 feet) deep covered by approximately 1 meter (3.3 feet) of gravel and soil.
**Location:** The site was located adjacent to the northeast corner of the 105-D Reactor Building, bordered on two sides by the reactor wall and foundation, and on the other two sides by the 100-D-48 cooling water effluent pipelines.
**Process Description:** The drain received domestic wastewater from the change room and wastewater from the mask decontamination station located in the cushion corridor during reactor operation from 1953 to 1967. Additional decontamination effluents and solvents were also likely disposed into this french drain.
**Waste Type:** Demolition and Inert Waste
**Waste Description:** The site received domestic water from the changing room and water from the mask decontamination station. The site may have received chemical decontamination wastes and solvents.
**Closure Info:** Because the site was bordered on two sides by the reactor wall and foundation, and on the other two sides by the 100-D-48 cooling water effluent pipelines, shallow soils associated with the 116-D-6 site had previously been excavated and disposed of at the ERDF during the remediation of the 100-D-48 cooling water effluent pipelines. Remedial action at the 116-D-6 site began on October 21, 1999. Excavation of the site involved removing the overburden

*Hanford Site Waste Management Units Report*
February 2015  242
materials, the contaminated structure, and the underlying deep zone soils. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF.

On January 3, 2000, the excavation reached the design limit at El. 137.9 meters (452 feet). At the completion of remedial action and removal of the engineered structure, the excavation was approximately 10.1 square meters (109 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 200 metric tons (221 tons) of material from the site were disposed of at ERDF. The excavation will be backfilled with appropriate materials to the reference grade of El. 142.5 meters (468 feet).

**Type:** Retention Basin

**Status:** Inactive

**Description:** The 116-D-7 Retention Basin was an open concrete basin with a vertical concrete baffle constructed lengthwise in the middle of the basin. The floor consisted of concrete slabs, with joints originally closed with neoprene water seals. The walls sloped from the floor to a point 3 meters (10 feet) above the floor level with the remaining wall (approximately 3.0 meters [10 feet]) being vertical. The sloping wall sections were 10 centimeters (4 inches), and the vertical walls were reinforced construction with a minimum thickness of 0.3 meters (1 foot) at the top and 1.75 meters (5.75 feet) at the bottom.

**Location:** The 116-D-7 site is located near the northern edge of the 100-D Area and is approximately 110 meters (360 feet) from the Columbia River.

**Related Sites/Structures:** The retention basin is associated with unplanned release UPR-100-D-4 and four sludge trenches that were excavated adjacent to the 107-D and 107-DR Retention Basins to dispose of sludge that had accumulated at the bottom of the basins. The sludge trenches were excavated in the spring of 1953 to facilitate repair of the retention basins. After use, they were covered with approximately 1.8 meters (6 feet) of clean soil. In 1955, an additional trench was excavated near the southeast side of the 107-DR Retention Basin to receive effluent from the 107-D and 107-DR systems following an undetermined amount of fuel cladding failures.

**Process Description:** The 116-D-7 Retention Basin was constructed in 1944 to hold cooling water effluent from the 105-D Reactor for a brief period of time to allow for thermal cooling and decay of short-lived radionuclides prior to release to the Columbia River. The retention basin received reactor cooling water effluent until 1967.

**Waste Type:** Construction Debris

**Waste Description:** This site retained cooling water effluent from the 105-D Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Total radionuclide inventories in the vicinity of the basin ranged from 5 curies to over 400 curies. Seventy percent of the total radionuclide inventory was contained within the soil adjacent to the unit. Approximately 10 curies had leached into the concrete floor and walls.

**Closure Info:** Excavation of the 116-D-7 site began on May 1, 1997, and involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. The excavation design limit elevation was El. 129.85 meters (425.9 feet). However, after the original excavation and sampling, hexavalent chromium concentrations were above the

Hanford Site Waste Management Units Report
February 2015
soil RAG for river protection (2.2 milligrams/kilogram). To remediate areas that were above the hexavalent chromium soil RAG for river protection, approximately two-thirds of the floor (deep zone sampling areas A2, B5, C7, C8, and C9) was excavated an additional one meter, to an elevation of El. 128.85 meters (422.6 feet).

The lowest elevation that the excavation extended to was El. 127 meters (417 feet), about 7.4 meters (24.4 feet) below the ground surface (backfill reference El. 134.43 meters [440.9 feet]). The low areas (El. 127 meters [417 feet]) of the site excavation are two relatively small areas near the east and west ends of the site. The remainder of the site, with the exception of the sidewalls, was generally excavated to the design elevation of El. 129.85 meters (425.9 feet).

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 12,940 square meters (139,200 square feet or 3.2 acres). Approximately 177,724 metric tons (195,941 tons) of material from the site were disposed of at ERDF.

The CVP demonstrates that remedial action at the 116-D-7 site achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and the RDR/RAWP (DOE-RL 1998). Materials that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils have been sampled, analyzed, and modeled to show that residual COC concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. This scenario, described in Section 5.2, assumes multiple exposure pathways (e.g., ingestion, inhalation, and direct exposure) for shallow zone soils.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone [i.e., below 4.6 m (15 ft)] are required. The verification package demonstrates that residual COC concentrations pose no threat to groundwater or the Columbia River. Thus, those areas of the 116-D-7 site represented by the CVP are verified to be remediated in accordance with the ROD.

---

### Code: 116-D-9

**Classification:** Accepted

**Names:** 116-D-9; 117-D Crib; 117-D Seal Pit Crib

**Reclassification:** Interim Closed Out (3/19/2001)

**Type:** Crib

**Start Date:** 1/1/1960

**End Date:** 1/1/1967

**Location:** The crib was located 90.7 meters (200 feet) southeast of the 105-D Building.

**Process Description:** The 116-D-9 Crib operated from 1960 to 1967. It received stack drainage through a 10-centimeter (4-inch)-diameter pipeline from the confinement system 117 Building seal pits. The 117 Building received exhaust fan discharges from the 105-D Reactor through an inlet duct and released the filtered air through the 132-D-4 exhaust stack. The crib was a 3 meter by 3 meter by 3 meter (10 by 10 by 10 foot) gravel-filled crib with a large steel vent cap extending above the ground surface. It received an estimated 420,000 liters of process effluent drainage from the confinement seal pits located at the 117-D Building. The seal pit effluent entered the 116-D-9 Crib through a 91.4 meter (300-foot) long, 10.2 centimeter (4 inch.) diameter asbestos cement...
pipe. Sampling in 1978 revealed contamination at the 116-D-9 site was at or below background.

Waste Type: Equipment
Waste Description: The site received drainage from the confinement system 117 Building seal pits.

Closure Info: Remedial action began on October 29, 1999. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed at ERDF. On August 11, 2000, the excavation reached the design limit at elevation 137.3 meters (447.2 feet).

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 598.4 square meters (6,441 square feet) in area with a maximum depth of approximately 5.5 meters (18 feet). An estimated 100 meters (328 feet) of pipeline was removed. The excavation was backfilled with appropriate materials to the reference grade elevation of 142.5 meters (467 feet). Approximately 7.3 metric tons (8.0 tons) of material was removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Code: 116-D-10
Names: 116-D-10; 105-D Fuel Storage Basin Cleanout Percolation Pit; 105-D Fuel Storage Discharge Ponds; 105-D Ponds
Type: Pond
Status: Inactive
Description: The waste site has been excavated and Interim Closed Out. It consisted of two open excavated pits with a crossover channel connecting them. The west excavation was 10.7 meters (35 feet) long, 6.7 meters (22 feet) wide, and 0.9 meters (3 feet) deep. The east excavation was 15.2 meters (50 feet) long, 7.3 meters (24 feet) wide, and 1.2 meters (4 feet) deep. Both pits had been back filled and graded to resemble the natural terrain.

Location: The site was located east of the 105-D Reactor Building and just outside of the AC-5-40 permanent markers.

Related Sites/Structures: 105-D Fuel Storage Basin

Process Description: The site was used during the 1984 cleanout of the 105-D Fuel Storage Basin (FSB) to dispose of water to the soil. During cleanout of the basin, radiologically contaminated shielding water was processed through ion-exchange columns and retained in holding tanks for analysis before being released to the soil. The water was released to two open excavated pits (ponds) with a connecting channel. The west pond was small and only allowed for the discharge of one holding tank per day, while the east pit was designed to handle an increase in needed capacity. During cleanout of the basin, radiologically contaminated shielding water was processed through ion-exchange columns and released to the ponds. It is reported that no hazardous substances were released with the water; however, chemical analysis was not a standard practice during that period. Additionally, as discussed in Decommissioning of the 105-D Fuel Storage Discharge Ponds Final Radiological Release Report (Beckstrom 1985), "minute quantities of radionuclides in the processed water presented a potential for accumulation of radionuclides in the soil" at the bottom of the ponds. On August 27, 1984, a process equipment failure affected approximately 2,350,000 L (620,000 gal) of water that was processed from the 105-D FSB and introduced very fine particles of sludge into the processed water holdup tanks (Beckstrom 1985). When the previously clean water from the holdup tanks (verified by radiochemical and isotopic analysis) was discharged, the fine sludge particles were
also released, allowing radioactive material to enter the soil. Water processing operations were immediately suspended and a detailed radiological survey was performed. Contamination levels ranged from 1 pCi/g to several hundred pCi/g. Equipment was repaired and operations resumed on September 6, 1984. The final tank of processed water was discharged on September 22, 1984. After discharge of the fuel storage basin water was complete, approximately 28 m³ (1,000 ft³) of contaminated soil was removed from the bottom of the ponds and taken to the 200 West Area for burial. Radiological surveys and sampling were then performed to support the completion of contamination removal. The mean alpha and beta-gamma activities were calculated to be less than 1 pCi/g and 17.7 pCi/g, respectively, which met the unrestricted release criteria of less than 1 pCi/g alpha activity and less than 20 pCi/g beta-gamma activity that was applicable at that time. The ponds were then filled to grade with 0.9 to 1.2 m (3 to 4 ft) of clean soil. A 2005 review of the maximum detected isotopic activity levels concluded that residual beta-gamma activity exceeded current remedial action goals (RAGs) in some areas.

Waste Type: Sanitary Sewage
Waste Description: The unit received processed water from the 105-D Fuel Storage Basin. During the cleanout of this basin, the radiologically contaminated shielding water was processed through ion exchange columns. Before discharging the water to the unit, composite samples were taken to ensure that radionuclide concentrations were below release criteria in Table II of DOE Order 5480.1. No known hazardous substances were present in the water, however chemical analysis was not a standard practice during that period and there is no evidence that analyses were performed. It should be noted that water removed from the 1608-D is believed to be comparable to the storage basin water, and EP-TOX testing results for the 1608-D water were negative.

Closure Info: Remedial action was performed from April 24 to May 13, 2008. Approximately 2,700 bank cubic meters (3,500 bank cubic yards) of soil was stockpiled. The excavation was approximately 33 meters (110 ft) long, 25 meters (84 ft) wide, and 5 meters (15 ft) deep. No contaminated soil was found during this remediation, likely because the contamination would have been localized in a very thin layer, located about 1 meter (3 ft) below grade, and would not be readily separated from the surrounding clean soil without using smaller tools than the large scale remediation equipment. Since the excavation reached a depth of 4.6 meters (15 ft), the contaminated soil was certainly blended within the soil stockpile as a result of the excavation and stockpiling. Although no radiological contamination was identified, the staged material was removed to the Environmental Restoration Disposal Facility because of the potential for residual contamination existing within the stockpile. This removal occurred on January 7 through 26, 2009.

Code: 120-D-2
Names: 120-D-2; 186-D Waste Acid Reservoir
Type: Surface Impoundment
Status: Inactive
Classification: Accepted
Reclassification: Interim Closed Out (7/28/2009)
Start Date: 1/1/1979
End Date: 1/1/1979
Description: The waste site has been remediated and Interim Closed Out. It consisted of the 186-D waste acid reservoir and associated soils. The above ground 186-D facilities were decommissioned and demolished in 1979. The fate of the lead flashing that was part of the waste acid reservoir was not documented and is assumed to have been disposed in place during demolition. The facilities were removed down to 1 meter (3 ft) below ground surface during demolition. The 120-D-2 reservoir was backfilled and leveled to grade at that time. The waste site was constructed of acid-proof brick, 3-ply waterproof membrane, vitrified pipe, #8 lead flashing, and gunnite. The sides of the reservoir were sloped 2:1 from 1.5 meters (5 feet) below grade level to the bottom. As of June 21, 1991 the site area was covered with gravel and annual weeds. No evidence remained on the surface of the building structure.
Location: The site is located west and south of the center of the 186-D Building.

Related Sites/Structures: The reservoir drains were connected to the 100-D Area process sewer system. The 186-D Building was originally constructed to be used as a water treatment plant, and the acid waste reservoir was constructed to receive waste acid from processes in the 186-D Building. The 186-D Building was never used as a water treatment plant, however it was used as a warehouse.

Process Description: The 120-D-2, 186-D Waste Acid Reservoir was part of the 186-D demineralization facilities (WHC 1994). The waste acid reservoir was located west and south of center of the 186-D Building. Unique to the 100-D Area, the 186-D Building originally contained demineralization facilities intended as a water treatment system for reactor cooling water. However, research indicates that the facilities were never used as intended. The building apparently was converted to a warehouse. An acid-proof brick-lined trench, running almost the entire length of the 186-D Building, was designed to gather waste acid from the demineralization process and deliver it to the 120-D-2 waste acid reservoir. Acid stored in the reservoir could be transferred to the 186-D acid mixing/neutralization tanks, and subsequently discharged to the 100-D-50:7 segment of the process sewer. Underflow and overflow drains in the waste acid reservoir could also discharge directly to the 100-D-31:9 segment of the process sewer.

Waste Type: Soil
Waste Description: This unit was never used for waste acid storage. No records have been found documenting the disposal of waste of any kind in this facility. No written documentation has been found concerning the disposal of the lead flashing that was used in the construction of the waste acid reservoir; however, it is assumed that the lead flashing was disposed in-situ during the demolition of the 186-D Facility.

Closure Info: The above-ground 186-D facilities were decommissioned and demolished in 1979. The facilities were removed down to 1 meter (3 ft) below ground surface during demolition. The 120-D-2 reservoir was backfilled and leveled to grade at that time. The fate of the lead flashing that was part of the waste acid reservoir was not documented and was assumed to have been disposed in place during demolition.

Remediation of the waste site was performed in May through July 2007. Approximately 3,361 cubic meters (4,396 cubic yds) of stained soil, stained concrete, demolition debris, and lead sheets were excavated and disposed directly to the Environmental Restoration Disposal Facility. Observations during remediation confirmed that the visible yellow stains were present outside of the waste acid reservoir. All of the visibly impacted soils were removed (WCH Logbook, EL-1607-1). The final excavation depth ranged from 3 to 5 meters (10 to 16 feet). Soil pH was monitored during excavation to help direct the extent of the excavation and ensure all of the impacted soils were removed. Piping associated with an overflow and an underflow drain in the northwest corner of the waste acid reservoir was removed from within the footprint of the 120-D-2 remediation. Remaining portions of the drain sewer will be removed with remediation of the 100-D-31:9 pipelines.

Code: 126-D-2
Names: 126-D-2; 184-D Coal Pit; Inert Landfill
Type: Inert/Demolition Landfill
Status: Inactive
Classification: Accepted
Reclassification: Interim Closed Out (10/14/2010)
Start Date: 1/1/1943
End Date: 1/1/1986
Description: The waste site has been remediated and Interim Closed Out. It was an excavated pit that was originally used to store coal for the 184-D Power House. Later it used as a demolition and inert waste landfill. This pit was full of debris. It had been covered with about 0.3 meters (1 foot) of pit run backfill material and graded to conform with the natural terrain. Numerous surface depressions were visible, indicating a potential cave-in hazard.

Hanford Site Waste Management Units Report
February 2015
Location: The site was located just west of the site of the demolished 184-D Power House, north of the 183-D Water Treatment Facility, and northwest of the 105-D Reactor Building.

Related Sites/Structures: The site was originally associated with the 184-D Power House.

Process Description: The site was first used as a coal pit in 1943. Use as a demolition and inert waste landfill began in 1970.

Waste Type: Process Effluent

Waste Description: The site is known to contain paint cans and paint wastes, solvents, acids, dry chemicals, photochemicals, and herbicide cans.

Waste Type: Process Effluent

Waste Description: The unit contains demolition and inert waste from demolished facilities in and around 100-D. This includes debris from 184-D (including stacks), 108-D, released portions of the 115-D/DR, and 186-D. The site is suspected to contain some radioactively contaminated solid wastes. Potential contaminates include: Chromate, lead, mercury, undetermined organic and inorganic chemicals.

Waste Type: Process Effluent

Waste Description: Asbestos containing waste has been disposed of at this site.

Closure Info: Initial remedial action at the site began on May 29, 2007, and excavation continued through October 6, 2008. Supplemental remedial action began on October 19, 2009 and excavation continued through March 16, 2010. The debris removed included concrete, steel reinforcing rod, metal pipes, reactor components, drums, various containers, transite material, and a white powdery substance. Approximately 41,873 BCM (54,770 BCY) of soil and debris were removed for disposal to the ERDF.

Excavation continued to a depth below the base of the original coal pit, at which debris was no longer present. The final depth of the excavation ranged from approximately 3 meters (10 ft) to 5.5 meters (18 ft) in a small portion of the southeast corner of the excavation. The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils.

Reclassification: 128-D-2; 128-D-2 Burn Pit

Burn Pit

Inactive

Interim Closed Out (9/8/2011)

The waste site has been remediated. The site was a large landfill area that showed evidence of surface burning and has no definite boundaries. The site was marked with signs of plant stress, depressions, and berms. Concrete and metallic debris exposed on the surface indicated the possibility that this site was also used as a solid waste landfill. The following items were also noted during the March 31, 1999, visit: rigging equipment, bricks, and unidentified white powder that may be ash, and a north-south running trench. The site has been used as a disposal site for compacted tumbleweeds collected from area fences. Knapweed was noted during the March 1999 walkdown.

Location: The site is located northeast of 105-D and southwest of 100-D-7.
**Waste Type:** Water

**Waste Description:** Some pieces of non-contaminated reactor hardware and graphite blocks were found at the site.

**Closure Info:** Remediation at the 128-D-2 waste site was performed between July 22, 2009 and January 14, 2010. Approximately 39,570 bank cubic meters (BCM) (51,756 bank cubic yards [BCY]) of contaminated soil and debris were removed from the 128-D-2 waste site. The debris removed from the 128-D-2 waste site consisted of miscellaneous noncombustible debris including concrete, metal, bricks, vitrified clay pipe, and electrical wiring. Although radionuclides cesium-137, potassium-40, thorium-228, thorium-232, radium-226, radium-228, and strontium-90 were detected in confirmatory soil samples at the 128-D-2 waste site, no radiologically contaminated material was discovered during remediation at the 128-D-2 waste site. No indications of previous spills or releases were detected during remediation at the 128-D-2 waste site.

The soil and debris from the 128-D-2 Burn Pit and the 100-D-7 Undocumented Solid Waste Site were staged in a staging pile to the east of the 128-D-2 waste site and southeast of the 100-D-7 waste site before being loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). The staging area includes a smaller area where topsoil from the waste sites was placed for use on top of the backfill to support successful revegetation as required by the ecological review for the 128-D-2 and 100-D-7 waste sites. All staged waste has been disposed to the ERDF. The staging area was then scraped to remove surface contaminated soil, which was disposed to the ERDF. The location of the staging pile was closed out with the 100-D-7 waste site.

Three anomalies were initially identified during the remediation at the 128-D-2 waste site. These consisted of white powder (anomaly 100D-AN-09-060), an area with clumps of yellow sand (anomaly 100D-AN-09-064), and a white solid material (anomaly 100D-AN-09-065). All these materials were sampled and characterized prior to removal and shipment to ERDF, and the sample results are reported in the Work Instruction for Verification Sampling of the 128-D-2 Burn Pit and the 100-D-7, Undocumented Solid Waste Site. The 100-D-7 waste site is located approximately 700 meters (2300 feet) northeast of the 105 Reactor Building, and immediately northeast of the 128-D-2 Burn Pit.

</tr>
</tbody>
</table>

**Names:** 130-D-1; 1706-D Gasoline Storage Tank; 1716-D Gasoline and Oil Storage Tanks

**Type:** Storage Tank

**Status:** Inactive

**Start Date:** 1/1/1944

**End Date:** 1/1/1968

**Description:** Originally the site consisted of two underground storage tanks. One of the tanks held leaded gasoline and had a capacity of 3,800 L (1,000 gal). The gasoline tank was removed in 1989 as part of the Hanford Site underground storage tank (UST) removal program. It was noted to be empty and heavily deteriorated. The underlying soils were visibly impacted. The other was an oil tank with a capacity of approximately 300 gallons (H-1-5017).

**Location:** The gasoline tank was located northeast of 190-D and on the east side of the demolished 1716-D Building. The oil tank was located on the west side of the 1716-D Building.

**Related Sites/Structures:** The two storage tanks were related to the former 1716-D Garage.

**Process Description:** From 1944 until 1968, the gasoline tank was used to support vehicle fueling operations at the 1716-D Garage. The oil tank was installed during construction of the lubrication pits in 1953.
The drawing shows two lines from the tank to the 1716-D Building. The text describing the tank in drawing (H-1-5017) is not legible. No other historical information is available about the oil tank. The oil tank was added to the 130-D-1 waste site after it was discovered while excavating the 100-D-31:7 pipeline subsite in 2010. The oil tank was subsequently removed and disposed of at ERDF.

When the garage operations were centralized following deactivation of the 100-D/DR Area, the gasoline tank was emptied of product and filled with water. In 1989, the tank was removed as part of the Hanford Site Underground Storage Tank (UST) removal program and was noted to be devoid of any contents and heavily deteriorated. Underlying soils were visibly impacted, and characterization showed elevated levels of petroleum hydrocarbons. (WHC-N-270) No soil remediation or removal activities were performed, and the excavation was backfilled with clean material. Slightly elevated concentrations of lead were detected in subsequent site characterization activities (DOE/RL-93-29).

The coordinates for the gasoline tank, provided in the Technical Baseline Report, are incorrect per H-1-1520, revision 1. The coordinates would place the gasoline storage tank by the water tower (sanitary water tank 1902-D) approximately 122 m (400 ft) west of the garage and gas station. During the April 1999 site walkdown, no evidence of the site could be found except for some soil gas probes left from the soil gas investigation (WHC-SD-EN-ES-031). The concrete marker mentioned in the Technical Baseline Report could not be found at either the coordinates mentioned in that document or at the site's mapped location. The top of the former gasoline UST is believed to have been located 1.3 to 1.5 m (4 to 5 ft) below ground surface, and soils impacted by past product releases may currently exist up to 3 m (10 ft) of clean overburden.

In June 2004, a geophysical survey was performed at the 130-D-1 site to verify the absence of the underground storage tank (UST) and delineate any residual anomalous subsurface features (CCN 115042). The survey was conducted using ground penetrating radar, electromagnetic induction, and magnetometry. No subsurface anomalous features with the characteristics of a UST were observed. Several subsurface anomalous features were observed during the survey, including linear anomalies and magnetic anomalies indicative of basalt-rich gravels commonly used for parking areas and roadways.

The project team conducted a site visit in February 2005. The objectives of the visit were as follows: (1) Evaluate the site in consideration of geophysical survey information and historic documentation to assist in the development of an effective environmental strategy, (2) Confirm the waste site boundary, (3) Locate and evaluate surface debris and anomalies that would require removal to allow for reclassification of the waste site, (4) Evaluate access and staging considerations for heavy excavation equipment. The suspected location of the former gasoline tank was identified during the site visit based on the presence of soil gas sampling debris and grid markings from the geophysical survey.

**Waste Type:** Construction Debris

**Waste Description:** The two storage tanks were related to the former 1716-D Garage. Contaminants of potential concern (COPCs) include TPH, SVOAs, VOCs, arsenic, barium, chromium, lead, selenium, silver, and polychlorinated biphenyls (PCBs). Radionuclides are not a COPC for this site. Based on a review of historical process information and the results of past characterization, the 130-D-1 site is expected to contain hazardous constituents at levels in exceedance of remedial action goals.

**Closure Info:** The gasoline tank was removed in 1989 as part of the Hanford Site underground storage tank (UST) removal program. It was noted to be empty and heavily deteriorated. The underlying soils were visibly impacted. In January 2009, a tank identified as the 1716-D Abandoned Oil Tank was discovered within the layback of the 100-D-31:7 excavation at a depth of approximately 3.3 m (10.8 ft). While moving the tank from the 100-D-31:7 excavation layback,
approximately 95 liters (25 gal) of oily fluid was spilled onto a lined containment area, adjacent to the tank. The 1716-D Abandoned Oil Tank and all associated piping within the 100-D-31:7 excavation were removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Remedial action at the 130-D-1 waste site began on July 21, 2010, and continued through July 26, 2010. Additional remediation was conducted on March 17, 2011, and April 15, 2011, due to residual contamination identified following verification sampling activities. The entire excavation resulted in approximately 780 bank cubic meters (BCM) (1,020 bank cubic yards [BCY]) of soil and debris being removed for disposal at the ERDF. The site was excavated to an approximate depth of 3.5 m (11.5 ft) deep.

Prior to being loaded out for disposal at ERDF, the contaminated soil and debris was staged in a staging pile area on asphalt located east of the 130-D-1 excavation. Following loadout of the waste material, the staging pile area was excavated, removing the asphalt and underlying soil to a depth of approximately 0.5 meter (1.5 ft) below the surface.

---

**Code:** 132-D-1  
**Classification:** Accepted  
**Names:** 132-D-1; 115-D/DR Gas Recirculating Facility  
**Reclassification:** Interim Closed Out (12/5/2011)  
**Type:** Process Unit/Plant  
**Start Date:** 1/1/1944  
**End Date:** 1/1/1967  
**Description:** The waste site has been remediated. It consisted of the demolished 115-D/DR Gas Recirculation Facility footprint, debris and pipe tunnels. This remedial action did not include some portions of the 115-D/DR facility (the seal pit, inlet and outlet ductwork, and tunnels connecting to the 105-D and 105-DR Reactors) that will be included in remedial activities of the 100-D-86:1 and 100-D-50:4. The 115-D/DR Gas Recirculation Facility was a single-story, reinforced concrete structure, 6.1 meters (20 ft) high, with a basement. At ground level, an operating gallery ran the length of the building and was flanked on either side by cells that contained the gas processing equipment. The cells, including walls, ceilings and floors, were constructed of reinforced concrete slabs with composition surfaces. At right angles to the operating gallery and extending across the full width of the building’s end, the fan room was constructed of concrete block and contained the ventilation fan, air compressor, office and locker room.

**Location:** The waste site was located south of the 105-D Reactor Building.

**Related Sites/Structures:** The building housed the gas dryers, injection and circulation equipment for the recirculating gas system for both the 105-D and 105-DR Reactors. The vacuum and pressure seal pit, and adjoining tunnels are part of the 100-D-86:1 waste site.

**Process Description:** The facility was built in 1943 with equipment for 105-D Reactor. The equipment for 105-DR Reactor was added in 1947 and placed in operation in 1950.

**Waste Type:** Barrels/Drums/Buckets/Cans  
**Waste Description:** The resident radionuclides are tritium, carbon-14, cobalt-60, strontium-90, cesium-137, europium-152, and plutonium-239.

**Closure Info:** Remedial action began on September 27, 2010. The excavation continued through March 3, 2011, to a depth of approximately 3.6 to 4.5 meters (12.0 to 15.0 ft), resulting in the removal of the 115-D/DR Building engineered structure. This remedial action did not include some portions of the 115-D/DR facility (the seal pit, inlet and outlet ductwork, and tunnels connecting to the 105-D and 105-DR Reactors) that will be included in remedial activities of the 100-D-86:1 and 100-D-50:4 waste sites.
While removing rebar on the east sidewall of the 132-D-1 waste site, the excavation came into contact with an old asphalt parking lot, resulting in chunks of asphalt breaking off and falling into the excavation. The larger, visible pieces of asphalt was removed from the east side slope and excavation floor. However, there is the possibility of smaller pieces of asphalt being present within the excavation.

**Code:** 132-D-2  
**Classification:** Accepted  

**Names:** 132-D-2; 117-D Filter Building  
**Reclassification:** Interim Closed Out (5/9/2006)  

**Type:** Process Unit/Plant  
**Start Date:** 1/1/1961  
**End Date:** 1/1/1967  

**Status:** Inactive  

**Description:** The building has been remediated and Interim Closed Out. This waste site the 117-D Building, the intake ventilation duct from the 105-D Reactor Building, and the exhaust ventilation ducts to the 116-D Reactor Exhaust Stack. The stack housed blowers and particulate filters used to treat the ventilation exhausted from the 105-D Reactor Building. The building and ducts were demolished in place in 1986 and now resembles a gravel parking lot.

**Location:** The site was located south of the 105-D Reactor (118-D-6), near the 116-D Stack (132-D-4).

**Related Sites/Structures:** The site was associated with the 105-D Reactor (118-D-6), the 116-D Stack (132-D-4), the 119-D Sample Building, and the 117-D Seal Pit Crib (116-D-9).

**Process Description:** The 117-D Building was constructed as part of the reactor confinement project. Prior to its use, unfiltered ventilation was exhausted directly from the reactor to the atmosphere. The confinement project diverted the exhaust just before the stack and routed it to the filter building where it passed through a series of filters. The filtered exhaust was then routed back to the ventilation exhaust stack where it was discharged to the atmosphere. Sealwells within the filter building provided the ability to direct the exhaust into one or both of the filter cells.

The building was divided into two large filter cells with a smaller operating area between them. The filter cells each held six filter frames (two wide and three deep). The filter frames were designed to hold twenty-eight filters that were 0.6 meters (2 feet) square by 0.3 meters (1 foot) thick. There were spaces between the frames to allow access for filter maintenance. The operating area between the two cells was divided into two levels. The upper level, called the access gallery had ten doors that led from it. Four doors opened into each of the filter cells and the two other doors provided access to the intake and exhaust ducts. The operating gallery was located below the access gallery. A sump was located at each end of the operating gallery to collect incidental drainage from above. A large open area extended the full length of the structure above the access gallery and the filter cells. It ranged in height between 2.5 and 2.4 meters (8.1 and 7.8 feet) due to the structure's sloping roof. The space provided access to the cement cover blocks that were positioned over each of the filter frames.

**Waste Type:** Demolition and Inert Waste  

**Waste Description:** The site contained radiological contamination from 105-D Reactor ventilation exhaust. Total radionuclide inventory in the 117-D building was estimated to be 3.9E-03 curies. The radionuclides comprising this figure were tritium, carbon-14, cobalt-60, strontium-90, cesium-137, europium-152, and plutonium-239.

**Closure Info:** Demolition and site grading were performed in 1986 using conventional heavy equipment, including a crane with a wrecking ball, bulldozer, and trucks. The 117-D building floors were perforated to allow for drainage and the roofs of the inlet and outlet ducts were collapsed. The building and ducts were then backfilled with demolished concrete and clean fill material. Demolition rubble was buried under at least 1 meter (3.3 ft) of clean fill, with rubble from the...
seal pits buried under at least 5 meters (16 ft) of clean fill, and the site graded to blend with the surrounding terrain.

RESidual RADioactivity (RESRAD) modeling was performed in 2005 to support the previous decision to demolish and bury the building in place. The model used the maximum radiological activities from the pre-demolition characterization data to represent residual contamination levels over 100% of the paint and concrete of the former building. The RESRAD modeling accounts for radioactive decay from 1985 (year of sampling) to 2005, and predicts that the site achieves the dose limits and risk objectives for rural residential land use with institutional controls, groundwater protection, and river protection. Further excavation of the site to collect more information (i.e., samples) was not likely to result in a change to the interim closed out decision because the residual contamination occurred within a thin surface layer of paint on the interior surfaces of the building and would be unlikely to be detected in the deep zone rubble resulting from demolition of the building. A baseline risk assessment for the river corridor portion of The Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final ROD for this site.

| Code: 132-D-3 | Classification: Accepted |
| Names: 132-D-3; 1608-D Effluent Pumping Station; 1608-D Waste Water Pumping Station | Reclassification: Interim Closed Out (5/9/2006) |
| Type: Pump Station | Start Date: 1/1/1944 |
| Status: Inactive | End Date: 1/1/1965 |
| Description: The waste site has been remediated and Interim Closed Out. It consisted of the effluent pumping station facility that was decommissioned and demolished in 1986. The area was backfilled to grade and a gravel cover added. It now resembles a gravel parking lot. As documented in the Remaining Sites Verification package RSVP-2005-033, the site meets the objectives for interim closure. |
| Location: The unit was located adjacent to the south side of the 105-D Reactor (118-D-6) within the 105-D/DR Exclusion Fence. |
| Process Description: This unit received water from the 105-D reactor building drains containing trace amounts of low-level radionuclides and decontamination chemicals. Water was pumped from the reactor collection pits into the reactor effluent lines near the reactor building and became part of the 107-D effluent (116-D-7) that was discharged to the Columbia River. |
| Waste Type: Equipment |
| Waste Description: |
| Waste Type: Equipment |
| Waste Description: This unit received water from reactor building drains containing trace amounts of low-level radionuclides and decontamination chemicals. Radionuclides were primarily miscellaneous fission and activation products. The decontamination chemicals consisted of sodium fluoride, oxalic acid, and citric acid. |
| Closure Info: Decommissioning was performed in two phases. Phase 1 consisted of water removal (910 liters [240 gallons]), asbestos removal/disposal (1.1 cubic meters [40 cubic feet]), and pump and piping removal, and was completed April 4, 1986. Phase 2 consisted of in situ demolition and site grading and was completed January 6, 1987. The facility was covered with 1 meter (3.3 feet) of soil. The waste was transported to the 200 Area for disposal. |
Demolition and site grading were performed in 1986 using conventional heavy equipment. The structure was demolished to at least 1 meter (3.3 feet) below grade and the rubble buried in situ under at least 1 meter (3.3 feet) of clean fill. The site was released for unrestricted use based on the post-decontamination characterization results and the Dose Assessment of In Situ Burial of the 1608-D Lift Station.

Soil cleanup levels were established in the interim action ROD based on a limited ecological risk assessment. A baseline risk assessment for the river corridor portion of Hanford began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final ROD for this site. Using the maximum radiological activities from the 1986, pre-demolition characterization data to represent residual contamination levels throughout all the residual concrete of the former building, RESidual RADioactivity (RESRAD) modeling was performed in 2005 to support the previous decision to demolish and bury the building in place.

Hanford Site Waste Management Units Report
February 2015
Names: 1607-D2:3; 1607-D2 Septic Pipelines

Names: 1607-D2:4; 1607-D2 Septic Tank

Names: 1607-D2:5; 1607-D2 Inlet Pipe to Replacement System Tile Field

Code: 1607-D2:1

Names: 1607-D2:1; Eastern 1607-D2 Tile Field; Original 1607-D2 Tile Field

Type: Septic Tank

Status: Inactive

Description: The 1607-D2:1 Abandoned Tile Field is a subsite has been remediated and Interim Closed Out. The tile field consisted of a clay pipe drain field positioned approximately 1 to 2 meters (3.3 to 6.6 feet) below surrounding grade. A thick layer of aggregate and native sandy gravel soils were placed around the clay pipes.

Location: The 1602-D2:1 tile filed was located near the east side of the 116-DR-9 Retention Basin.

Process Description: The 1607-D2:1 tile field was built in 1944. Sewage liquid from the 553 person-capacity 1607-D2 septic tank discharged to the tile field from 1944 to 1950. The septic tank was designed to capture the solids, and decant liquid effluent which was transported to the tile field. Solids and sludge were retained in the 91,500 liter (24,160 gallon) septic tank (the septic tank is subsite 1607-D2:4).

Closure Info: In 1950 the tile field was partially demolished for the construction of the 116-DR-9 Liquid Effluent Retention Basin. A replacement tile field (subsite 1607-D2:2) was constructed north of the retention basins. The name "abandoned tile field" was assigned to the infrastructure that remained, adjacent to the 116-DR-9 retention basin.

Excavation of the 1607-D2:1 site began on January 8, 1998, by removing the overburden materials, contaminated soil, and the engineered structure (i.e., clay tiles and aggregate). This first excavation effort removed approximately the top 2 meters (6.6 feet) of soil. All overburden material was found to be contaminated based on field screening results and was disposed at the ERDF with other contaminated material. Contamination was encountered at the base of the first excavation (i.e., below the engineered structure elevation) based on field screening results. A second excavation effort was initiated on January 9, 1998, and was completed on February 4, 1998. The site was judged to be clean based on field screening results. Cleanup verification sampling was initiated at the final excavation elevation of 131.6 meters (431.8 feet).

During excavation of the overburden materials, field screening was used to distinguish between potentially clean materials and contaminated materials for disposal at the ERDF. The field screening results indicated that all removed overburden material did not meet direct exposure RAGs. The overburden material was disposed of at the ERDF.

At the completion of the remedial action, the area of the excavation was approximately 1,203 square meters (12,949 square feet) at a depth of 3.4 meters (11 feet), and approximately 10,040 metric tons (11,064 tons) of material from the site were disposed at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 135 meters (443 feet). Clean backfill will be taken from Borrow Pit 21, which is located due south of the 1607-D2:1 site. The material in the borrow pit has been surveyed in accordance with the Hanford Site Waste Management Units Report

February 2015
The SubSite is Part Of:

**Code:** 1607-D2

**Names:** 1607-D2; 1607-D2 Sanitary Sewer System; 1607-D2 Septic Tank; 1607-D2 Septic Tank and Associated Drain Fields; 124-D-2

---

**Code:** 1607-D2:2

**Classification:** Accepted

**Reclassification:** Interim Closed Out (9/16/2010)

**Names:** 1607-D2:2; Northern Tile Field; Replacement 1607-D2 Tile Field

**Type:** Septic Tank

**Status:** Inactive

**Description:** This subsite has been remediated and Interim Closed Out. The 1607-D2:2 drain field replaced the original drain field in 1950 when the 116-DR-9 Retention Basin was built and placed over a portion of the original drain field.

**Process Description:** The replacement drain field serviced buildings in the 100-D Area until 1996, when a new underground septic system was installed to support facilities associated with the 100-D waste sites remediation. Buildings serviced by the replacement drain field included the 189-D Storage Yard and Mechanical Development Laboratory, 185-D Thermal-Hydraulics Laboratory, 182-D Reservoir and Pump House, 183-D Water Filter Plant, 1700-D Administration and Services Building, and the 105-D Reactor Building.

**Closure Info:** Remedial action at the subsite began on April 7, 2008, and concluded on April 23, 2008 with approximately 3,471 bank cubic meters of material removed and disposed to ERDF. The excavation was approximately 100 meters (330 ft) long, 60 meters (200 ft) wide, and ranges from 1.8 meters (6 ft) to 3.1 meters (10 ft) deep.

During remediation, the inlet pipeline to the drain field was located in the sidewall of the excavation at Washington State Plane Coordinates N151445/E573808. A review of the excavation footprint for the 1607-D2:3 subsite (CVP-2000-00004) indicated that a portion of the pipeline north of the perimeter road had not been removed. It was also observed that the active 100-D Area Pump-and-Treat Project pipelines run directly over the ground surface in this location. A fifth subsite, 1607-D2:5, was created to accommodate a section of inlet piping to the replacement drain field that could not currently be removed due to overlaying pipelines of a pump and treat system. Remediation of the 1607-D2:5 subsite will occur at a future date.

A geophysical survey was conducted in February 2008 to locate electrical utilities in the vicinity of the 1607-D2:2 Replacement Drain Field. The survey identified surface electrical lines from a nearby pump-and-treat operation. Piping and electrical lines from the pump-and treat operation precluded the excavation of a section of the inlet piping to the replacement drain field. This small section was administratively placed in to the 1607-D2:5 subsite to ensure the section of pipe will be remediated at a later date. Other than the surface electrical lines, the geophysical investigation did not find anything in the data to indicate other structures or hazards at the 1607-D2:2 subsite. Radiological surveys did not detect any elevated radiological activity.

**Description:** This section of the sanitary sewer pipelines has been removed and Interim Closed Out. It ran from Manhole S-250, through the 1607-D2 Septic Tank, and across the D Area North Perimeter Road to the tile field.

**Location:** The 1607-D2 pipeline site was located in the northern part of the 100-D Area, approximately 30 meters (100 ft) southeast of the 116-D-7 Retention Basin.

**Process Description:** The 1607-D2 Septic Pipelines were constructed in 1944 as part of the 1607-D2 septic system, which included tile fields and a septic tank. The pipelines were fed by the 189-D Storage Yard and Mechanical Development Laboratory, the 185-D Thermal Hydraulics Laboratory, the 182-D Reservoir and Pump House, the 183-D Water Filter Plant, the 1700-D Administration and Services Building, and the 105-D Reactor Building.

**Closure Info:** Remedial action at the 1607-D2:3 pipeline waste site began on August 20, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and the underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. On August 30, 1999, the excavation reached the design limit at elevation 131 meters (430 feet).

At the completion of remedial action and removal of the engineered structure, the shallow zone excavation was approximately 1,780 square meters (19,200 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). The overburden area was approximately 1,850 square meters (19,900 square feet). The excavation has been backfilled to the reference grade of elevation 136 meters (445 feet). Backfill was taken from the clean stockpile and/or from other sources of clean material surveyed in accordance with the SAP and that are appropriate for use as backfill.

**Description:** The 1607-D2:4 Septic Tank subsite has been remediated and Interim Closed Out. It was constructed of reinforced concrete and had a 553 person capacity (130 L [35 gal] per capita). It had an average retention period of 24 hours. Two tile fields were associated with this septic tank and were 4.1 meters (13.5 ft) deep.
The septic tank was located approximately 30 meters (100 ft) southeast of the 116-D-7 Retention Basin.

The 1607-D2 Septic Tank was constructed in 1944 and is located approximately 30 meters (100 ft) southeast of the 116-D-7 Retention Basin. The site serviced the 189-D Storage Yard and Mechanical Development Laboratory, the 185-D Thermal Hydraulics Laboratory, the 182-D Reservoir and Pump House, the 183-D Water Filter Plant, the 1700-D Administration and Services, and the 105-D Reactor Building. The 1607-D2 Septic Tank was 4.1 meters (13.5 ft) deep, constructed of reinforced concrete, and had a 553 person capacity (130 L [35 gal] per capita) and an average retention period of 24 hours. Two tile fields were associated with this septic tank. The original tile field was built in 1944 and was located northeast of the septic tank. This tile field was abandoned in 1950 due to the construction of the 116-DR-9 Retention Basin. A replacement tile field was built approximately 60 meters (66 yd) north of the 116-D-7 Retention Basin, north of the perimeter road. The original and replacement fields are considered subsites of the 1607-D2 Septic System. The original the field has been addressed by a separate remedial action effort and supporting documentation. Remedial action for the replacement tile field is yet to be determined. The system was replaced by a holding tank in 1996.

Excavation of the 1607-D2 site began on July 17, 1998, by removing the soil surrounding the septic tank and breaking in place the cover and sides of the tank prior to drying and sampling sludge. The 1607-D2 Septic Tank cover, side walls, and excavated soil were found to be contaminated and were disposed of at the ERDF. The sludge was sampled on September 29, 1998, to determine contamination levels. The sludge was tested for free liquids using the paint filter test on October 20, 1998. The second phase of excavation began on October 21, 1998, and was completed on October 27, 1998. Excavated materials were disposed of at the ERDF. At the completion of the remedial action and removal of the engineered structure, the area of the excavation was approximately 506 square meters (5,449 sq. ft.) at a depth of 4.7 meters (15.4 ft). Approximately 2,041 metric tons (2,250 tons) of material from the site were disposed at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 137 meters (449 ft).

This subsite consists of approximately 14 meters (46 feet) of sanitary sewer pipeline extending from a manhole to the replacement tile field. The pipeline was used to pass treated septage to the tile field. The site runs from a point adjacent to a manhole to the D Area North Perimeter Road. It connects into the replacement tile field (1607-D2:2).

The replacement tile field is located approximately 244 meters (800 feet) north of the septic tank, north of the perimeter road.

This subsite is related to the 1607-D2 Replacement Tile Field (Subsite 1607-D2:2), the 1607-D2 Septic Tank (Subsite 1607-D2:4), and the 1707-D2 Septic Pipelines (Subsite 1607-D2:3).
The SubSite is Part Of:
Code: 1607-D2
Names: 1607-D2; 1607-D2 Sanitary Sewer System; 1607-D2 Septic Tank; 1607-D2 Septic Tank and Associated Drain Fields; 124-D-2

Code: 1607-D4
Names: 1607-D4; 1607-D4 Sanitary Sewer System; 1607-D4 Septic Tank; 1607-D4 Septic Tank and Associated Drain Field; 124-D-4
Type: Septic Tank
Status: Inactive
Description: The site has been remediated and Interim Closed Out. The site consisted of a small septic tank and drain field.

The unit was a septic tank and tile field. The tank was 2.5 meters (8 feet 4 inches) deep, constructed of reinforced concrete, and had a 6-person capacity [130 liters (35 gallons) per capita] with an average detention period of 24 hours. The walls were 20 centimeters (8 inches) thick, and the floor was 15 centimeters (6 inches) thick. The tile field was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a minimum of 2.4 meters (8 feet) per capita. The laterals were open jointed and spaced 2.4 meters (8 feet) apart.

Location: The system was located between the 105-D and the 105-DR Reactors.

Related Sites/Structures: The site serviced the 115-D and 115-DR (Gas Recirculation Buildings).

Process Description: The system received sanitary sewage from the 115-D/DR Gas Recirculation Facility. Historic drawings indicate that the 1607-D4 Septic System consisted of a rectangular prismatic septic tank and tile field. The tank dimensions were 0.6 by 1.2 meters (2 by 4 feet) in plan view and 2.5 meters (8.3 feet) deep. The design waste capacity of the tank was 795 Liters (210 gallons), leaving up to 1.4 meters (4.5 feet) of freeboard/headsapce. The tank was constructed of reinforced concrete with 0.2 meters (8-inches)-thick walls and a 0.15-meter (6-inch)-thick floor. Historic piping layouts show the influent to the tank as a 0.15-meter (6 inch) vitrified clay pipe (VCP) running from the southeast corner of the 115-D/DR Building.

Waste Type: Water
Waste Description: This unit received an unknown amount of sanitary waste from the 115-D Gas Recirculation Building.

Closure Info: The 115-D/DR facility was decommissioned in 1985 and 1986, including demolition of above-grade features. The septic system may have been filled in as part of the decommissioning of the facility, or at some other time after its operational lifetime ended in 1968.

A geophysical survey conducted in 1992 and field observations made during a site visit in February 2005 were used to confirm the location of the site. Existing historical information was used to identify the contaminants of potential concern (COPCs) for the system. The COPC list identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) included lead, pesticides, and semivolatile organic compounds. Based on further site-specific evaluations of septic systems, polychlorinated biphenyls were also included as COPCs in the work instructions.

Confirmatory sampling of the 1607-D4 Septic System was conducted on July 5, 2005. One test trench was excavated in the area identified as the most likely location of the septic tank. The
A septic tank was located within the trench and a sample collected from below it. The tank had been backfilled with clean fill unrelated to the operational history of the septic tank. No sludge was available to be sampled from within the septic tank. A sediment sample was also collected from within the VCP pipeline "tee", at 2 meters (6.5 ft) below ground surface. The sample results indicated that the previous waste removal action achieved compliance with the remedial action objectives for the 1607-D4 site.

Examination of the data has led to the conclusion that the site passes the RAGs without further remedial action. In accordance with this evaluation, the confirmatory sampling results support a reclassification of the site to interim closed out. The analytical results from soil and drain field samples were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

---

**Code:** 1607-D5  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (10/10/2011)

**Names:** 1607-D5; 1607-D5 Sanitary Sewer System; 1607-D5 Septic Tank; 1607-D5 Septic Tank and Associated Drain Field; 124-D-5

**Type:** Septic Tank  
**Start Date:** 1/1/1944

**Status:** Inactive  
**End Date:**

**Description:** The site resembles a gravel covered parking area. There are no signs designating the septic and tile field areas.

**Location:** The unit was located east of the northeast corner of the 181-D Pumphouse.

**Related Sites/Structures:** The site received effluent from the 181-D (River Pump House). The influent pipe is assigned to waste site 100-D-84:2.

**Process Description:** The unit consists of a septic and a tile field. The septic was a concrete tank measuring approximately 3 by 5 ft (0.9 by 1.5 m) in plan and 7 ft 10 in (2.4 m) deep, with a metal cover. The septic tank had a 6-person capacity (35 gal [130 L] per capita) with an average detention period of 24 hours. The walls were 8 in (20 cm) thick, and the floor is 6 in (15 cm) thick. The tile field is constructed of 6-in (15 cm) or 8-in (20 cm) vitrified pipe, concrete pipe, or drain tile with a minimum of 8 linear feet (2.4 m) per capita. The laterals were open jointed and spaced 8 ft (2.4 m) apart.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** This unit received sanitary waste from the 181-D Pumphouse. The flow rate to this unit was estimated at 35 gallons per day (130 Liters per day).

**Closure Info:** Remedial action at the 1607-D5 waste site was performed between October 22 and 26, 2010. Excavation continued to a maximum depth of 3.3 m (11 ft) until all contaminated soil and debris associated with the waste site had been removed. The post-excavation civil survey is shown in Figure 3. Approximately 500 bank cubic meters (BCM) (654 bank cubic yards [BCY]) of contaminated soil and debris were removed from the excavation and directly loaded out for disposal at the Environmental Restoration Disposal Facility. The originally planned above cleanup level (ACL) stockpile proved to be in an inaccessible location. A second location was planned for the ACL, but it proved to be easier to direct load the material. Therefore, neither of the potential stockpile locations was used. No overburden material was retained for use as clean backfill.
Names: 116-DR-1&2; 116-DR-2; Emergency Crib Trench; 107-DR Liquid Waste Disposal Trench #1; 107-DR Liquid Waste Disposal Trench #2; 116-DR-1

Reclassification: Interim Closed Out (9/26/2000)

Type: Trench

Start Date: 1/1/1950

Status: Inactive

End Date: 1/1/1967

Description: The site has been remediated and Interim Closed Out. It is no longer marked or posted. The site was constructed as two separate trenches that were later joined together to form a single trench.

Location: The site was located east of the northeast corner of 107-DR Retention Basin.

Process Description: The site received effluent from the 107-D and 107-DR Retention Basins when cooling water was contaminated due to ruptured fuel elements. The 116-DR-1 and 116-DR-2 Trenches were originally connected by an underground pipe. They were joined together sometime before 1967 by removing the soil between them. The enlarged single trench was used for a four month test in which the total coolant volume was deposited to the soil column.

Waste Type: Chemical Release

Waste Description: The site received effluent from the 107-D and 107-DR Retention Basins when cooling water was contaminated due to ruptured fuel elements. In addition to the 4.0E+07 liters (1.06E+07 gallons) of effluent from ruptured fuel elements listed in PNL-6456 (Stenner et al), the site also received 3.87E+08 liters (1.02E+08 gallons) of cooling effluent daily during the four month test. Waste site COCs identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE-RL 1998a). The COCs identified for this site are: americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, and hexavalent chromium.

Closure Info: Remedial action at the 116-DR-1&2 Trench began on November 25, 1996. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On October 21, 1999, the excavation reached the design limit at elevation 131.1 meters (430.1 feet). At the completion of the remedial action, the total excavation was approximately 9,730 square meters (104,734 square feet) in area with a maximum depth of approximately 5.0 meters (16.4 feet). Approximately 82,768 metric tons (91,236 tons) of material from the site were disposed of at the ERDF.

Code: 116-DR-5

Classification: Accepted

Names: 116-DR-5; 1904-DR; 1904-DR Outfall Structure

Reclassification: Interim Closed Out (1/6/2011)

Type: Outfall

Start Date: 1/1/1956

Status: Inactive

End Date: 1/1/1967

Description: The site has been remediated and Interim Closed Out. It consisted of an open, reinforced, compartmentalized concrete outfall structure that routinely discharged effluent to the Columbia River via the river effluent pipelines (100-D-60). When the river pipelines were blocked, damaged or undergoing maintenance, the flow was diverted to a concrete overflow spillway (flume) (100-D-66).

Location: The site was located at the top of the river bank, north of the northwest corner of 116-D-7 (107-D Retention Basin).

Related Sites/Structures: The site is associated with the D Island Contamination (100-D-67), 107-D Retention Basin.
Process Description: Reactor cooling water collected and temporarily stored in the 116-D-7 and 116-DR-9 retention basins, could be pumped to the river via the 116-DR-5 outfall structure and associated river effluent pipeline (100-D-60).

Waste Type: Water

Waste Description: This unit received reactor coolant from the 107-D and 107-DR Retention Basins. The contaminants of concern include C-14, Cs-137, Sr-90, U-235, -238, and Pu-239/240.

Closure Info: Remedial action at the 116-DR-5 outfall waste site began on January 12, 2009, and continued through May 13, 2009. The site was excavated to a maximum depth of approximately 11 meters (36 ft) resulting in approximately 2,613 bank cubic meters (BCM) (3,417 bank cubic yards [BCY]) of soil and debris removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 1,190 BCM (1,556 BCY) of overburden and layback material was removed and stockpiled for evaluation for use as clean backfill. The excavation extended into the deep zone (greater than 4.6 meters [15 ft] deep); however, the entire site was closed out using shallow zone criteria (i.e., including consideration of direct contact cleanup levels).

Contaminated soil and debris were excavated and removed from the 116-DR-5 outfall waste site and stockpiled southeast of the excavation for loadout and disposal to ERDF. Field observations during excavation indicated the presence of concrete, rebar, piping, and miscellaneous debris consistent with the outfall structure and manhole. A small, (1 to 2 oz) polyurethane bottle was found during excavation. The bottle was found to be empty; therefore no waste characterization sample was collected. The bottle was disposed at ERDF.

**Code:** 116-DR-9  
**Classification:** Accepted

**Names:** 116-DR-9; 107-DR; 107-DR Retention Basin  
**Reclassification:** Interim Closed Out (1/6/2000)

**Type:** Retention Basin  
**Start Date:** 1/1/1950

**Status:** Inactive  
**End Date:** 1/1/1967

**Description:** This site has been remediated and Interim Closed Out. The retention basin was an open concrete structure with a vertical concrete baffle constructed lengthwise in the middle. The floor consisted of concrete slabs whose joints originally closed with neoprene water seals. The walls sloped from the floor to a point 3 meters (10 feet) above the floor level, with the remaining wall (about 3 meters [10 feet]) being vertical. The sloping wall sections were 10 centimeters (4 inches) thick, and the vertical walls were reinforced construction with a minimum thickness of 0.3 meters (1 foot) at the top and 1.75 meters (5.75 feet) at the bottom.

**Location:** This site was located north of the 105-D Reactor Building.

**Related Sites/Structures:** The retention basin is associated with unplanned release 100-D-25 and four sludge trenches that were excavated adjacent to the 107-D and 107-DR Retention Basins to dispose of sludge that had accumulated at the bottom of the basins. The sludge trenches were excavated in the spring of 1953 to facilitate repair of the retention basins. After use, they were covered with approximately 1.8 meters (6 feet) of clean soil. In 1955, an additional trench was excavated near the southeast side of the 107-DR Retention Basin to receive effluent from the 107-D and 107-DR systems following an undetermined amount of fuel cladding failures.

**Process Description:** The 116-DR-9 Retention Basin was constructed in 1950 to hold cooling water effluent from the 105-DR Reactor for a brief period of time to allow for thermal cooling and radioactive decay prior to release to the Columbia River. The retention basin was a rectangular, reinforced-
A concrete reservoir measuring 183 meters by 83 meters, 6 meters deep (600 ft by 273 ft by 20 ft). It was located immediately east of the 116-D-7 Retention Basin, and approximately 329 meters (1,079 ft) from the 100-year flood level of the Columbia River. The basin was partially above ground and divided into two sections by a vertical concrete baffle that ran the length of the basin. The retention basin received cooling water effluent from the 105-DR Reactor from 1950 until 1965. After the 105-D Reactor was deactivated in 1965, the basin remained active until 1967 as part of the 105-D Reactor effluent system.

**Waste Type:** Soil  
**Waste Description:** This site received cooling water effluent from the 105-DR Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Total radionuclide inventories in the vicinity of the basin ranged from 5 curies to over 400 curies. Seventy percent of the total radionuclide inventory is contained within the soil adjacent to the unit. Approximately 10 curies have leached into the concrete floor and walls. The basin was known to have leaked on several occasions.

**Closure Info:** The 116-DR-9 retention basin received cooling water effluent from the 105-DR Reactor from 1950 until 1965. After the 105-D Reactor was deactivated in 1965, the basin remained active until 1967 as part of the 105-D Reactor effluent system. Leakage occurred as unplanned releases in 1951 beneath the basin and outside the south end of the basin when seals in the concrete floor of the basin failed and the pipes pulled away from the basin walls at the retention basin inlet. The basin had a history of leaking and underwent repairs in 1951. Waste site 100-D-25 documents leakage beneath the basin and outside the south end of the basin where the neoprene seals in the concrete floor failed and the pipes pulled away from the basin walls at the retention basin inlet. The contamination could not be distinguished from other contaminated soil. It was remediated with the 116-DR-9 Retention Basin under the provisions for "proximity sites."

Excavation began on October 21, 1997, by removing the overburden materials and underlying contaminated soil. Overburden materials, which were contaminated, were disposed at the ERDF. On December 28, 1998, the excavation had reached the design limits below the base of the engineered structure (El. 130.25 m [427.35 ft]) and cleanup verification sampling was initiated. At the completion of the remedial action, the excavation area floor was approximately 16,352 square meters (176,013 sq ft) at a depth of 4.75 meters (15.6 ft), and approximately 201,519 metric tons (222,122 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 135.0 meters (443 ft).

Contaminated soil associated with the process effluent pipelines was not removed completely, but deferred for final remediation with the pipeline waste sites. The 116-DR-9 sidewall areas that are adjacent to future pipeline excavation areas were not sampled as part of the basin cleanup verification effort. These areas will be sampled and verified clean as part of the effluent pipeline remediation efforts.

**Classification:** Accepted  
**Reclassification:** Interim Closed Out (5/11/2011)  
**Start Date:**  
**End Date:**

---

**Code:** 628-3  
**Names:** 628-3; 628-3 Burn Pit  
**Type:** Burn Pit  
**Status:** Inactive  
**Description:** The site has been remediated and Interim Closed Out. It was an oval shaped area with a length of 76 meters (250 ft), a width of 12 meters (40 ft), and a depth of 1.2 meters (4 ft). The center of the burn pit was distinguished by a 1.2-inch (4-ft) depression. The waste site showed signs of severe plant stress and soil discoloration, and there was debris consisting of burnt wood, nails,
metal pipes, rebar, and glass scattered across the area. The depression shows signs of severe plant stress and soil discoloration. The depression, as well as the area around it, was littered with debris. It appears that at one time tractors bulldozed some of the surrounding soil.

**Location:**
The unit was located approximately 300 meters (1,000 feet) east of 128-D-2 and approximately 92 meters (300 feet) east of the D Area Perimeter Road.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** Debris, consisting mostly of burnt wood, nails, metal pipes, rebar, and glass, is scattered over the area. In some spots, the site also contains what looks like friable and nonfriable asbestos. The site could not definitely be found in 1992 surveys of the area.

**Closure Info:** Remedial activities were carried out from March to June 2009. The excavation depth reached a maximum depth of 4.6 meters (15 ft) near the center of the pit. All contaminated material consisting of soil, concrete/debris, suspected asbestos-contaminated material, and metal pipe and concrete debris was disposed of at the Environmental Restoration Disposal Facility (ERDF).

After further review of the post-excavation civil survey and comparison to the geophysical survey the northern excavation boundary was extended. This excavation was completed in January 2010. The additional area of investigation was excavated to 1 meter (3 ft). No debris or indication of previous subsurface disturbance was encountered; therefore, the sample design was not changed to reflect this extended boundary. The geophysical anomalies present in the survey were believed to have been interference from surface debris and/or the basalt layer in this area.

Names: UPR-100-D-2; Effluent Line Leak #1

Type: Unplanned Release

Status: Inactive

Description: The Unplanned Release was remediated with the source pipelines (100-D-48 100-D Reactor Cooling Water Effluent Underground Pipelines and 100-D-49 100-DR Reactor Cooling Water Effluent Underground Pipelines) and Interim Closed Out on September 26, 2000. UPR-100-D-2 was associated with subsite 100-D-48:2 (West Pipelines from D Avenue to 116-D-7).

Location: The release site was located southeast of the 107-D Basin and west of the 107-DR Basin.

Release Description: In 1951, extensive leakage of effluent water was detected above ground southeast of the 107-D Basin. A maximum dose rate of 50 millirads/hour was observed at the surface. Two excavations were made to investigate the leakage, but the effluent continued to seep to the surface. In 1951, the area was marked with a rope fence and marked as a "Radiation Area" (see Drawing H-1-4046).

Waste Type: Chemicals

Waste Description: The site received radioactively contaminated water from the 107-D/DR Retention Basins.

Closure Info: Remediation at the 100-D-48:2 and 100-D-49:2 pipelines and the associated releases UPR-100-D-2 and UPR-100-D-3 were remediated together. Remedial activities began in July 1997. Excavation of the waste sites involved removing the overburden material, contaminated structures, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Excavated material found to be contaminated was disposed of at the ERDF. In August 1999, the excavation reached the design limit. The excavation design depth generally corresponded with the invert elevation of the pipelines. Because of the length of the pipeline site, the top-of-excavation elevation ranges from 138 meters (453 feet) near the retention basins to 143 meters (469 feet) near D Avenue.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 20,475 square meters (220,280 square feet) in area with a maximum depth of approximately 6 meters (20 feet) below ground surface. During the time of excavation and waste disposal (December 1998 through September 1999) approximately 57,106 metric tons (62,960 tons) of material from 100-DR-1 Operable Unit pipelines were disposed of at the ERDF.

Names: UPR-100-D-3; Effluent Line Leak #3

Type: Unplanned Release

Status: Inactive

Description: The Unplanned Release was remediated with the source pipelines (100-D-48 100-D Reactor Cooling Water Effluent Underground Pipelines and 100-D-49 100-DR Reactor Cooling Water Effluent Underground Pipelines) and Interim Closed Out on September 26, 2000.
Location: The unplanned release site was along the south perimeter of the 116-DR-9 (107-DR) Basin.

Release Description: In 1951, extensive leakage of effluent water was caused by pipes pulling loose from the retention basin wall.

Waste Type: Equipment

Waste Description: The site was soaked with radioactively contaminated reactor cooling water from the 107-DR Basin.

Closure Info: Remediation at the 100-D-48:2 and 100-D-49:2 pipelines and the associated releases UPR-100-D-2 and UPR-100-D-3 were remediated together. Remedial activities began in July 1997. Excavation of the waste sites involved removing the overburden material, contaminated structures, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Excavated material found to be contaminated was disposed of at the ERDF. In August 1999, the excavation reached the design limit. The excavation design depth generally corresponded with the invert elevation of the pipelines. Because of the length of the pipeline site, the top-of-excitation elevation ranges from 138 meters (453 feet) near the retention basins to 143 meters (469 feet) near D Avenue.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 20,475 square meters (220,280 square feet) in area with a maximum depth of approximately 6 meters (20 feet) below ground surface. During the time of excavation and waste disposal (December 1998 through September 1999) approximately 57,106 metric tons (62,960 tons) of material from 100-DR-1 Operable Unit pipelines were disposed of at the ERDF.

Code: UPR-100-D-4
Names: UPR-100-D-4; Unplanned Release: 107-D Basin Leaks
Type: Unplanned Release
Status: Inactive

Description: This waste site has been remediated and Interim Closed Out. The waste site represents multiple occurrences of cooling water leaking from the 116-D-7 Retention Basin.

Location: The unplanned release site was located on the north side of the 107-D Basin, between the basin and the river.

Release Description: In 1950, a large effluent leak occurred. The water drained under the road to a section between the road and the perimeter fence. Rad readings of 10,000 counts/minute were detected. No attempt was made at the time to cover the contamination. In 1950, the area was marked with a rope fence and posted with "Radiation Zone" signs. Today the area is not marked or posted.

Related Sites/Structures: UPR-100-D-4 is associated with the 116-D-7 Retention Basin. This UPR site was closed out in conjunction with the 100-D-48:1 and 100-D-49:1 pipelines and the 100-D-19 Sludge Trench.

Waste Type: Process Effluent

Waste Description: The site was soaked with radioactively contaminated reactor cooling water effluent.

Closure Info: Waste sites 100-D-48:1, 100-D-49:1, 100-D-19 and UPR-100-D-4 were co-located and remediated together. The CVP document referred to the four, combined waste sites as the 100-D-48:1/49:1 Pipeline site. Remedial action at the 100-D-48:1/49:1 Pipelines site began on...
December 28, 1998. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation reached the design limit. Because remediation of the 100-D-48:1/49:1 Pipelines site required moving an active overhead power line, site remedial action and sampling were conducted in two phases. These separate phases are reflected by the long time period between the start and finish dates for excavation.

The excavation design depth generally corresponded with the invert elevation of the pipelines. At the completion of remedial action and removal of the engineered structure, the excavation was approximately 15,504 square meters (166,800 square feet) in area with a maximum depth of approximately 6.0 meters (20 feet) below ground surface. Approximately 107,266 metric tons (118,241 tons) of material from the D Area pipelines site have been disposed of at the ERDF through July 2000. Cleanup verification sampling began on April 3, 2000, and was finished on August 8, 2000. The ground surface in the vicinity of the site varies with an average elevation of approximately 134.4 meters (441 feet).

<td></td>
<td></td>
</tr>
<tr>
<td>Waste Description</td>
<td>The release consisted of radioactively contaminated effluent from reactor cooling water. Pipeline leaks contaminated the soil around the effluent lines. Potential contaminants include Co-60, Cs-134, Cs-137, Eu-152,154,155; H-3, Pu-238, 239, 240; Am-241, Sr-90 and U-235.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info</td>
<td>Remediation occurred between March 7 and April 3, 2008. Approximately 4,485 bank cubic meters (5,586 bank cubic yards) of soil was excavated and stockpiled adjacent to the site. No radiological contamination was detected in the excavated material. Therefore, no soil was taken to the Environmental Restoration Disposal Facility. The excavation is approximately 4.6 meters (15 ft) deep and 30.5 meters (100 ft) long with variable width. Based on field observations during excavation; the absence of field detectable contamination associated with a retention basin leak and the lack of documentation other than a site location in a historical drawing (GE 1964), it is suspected that an effluent leak may never have occurred. An alternative possibility is that previous remedial actions associated with the 107-D and 107-DR retention basins, sludge trenches, and other effluent leaks may have removed any residual contamination.</td>

_Hanford Site Waste Management Units Report_  
February 2015  
268
Disposal Facility. The tank was filled with soil. The entire dosing tank was removed and the area backfilled with soil. All materials were directly loaded for disposal at the ERDF.

The system consisted of an IMHOFF tank, a chlorination house, a dosing tank, a filter bed, and associated piping. The septic tank is surrounded by a steel pipe fence. The filter bed is distinguishable as a rock-filled depression with distribution piping visible on the surface.

Location:
The septic tank is approximately 240 meters (800 feet) east-southeast of the of 105-DR, south of the power line road. The filter bed is approximately 120 meters (400 feet) east of the tank on the north side of the road. The pipeline that flows to the tank has been mapped from the 117-DR Building, and surrounds the 105-DR Building, but no connection to the reactor has been found on drawings.

Waste Type: Equipment

Waste Description: The tank received sanitary waste from temporary construction facilities at 105-DR. The 100-D Area Technical Baseline Report indicates that the tank also received overflow from the high tanks (water towers) at 105-DR, but no drawings could be found to verify this. The tank may have also received waste from the 105-DR Reactor (see Site Comment), so radioactive contamination may be present.

Closure Info: Confirmatory sampling of the 100-D-13 waste site was conducted on July 11 and 12, 2005. The septic tank was discovered to contain residual free liquid and sludge, and appropriate waste characterization samples were collected. Confirmatory samples were collected from surface and underlying soils at the filter bed. On August 18, 2010, an additional pipeline sample was collected in order to characterize the pipeline between the septic tank and dosing tank and to confirm that no contamination was present between the septic tank and the dosing tank. The sample results indicated that the 100-D-13 waste site achieved compliance with the remedial action objectives and goals (RAOs) and RAGs. Therefore remediation was not necessary.

The liquid levels in the septic tank observed on August 18, 2010 were compared to the liquid levels observed during the confirmatory sampling effort in 2005. The liquid level check confirmed that the tank had not leaked any fluids since 2005. The lid of the tank was removed during the efforts to appropriately disposition the residual tank contents. The contents of the tank were treated, solidified, and then removed and disposed at Environmental Restoration Disposal Facility. The septic tank was filled with soil.

The Imhoff tank extended down to 7.3 meters (24 ft) below ground surface. To completely remove the solidified liquids from the tank, the top portion of the tank had to be broken off and removed. An engineered excavation was designed in order to access and appropriately disposition the septic tank. Approximately 885 bank cubic meters (BCM) (1,159 bank cubic yards [BCY]) of solidified liquid and septic tank components were removed from the excavation and staged in the staging pile area before being loaded for disposal at the ERDF.

In January 2011, the smaller dosing tank was uncovered to perform visual observation of the tank contents. The wooden lid was found to be partially deteriorated. Rainwater collection inside the tank was expected. The dosing tank was partially backfilled with soil. It contained a small amount of water in two corners of the tank. On March 14, 2011, the dosing tank was removed and disposed. The dosing tank measured to be approximately 10 feet by 5 feet by 8 feet. The entire dosing tank was removed, resulting in approximately 100 BCM (131 BCY) of dosing tank components, backfill materials and soil. All materials were directly loaded for disposal at the ERDF.

On March 14, 2011, following the removal of the dosing tank, three soil samples were collected from soils underlying the dosing tank.

**Description:** The waste site has been remediated and Interim Closed Out. It had been a vegetation-covered field with a small depression that may have indicated the location or presence of the tank. A 10-centimeter (4-inch) cement vent pipe to the drain field was visible.

**Location:** The tank location was located south of the 105-DR Building, outside the 100-D perimeter fence and north of Route 2 North.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The unit received sanitary wastes.

**Closure Info:** Confirmatory sampling at the 100-D-14 waste site was conducted on January 4, 2006, and July 11, 2007. On January 4, 2006, excavation of a 4 inch vertical concrete pipe, the only feature visible at the surface, showed that the pipe extended approximately 1 meters (3 ft) below ground surface to an elbow connected to a concrete pipeline extending to the east. Approximately 6 meters (20 ft) of this pipeline was excavated. No perforations or other features suggestive of a drain field were discovered. Following this excavation, evidence was discovered that indicated the septic tank location was in a different orientation, farther east of the originally assumed location. Excavation at the suspect septic tank location on July 11, 2007, revealed a suspected influent vitrified clay pipe (VCP) and suspected effluent VCP that was belled at one end (consistent with the configuration for connection to a tank). A gap of approximately 5 meter (16.4 ft) between the two pipes indicated that the septic tank had been removed. Based on the confirmatory data evaluation, residual concentrations of nitrate (as nitrogen), DDE, and DDT exceeded the soil remedial action goals (RAGs) for the protection of groundwater and/or the Columbia River.

Remediation of the 100-D-14 waste site was performed from March 28 through March 29, 2012. Approximately 936 bank cubic meters (1,224 bank cubic yards) of excavated materials were removed and stockpiled in a staging pile area west of the excavation prior to disposal at the Environmental Restoration Disposal Facility. The lowest depth of the waste site excavation was approximately 4.6 meters (15 ft) at the location of the former drain field. No septic tank or anomalous materials were encountered during the excavation. No overburden material was associated with the waste site.

**Description:** 100-D-15 has been remediated and Interim Closed Out. The site consisted of two separate areas containing debris. The northern area of the site contained debris consisting of concrete rubble, metallic and asphalt debris, and other inert materials. Potential asbestos-containing materials were also found to be present. The southern area of the 100-D-15 waste site was used as a
disposal location for sediment that was removed during the cleanout of the 182-D Basin. The sediment was observed to contain clamshells and clumps of asphalt-type sealant used in the 182-D Basin.

Location: There were two solid waste disposal pits containing debris located south of 100-D Area near the perimeter road. One disposal area was located north of the perimeter road and west of the railroad track. The other disposal area was south of the perimeter road, inside Gravel Pit #21 (site code 100-D-55).

Related Sites/Structures: The site is associated with Gravel Pit #21 (100-D-55).

Process Description: The 100-D Area Technical Baseline Report states that this location contains construction debris consisting of concrete rubble, metallic materials, asphalt material, and broken floor tiles (potentially asbestos-containing). The site was also reportedly used to dispose of empty cans formerly containing oil and cleaning solvents from Army sites located northeast of the 100-D Area.

Waste Type: Equipment

Waste Description: The northern pit is assumed to be the older of the two pits. The pit has been reported to have been used as a disposal site for empty cans collected from army sites located northeast of the 100-D Area. Army wastes could include oil cans, solvent cans, and other miscellaneous solid wastes. Asbestos may be present. The exact contents of the debris is unknown.

Waste Type: Equipment

Waste Description: The southern pit contains construction debris including concrete, metal, asphalt, and other debris. Asbestos may be present. The exact contents of the debris are unknown. In August 1994, Kaiser Engineers Hanford (KEH) removed sediments from the 182-D River Water Basins and deposited the material in the east end of the pit over part of the existing waste site. This disposal option was chosen rather than the demolition landfill option because the sediment did not meet the demolition landfill acceptance criteria. In a September 1997 memo, it was determined that the material classified as "clean soils or clean dredge soils" as defined in Washington Administrative Code (WAC) 173-304 definition that "Clean soils or clean dredge soils" means soils which are not dangerous waste or problem wastes. This classification excludes material from regulation and requires no specific management or disposal requirements. Therefore, there is no requirement to dispose of the material in any type of permitted landfill.

Closure Info: The northern area of the site contained debris consisting of concrete rubble, metallic and asphalt debris, and other inert materials. Potential asbestos-containing materials (floor tiles) were also found to be present. The southern area of the 100-D-15 waste site was used as a disposal location for sediment that was removed during the cleanout of the 182-D Basin. The sediment was observed to contain clamshells and clumps of asphalt-type sealant used in the 182-D Basin. Remediation included removing a layer of underlying soil.

Remedial action at the site was performed between October 6 and December 1, 2008. The northern location was excavated to a depth ranging from 2 meters (6.6 ft) to 4 meters (13 ft) below grade. The southern location was excavated to a depth of 3.5 meters (11.5 ft) below grade. Approximately 9,198 bank cubic meters (BCM) (10,059 bank cubic yards [BCY]) of soil and debris were removed from the north area, and 4,003 BCM (4,378 BCY) was removed from the south area. All material was direct loaded for disposal at the Environmental Restoration Disposal Facility. Two pot holes were dug to a depth of 1.2 meters to 1.5 meters (4 to 5 feet) No material was found in the first pot hole, but roofiing material was found in the second pot hole. A decision was made to remove this layer of debris.

</tr>
<tr>
<td>Closure Info:</td>
<td>Note - The 105-DR reactor operated between 1950 and 1964 for plutonium production. In 1973, the exhaust system portions of the 105-DR reactor were reactivated and re-purposed to support the Large Sodium Fire Facility (LSFF). The LSFF (sitecode 122-DR-1) was a RCRA TSD. Most of the components of the reactor exhaust system have two entries in the WIDS database, one representing the CERCLA (radioactive) contaminants and the other representing the RCRA hazardous chemical contaminants. The portions of the LSFF TSD that are included in this remedial activity are the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the underground exhaust tunnel (122-DR-1:2), the 119-DR Exhaust sample building (100-D-64), two dry wells (100-D-23 and 100-D-54) and the 116-DR Exhaust Stack (132-DR-2/122-DR-1:5) Four of the seven 122-DR-1 subsites (122-DR-1:1, 122-DR-1:3, 122-DR-1:6 and 122-DR-1:7) were closed out under the 105-DR Large Sodium Fire Facility RCRA Closure Plan (LSFF Closure Plan) are not discussed in the CVP-2003-00018 Cleanup Verification Package. The remedial objective for the structures was to remove each structure to a minimum of 0.9 meters (3 feet) below surface grade. In July 2003, remedial/removal action activities removed the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the downstream (post-filter) tunnel and the additional 0.9 meters (3 ft) of the 116-DR Reactor Exhaust Stack (132-DR-2/122-DR-1:5). The aboveground portion of the 132-DR stack had been demolished in 1999. Large Sodium Fire Facility (LSFF) subsite 122-D-1:2 (underground tunnel between the 105-DR Building) and the 117-DR Exhaust Filter Building were entirely removed. The 315 and 316 exhaust plenums, (aka upper and lower exhaust tunnels) are also associated with the 122-D-1:2 subsite. The upper exhaust tunnel and approximately the top 0.9 meters (3 ft) of the lower exhaust tunnel were removed. The 119-DR Exhaust Stack Sampling Building and two stack sampling building dry wells (100-D-23 and 100-D-64) were also demolished and excavated as part of the remedial/removal action activities in July 2003.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
At the completion of the remedial action, the total excavation was approximately 1,010 square meters (10,872 square feet) in area with an approximate depth of 5 meters (16.4 feet). Approximately 14,011 metric tons (15,412 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

### 100-D-27; 151-D Substation UPR; A-2 Substation Transformer #A401C Leak

**Names:** 100-D-27; 151-D Substation UPR; A-2 Substation Transformer #A401C Leak

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The site has been reclassified to Closed Out. The site consisted of an unplanned release of less than 100 gallons of PCB oil within the 151-D Substation. The transformer was power washed, the contaminated material was shoveled into seven 208 liter (55 gallon) drums, and the site was backfilled.

**Location:** The release occurred at the #A401C transformer, located in the 151-D Substation. The substation is west of the 105-DR Reactor and southwest of the 105-D Reactor.

**Release Description:** During a routine inspection of the 151-D substation, a non-PCB oil leak was discovered. Occurrence report RL--WHC-KHELEC-1995-0013 was issued.

**Waste Type:** Chemicals

**Waste Description:** The release was less than 100 gallons (380 L) of non-PCB mineral oil. According to a transformer inventory, oil in the #A401C transformer contains 42.0 parts per million PCBs.

**Closure Info:** The oil leak occurred in June 1995. The transformer was power washed, the contaminated material was shoveled into seven 208 liter (55 gallon) drums, and the site was backfilled. The drums were taken to a staging area.

Waste Site Reclassification form 2005-014 states the spill was less than 100 gallons of 42 ppm PCB oil. Therefore, no more than 0.016 kilogram PCB would have been released, significantly less than the CERCLA RQ of 0.45 kilogram (1 pound). The remedial action objectives and remedial action goals in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (EPA 1999) are therefore not applicable to the 100-D-27 waste site. The site will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario and no institutional controls are required.

### 100-D-28; 190-DR Building Septic System

**Names:** 100-D-28; 190-DR Building Septic System

**Type:** Septic Tank

**Status:** Inactive

**Description:** The site consists of two septic systems, the original septic and the replacement. See the subsites for more detail.

**Location:** The unit is located southwest of the 190-DR Building.
Related Sites/Structures: 190-DR Building and Annex

Process Description: The system processed and disposed of septage from the 190-DR Main Pump House. The 190 DR Building housed the pumps and related equipment used to supply the 105-DR Reactor with cooling water from the 183 DR Clearwells. Until August 2004, part of this building was also used for the storage of radiological material. A confirmatory radiological survey of the area following removal of the material located no contamination (RSR-105DR-04-0077).

Waste Type: Oil

Waste Description: The system received sanitary wastes.

This Site has the Following SubSites:

Code: 100-D-28:1
Names: 100-D-28:1; Replacement Septic System

Code: 100-D-28:2
Names: 100-D-28:2; Original Septic System

Code: 100-D-28:1
Names: 100-D-28:1; Replacement Septic System
Type: Septic Tank
Status: Inactive
Description: The 100-D-28:1 subsite has been remediated and Interim Closed Out. It consisted of a septic tank and drain field located approximately 25-meters (82-feet) southwest of the 190-DR Building. The septic system included a 2,730 liters (720-gallons) steel tank and a vitrified clay pipe drain field due west of the septic tank used in association with the 190-DR Building.

The 190-DR Annex constructed in 1955 added approximately 21.3 m (70 ft) to the east side of the 190-DR Building. The 190-DR Annex is approximately 3 m (10 ft) below grade. Photographs from 1955 (see attachment) show the depth and amount of disturbance for the excavation of the annex. It does not appear that this septic tank and tile field could have survived the construction of the 190-DR Annex. Likely a new septic system (100-D-28:1) was installed per drawing H-9923 southwest of the 190-DR as a replacement system.

Location: The septic system was located approximately 25 m (82 ft) southwest of the former 190-DR Building. The drain field is centered at E573491.6, N151105.6 and the septic tank at E573498.7, N151104.8.

Process Description: The system processed and disposed of sewage from the 190-DR Main Process Water Pumphouse.

Waste Type: Oil

Waste Description: The waste would be septage from the 190-DR Main Pump House.

Closure Info: Remediual action at the 100-D-28:1 subsite was performed between July 27 and August 17, 2010. Additional remediation was conducted on March 17, 2011 due to residual contamination identified following verification sampling activities. The excavation continued to a maximum depth of 5 meters (16 ft) until all contaminated soil and debris associated with the waste site had been removed. Approximately 2,760 bank cubic meters (BCM) (3,610 bank cubic yards...
[BCY]) of contaminated soil and debris were removed from the excavation and staged in a staging pile area (SPA) to the north of the excavation before being loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 1,275 BCM (1,668 BCY) of overburden material was stockpiled for use as clean backfill. However, verification sampling found unacceptable contaminant concentrations and after additional remediation and resampling, contamination was still present above direct exposure remedial action goal (RAGs); therefore, the entire overburden soil stockpile was loaded out for disposal at the ERDF between April 20 and 21, 2011.

Three miscellaneous pipeline sections were encountered during remediation of the 100-D-28:1 subsite. Two of the pipeline sections found are part of the 100-D-50:6 pipeline subsite and one section is part of the 100-D-63 pipeline site. The 100-D-50:6 and 100-D-63 pipelines will be addressed separately from the 100-D-28:1 subsite.

The debris removed from the 100-D-28:1 subsite consisted of contaminated soil, concrete, and piping associated with the septic tank and drain field. No anomalous material was encountered during excavation.

**The SubSite is Part Of:**
- **Code:** 100-D-28
- **Names:** 100-D-28; 190-DR Building Septic System

**Code:** 100-D-28:2
- **Classification:** Accepted
- **Reclassification:** Rejected (8/1/2005)
- **Type:** Septic Tank
- **Start Date:**
- **End Date:**
- **Description:** The 100-D-28:2 site consisted of a septic tank and drain field located approximately 15.2-meters (50-feet) from the northeast side of the original 190-DR Pump House. The tank capacity was 2,839-liters (750-gallons). The 190-DR Annex constructed in 1955 added approximately 21.3-meters (70-feet) to the east side of the 190-DR Building. It does not appear that the 100-D-28:2 septic tank and tile field could have survived the construction of the 190-DR Annex. The 100-D-28:1 septic system was installed per drawing H-9933-DR on the southwest side of the 190-DR Building as a replacement system.

The 190-DR Annex constructed in 1955 added approximately 21.3 meters (70 feet) to the east side of the 190-DR Building. The 190-DR Annex is approximately 3 meters (10 feet) below grade. Photographs from 1955 (see attachment) show the depth and amount of disturbance for the excavation of the annex. It does not appear that this septic tank and tile field could have survived the construction of the 190-DR Annex. Likely a new septic system (100-D-28:1) was installed per drawing H-9923, southwest of the 190-DR as a replacement system.

Based on the historical documentation, the 100-D-28:2 septic system has not existed or been used in over 50 years. A reclassification status of Rejected has been assigned for the 100-D-28:2 septic system. The site achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington. The site will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario and no institutional controls are required.

**Location:** This subsite is located approximately 15.2 m (50 ft) from the northeast side of the original 190-
DR Pump House.

**Waste Type:** Chemicals

**Waste Description:** No cleanup was performed at this site.

**The SubSite is Part Of:**

**Code:** 100-D-43

**Names:** 100-D-43; 118-D-4C; Burial Ground 4C; Buried VSR Thimble Site

**Classification:** Accepted

**Reclassification:** Interim Closed Out (5/13/2010)

**Type:** Burial Ground

**Status:** Inactive

**Description:** The waste site has been remediated and Interim Closed Out. It was a solid waste burial ground. The 100-D-42, 100-D-43, and 100-D-45 waste sites were located in the same area and were remediated as one decision unit. The burial ground was in very close proximity to the (exhumed) 152-centimeter (60-inch) effluent lines.

**Location:** The site is located east of the 105-D Reactor Building, outside the reactor security fence and south of the railroad spur that services 105-D.

**Waste Type:** Process Effluent

**Waste Description:** The waste is a buried Vertical Safety Rod (VSR) thimble. The VSR thimbles were made of aluminum similar to the that used in the process tubes and should contain similar isotopic composition. Sampling of process tubes was conducted in March 1967. The radionuclide levels, when decay corrected by Dorian and Richards to March 1977, were 5.9E+03 picocuries of manganese-54 per gram of aluminum and 2.5E+07 picocuries of cobalt-60 per gram of aluminum. When buried, the thimble's exterior surfaces would also have been contaminated with activated graphite products and potassium borate.

**Closure Info:** The 100-D-42, 100-D-43, and 100-D-45 waste sites were located in the same area and were remediated as one decision unit. Remedial action at the sites began on September 6, 2007, and was completed on April 22, 2008. Contaminated soil and debris were excavated and removed from the burial grounds for shipment to ERDF. Field observations during excavation indicated the presence of VSR thimbles in two of the three burial grounds. Only concrete debris and plastic sheeting were found to be present in the 100-D-42 Burial Ground. The 100-D-43 Burial Ground contained VSR thimbles and other reactor hardware. Mastic, aluminum pipe, VSR thimbles, reactor hardware, and a drum containing rags were found in the 100-D-45 Burial Ground. Due to the close proximity to each other and the type of debris encountered during excavation, the three sites were included in one CVP and interim closed out as one decision unit.

Remedial action at the 100-D-45 Burial Ground began on September 6, 2007, with the removal of 930 bank cubic meters (BCM) (1,216 bank cubic yards [BCY]) of overburden material. Excavation began on September 11, 2007 and continued through July 23, 2008 to a depth of approximately 7 meters (23 ft) resulting in approximately 2,605 BCM (3,407 BCY) of contaminated soil and debris removed for disposal at ERDF. Remedial action at the 100-D-43 Burial Ground began on September 10, 2007, with the removal of 165 BCM (216 BCY) of overburden material. Excavation began on September 25, 2007 and continued through October 10, 2007, to a depth of approximately 5 meters (16 ft), resulting in approximately 803 BCM...
(1,050 BCY) of contaminated soil and debris removed for disposal at ERDF. Remedial action at the 100-D-42 Burial Ground began on April 22, 2008, with the removal of 495 BCM (647 BCY) of overburden material. Excavation of the burial ground was initiated on April 25, 2008 and continued through May 13, 2008, to a depth of approximately 5 meters (16 ft), resulting in approximately 530 BCM (693 BCY) of contaminated soil and debris removed for disposal at ERDF.

A geophysical survey was conducted in June 2004 at the 100-D-42, 100-D-43, and 100-D-45 Burial Ground locations, and an additional survey was conducted at the 100-D-45 Burial Ground location in September 2004. No notable features with the characteristics of an excavated area or buried debris were detected at the documented location of the 100-D-42 site. Immediately to the south of the 100-D-42 Burial Ground was an area with distinct excavation boundaries and notable concentrations of anomalies with the characteristics of buried debris. This area correlates more closely with the documented locations of the 100-D-43 and 100-D-45 Burial Grounds. One anomaly was encountered in the 100-D-43 Burial Ground. A 57 liter (15 gal) metal container partially filled with liquid was found during excavation. The container was found to have been breached and the contained liquid is suspected to have been water used for dust suppression during excavation activities. No suspect spent nuclear fuel was present in the burial grounds.

The excavation area has a maximum depth of approximately 7 meters (23 ft). However, the entire excavation area is considered one decision unit and meets the more restrictive shallow zone cleanup criteria.

<td>Closure Info:</td>
<td>The 116-D-1A and 116-D-1B Storage Basin Trenches received contaminated water and sludge from the 118-D-6 Fuel Storage Basin. The 100-D-46 Burial Ground received solid waste and construction debris from modifications made to 105-D after 1967 and was co-located with the trenches. The three waste sites were remediated together, with the documentation presented in the same Cleanup Verification Package (CVP-2000-00010). The document referred to the collective three waste sites as the 116-D-1A/116-D-1B site.</td>
</tr>
</tbody>
</table>
The selected remedial action for the 116-D-1A/116-D-1B sites included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, RAGs were established to identify radionuclide and nonradionuclide contaminants of concern (COCs) and contaminants of potential concern (COPCs). Waste site COCs and COPCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22).

Remedial action at the 116-D-1A/116-D-1B site began on October 21, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 11, 2000, the excavation reached the design limit at El. 138.4 m (454 ft).

At the completion of the remedial action, the total excavation was approximately 2,648 square meters (28,470 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 10,987 metric tons (12,111 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

---

**Code:** 100-D-47  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (1/15/2010)  
**Names:** 100-D-47; 118-D-4E; Burial Ground 4E; Construction C.G. 558-Rod Burial  
**Type:** Burial Ground  
**Status:** Inactive  
**Description:** 100-D-47 has been remediated and interim Closed Out. It was located within the 118-D-4 cobble field, but was not separately marked. Following remediation activities, the project was authorized to remove radiological postings.  
**Location:** The site is located east of the 105-D Reactor Building, outside the reactor exclusion area fence and south of the railroad spur that services the reactor building. The burial ground is west of Burial Ground 4F (118-D-4) and south of Minor Construction Burial Ground #5 Pit (100-D-40) and Trench (100-D-41).  
**Process Description:** The site is a burial ground used to dispose of fuel rod waste during project CG-558.  
**Waste Type:** Process Effluent  
**Waste Description:** The site is described as a rod burial site. The type and quantity of rods disposed of at this site is not known. Potential contaminants include: C-14, Co-60, Ni-63, H-3, Nb-94, Ni-59, Pd-102, Sm-151, Tc-99, Am-241, Ag-108m, Ba-133, Cs-137, Eu-152 and 154, Pu-238, 239 and 241, Ca-41, Cd-113m, Kr-85, Zr-93, cadmium, lead.  
**Closure Info:** Remedial action began on January 16, 2008, and continued through March 20, 2008. A total of approximately 2,800 bank cubic meters (BCM) (3,660 bank cubic yards [BCY]) of material was removed for disposal at ERDF. Approximately 247 BCM (323 BCY) of overburden and layback was stockpiled for use as clean fill. The material excavated was consistent with the burial of scrap (piping, concrete, valves, etc.) from miscellaneous equipment modifications accomplished during Project CG-558. The horizontal control rods, if present, were not
distinguishable from the other debris.

<tbody>
<tr>
<td>Note - The 105-DR reactor operated between 1950 and 1964 for plutonium production. In 1973, the exhaust system portions of the 105-DR reactor were reactivated and re-purposed to support the Large Sodium Fire Facility (LSFF). The LSFF (sitecode 122-DR-1) was a RCRA TSD. Most of the components of the reactor exhaust system have two entries in the WIDS database, one representing the CERCLA (radioactive) contaminants and the other representing the RCRA hazardous chemical contaminants.</td>
</tr>
</tbody>
</table>

The portions of the LSFF TSD that are included in this remedial activity are the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the underground exhaust tunnel (122-DR-1:2), the 119-DR Exhaust sample building (100-D-64), two dry wells (100-D-23 and 100-D-54) and the 116-DR Exhaust Stack (132-DR-2/122-DR-1:5) Four of the seven 122-DR-1 subsites (122-DR-1:1, 122-DR-1:3, 122-DR-1:6 and 122-DR-1:7) were closed out under the 105-DR Large Sodium Fire Facility RCRA Closure Plan (LSFF Closure Plan) are were not discussed in the CVP-2003-00018 Cleanup Verification Package.

The remedial objective for the structures was to remove each structure to a minimum of 0.9 meters (3 feet) below surface grade. In July 2003, remedial/removal action activities removed the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the downstream (post-filter) tunnel and the additional 0.9 meters (3 ft) of the 116-DR Reactor Exhaust Stack (132-DR-2/122-DR-1:5). The aboveground portion of the 132-DR stack had been demolished in 1999.

Large Sodium Fire Facility (LSFF) subsite 122-D-1:2 (underground tunnel between the 105-DR Building) and the 117-DR Exhaust Filter Building were entirely removed. The 315 and 316 exhaust plenums, (aka upper and lower exhaust tunnels) are also associated with the 122-D-1:2 subsite. The upper exhaust tunnel and approximately the top 0.9 meters (3 ft) of the lower exhaust tunnel were removed. The 119-DR Exhaust Stack Sampling Building and two stack sampling building dry wells (100-D-23 and 100-D-64) were also demolished and excavated as part of the remedial/removal action activities in July 2003.

At the completion of the remedial action, the total excavation was approximately 1,010 square meters (10,872 square feet) in area with an approximate depth of 5 meters (16.4 feet). Approximately 14,011 metric tons (15,412 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.
Reclassification: 100-D-62; 183-DR Headhouse Septic Tank

Status: Inactive

Type: Septic Tank

Start Date: Interim Closed Out (10/16/2013)

Classification: Accepted

Names: 100-D-62; 183-DR Headhouse Septic Tank

The septic system has been remediated and Interim Closed Out. It included the septic tank, drain field and associated piping. It received sanitary sewage from the 183-DR headhouse. The entire 183-DR water treatment facility is a non-radiological area, therefore, the 100-D-62 septic system waste site is not considered radiologically contaminated. This system was designed for the use of 6 people with a 2,271 liter (600 gal) capacity.

Location: The septic system was located about 15.2 meters (50 ft) south of the 183-DR Head House and west of the 183-DR Flocculation Basin. The drain field extended 6.1 meters (20 ft) from the south end of the septic tank.

Related Sites/Structures: The site was associated with the 183-DR Head House.

Process Description: The 100-D-62 septic system waste site received sanitary sewage from the 183-DR water treatment facility headhouse. The 183-DR water treatment facility was operational from 1952 to 1964, per documentation these facilities were demolished to grade in 1978. The operational period of the septic system is assumed to be the same as the 183-DR facility. The 183-DR water treatment facility filtered and chemically treated raw Columbia River water prior to use to cool components within the 105-DR Reactor. Sulfuric acid, potentially containing impurities such as lead and mercury, was added to raw river water prior to entry into the flocculation basins. Sodium dichromate was added to the water in the filter building to inhibit metal corrosion of reactor components. The 183-DR headhouse served as a receiving, storage, and transfer point for sodium dichromate. Sodium dichromate was received from the 185-D Building into one or more storage tanks located in the equipment room in the northeast corner of the headhouse on the ground floor. The sodium dichromate solution was pumped via an overhead line across the flocculation and sedimentation basins to the eastern end of the filter building. It was then injected into a mixing flume that was located along the eastern side of the building. The 183-DR headhouse was the western most building of the water treatment facility. The building was 34 m by 24 m (1.10 ft by 80 ft) and supplied an appropriate mixture of chemicals to provide the desired treated water to the reactor. River water entered the headhouse through two 9.1 cm (36 in) diameter steel pipes. The 183-DR headhouse contained inlet control valves, flash mixer chambers, chlorinators, and the ferric sulfate, lime, and silicate storage and feeding equipment used to chemically treat water. The 183-DR headhouse received 10% sodium dichromate solution from the 185-D Building through a 7.6 cm (3 in) diameter pipeline that connected with two tanks, each with a 15,142 L (4,000 gal) capacity. From the storage tanks, two, 1.9 cm (0.75 in) diameter sodium dichromate pipes crossed above the flocculation and sedimentation basins where they entered the sample room and mixing pumps in the filter building.

Waste Type: Water

The waste is the remaining septic system (tank and piping) and any remaining septage. The Contaminants of potential concern (COPCs) for the 100-D-62 waste site were identified based on existing historical information for the 183-DR water treatment facility and contaminants associated with previously sampled septic systems. The COPCs for the 100-D-62 septic system include constituents associated with the chemicals used in the 183-DR headhouse: chromium, hexavalent chromium, mercury, lead, and anions. Although not COPCs, arsenic, antimony, barium, beryllium, boron, cadmium, cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc concentrations will be evaluated by performing the expanded inductively coupled plasma metals analytical list. Based on findings from other septic systems in the 100-D Area, semivolatile organic compounds, pesticides, and polychlorinated biphenyls
are also considered COPCs. Additional COPCs may be identified as part of planning for remedial actions. Radionuclides are not COPCs for this site. However, the presence of radiological contaminants should be evaluated using field radiological survey instrumentation (capable of detecting alpha, beta, and gamma radiation) during remediation of the septic system. If radiological activity is detected during remediation, the verification sampling work instruction will incorporate specific requirements for radionuclide analysis.

**Closure Info:**

Remedial action at the 100-D-62 waste site was conducted on May 2 and 3, 2011. A reinforced concrete septic tank, associated concrete piping, and soil were removed as part of the remediation and staged at the Spoil Pile Areas. Approximately 793 bank cubic meters (BCM) (1,037 bank cubic yards [BCY]) of soil and debris was loaded on July 12 and 13, 2011, for disposal at the Environmental Restoration Disposal Facility (ERDF).

Remedial action at the 100-D-77 waste site began on May 3, 2011, and continued through July 13, 2011. The 100-D-83:1 subsite consisted of the pipeline segments associated with the 183-DR Acid Facility. Most of the pipelines were within the 100-D-77 acid trench and were removed during the 100-D-77 waste site remediation. Remediation continued to a depth of approximately 4.5 meters (15 ft) below ground surface (bgs) resulting in approximately 7,103 BCM (9,290 BCY) of contaminated soil and debris that was removed and staged at the staging pile areas (SPAs) prior to loadout and disposal.

The 100-D-83:1 waste site was inside the 100-D-77 site and was fully removed with the 100-D-77 excavation. Verification samples were collected from these three locations on May 29, 2013.

A 20 meter (65.6 ft) section of the 100-D-56:2 pipelines, located at the entrance into the 183-DR Head House, and the 183-DR Filter Building sample room were also remediated with 100-D-77. Loadout of waste material with subsequent disposal at ERDF was conducted between July 13 and October 18, 2011.

At the completion of the remediation, in-process soil samples were collected on July 6 and July 11, 2011, to determine if additional remediation of the waste site was necessary. Mercury was measured above the direct exposure remedial action goals (RAGs) in the in-process sample data. Based on these results, a second tier (Tier 2) of excavation was designed.

The Tier 2 remediation began on December 8, 2011, and continued through January 16, 2012. Approximately 7,126 BCM (9,320 BCY) of contaminated soil and debris were removed from the excavation and moved to the SPAs for loadout and disposal at ERDF. The excavation depth extended a maximum of 9.5 meters (31 ft) bgs. Loadout of the Tier 2 waste material began on December 14, 2011.

The presence of elevated PAH within the excavation area was attributed to cross-contamination of asphalt. Additional remediation of benzo(a)pyrene at location EXC-3 was a result of cross-contamination with asphalt. Additional soil was removed at and around the sample location (EXC-4) with elevated mercury on March 15, 2013. An additional 76 BCM (100 BCY) of contaminated soil and debris were removed from the excavation and staged prior to disposal at ERDF. The area in which additional removal was performed included the FS-1 sample location. Replacement verification samples were collected at the EXC-4 and FS-1 locations on March 15, 2013.

Contaminated soil, concrete, and rebar from previously demolished buildings, piping, and a brick-lined concrete acid trap were among the types of material removed from the excavation. All materials removed from the 100-D-62, 100-D-77, and 100-D-83:1 excavation were staged at five SPAs prior to loadout and disposal at ERDF.
The waste site has been remediated and Interim Closed Out. It was the 183-DR Water Treatment Facility. It included the 183-DR filter building, head house, flocculation and sedimentation basins, acid facility and train shed. The entire water treatment system was demolished to grade in 1978. The flocculation and sedimentation basins remain below grade and were demolished in situ.

The site includes the sodium dichromate systems that were located within the 183-DR Head House and 183-DR Filter Building, Acid Facility, the six 183-DR Flocculation Basins, and the six 183-DR Sedimentation Basins, all of which were components of the cooling water treatment system to support the 105-DR Reactor.

The site is located west of 105-DR, west the remediated 183-DR Clearwells (126-DR-1).

The 183-DR Head House is on the west side and immediately adjacent to the 183-DR Coagulation Basins. The 183-DR Filter Building is located between the 183-DR Sedimentation Basins and the 190-DR Storage Tanks.

These components are of interest because they stored, mixed, or processed liquid contaminants of concern, especially sodium dichromate and sulfuric acid (potentially contaminated with lead and mercury). The sedimentation basins and possibly the flocculation basins received demolition debris from the 183-DR area facilities that may have been contaminated. Sodium dichromate was supplied to the 183-DR Head House through a 7.6 centimeter (3 inch) diameter pipeline (100-D-56) that entered the west side of the 183-DR Head House. The 183-DR Head House contained the inlet control valves, flash mixer chamber, chlorinators, ferric sulphate and lime storage, and feeding equipment, silicate and sodium dichromate solution storage and feeding equipment. The 183-DR Head House had its own sodium dichromate storage facility that consisted of two tanks with a 15,200 liter (4,000 gallon) capacity. Sodium dichromate solution was pumped and injected into the process water after the filters in the filter building by the proportioning pumps in the head house. The 183-DR Filter Building also received sodium dichromate from the 183-DR Head House. Two 1.9 centimeter (0.75 inch) diameter sodium dichromate pipelines extended from the mixer in the 183-DR Head House, over the flocculation and sedimentation basins, to the 183-DR Filter Building where it entered the sample room, mixing pumps, and flume. Acid Facility: The Acid Facility was located on the north side of the 183-DR Head House. Sulfuric acid was received by railroad car and stored in two outside above grade acid storage tanks. The acid facility contained two acid storage tanks (No. 1 & 2), two acid pumps, car spot, acid head tank, one drywell, two sumps, acid piping, pipe flume/trench and an acid pit (H-1-5662). The acid pumps were designed to transport sulfuric acid from the railroad cars to the storage tanks and from the storage tanks to the acid head tank (H-1-5663). The GPS coordinates for the acid pumps are E573251, N151223. The railroad car spot was located west of the pipe trench and south of acid storage tank No. 1. Sulfuric acid was unloaded at this location and pumped to either storage tank No. 1 or 2 (H-1-5663). Between the sulfuric acid tanks was a pipe flume/trench that contained seven pipes that included, two 5 centimeter (2 inch) sulfuric acid pipes (100-D-83), a 10 centimeter (4 inch) overflow pipe, a 2.5 centimeter (1 inch) low pressure steam pipe, 3.2 centimeter (1.25 inch) compressed air pipe, 5 centimeter (2 inch) lime slurry pipe, and a 5 centimeter (2 inch) filtered water pipe (H-1-5663). From the acid tanks, material was transported through the pipe trench to the acid head tank then...
to the 183-DR Head House. Each of the other pipes also connected to the northwest wall of the 183-DR Head House (H-1-5662). The acid head tank was located on the east side of the pipe trench and south of acid tank No. 2. A 5 centimeter (2 inch) sulfuric acid line and a 5 centimeter (2 inch) sulfuric acid drain line connected the tank to the pipe trench. Another 5 centimeter (2 inch) pipe connected to the flume/trench between the 183-DR Head House and the flocculation basin (H-1-5663). The GPS coordinates for the acid head tank are E573256, N151222. There is one drywell and two sumps associated with the acid facility. The 31 centimeter (12 inch) diameter drywell was located on the west side of the acid trench and south of acid tank No. 1 (E573251, N151220). There is a sump located on the west side of acid tank No. 1. The sump was a 61 centimeter (24 inch) diameter feature that was installed in 1957 (E573248, N151121). The second sump is west of the pipe trench and the acid pumps. It is 61 centimeter (24 inch) in diameter (H-1-5663) (E573249, N151232). The acid pit was located north of the acid storage tanks. The pipes in the flume/trench drained into the pit (H-1-5663) (E573252, N151239). The former site of the tanks and the unloading and transfer systems have the potential for contaminated soils caused by leaks and spills (potential lead and mercury). Although the facility has been demolished, subsurface contamination may be present.

The 183-DR Head House was the western most segment of the water treatment facility. The building contained three floors that included a basement. The basement contained a sump pit. The first floor contained the equipment room, electrical room, control room, chlorinator room, lab, and chlorine room. The top floor contained the chemical feeder (H-1-915). The dimensions were 34 m by 24 meters (110 feet by 80 feet). It was designed to supply the appropriate mixture of chemicals to provide the desired water treatment to the reactor. Chemicals were received by railcar at the train shed located on the west side of the Head House. River water entered the west side of the head house through two 91 centimeter (36 inch) diameter steel pipes. The 183-DR Head House contained the inlet control valves, flash mixer chamber, chlorinators, ferric sulphate and lime storage, and feeding equipment, silicate and sodium dichromate solution storage and feeding equipment used to chemically treat water (HDC-1418). Alum, sulfuric acid, chlorine and sodium dichromate were mixed in the facility. The 183-DR Head House never received sodium dichromate in pure form. It received a 10% sodium dichromate solution from the 185-D Building through a 7.6 centimeter (3 inch) diameter pipeline (100-D-56) that connected with two tanks, each with a 4,000 gallon capacity. From the storage tanks, two 1.9 centimeter (0.75 inch) diameter sodium dichromate pipes crossed above the flocculation and sedimentation basins where the pipes entered the sample room and mixing pumps in the filter building. From the filter building treated water entered the 190-DR Storage Tanks (H-1-9147, H-1-9601, HW-28360, and SK-1-8261). Water treated with sodium dichromate entered the 190-DR Clearwells followed by the 190-DR Pump House and through the pipe tunnels to the 105-DR Reactor. From the reactor, effluent was pumped to the retention basin (116-DR-9) and to the outfalls (100-D-65 and 1 16-DR-5). Sulfuric acid and sodium dichromate were mixed in the facility. Sulfuric acid was received from the Acid Facility into the head tank. Sodium dichromate was received through the 7.6 centimeter (3 inch) pipelines (100-D-56) from 185-D Building into two storage tanks, located on the ground floor of the Equipment Room in the northeast corner of the head house. Sulfuric acid was added immediately to the river water arriving from the 182-D Reservoir to adjust the pH. With the addition of the sulfuric acid early in the water treatment system, there is a potential for trace amounts of lead and mercury in the flocculation basins, sedimentation basins, and filter buildings. 183-DR Flocculation and Sedimentation Basins The flocculation and sedimentation basins received hundreds of millions of gallons of river water treated with sulfuric acid. The 183-DR flocculation and sedimentation basins were designed to allow heavier particulate matter to settle out of the water before it entered the filter building. The flocculation basins were located between the 183-DR Head House and the sedimentation basins. The flocculation basins contained six chambers, each containing a paddle wheel to mix chemical additives. The six chambers were 112.5 meters (369 feet) wide and 13 meters (43 feet) wide (H-1-9212). Also located in the basins were at least two drywells (H-1-9213 and H-1-9214 sht 2). The sedimentation basins joined the east side of the flocculation basins and also contained six chambers. There were six sludge hoppers, one for each basin, near the west wall of the
sedimentation basins (H-1-9211, H-1-9212, H-1-9216). Combined they were 112.5 meters (369 feet) wide, 58.5 meters (200 feet) long, and at least 5 meters (16 feet deep). The sedimentation basins later received demolition material from the D & D of the head house and the filter building in 1978 (both of which may have had sodium dichromate, mercury, and/or lead contamination). This component of the site is analogous to the 183-B flocculation and sedimentation basins contamination.

183-DR Filter Building
The filter building received water treated with sodium dichromate and sulfuric acid. The 183-DR Filter Building was located on the east side of the sedimentation basin. The filter building contained a pipe galley and operating floor. The operating floor contained the ventilation equipment, switchgear room, pump room, and suction header and hot well bay. (H-1-9401). The facility was 171 meters by 15 meters (560 feet by 52 feet) and contained two halves with a gullet between them. The original filters were modified and replaced with 30.48 centimeters (12 inch) of graded gravel, 15 centimeters (6 inch) of sand and 61 centimeters (24 inch) of crushed and graded anthracite coal. Water entered the gullet from the influent flume through an influent valve and flowed to both halves of the filter components through port openings. There were 10 filters in the facility. From the filter building, water entered the 190-DR Clearwells and pump house (H-1-9606). After demolition, the facility was disposed of in the 183-DR sedimentation basins.

| Waste Type: | Process Effluent |
| Waste Description: | The waste form would be contaminated soil from leaks and spills during operation, and contaminated fill material from the demolition of the two buildings. Sodium dichromate, lead, and mercury may be present under the site footprint and in the flocculation and sedimentation basins. |
| Closure Info: | Remedial action at the 100-D-62 waste site was conducted on May 2 and 3, 2011. A reinforced concrete septic tank, associated concrete piping, and soil were removed as part of the remediation and staged at the Spoil Pile Areas. Approximately 793 bank cubic meters (BCM) (1,037 bank cubic yards [BCY]) of soil and debris was loaded on July 12 and 13, 2011, for disposal at the Environmental Restoration Disposal Facility (ERDF). Remedial action at the 100-D-77 waste site began on May 3, 2011, and continued through July 13, 2011. The 100-D-83:1 subsite consisted of the pipeline segments associated with the 183-DR Acid Facility. Most of the pipelines were within the 100-D-77 acid trench and were removed during the 100-D-77 waste site remediation. Remediation continued to a depth of approximately 4.5 meters (15 ft) below ground surface (bgs) resulting in approximately 7,103 BCM (9,290 BCY) of contaminated soil and debris that was removed and staged at the staging pile areas (SPAs) prior to loadout and disposal. The 100-D-83:1 waste site was inside the 100-D-77 site and was fully removed with the 100-D-77 excavation. Verification samples were collected from these three locations on May 29, 2013. A 20 meter (65.6 ft) section of the 100-D-56:2 pipelines, located at the entrance into the 183-DR Head House, and the 183-DR Filter Building sample room were also remediated with 100-D-77. Loadout of waste material with subsequent disposal at ERDF was conducted between July 13 and October 18, 2011. At the completion of the remediation, in-process soil samples were collected on July 6 and July 11, 2011, to determine if additional remediation of the waste site was necessary. Mercury was measured above the direct exposure remedial action goals (RAGs) in the in-process sample data. Based on these results, a second tier (Tier 2) of excavation was designed. The Tier 2 remediation began on December 8, 2011, and continued through January 16, 2012. Approximately 7,126 BCM (9,320 BCY) of contaminated soil and debris were removed from the excavation and moved to the SPAs for loadout and disposal at ERDF. The excavation depth extended a maximum of 9.5 meters (31 ft) bgs. Loadout of the Tier 2 waste material began on |
The presence of elevated PAH within the excavation area was attributed to cross-contamination of asphalt. Additional remediation of benzo(a)pyrene at location EXC-3 was a result of cross-contamination with asphalt. Additional soil was removed at and around the sample location (EXC-4) with elevated mercury on March 15, 2013. An additional 76 BCM (100 BCY) of contaminated soil and debris were removed from the excavation and staged prior to disposal at ERDF. The area in which additional removal was performed included the FS-1 sample location. Replacement verification samples were collected at the EXC-4 and FS-1 locations on March 15, 2013.

Contaminated soil, concrete, and rebar from previously demolished buildings, piping, and a brick-lined concrete acid trap were among the types of material removed from the excavation. All materials removed from the 100-D-62, 100-D-77, and 100-D-83:1 excavation were staged at five SPAs prior to loadout and disposal at ERDF.

---

**Code:** 100-D-94  
**Classification:** Accepted  
**Reclassification:** Interim No Action (3/31/2011)  
**Names:** 100-D-94; Dichromate Contaminated Pit Associated with 187-DR  
**Type:** Depression/Pit (nonspecific)  
**Status:** Inactive  
**Description:** The site was evaluated and determined to require No Action. It consists of an area of yellow material observed inside a pit under the DR water tower. This area was identified during the D Area Orphan Site Evaluation.  
**Location:** The site was located directly under the 100-DR water tower, south of the 105-DR Reactor.  
**Related Sites/Structures:** This site is associated with the 187-DR high tower.  
**Process Description:** This site served as a valve pit for process water stored in the 187-DR water tower. The water tower provided emergency cooling water to the 105-DR reactor. The reinforced concrete valve pit with a 1.06 meter (3.5 ft) thick floor slab, 0.3 meter (1 ft) thick side walls and 0.76 meter (2.5 ft) thick roof, was located below ground directly beneath the tank. A central riser extended into this pit from the water tank.  
**In August 2010, during confirmatory sampling of 100-D-83:4 in Test Pit 3. Beta and gamma readings up to 6,000 dpm were detected on a piece of broken pipe. The pipe was located approximately 0.3 meters (1 foot) to 2.4 meters (8 feet) below ground surface.**  
**Waste Type:** Chemical Release  
**Waste Description:** Potential Contaminant of Concern, Chromium.  
**Closure Info:** Based on observations during the site visit, review of historical drawings, process knowledge, and a geophysical survey of the 100-D-94 waste site, confirmatory sampling was performed in August 2010.  

Two focused soil samples and one duplicate were collected from the excavated test pit and were used to evaluate whether contamination associated with the dichromate contaminated pit was present at the 100-D-94 waste site. The test pit was excavated to 2.0 meters (6.6 ft) below ground surface (bgs). The soil appeared to be fill material consisting of dark gray sandy soil and unsorted cobble. The test pit was extended to a depth of 3 meters (9.8 ft) bgs, where a second
soil sample was collected. One pipe flange was found loose in the excavation. No other debris or staining was observed. The soil appeared to be fill material at this depth also. No undisturbed native soil was encountered during the excavation. Field surveys for radiological activity and volatile organic compounds were conducted during sampling. No radiological activity or volatile organic compounds were detected.

The confirmatory sampling results indicated that environmental contamination was not present at the 100-D-94 waste site; therefore, remedial action was determined to be unnecessary. The confirmatory sampling data has been used to document this waste site for reclassification as a No Action site.

**Names:**

100-D-100; Sodium Dichromate Near Southern Portion of 100-D-56; Stained soil near 183-DR Railroad Track

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The site consists of chromate contaminated stained soil near the former sodium dichromate/acid railcar and truck unloading station (100-D-12).

**Location:** The stained soil was located in an area north of the 183-DR Headhouse and approximately 50 meters (164 feet) south of Paddock Street, adjacent to the remediated 100-D-56 pipeline. The staining was between the 100-D-56 pipelines and the railroad tracks that previously serviced the 183-DR building. The lateral and horizontal extent of contamination has not been defined. The center of the site is located at Washington State Plane coordinates E573351 N151359.

**Related Sites/Structures:** The nearest structures (including those previously demolished) include the railroad spur leading to the 183-DR building and the sodium dichromate/acid railcar and truck unloading station (100-D-12). The stain was approximately 38 meters (125 feet) south of the 100-D-12 waste site.

**Process Description:** To inhibit corrosion, sodium dichromate was added to the reactor cooling water. Initially the chemical was prepared in the 108-D Chemical Pump House. The concentrated solution was pumped to feed tanks in the 105-D and 185-D Buildings. The preparation of the sodium dichromate feedstock was relocated from the 108-D Chemical Pump House to the 185-D Deaeration Plant in 1950. Two 7.6 centimeter (3 inches) diameter dichromate lines (100-D-56) were installed between the 185-D building and 183-DR building during the 100-DR Water Plant construction. A new spur track was also installed leading to the 183-DR building from the existing railroad tracks south of the 186-D building.

**Waste Type:** Stormwater Runoff

The waste consists of hexavalent contaminated soil. The potential contaminant of concern is hexavalent chromium.
degreasing pits, and french drains, was removed in its entirety. It had been surrounded with Underground Radioactive Material signs. It had also been posted with Cave-in Potential signs, but the Cave-in potential signs were removed in November 1999.

**Location:**
The site was located on the west side of the 100-DR Reactor, outside the fence.

**Related Sites/Structures:**
The site was associated with 100-D-50:1, 100-D-50:2 and the 1607-DR3 Sanitary Sewer Pipelines that may discharge to the 100-D-50:9 pipeline.

**Process Description:**
During the construction of the 105-D Reactor, this site functioned as the foundation and degreasing pits for a temporary airlock to clean and store reactor components before their installation. Subsequently, the concrete pad was modified to provide storage and a decontamination station for shielded casks used for shipping irradiated materials. After the 105-D Reactor was shut down in 1967, the casks and other materials were stored on the pad until general cleanup was performed in 1987. Surface contamination on the pad was stabilized by application of an asphalt fixative.

The concrete pad had two drains. The drain that handled pad decontamination and rain runoff, discharged into the 105-DR process sewer. The second drain discharged to a french drain, the location of which is unknown; however, an excavation that may be the drain was dug in 1949. There may also be a french drain beneath the loading dock, located on the west side, that provided drainage for storm runoff which is likely to be contaminated. The pad has been stabilized with a sprayed grout material and reinforced with a metal mesh material. There are two structures just south of the pad - one is a red aluminum storage tank and the other appears to be a furnace or shipping cask.

**Waste Type:**
Construction Debris

**Waste Description:**
This site contains trace amounts of radionuclides and decontamination chemicals.

**Closure Info:**
The grout-covered concrete pad, including the truck loading pit, degreasing pits, and french drains, was removed in its entirety. Remediation was performed from August 19, 2008 through February 8, 2009. Approximately 1,170 bank cubic meters (BCM) (1,530 bank cubic yards [BCY]) of concrete debris, asphalt emulsion, tan fibrous material, black plastic, grout, steel, and soil was removed from the waste site and disposed at the Environmental Restoration Disposal Facility (ERDF). In January 2011 an additional 0.53 BCM (0.69 BCY) of soil was removed from the area at the south degreasing pit. Approximately 1.0 BCM (1.2 BCY) of soil was removed from the south radiological contamination area. This material was also disposed of at ERDF. This is in the ecologically sensitive area associated with the 100-D-50:2 cooling water tunnel. The deepest part of the waste site excavation was approximately 1.5 meters (5 ft) deep at the location of the former degreasing pits.

The 116-D-8 waste site is located above a section of vitrified clay sewer pipeline associated with the 100-D-50:1 waste site. On August 25, 2008, a manhole was discovered during excavation of the 116-D-8 waste site. Based on the coordinate location, it was determined that the manhole was associated with the 100-D-50:1 subsite. The manhole was filled with clean borrow pit soil to eliminate a safety concern and left in place. No further remediation can be conducted at the location with the cesium-137 direct exposure exceedance, without incurring significant adverse impacts to the bat colonies at the 100-D-50:2 pipeline subsite. A study conducted between June 2007 and September 2008 (WCH 2009a) showed that the bats in the 100-D-50:2, Reactor Cooling Water Pipelines (concrete tunnel) from 190-DR Pumphouse subsite use the site as a maternity roost where they give birth and rear their young.

The preferred alternative to eliminate or mitigate impacts to the bat colony is to leave the structure intact and add perimeter fencing and signage to deter human entry. Therefore, institutional controls are required at the location of the cesium-137 contamination south of the

*Hanford Site Waste Management Units Report*
February 2015 287
116-D-8 cask storage pad.

A summary of the cleanup evaluation for the soil results against the applicable criteria is presented in Table ES-1. The results of the verification sampling are used to make reclassification decisions for the 116-D-8 waste site in accordance with the Tri-Party Agreement Handbook Management Procedures (DOE-RL 2007).

### Code: 118-D-1

| Names: 118-D-1; 100-D Burial Ground No. 1 |
| Status: Inactive |
| Description: The waste site has been remediated and Interim Closed Out. It was a burial ground that contained multiple trenches running north and south. The trenches were approximately 90 meters (300 feet) long by 6 meter (20 feet) wide and 6 meters (20 feet) deep with a 6 meters (20 feet) of space between them. Several trenches were greater than 6 meters (20 feet) deep. A 106 centimeter (42 inch) diameter, reinforced concrete water pipe runs through the northwest corner of the burial ground boundary, but not through any of the waste trenches (see WIDS sitecode 100-D-50). |
| Location: The unit is located south of the 105-DR Building just outside of the 100-D Perimeter Fence. |
| Process Description: The burial ground was constructed in 1944 as a solid waste disposal facility used for the disposal of irradiated reactor hardware, including thimbles, dummies, control rods, gun barrels, and other contaminated solid waste. Other waste items included soft waste, desiccant, miscellaneous waste, and thermocouple waste. |
| Waste Type: Chemical Release |
| Waste Description: The unit was used for the disposal of irradiated dummies, thimbles, rods, gun barrels, and other contaminated solid waste. It may contain spent nuclear fuel elements. Potential contaminants include: H-3, C-14, Co-60, Ni-63, Sr-90, Ag-108m, Cs-137, Eu-152, Eu-154, am-241, Pu-238,239 and 241, Sm-151, Se-79, Tc-99, U-235 and 238, Kr-85, Zr-93, cadmium, lead, mercury. Historical research identified some specific buried items that include a one ton Aimer track cut into 12 pieces, mattress plate extensions, poison pieces, vertical safety rods, rod guides and tips, shield plugs and contaminated soil. |
| Closure Info: Remedial action at the 118-D-1 Burial Ground began on November 28, 2008, and continued through May 5, 2011. Remedial action activities involved removing and stockpiling the uncontaminated overburden, and removing the buried waste and the underlying contaminated soil for disposal. The maximum depth of excavation was 6.5 meters (21 feet). Miscellaneous reactor hardware including piping, lead, splines, rods, a thimble head, and drums were excavated. No spent nuclear fuel was found to be present in the burial ground. Some stained soil was noticed during the remedial excavation. Focused samples were collected at these locations. |
| All waste materials were disposed at the Environmental Restoration Disposal Facility (ERDF). |

### Code: 118-D-2

| Names: 118-D-2; 100-D Burial Ground No. 2 |
| Status: Inactive |
| Description: The burial ground was constructed in 1949 as a solid waste disposal facility used for the disposal of irradiated reactor hardware, including thimbles, dummies, control rods, gun barrels, and other contaminated solid waste. Other waste items included soft waste, desiccant, miscellaneous waste, and thermocouple waste. |
| Location: The unit is located south of the 105-DR Building just outside of the 100-D Perimeter Fence. |

| All waste materials were disposed at the Environmental Restoration Disposal Facility (ERDF). |
The 118-D-2 waste site included the entire disturbed area visible in historical aerial photographs known as the 100-D Burial Ground No. 2. During remediation, it was split into two subsites: 118-D-2:1, 100-D Burial Ground No. 2 Trenches and Disposal Pits and 118-D-2:2, Anomaly Characterization Area. Both subsites have been remediated and Interim Closed out, so the parent site is also Interim Closed Out. The radiological postings were removed in September 2012.

This unit is located 400 meters (1,312 feet) west-southwest of the 183-DR Headhouse.

The waste site was the primary burial ground for the disposal of 105-D Reactor operations waste, including irradiated dummies, splines, rods, thimbles, and gun barrels. The 118-D-2 Burial Ground operated from 1949 to 1970 and was the primary burial ground for the disposal of 105-D Reactor operations waste, including aluminum tubes and spacers; metallic wastes of aluminum, cadmium, and lead; irradiated dummies; splines; vertical safety rods; thimbles; and gun barrels. The burial ground was extended in April 1966 to provide space for the burial of contaminated solid wastes from the 100-N Area. The burial ground consisted of several trenches running east to west and five pairs of disposal pits. The trenches were said to be 20 meters (66 ft) wide at the surface, 6.1 meters (20 ft) wide at the bottom, and 6.1 meters (20 ft) deep, and were used for the disposal of 105-D Reactor operations waste. The disposal pits were constructed by stacking railroad ties, creating two spaces with interior dimensions of approximately 1.8 by 1.8 meters (6 by 6 ft) that shared a common wall. The structures were built within an excavation reportedly 7.3 meters (24 ft) wide by 7.3 meters (24 ft) deep.

The unit was used for miscellaneous contaminated solid waste such as irradiated dummies, splines, vertical safety rods, thimbles, and gun barrels. Waste includes 16,329 kg of aluminum tubes, 36,287 kg of aluminum spacers, 89,040 kg of lead poison plugs, 37,192 kg of cadmium poison plugs, 5,987 kg of aluminum poison plugs, 54 kg of lead, and 16,329 kg of miscellaneous metallic waste. This burial ground has the potential to contain spent nuclear fuel rods.

Beginning in April 1966, 100-N Area solid wastes were also buried here. A large fire in this burial ground in March 1958. The large volumes of water that were required to extinguish the fire could have potentially washed contaminants into the soil column beneath the burial ground. Potential contaminants include H-3, carbon-14, cobalt-60, Ni-63, Sr-90, Ag-108, Ba-133, Cs-137, Eu-152 and 154, Pu-238, 239 and 241, Ca-41, Cd-113, Kr-85 and Zr-93.
Location:
The site is located 417 meters (1,368 feet) southwest of the 183-DR Headhouse.

Process Description:
The 118-D-2 Burial Ground operated from 1949 to 1970 and was the primary burial ground for the disposal of 105-D Reactor operations waste, including aluminum tubes and spacers; metallic wastes of aluminum, cadmium, and lead; irradiated dummies; spines; vertical safety rods; thimbles; and gun barrels. The burial ground was extended in April 1966 to provide space for the burial of contaminated solid wastes from the 100-N Area. The burial ground consisted of several trenches running east to west and five pairs of disposal pits. The trenches were said to be 20 meters (66 ft) wide at the surface, 6.1 m (20 ft) wide at the bottom, and 6.1 m (20 ft) deep, and were used for the disposal of 105-D Reactor operations waste. The disposal pits were constructed by stacking railroad ties, creating two spaces with interior dimensions of approximately 1.8 by 1.8 meters (6 by 6 ft) that shared a common wall. The structures were built within an excavation reportedly 7.3 meters (24 ft) wide by 7.3 m (24 ft) deep.

In 1953, the 118-D-2 burial ground consisted of one covered trench and one open trench that ran east and west. The waste site was the primary burial ground for the disposal of 105-D Reactor operations waste, including irradiated dummies, spines, rods, thimbles, and gun barrels. Each pair of pits was constructed by stacking railroad ties, creating two spaces with interior dimensions of approximately 1.8 by 1.8 meters (6 by 6 ft) that shared a common wall. The structures were built within an excavation 7.3 meters (24 ft) wide by 7.3 m (24 ft) deep. All were covered with 1.8 meters (6 ft) of soil. It was extended in April of 1966 to provide space for the burial of contaminated solid wastes from N-Area. The waste site was used for miscellaneous contaminated solid waste, irradiated dummies, spines, rods, thimbles, and gun barrels. After April 1966, 100-N Area solid wastes were also buried here. It was reported that there was a large fire in this burial ground sometime around 1960. The large volumes of water that was required to extinguish the fire could have potentially washed contaminants into the soil column beneath the burial ground. The metallic waste disposed in the waste site consists of 16,329 kg of aluminum tubes, 36,287 kg of aluminum spacers, 89,040 kg of lead poison slugs, 3,719 kg of cadmium poison slugs, 54 kg of graphite, 14 kg of desiccant, 5,987 kg of aluminum poison slugs, 816 kg of boron poison spines, 58,966 kg of lead, and 16,329 kg of miscellaneous metallic waste. Radioactively contaminated trash from N Reactor was sent to the Irradiation Processing Department D Reactor's burial trenches. The trash amounted to approximately 14 cubic meters (500 cu ft) per month. It is assumed the trash was delivered to 118-D-2. Three layers of contaminated express car flooring covering a 5 sq ft area were removed. Alpha contamination was maximum 140,000 dpm and the maximum dose rate was 950 mrem/hr. It is assumed the material was delivered to the 118-D-2 burial ground. The cutter wheel of the can cutter in the transfer area was found contaminated to 3,000 dpm of alpha and subsequently discharged, assumed buried in 118-D-2. In February of 1950, sections of thimbles were buried, assumed into 118-D-2. In July of 1950, the can of water used to receive the metal downstream of a ruptured piece of the dummies were buried. Water samples showed 1.1E-3 uc/cc. All material are assumed to be buried in 118-D-2. In 1951, a VSR thimble section with a reading of 5r/hr was momentarily removed from the burial trench. A box containing swabs from a process tube from 105-D were buried. That same year, from the 105-D decontamination vat and two small chips were found during the removal of a tip-off contained dosage rates of 200 and 10r/hr respectively. All material was believed to be buried in 118-D-2. Sections of the effluent line...
and expansion joints were removed and buried during repair work on the 100-D Reactor effluent lines. The material may have been buried at the waste site. In July 1955, Zirconium tube samples were recovered from the burial ground and are assumed to be from 118-D-2. Dose rates up to 8 rad/hr were encountered while transferring waste from a cave in the Pile Coolant Studies Metallurgy Laboratory to a cask from removal to burial ground, assumed to be 118-D-2.

**Closure Info:** Remediation of the 118-D-2:1 Burial Ground began in February 2009 and continued through May 2011. Approximately 14,524 bank cubic meters (BCM) (18,997 bank cubic yards [BCY]) of overburden soil was removed and stockpiled west of the burial ground for use as clean backfill. Approximately 45,752 BCM (59,842 BCY) of contaminated soil and debris were removed for disposal at ERDF. The remedial design allowed for the construction and use of sorting cells to be located east of the burial ground. However, all excavated materials were sorted within the burial ground and direct loaded for disposal to ERDF. The sorting cells were never constructed. The initial verification sampling conducted in September 2011 indicated contamination remained in the excavation (Trench 7). A recommendation to remove the contaminated soil and resample for all COPCs at the failed sample locations was presented to Ecology, and a path forward was agreed upon. Additional material was removed in February 2012, resulting in an additional 1,700 BCM (2,223 BCY) of material disposed at ERDF. Field observations during the excavation and sorting of material identified miscellaneous metal debris, piping, lead pigs, and perforated tubes among the types of debris removed from the burial ground excavation. Twelve pieces of suspect spent nuclear fuel (SSNF) were discovered at the 118-D-2:1 Burial Ground subsite. The SSNF was then transferred to the 118-D-3:2 subsite for characterization. Of the 12 pieces of SSNF, 10 were characterized as spent nuclear fuel and 2 were characterized as reactor debris. All waste material has been disposed. Several anomalous items capable of containing liquids or solids were encountered during excavation of the 118-D-2:1 Burial Ground subsite. These items were inspected within the burial ground footprint and were either determined to be empty and loaded out for disposal at the ERDF, or the contents were unknown. The items were moved to the 118-D-2:2 or 118-D-3:2 anomaly characterization area.

**The SubSite is Part Of:**

- **Code:** 118-D-2
- **Names:** 118-D-2; 100-D Burial Ground No. 2

**Description:** The subsite has been remediated and Interim Closed Out. It was consisted of remediation support areas located in the northern portion of the 118-D-2 burial ground, where geophysical surveys found no buried waste. The support areas were used for decontamination and staging areas during the 118-D-2 remediation activities.

The six support areas were the (1) Bunker, used to store suspect spent nuclear fuel (SSNF) removed from the 118-D-2 Burial Ground; (2) the Radioactive Materials Area (RMA), used to stage pigs and anomalous items removed from the 118-D-2 Burial Ground; (3) The Carport, used to stage clean equipment; (4) the Radiological (RAD) area, used to examine and process pigs; (5) the Control area, that provided a safety buffer around the RAD area and (6) the Decontamination Pad, where equipment was decontaminated.

**Location:** The subsite was within the original 118-D-2 waste site, approximately 379 meters (1,243 feet) west-southwest of the 183-DR Headhouse.
Process Description: The anomaly characterization area was used to characterize anomalous materials found in the 118-D-2 Burial Ground during remediation. During remediation, various containers designed to transport radioactive materials were found. The containers were known as pigs. Suspect spent nuclear fuel (SSNF) was also found within the burial ground. The SSNF and pigs required special processing prior to disposal and were staged in the 118-D-2:2 support areas.

Closure Info: On June 13, 2011, a 0.3 meter (1 ft) scrape and soil removal was performed at the RAD area, the Bunker, the RMA, and portions of the control area. A 0.9 meter (3 ft) scrape was performed at the decontamination pad. The carport area was covered in plastic and a layer of clean gravel during the scraping activity. June 13, 2011, to determine if elevated radiological activity was present after the initial scrape and removal. The GPERS survey was conducted to include all six of the support. The results found no gamma readings above twice the background level.

Cleanup verification sampling of the site was performed on January 31, 2012. The verification sampling results indicated that a small area in the RMA required additional remediation. On April 18, 2012, an additional 0.45 meter (1.5 ft) of material was scraped and removed from the southern edge of the RMA. The material removed was disposed to the Environmental Restoration Disposal Facility (ERDF). A total of approximately 543 BCY (415 BCM) of material was disposed to ERDF from the 118-D-2:2 subsite.

None of the pigs or other anomalous materials were found to contain hazardous materials and were disposed to ERDF. The suspect spent nuclear fuel (SSNF) was transferred to the 118-D-3:2, Fuel and Anomaly Characterization Areas site for characterization. The SSNF was ultimately disposed to the 100-K Fuel Storage Basins.

The SubSite is Part Of:

Code: 118-D-2
Names: 118-D-2; 100-D Burial Ground No. 2

Code: 118-D-3
Names: 118-D-3; 100-D Burial Ground No. 3
Type: Burial Ground
Status: Inactive
Classification: Accepted
Reclassification: Interim Closed Out (8/2/2012)
Start Date: 1/1/1956
End Date: 1/1/1973
Description: The waste site has been remediated and Interim Closed Out. The waste site encompassed the 100-D Burial Ground Number 3 which consisted of two subsites. Subsite one included multiple (6 to 8) trenches running east and west. Subsite two was the fuel characterization area and the anomaly characterization area. Both subsites have been remediated and Interim Closed Out, so the parent site is also Interim Closed Out. The radiological postings were removed in September 2012.

Location: The unit is located 106.7 meters (350 feet) east of the 105-DR Building.

Related Sites/Structures:
The site received waste from the 105-DR Reactor and 100-N area solid waste.

Process Description: The burial ground was the primary disposal site for 105-DR Reactor operations waste, including irradiated dummies, splines, rods, thimbles, and gun barrels. The burial ground has the potential to contain spent nuclear fuel elements. The site also contained a burning pit used to dispose of low-level radioactive combustible materials. The eastern boundary was used for the disposal of 100-N solid wastes.

Waste Type: Equipment
### Waste Description:
The waste site received 23.8 tons of lead, 97 tons of aluminum, 137.7 tons of Pb/Cd, 1 ton of boron, and 0.06 tons of graphite.

### Waste Type:
Equipment

### Waste Description:
The unit contains miscellaneous contaminated solid wastes and irradiated dummies, splines, rods, thimbles, and gun barrels. This burial ground has the potential to contain spent nuclear fuel rods. It was also used for disposal of 100-N solid wastes. Potential contaminates include: H-3, C-14, Co-60, Ni-63, Sr-90, Ag-108m, Cs-137, Eu-152, Eu-154, Kr-85, Zr-93, Cd-113, Se-79, Te-99, Sm-151, Am-241, Pu-238, 239 and 241, U-235 and 238, Ba-133, cadmium, lead, and mercury.

### This Site has the Following SubSites:

**Names:** 118-D-3:1; 100-D Burial Ground No. 3 and Process Cells

**Code:** 118-D-3:1

**Names:** 118-D-3:2; Fuel and Anomaly Characterization Areas

**Code:** 118-D-3:2

### Classification:
Accepted

### Reclassification:
Interim Closed Out (7/11/2012)

### Description:
The subsite has been remediated and Interim Closed Out. It consisted of multiple trenches in the burial ground that were oriented east to west. The trenches were 61 meters (200 ft) long by 6.1 meter (20 ft) wide at the bottom and 6.1 meters (20 ft) deep. The spacing between trenches was not uniform. The subsite also included the process (sorting) cells used to determine the presence of suspect spent nuclear fuel and the north anomaly storage area.

The burial ground was the primary disposal site for 105-DR Reactor operations waste, including irradiated dummies, splines, rods, thimbles, and gun barrels. The burial ground had the potential to contain spent nuclear fuel elements. The site also contained a burn pit used to dispose of low-level radioactive combustible materials. The eastern boundary was used for the disposal of 100-N solid wastes.

### Location:
The burial ground was located 106.7 meters (350 ft) east of the 105-DR Building. The sorting cells were 137 meters (449 feet) south of the burial ground. The coordinates of centroid of the two sorting cells was N 151139.7, E 573966.5 and N151109.0, E 573967.1. The north anomaly storage area covered a portion of the burial ground along the north side. The centroid of the north anomaly storage area was N 151348.2, E 574047.3.

### Closure Info:
Remedial action at the 118-D-3:1 Burial Ground began in July 2007 and continued through June 2011. Remedial action activities involved removing and stockpiling the uncontaminated overburden and removing the buried waste and the underlying contaminated soil for disposal. Approximately 9,120 bank cubic meters (BCM) (11,929 bank cubic yards [BCY]) of overburden and layback soil were removed from the burial ground and stockpiled for use as clean backfill. Approximately 86,165 BCM (112,700 BCY) of contaminated soil and debris were disposed at the Environmental Restoration Disposal Facility (ERDF). Twenty-five confirmed pieces of spent nuclear fuel were packaged and shipped to the 100 Area KE Basin for disposal. Additional material was removed in January 2011 from the locations exceeding direct exposure RAGs, and those areas were resampled in January 2011. Remedial actions resumed within the burial ground in March 2011 and continued through June 2011. The
additional remediation resulted in approximately 19,000 BCM (24,851 BCY) of contaminated soil and debris removed from the burial ground for disposal at ERDF.

Field observations during the excavation and sorting of material identified miscellaneous reactor hardware, including dummies, splines, rods, and piping. Lead pigs, drums, and suspect spent nuclear fuel were also observed within the excavation, and were removed to the anomaly characterization area for further characterization. Three potentially stained soil locations were identified during the remedial activities at the 118-D-3:1 Burial Ground, including two suspect oil-stained locations and one orange stained soil location.

The 118-D-3:1 Burial Ground waste site was divided into seven decision units. The excavation extended approximately 14 meters (46 ft) deep. The burial ground excavation includes both shallow-zone and deep zone decision units.

The SubSite is Part Of:
Code: 118-D-3
Names: 118-D-3; 100-D Burial Ground No. 3

Code: 118-D-3:2
Names: 118-D-3:2; Fuel and Anomaly Characterization Areas
Type: Burial Ground
Status: Inactive
Description: The subsite has been remediated and Interim Closed Out. It included two areas, the fuel characterization area and the anomaly characterization area. The 118-D-3:2 fuel and anomaly characterization area consists of the anomaly staging area, characterization area, suspect spent nuclear fuel (SSNF) bunker area, sodium-potassium alloy (NaK) processing area, and the new bunker area. It was used to investigate suspect spent nuclear fuel and confirm the presence of spent nuclear fuel pieces. The original SSNF bunker area was used to shield and store the NaK and uranium specimens. The new bunker area was a plastic-lined bermed area added to relocate the NaK specimens for the purpose of facilitating scraping of the original bunker. The anomaly characterization area was used to characterize anomalous materials found at 100-D. These materials included irradiated dummies, splines, rods, and spent fuel rods.
Location: The site was located 321 meters (1053 feet) southeast of the 105-DR building.
Closure Info: Remedial action at the 118-D-3:2 subsite was performed on January 9, 2012, and February 6, 2012. The subsite was scraped in two stages to a total depth of 0.3 meter (1-ft). The first 0.3 meter (1-ft) scrape incorporated everything inside the area of contamination (AOC) surrounding the 118-D-3:2 subsite except the new bunker area. This allowed in-process samples to be taken at the majority of the site. On February 6, 2012, the new bunker area was moved outside of the AOC to expedite the closure of the 118-D-3:2 subsite. This allowed a second and final scrape to be done on the same day, February 6, 2012, at the original new bunker area location. The material scraped was disposed at the ERDF. Uranium capsules (from NaK test specimens) were shipped to the Central Waste Complex on March 1, 2012. No stained soil was observed.

The SubSite is Part Of:
Code: 118-D-3
Names: 118-D-3; 100-D Burial Ground No. 3

Code: 118-D-4
Classification: Accepted

Hanford Site Waste Management Units Report
February 2015
294
Names: 118-D-4; 118-D-4F; Burial Ground 4F; Construction Burial Ground

Reclassification: Interim Closed Out (10/14/2010)

Type: Burial Ground

Start Date: 1/1/1956

Status: Inactive

End Date: 1/1/1967

Description: The waste site has been remediated and Interim Closed Out. The site surface had been a gravel and cobble field.

Location: The site was located 300 meters (1000 feet) southeast of 105-D Reactor Building and 30 meters (100 feet) south of the 100-D railroad tracks.

Process Description: This irregularly shaped burial ground received construction waste, primarily reactor components and hardware, associated with Project CG-558. Based on historical photograph 3738-Photo, this site (118-D-4F) likely began operations around 1956 instead of 1953. A geophysical survey detected three distinct trenches.

Waste Type: Equipment

Waste Description: This unit contains contaminated material generated during Project CG-558. The contaminated material consisted mainly of reactor components and hardware. Potential contaminants include: C-14, Co-60, Ni-63, H-3, Nb-94, Ni-59, Pd-102, Sm-151, Tc-99, Am-241, Ag-108m, Ba-133, Cs-137, Eu-152 and 154, Pu-238, 239 and 241, Ca-41, Cd-113m, Cr-85, Zr-93, cadmium, lead.

Closure Info: Remedial action began on October 10, 2007, with the removal of 5,500 bank cubic meters (BCM) (7,200 bank cubic yards [BCY]) of overburden material. The overburden was stockpiled southeast of the burial ground. Excavation continued through March 20, 2008, to a maximum depth of approximately 6.5 m (21 ft), resulting in approximately 7,067 BCM (9,243 BCY) of waste material removed for disposal at ERDF. Although the excavation extended into the deep zone, the entire excavation area is treated as shallow zone for verification sampling.

The waste encountered consisted of primarily contaminated reactor components and hardware associated with Project CG-558. Field observations during excavation indicated the presence of piping, lead, concrete, steel, reactor hardware, valves, a metal solvent container, and leaded glass. A 19 liter (5 gal) metal solvent container with an unknown amount of liquid was removed from the excavation. In addition, red-stained soil was also observed on the floor of the center excavation. A waste characterization sample was collected of the red-stained soil and showed elevated levels of cadmium, total chromium, and nickel. The soil was excavated and disposed. Focused samples were collected at the location where the metal container and red-stained soil were observed.

The 118-D-4 excavation area had a maximum depth of approximately 6.5 meters (21 ft), which included both shallow zone and deep zone soils. However, the entire excavation area was considered one decision unit, and was closed out using the more restrictive shallow zone cleanup criteria.
Description: The site has been remediated and Interim Closed Out. The unit consisted of two burial trenches located parallel to each other. Each trench was 12.2 meters (40 feet) long by 6.1 meters (20 feet) wide.

Location: The unit is located 30.5 meters (100 feet) south of the 105-DR Building, just outside the exclusion area fence. Hanford drawings H-1-4046 and H-1-19823 show a discrepancy in the site location.

Process Description: This burial ground received thimbles from the 105-DR Reactor during the Ball 3X Project in 1954.

Waste Type: Chemical Release
Waste Description: This site received thimbles removed from the 105-DR Reactor during the Ball 3X work in 1954. Potential contaminates include: Co-60, Ni-63, Ag-108, Ba-133, Cs-137, Eu-152 and 154, Pu-238, 239 and 241, Ca-41, Cd-113, Kr-85, Zr-93, cadmium, lead.

Closure Info: Remedial action at the 118-D-5 Burial Ground began on June 2, 2008, and continued through August 12, 2008. Approximately 1,943 bank cubic meters (BCM) (2,541 bank cubic yards [BCY]) of overburden material was stockpiled for use as clean fill. Approximately 314 BCM (411 BCY) of soil and debris were removed for disposal to the Environmental Restoration Disposal Facility (ERDF).

The depth of the excavation ranged from 2 meters (6.5 ft) in the easternmost portion of the excavation to 7 meters (23 ft) in the westernmost portion of the excavation. Although defined trenches were not observed on the geophysical data, the debris removed indicates that the 118-D-5 Burial Ground was located and remediated. Concrete, piping, and split tubes (reactor process tubes that were split to allow removal from the reactor core) were among the type of debris removed from the burial ground excavation. No thimbles were identifiable in debris found during the remediation of the burial ground.

A concrete junction vault located in the southern portion of the burial ground was opened prior to the start of the burial ground excavation and found to contain a breached 15-cm (6-in.) vitrified clay pipe. The pipeline is part of the 100-D-50-9, 1607-DR-3 Sanitary Sewer. The concrete junction vault and pipe located within the excavation were removed for disposal to ERDF. A section of the 100-D-50:10, Potable Water Supply Lines subsite, running east-west and west of the northern boundary of the burial ground, was removed and disposed. Another 15-cm (6-in.) pipe, part of the 100-D-50:10 Potable Water Supply Lines subsite, was found in the east sidewall of the easternmost excavation. The pipeline remains in place.

Code: 128-D-1
Names: 128-D-1; 100 D/DR Burning Pit
Type: Burn Pit
Status: Inactive
Classification: Accepted
Reclassification: Interim No Action (4/12/2004)
Start Date: 1/1/1944
End Date: 1/1/1967
Description: The waste site has been evaluated and determined to require No Action. Reviews of historical information demonstrated that this site is a duplicate entry of 128-D-2 and/or 628-3.
Location: This site location was indicated as being east of the intersection of the perimeter road and the railroad track that leads to the 184-D Powerhouse, just northeast of 100-D Area. The exact location of the site is unknown.
Release Description: An incident report (#180), dated September 29, 1951, states that radioactive material was detected in the burning pit during a routine, monthly survey. The contaminated material was...
removed and taken to the radioactive burial ground for proper disposal. Judging from the 1956 aerial photo, 628-3 appears to have been the main burning ground in operation at the time.

**Process Description:** The site was originally thought to have been used for the disposal of nonradioactive, combustible materials, such as paint waste, office waste, and chemical solvents.

**Waste Type:** Process Effluent

**Waste Description:** The site was used for the disposal of nonradioactive, combustible materials, such as paint waste, office waste, and chemical solvents. The exact location of this waste site is unknown, although evidence of burning and waste materials were found at the site. On September 29, 1951, contaminated materials were found in the burning pit (Radiation incident: Class 1 #180). All contaminated materials were removed to the radioactive burial ground for proper disposal.

**Closure Info:** A Ground Penetrating Radar scan of the waste site's suspected location was done in 2003. No underground anomalies were detected.

The location mapped as 128-D-1 and the surrounding area were examined in the field on March 12, 2003. The location, while level where staked, is on a side slope to the perimeter road and is covered with bunchgrasses, cheatgrass, and rabbitbrush. There are no areas of disturbance, old roads, or burned remnant debris in the area.

The lack of physical evidence (aerial photos and on the ground) at the mapped location, the proximity of two other burial pits, and the disconnect between Stenner et al. (1988) and Carpenter (1993) point to the conclusion that 128-D-1 is not a separate third burning pit, but a duplicate for either 128-D-2 or 628-3.

---

**Code:** 1607-D1  
**Classification:** Accepted

**Names:**  
1607-D1; 1607-D1 Sanitary Sewer System; 1607-D1 Septic Tank; 1607-D1 Septic Tank and Associated Drain Field; 124-D-1

**Reclassification:** Interim Closed Out (5/14/2012)

**Type:** Septic Tank  
**Start Date:** 1/1/1944  
**End Date:** 1/1/1965

**Description:** The waste site has been remediated and Interim Closed Out. It was a septic tank and associated drain field. The tank was 3.4 meters (11 feet) deep, constructed of reinforced concrete, and has a 125-person capacity (130 liters [35 gallons] per capita) with an average detention period of 24 hours. The walls and floor were 25 centimeters (10 inches) thick. The tile field was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a minimum of 2.4 meters (8 feet) per capita. The laterals were open jointed and spaced 2.4 meters (8 feet) apart.

**Location:** The 1607-D1 waste site was located in close proximity to the patrol road that bends along the original perimeter fence bordering the site. The septic tank was located at Washington State Plane coordinates N150833, E574534.

**Related Sites/Structures:** The septic system is associated with the 1701-D Badgehouse and the 1709-D Patrol Change Room and Offices.

**Process Description:** The 1607-D1 septic system was one of five systems installed under Hanford Engineering Works in the 100-D Area. The septic system operated from 1944 to around 1965 when the 105-DR Reactor was shut down and received sanitary sewage from 100-D/DR entrance facilities that housed fire and patrol personnel.

**Waste Type:** Equipment
Waste Description: This unit received an unknown amount of sanitary waste from the 1701-D Badgehouse (security check point) and the 1709-D Patrol Change Room and Offices.

Closure Info: Remediation of the 1607-D1 waste site occurred from December 16, 2010 to February 4, 2011, and resulted in approximately 3,705 bank cubic meters (4,846 bank cubic yards) of waste materials being removed and stockpiled southeast of the septic tank prior to disposal at the Environmental Restoration Disposal Facility. No overburden material was associated with the site. The drain field was excavated to a depth of 2 meters (6.6 ft) below ground surface. It consisted primarily of gray and brown sand, gravel, and sections of vitrified clay pipe. The outlet pipeline north of the waterline was excavated to about 1 to 1.5 meters (3.3 to 5 ft) bgs.

An active waterline (100-D-63) runs perpendicular to the waste site and crosses the 1607-D1 outlet pipeline along an existing service road over the site. An estimated 9 meter (30 ft) section of 1607-D1 outlet pipe was left in place to avoid impact to the waterline during excavation. Ecology agreed that samples would be taken from within and beneath the pipeline from either side of the waterline to determine if the portion of pipeline left in place met cleanup criteria. However, no material was present inside the pipe during sampling. Therefore, each pair of samples was collected from the bottom (below the pipe), one on the east side and one on the west side.

The septic tank excavation of the 1607-D1 waste site south of the waterline involved demolition of the reinforced concrete tank prior to removal. The septic tank contents, including battery debris, were removed. The reinforced concrete was sheared for removal. The septic tank excavation extended to a depth of 3.5 meters (11.5 ft) bgs. Excavation of the pipeline south of the active waterline included work beneath active power lines. A front-end loader was utilized to excavate this portion of the 1607-D1 pipeline to about 1.5 to 2 meters (5 to 6.6 ft) bgs.

<tr>
<td>Closure Info:</td>
<td>In November 1999, the Environmental Restoration Contractor (ERC) excavated a series of four trenches and two test pits in the 116-DR-3 WIDS site location and surrounding area in an attempt to locate the 116-DR-3 site. Based on field screening, there were no indications of contamination in any of the excavated trenches or test pits. No samples were collected. The depth of the trenches is not given in the documentation, but the trenches are described as</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
shallow. The inference is that the trenches and test pits were likely excavated to a depth of less than 4.6 meters (15 ft) bgs.

In January 2000, an additional test pit was excavated (by Bechtel Hanford, Inc), at another potential location for the 116-DR-3 site. Based on field screening, there were no indications of contamination. Samples were not collected. This test pit was within the excavation of the 118-D-5 Burial Ground waste site. In 2008, the 118-D-5 Burial Ground was excavated and remediated.

In April 2011, confirmatory samples were collected from two, 20 foot deep test pits. Confirmatory sampling was performed, and the analytical results indicate that the residual concentrations of COPCs at this waste site meet the RAOS for direct exposure, groundwater protection, and river protection.

*Hanford Site Waste Management Units Report*

February 2015
Inactive

Status: 1/1/1965

End Date: 1/1/1965

Description: The site has been remediated and was Interim Closed Out on October 23, 2000. It is no longer marked or posted.

Location: The 116-DR-6 Liquid Disposal Trench was located approximately 37 meters (120 feet) east of 100-DR Reactor and approximately 1,120 meters (3,670 feet) from the Columbia River.

Process Description: The 116-DR-6 Trench received DR Reactor cooling water effluent during upgrade of the reactor emergency shutdown system (Ball 3X upgrade). During reactor shutdown, the trench also received water during maintenance of the cooling water effluent system. In addition, decontamination effluents from the DR fuel storage decontamination pad were routed into the trench. The trench received an estimated 7 million liters (26.5 million gallons) of liquid during its use between 1953 and 1965. The 116-DR-6 Trench has also been described as a crib (subsurface trench) that would sometimes receive effluent volumes great enough to cause seepage to the surface with drainage across the ground surface to the east. Aerial photographs from the period of trench operation (1953-1965) do not indicate the presence of an open trench in the 116 DR-6 site area. Upon closure in 1965, the area of the 116-DR-6 Trench was covered with about 1.8 meters (6 feet) of soil.

Waste Type: Equipment

Waste Description: The site received diverted coolant during the Ball 3X upgrade. It also received diverted water when maintenance was necessary on the effluent system during a reactor shutdown. It is reported that the volume of liquids disposed of at this unit would cause it to overflow, and a solvent odor was present at the site on very hot days.

Closure Info: Remedial action at the 116-DR-6 site began in November 2, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. The excavation design floor elevation was 138.5 meters (454 feet), but because field screening at that depth indicated the presence of radionuclides above the RAGs, an additional meter of soil was removed from the bottom of excavation. The final floor elevation was 137.5 meters (451 feet).

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 485 square meters (5,218 square feet) in area with a maximum depth of approximately 4.8 meters (16 feet). Approximately 2,140 metric tons (2,354 tons) of material from the site were disposed of at the ERDF.

Code: 116-DR-7

Classification: Accepted

Reclassification: Interim Closed Out (9/26/2000)

Start Date: 1/1/1953

End Date: 1/1/1953

Names: 116-DR-7; 105-DR Inkwell Crib

Type: Crib

Status: Inactive

Description: The site was remediated in December 1999 by removing the structure and associated contaminated soil. As of September 2000, the excavation was still open, but was expected to be backfilled in the near future to a grade of elevation 142.0 meters (466 feet).

Location: The site was located south of the 105-DR Building and was approximately 1,100 meters (3,609 ft) from the Columbia River. The site was marked by a single concrete marker and was adjacent to a concrete pad that once supported a storage building.
Process Description: The crib was used to receive the liquid potassium borate solution (called "ink" because it resembles printers ink in color and viscosity) that was drained from the 3X system prior to the Ball 3X system upgrade. The requirements were re-evaluated in 2005. Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, No Institutional Controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Waste Type: Soil
Waste Description: Liquid potassium borate solution was drained from the 3X System prior to the Ball 3X System upgrade.

Closure Info: Remedial action of this site began on December 7, 1999, and ended on December 8, 1999. Approximately 59 metric tons (65 tons) of material were disposed at the Environmental Restoration Disposal Facility (ERDF). The excavation reached a final depth of 4.6 meters (15 feet) [at an elevation of 137.2 meters (450 feet)], and had an area of approximately 250.6 square meters (2,697 square feet).

Code: 116-DR-8
Names: 116-DR-8; 117-DR Crib; 117-DR Seal Pit Crib (CERCLA)
Type: Crib
Start Date: 1/1/1960
Status: Inactive
End Date: 1/1/1964
Description: This waste site has been remediated and Interim Closed Out for CERCLA. The 117-DR Seal Pit Crib is documented in WIDS as two separate sites. The first site, 122-DR-1:6 was the portion of the Large Sodium Fire Facility that had been a RCRA TSD. The RCRA permit has been closed for hazardous/dangerous constituents. The second site, 116-DR-8, represents the radioactive constituents remaining at the site that was addressed under CERCLA. Portions of the 100-D-50:8 and 100-D-50:10 pipelines were encountered during remedial activities.

Based on the results of the applicable cleanup verification package (CVP or RSVP) documents, authorization was given to remove the Soil Contamination Area and Underground Radioactive Material Area postings from this waste site.

Location: The unit is located south of the exclusion area fence and directly east of the 118-DR-1 Burial Ground.

Related Sites/Structures: The site received effluent from the 117-DR HEPA Filter Building seal pits and wash water from the 105-DR Large Sodium Fire Facility.

Waste Type: Soil
Waste Description: The site received drainage from the 117-DR Building seal pits.

Closure Info: Confirmatory sampling was conducted in July 2005. The sample results indicated several analytes were above regulatory limits. Remedial action at the 116-DR-8 waste site was performed from June 18 through July 24, 2008. Approximately 3,056 bank cubic meters (BCM) (3,997 bank cubic yards [BCY]) of soil overlying the crib was removed and stockpiled as overburden for potential use as clean backfill. The depth of overburden was determined using confirmatory sampling information and construction history for the crib. The site was then
further excavated to a depth of approximately 6.8 meters (22 ft) below grade resulting in approximately 1,991 BCM (2,604 BCY) of material that was directly loaded out and disposed at the Environmental Restoration Disposal Facility (ERDF). Portions of the 100-D-50:8 and 100-D-50:10 pipelines, among others, were encountered during remediation.

<td>The unit received processed water from the 105-DR Fuel Storage Basin. During the cleanout of this basin, the radiologically contaminated shielding water was processed through a system using ion exchange columns. Before discharging the water to the unit, composite samples were taken to ensure that radionuclide concentrations were below release criteria in Table II of DOE Order 5480.1. Although the water was cleaned to applicable release limits, minute quantities (below release limits) of radionuclides remaining in the water accumulated in the soil at some low points in the floor. No known hazardous substances were present in the water; however, chemical analysis was not a standard practice during that period, and there is no evidence that one was performed. It should be noted that water removed from the 1608-DR is believed to be comparable to the storage basin water, and EP-TOX testing results for the 1608-DR water were negative.</td>

| Remedial activities at the 116-DR-10 waste site began on November 11, 2008, and concluded on January 7, 2009. The depth ranged from 2.7 meters (9 ft) to 4 meters (13 ft), resulting in approximately 6,000 bank cubic meters (BCM) (7,847 bank cubic yards [BCY]) of soil being removed to the Environmental Restoration Disposal Facility. Approximately 2,462 BCM (3,220 BCY) of overburden material was stockpiled adjacent to the site. The historical information provided in Beckstrom (1987) was used to develop a remediation strategy for the percolation pond. Since the bottom of the pond ranged from 1.8 to 2.4 meters (6
to 8 ft) below surface grade and was then later backfilled to the local terrain, the remediation strategy consisted of removing the surface soil at the site to a depth of approximately 1.2 meters (4 ft) and stockpiling it at the site as overburden soil. The soil from 1.2 m (4 ft) to a depth of approximately 2.7 meters (9 ft) was to be excavated and direct loaded for disposal to the Environmental Restoration Disposal Facility (ERDF) since it delimited the original bottom of the pond that was reported as having residual radiological contamination.

<tr>
<td>Closure Info:</td>
<td>Remedial action at the 118-DR-1 Burial Ground began on June 3, 2008, and continued through July 23, 2008. Approximately 1,673 bank cubic meters (BCM) (2,188 bank cubic yards [BCY]) of soil and debris was removed for disposal at ERDF. Approximately 221 BCM (290 BCY) of clean soil was removed from outside of the burial ground excavation footprint and stockpiled west of the burial ground excavation. The excavation area had a maximum depth of approximately 6 meters (20 ft), which included both shallow zone and deep zone soils. Contaminated debris included concrete, piping, metal and drums. The soil was removed during construction of a ramp into the excavation, allowing the excavator equipment access to continue to remove soil and debris at a greater depth. The ramp soil stockpile is not considered overburden; therefore, it was not included in the closeout sample design. This material will be used as backfill material during general backfill of the site. A geophysical survey was conducted at the 118-DR-1 Burial Ground site in June 2004. The survey identified several geophysical anomalous zones within the survey boundary exhibiting the characteristics of buried debris. One anomalous waste item was encountered in the 118-DR-1 Burial Ground. A breached 208-L (55-gal) drum suspected of containing an undetermined amount of liquid was removed from the sidewall of the excavation. The drum, along with the soil directly below the drum, was placed on a plastic sheet within the burial ground footprint for waste characterization sampling. However, the drum was found to be empty so the soil that was removed with the drum was sampled for waste characterization. No spent nuclear fuel was discovered at the 118-DR-1 Burial Ground.</td>

Hanford Site Waste Management Units Report
February 2015
### Status: Inactive

### Description:
The site has been remediated and interim closed out. The waste site was an open excavation area located between the 183-DR and 190-DR that originally contained four 1.42E+07 liter (3.75E+06-gallon) steel water storage tanks. The four tanks were removed in 1979 but the concrete slab foundations remained. The open excavation was used for disposal of demolition debris. The 126-DR-1 waste site was used as demolition waste burial ground between 1975 and 1988. The northwest section of the pit contained approximately 25% of the concrete slab area and a layer of debris waste that was 1.5 to 3 meter (5 to 10 feet) deep and covered with pit run backfill. The southern section of the pit was posted as an asbestos area.

### Location:
The waste site is located directly east of the site of the demolished 183-DR Water Treatment Facility and west of the demolished 190-DR building. It is west-southwest of the 105-DR Reactor Building.

### Related Sites/Structures:
The unit is associated with the 183-DR Water Treatment Facility and the 190-DR Main Pump House. Both of these facilities were involved in providing primary coolant water for the 105-DR Reactor.

### Process Description:
The tanks were constructed in 1950 and operated until 1964 when the 105-DR Reactor was deactivated. The tanks were most likely dismantled by a salvage operator between 1978 and 1979 when all salvageable material was removed from the 190-D Main Pump Room. After the tanks were removed, the open excavation was used as a dump site for 100-D Area rubble. This site was also suspected of containing hazardous materials, including low-level radioactive waste because of uncontrolled dumping. Other waste that has been observed include paint and solvent cans, oil drums, sodium dichromate crystals, alum, creosote drums, herbicide cans, carbon tetrachloride containers, methanol containers, acetone containers, welding materials, laboratory glassware, furniture, and other solid wastes. The site may contain chromates in both the soil and underground piping because of the use of chromates in water treatment.

### Waste Type:
Demolition and Inert Waste

### Waste Description:
The unit contains demolition and inert waste from demolished facilities, including rubble from released portions of the 115-D/DR, and some rubble from 183-DR. In 1989, small amounts of friable asbestos were found scattered throughout the southern sector. The asbestos is believed to be the result of salvage operations during the 1970's. This site may contain chromates in both the soil and underground piping as a result of its association with water treatment. Because of this potential, it is closed to waste disposal. There is potential for chemical and radioactive contamination similar to that found in the 126-D-2 Burial Ground as uncontrolled dumping reportedly occurred at the site, but it is thought to be in much smaller volumes. Potential contaminants include: Chromate, lead, undetermined organic and inorganic chemicals.

### Closure Info:
Field work to remediate the 126-DR-1 Waste Site commenced on April 5, 2007, by demarking the excavation boundary. Heavy equipment was used to construct a ramp and prepare the haul road for transportation of the waste out of the area. The site was prepared by leveling the surface and constructing a soil berm around the open face of the waste pile. The soil berm was built to prevent the spread of contamination by rainwater and/or dust suppression water during excavation of the waste. An excavator was the primary piece of equipment used for excavation, sorting, segregation, and load out of waste material. The excavated material was directly loaded into roll-off boxes.

Remediation of the waste site concluded on July 24, 2008, after 23,790 metric tons (26,230 U.S. tons) were removed, transported, and disposed at Environmental Restoration Disposal Facility (ERDF). A radiation detector on the arm of the backhoe was used during excavation of this waste site. There was no evidence of radiation detected during the excavation activities.

The majority of waste was described as construction and demolition debris including concrete...
rubble, rebar, soil, and rocks. The debris also contained pipe insulation, suspected to contain asbestos; cans of dry paint; empty drums; welding material; laboratory glassware; steel beams; empty process tanks; electrical panels and fuses; actuators; empty cylinders; and structural steel, piping, valves, and duct work. There was no low-level radioactive waste; sodium dichromate crystals; alum; or containers of creosote, herbicide, carbon tetrachloride, or methanol discovered, as stated in the 100 Area Burial Ground ROD. A number of anomalous waste items were identified, characterized, and disposed during the project. The analytical data associated with these items are included in the RSVP. All but one of these items was determined to be inert debris and required no additional treatment prior to disposal at ERDF. The single exception was the discovery of three drums filled with white granular material on June 21, 2007. After treating, the material was spread out in small batches, neutralized with water, then mixed with soil and loaded into a roll-off box. The treated material was sampled (J16VK2) and analyzed prior to disposal at ERDF.

<tr>
<td>Waste Description:</td>
<td>This site received water from reactor building drains containing trace amounts of low-level radionuclides and decontamination chemicals. Radionuclides were primarily miscellaneous fission and activation products. The decontamination chemicals consisted of sodium fluoride, oxalic acid, and citric acid. Water was pumped from the reactor collection pits into the reactor effluent lines near the reactor building and became part of the 107-DR effluent that was discharged to the Columbia River.</td>
</tr>
</tbody>
</table>
| Closure Info:      | Decommissioning activities began in July 1987 and were completed on September 30, 1987. Decommissioning consisted of removal and disposal of approximately 3.85 cubic meters (136 cubic feet) of asbestos, the pump equipment and related piping, 4.8E+05 liters (1.27E+05 gallons) of sump water, and fifteen 208-liter (55-gallon) drums of sludge from the sumps. The material was transported to the 200 Area for disposal. The pump station was demolished and the site was leveled and graded. The site was released for unrestricted use based on the post-decontamination characterization results and the Dose Assessment of In Situ Burial of the 1608-
DR Lift Station. Consequently, demolition and site grading were performed in 1987 using conventional heavy equipment. The structure was reduced to 5 meters (16.4 feet) below grade using a wrecking ball, the rubble was buried under 5 meters (16.4 feet) of clean fill. The site was graded to blend with the natural terrain.

Prior to demolition in 1987 samples of sludge from the sumps were taken and sent to the Pacific Northwest National Laboratory for analysis. The sludge was designated based on the equivalent concentration of various possible toxic compounds in the sludge. Equivalent concentrations were derived by making "worst-case" assumptions about the form of the various cations in the waste. The sludge did not designate as a hazardous waste. However, the concentrations of lead and phosphate were used to calculate a concentration of lead phosphate (7,300 ppm) that resulted in designating the sludge as a state-only toxic dangerous waste (i.e., extremely hazardous waste) according to Washington State regulations (WAC 173-303). The sludge was also radioactive, giving it the classification of radioactive mixed waste.

After removal of equipment, water, and sludge from the 1608-DR Effluent Pumping Station, extensive radiological surveys of the floors, ceilings, and walls of the equipment room and sump areas and of the piping left in the facility were performed. At the time of decommissioning of the 1608-DR facility, the allowable residual contamination level (ARCL) calculation determined that the site would contribute less than 1 millirem/year to an overall hectare dose rate and, therefore, no further decontamination to reduce the source term was necessary and the facility could be buried in-situ.

In 2005, RESidual RADioactivity (RESRAD) modeling was performed in accordance with the RDR/RAWP (DOE-RL 2005) to support the interim closure decision. The RESRAD evaluation used the 1987 sampling data adjusted for decay from 1987 to 2005. The highest decayed value for each radionuclide was conservatively used in the RESRAD modeling.

*Hanford Site Waste Management Units Report*

February 2015
scraping 0.5 to 1 meter (1.6 to 3.3 ft) of soil and debris into piles that were then loaded into Environmental Restoration Disposal Facility (ERDF) containers. Scraping removed the surface debris at the site. At two locations the excavation extended to 1.5 m (4.9 ft) deep to remove additional sub-surface material.

Additional materials discovered during remediation included lead acid batteries and a suspected fire extinguisher. The batteries stacked in two shallow pits were hand removed from the ground, drummed and then disposed at ERDF. There was no indication that the fire extinguisher had leaked hazardous material to the ground, therefore, it was disposed using anomalous media procedures. No other items were discovered during remediation that were considered anomalous. Approximately 7,400 bank cubic meters (BCM) (9,679 bank cubic yards [BCY]) of material were removed and disposed at ERDF.

Following initial remediation, verification sampling performed in August 2009 found a sample result that exceeded the direct exposure RAG for lead at 2,770 mg/kg. A walkdown of the area determined that lead acid debris was widespread. The recommended path forward was to remediate a 45.7- by 6.1- by 0.6-m (150- by 20- by 2-ft) area, combining the rectangular area and a circular area.

Additional remediation was performed in February and March 2011, which involved scraping 0.5 to 1 meter (1.6 to 3.3 ft) of soil and debris across the northern boundary of the waste site (area 1) and the lead-contaminated area associated with sample locations F-5 and F-6 (area 2). Approximately 3,500 additional BCM (4,578 BCY) of soil was removed for disposal at ERDF.

</tbody>
</table>
The site has been remediated and closed out. The french drain was constructed of 30-centimeter (12-inch) vitrified clay pipe, or similar material and was filled with gravel. A 1.3-centimeter (0.5-inch) steel pipe entered the drain from the 108-F Building. The drain was visible on Hanford photograph 106669-90-CN. Documentation suggests that the drain was likely removed as part of the layback zone of the 108-F Building excavation.

The site was located adjacent to the southwest wall of the 108-F Building, just west of the building's southwest corner.

The site served as a french drain for the 108-F building (site 100-F-36).

Waste Type: Process Effluent
Waste Description: The types and quantities of waste the unit received are unknown.

Site excavation was completed as reported in the 108-F Biological Laboratory D&D Project Closeout Report. The 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains were removed during decommissioning and demolition activities and backfilled with clean material. The CVP report documents that the 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 362.2 square meters (3898.7 square feet) in area with a depth of 4.6 meters (15.0 feet). No material from the sites was disposed of at the Environmental Restoration Disposal Facility as a result of the Remedial Action Project activities described here. Verified clean materials were used as backfill at the completion of the remedial action.

The tank was located north-northwest of the northwest corner of the 107-F Retention Basin fence and north-northeast of the northeast corner of 108-F Building.

The tank supplied the oil furnace in the 1705-F Building heater room.

The site was an underground fuel tank that supplied the oil furnace in the 1705-F Building Heater Room. The building was decommissioned and demolished in 1975. Debris and asphalt are strewn about the area. The tank's presence could not be confirmed with a metal detector due to multiple underground magnetic anomalies in the area. During an April 1999 visit, a survey grade GPS was used to locate the site based on its mapped coordinates. No evidence of the site could be found at this point.

The site consisted of an underground fuel tank that supplied the oil furnace in the 1705-F Building heater room. The tank was installed in 1948 and had a capacity of 3,800 Liters (1,000 gallons). When the 1705-F Building and surrounding facilities were demolished in 1975, no
mention was made to indicate the tank was also removed. The presence of the tank could not be confirmed during various site walkdowns or Geophysical surveys.

A site evaluation conducted as part of the Remaining Sites Verification Package attached to the Reclassification Form 2004-124 through field observations and focused sampling and analysis to assess the presence of contaminated media and to determine if the underground fuel tank was still present. One test pit was excavated at the center of the suspected underground fuel tank location, to a depth of 2.4 meters (8 feet), where native soil was encountered. The tank was not present. A soil sample was collected from the bottom of the test pit and submitted for laboratory analysis.

**Code:** 100-F-9  
**Classification:** Accepted  
**Names:** 100-F-9; French Drain at East End of 105-F Storage Room (Northeast Corner)  
**Reclassification:** Interim No Action (2/15/2005)  
**Type:** French Drain  
**Start Date:**  
**Status:** Inactive  
**End Date:**  
**Description:** The waste site has been evaluated and determined to require No Action. No remnants of this french drain have been identified, indicating that it was likely removed during the 105-F Reactor decommissioning project.  
**Location:** The french drain was located adjacent to the northeast corner of the Miscellaneous Storage Room of the 105-F Reactor Building. The Storage Room was the eastern-most portion of the 105-F Reactor Building.  
**Related Sites/Structures:** 105-F miscellaneous storage room and the 105-F Reactor.  
**Waste Type:** Water  
**Waste Description:** Field observations and confirmatory sampling were used to evaluate the site for reclassification. It was believed that the 100-F-9 French Drain received steam condensation via lines from the 105-F miscellaneous storage room building's steam heaters. The storage room facilitated the lunchroom, shower, and locker room and was demolished in 1999 during the 105-F Reactor decommissioning project. Apparently the french drain was removed during that operation.  
Focused sampling and analysis were used to determine if the french drain had been removed and if hazardous or radiological contaminants were still present. One test pit was excavated to native soil at the WIDS coordinates for the site. No remnants of the french drain were found, indicating that it was likely removed during the 105-F Reactor decommissioning project. No notable anomalies were detected that would suggest the presence of a french drain. However, french drains usually have a very subtle geophysical signature. The abundance of disturbed soil and buried debris from the 105-F Reactor D &D activities could hide an intact drain.

**Code:** 100-F-10  
**Classification:** Accepted  
**Names:** 100-F-10; French Drain at East End of 105-F Storage Room (Southeast Corner)  
**Reclassification:** Interim Closed Out (5/6/2004)  
**Type:** French Drain  
**Start Date:**  
**Status:** Inactive  
**End Date:**  

*Hanford Site Waste Management Units Report*  
February 2015  
310
Description: The site has been remediated and Interim Closed Out. The french drain was totally removed during the excavation of the 100-F-19:2 pipeline remediation. The waste site consisted of a 91 centimeter (36-inch) concrete pipe buried to an unknown depth. The upper surface was a few inches above grade and was cobble-filled. The unit was fed by one or more 2.5 centimeter (1 inch) steel pipes coming from the 105-F Building. Only one pipe was visible. A 1.9 centimeter (0.75-inch) pipe also entered the top of the drain.

Location: The french drain was outside and adjacent to the southeast corner of the Miscellaneous Storage Room of the 105-F Reactor Building. The Storage Room was the eastern-most portion of the 105-F Reactor Building.

Waste Type: Chemicals

Waste Description:

Closure Info: The remediation area was divided into four zones based on process history and structure depth. The 118-F-8:3 was the underlying soils beneath the Fuel Storage Basin and was Zone 1. The 118-F-8:1 was divided into the other zones (Zones 2, 3, and 4).

Removal and disposal activities at the 105-F site began in 1999 and concluded in December 2003. Excavation of the site involved removing the building structures, debris, and underlying contaminated soil. The 105-F D&D activities resulted in removal of above and below-grade structures outside of the 105-F Reactor core shield walls to a minimum of 0.9 meters (3 ft) below surrounding grade. Approximately 22,132 metric tons (24,345 tons) of contaminated materials were disposed of at ERDF. The equipment decontamination pads were areas where decontamination of equipment occurred during the removal actions and ISS activities. In 2003, approximately 1 meter (3.3 ft) of contaminated soil from equipment decontamination activities was removed and disposed of at ERDF.

Zone 1 was soil beneath the fuel storage basin (FSB), located on the south side of the 105-F Reactor Building. The FSB held treated water and served as an underwater collection, storage and transfer facility for irradiated fuel elements discharged from the reactor. The FSB was approximately 23.8 by 21.6 by 6.4 meters (78 by 71 by 21 ft) deep. Deactivation of the storage basin occurred in 1970. Deactivation was accomplished by pumping the majority of the water from the basin and filling with sand. The Zone 1 Fuel Storage Basin was excavated and removed in 2003. The south and east portions of the FSB excavation are not included in this activity. They were remediated with the adjacent 100-F-19:2 pipeline excavation. Contaminated soil on the western side of the FSB became subsite 118-F-8:4. Remediation of the 118-F-8:4 soil area was deferred by the D&D Project to the Remedial Action Project to be completed at a later date (see CVP-2007-00004).

Zone 2 was the valve pit walls. They were removed to a minimum of 0.9 meters (3 ft) below the surrounding surface grade. Because of elevated levels of hexavalent chromium and polychlorinated biphenyls (PCBs) in the valve pit floor, the concrete floor was removed and disposed of at ERDF. The floor of the Zone 2 valve pit was located 4.8 meters (15.8 ft) below surrounding grade. The soils underlying the former floor were sampled and analyzed for hexavalent chromium and PCBs.

Zone 3 included the shallow zone structures (4.6 meters [15 ft] or less below ground surface). It included the solids feed area, the gas recirculation tunnel, the trench under the accumulator room, the east water tunnel, and the flow laboratory basement. The gas recirculation tunnel was removed so that the underlying pipe tunnel (in Zone 4) could be accessed. All of the other below-grade walls, including ceilings, associated with the Zone 3 structures were removed to a minimum of 0.9 meters (3 ft) below the surrounding grade. Because of elevated levels of hexavalent chromium, the solids feed area concrete floor was removed and disposed of at
ERDF. The former floors of the solids feed area and the gas recirculation tunnel were located, at respective depths of 3.4 meters (11 ft) and 4.4 meters (14.5 ft). The floors of the trench under the accumulator room, the east water tunnel, and the flow laboratory are located at the respective depths of 4.4 meters (14.5 ft), 3.8 meters (12.5 ft) and 3 meters (10 ft) below surrounding grade. The soils underlying the former solids feed area floor were sampled and analyzed for hexavalent chromium.

Zone 4 included the deep zone structures. The concrete floors of the Zone 4 structures were within the deep zone (greater than 4.6 meters [15 ft] below ground surface). Zone 4 included the east and west inlet water tunnels, the pipe tunnel, the 315 and 316 exhaust plenums, and the southeast tunnel. All of the concrete ceilings associated with zone 4 structures were removed. All of the Zone 4 walls were removed to a minimum of 0.9 meters (3 ft) below the surrounding surface grade. None of the Zone 4 concrete floors required removal and were left in place. The floors of the east and west inlet water tunnels, the pipe tunnel, the 315 plenum, the 316 plenum, and the southeast tunnel were located at the respective depths of 4.6 meters (15 ft), 5 meters (16.5 ft), 4.9 meters (16 ft), 5 meters (16.5 ft) and 6.1 meters (20 ft) below surrounding grade.

Because the removal of the 100-F-10 French Drain was inadvertently omitted from the 100-F-19:2 pipeline Closeout Verification Package (CVP-2001-00003) report, the activity was included in the 118-F-8:1 and 118-F-8:3 report (CVP-2003-00017) to document the french drain's reclassification to Interim Closed Out. The 100-F-10 French Drain was completely removed during excavation of the 100-F-19:2 pipelines. The cleanup verification sampling results for the 100-F-10 French Drain are included in the CVP-2001-00003 report.

Code: 100-F-11
Classification: Accepted
Names: 100-F-11; 108-F Building 18-Inch French Drain
Reclassification: Interim Closed Out (7/25/2002)
Type: French Drain
Start Date: Interim Closed Out (7/25/2002)
Status: Inactive
End Date: Interim Closed Out (7/25/2002)
Description: The site has been remediated and closed out. The french drain was constructed of 46-centimeter (18-inch) concrete pipe of unknown length. The unit had no cover and was filled with gravel. A 2.5-centimeter (1-inch) steel pipeline entered the drain from the 108-F Building. The drain was visible on Hanford photograph 106669-90-CN.

Documentation suggests that the french drain was likely removed with the layback zone of the 108-F Building.

Location: The unit was adjacent to the southwest corner of the 108-F Building.

Related Sites/Structures: This site served as a french drain for the 108-F building (site 100-F-36).

Waste Type: Misc. Trash and Debris

Closure Info: Site excavation was completed as reported in the 108-F Biological Laboratory D&D Project Closeout Report. The 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains were removed during decommissioning and demolition activities and backfilled with clean material. The CVP report documents that the 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 362.2 square meters (3898.7 square feet) in area with a depth of 4.6 meters (15.0 feet). No material from the sites was disposed of at the
Environmental Restoration Disposal Facility as a result of the Remedial Action Project activities described here. Verified clean materials were used as backfill at the completion of the remedial action.

<td>The site has been evaluated and determined to require No Action. The area where the french drain was located was a flat, cobble-covered area. The french drain was not visible on the surface due to previous building demolition activities. Location: The site was located at the northeast corner of the 105-F Reactor Building, adjacent to a steel door marked &quot;Electrical Equipment Room No. 1&quot;. Related Sites/Structures: The site was associated with the 105-F Reactor Building and sitecode 100-F-61. Process Description: The site was a French drain, 0.9 meters (3 feet) diameter concrete pipe, buried to an unknown depth. The upper surface of the drain was a few inches above grade and had a steel lid (manhole cover) marked &quot;confined space.&quot; The drain was fed by four 19-millimeter (0.75 inch) and one 25-millimeter (1-inch) steel pipes coming from the northeast corner of the 105-F Building. Based on the pipe size it is believed that these pipes may have been steam condensate lines associated with the building's steam heaters. Waste Type: Misc. Trash and Debris Waste Description: The french drain was not visible on the surface due to previous building demolition activities. A test pit was excavated to locate the french drain. The drain structure was found and soil samples were collected. Stained soil was discovered at a depth of 1 meter (3.3 ft) on the north side of the test pit. It was determined that the stained soil was not part of the french drain and became sitecode 100-F-61. Although the 100-F-12 french drain was a No Action site, the drain structure was removed with the 100-F-61 soil remediation on February 23, 2011. The removed material was disposed to ERDF. The site backfilled with clean borrow material.</td>

**Description:** This site included the 100-F Reactor cooling water effluent lines. They were divided into three subsites. All three subsites have been remediated and Interim Closed Out, therefore the parent site is also Interim Closed Out. The large effluent lines that ran between the 105-F Reactor Building and the 107-F Retention Basin were underground lines at the western end of the lines and above ground for the remainder. The above ground portions of each line had previously been removed, cut into sections, and placed inside the retention basin.

Subsite 1 contained a pipeline that was constructed of steel (152 centimeters [60 inches] in diameter, 235 meters [770 feet] long) and concrete (182 centimeters [72 inches] in diameter, 280 meters [920 feet] long) from the basin to the 1904-F Outfall Structure.

Subsite 2 consisted of effluent lines that transported 105-F Reactor cooling water from the reactor core to the 107-F Retention Basin (three lines - one measuring 106-centimeters [42-inches] in diameter and 635 meters [2,080 feet] long, a second measuring 152 centimeters [60 inches] in diameter and 283 meters [930 feet] long and the third measuring 105 centimeters [41 inches] in diameter and 238 meters [781 feet] long). The large effluent lines running between the 105-F Reactor Building and the 107-F Retention Basin were underground for the western section of the lines and above ground for the remainder. The above ground portions of each line had previously been removed, cut into sections, and placed in the retention basin. They were covered with a layer of soil.

Subsite 3 consisted of the effluent line that ran from the 105-F Reactor and the 182-F and 183-F Buildings to the 116-F-1 Lewis Canal. It also included all associated expansion and valve boxes, but excluded the retention basin, outfall structure, and those effluent lines that were within the confines of the 105-F Reactor Building. Other excluded lines were all the clean water pipelines that were upstream of the reactor building, all underground lines that were unique to the Experimental Animal Farm, and the smaller reactor effluent lines on the southwest side of the reactor.

Effluent pipe ends were exposed on the east side of the 100-F Area entrance road.

**Location:** Subsite 100-F-19:1 included the pipelines from the 107-F Retention Basin that extend to the north where they met the 116-F-8 (1904-F) Outfall Structure. These pipelines are in the northeast section of the 100-F Area, near the 146-F biology facilities, the 100-F Retention
Basins, and the 100-F Outfalls.

Subsite 100-F-19:2 included the main effluent lines that exited the 105-F Reactor Building, extending to the east and then curving to the north where they discharged to the 107-F Retention Basin. This subsite also included the pipeline that exited the north side of the reactor and extended to the west emptying into the Lewis Canal.

Subsite 100-F-19:3 included pipelines from both the 182-F and 183-F Buildings to the Lewis Canal, and the process sewer line connecting 182-F and 183-F.

**Related Sites/Structures:**
- Related sites include the 105-F Reactor Building, the 1608-F Lift Station, the 107-F Retention Basin (116-F-14), the 1904-F Outfall Structure (116-F-8), the 107-F Liquid Waste Disposal Trench (116-F-2), and the 116-F-1 Lewis Canal. The water treatment pipelines are site 100-F-26, the clean water pipelines are 100-F-41, and pipes associated with the animal farm are 100-F-29.

**Process Description:**
Effluent water passed from the reactor rear face and flowed via gravity through the underground effluent lines, junction boxes and diversion boxes to the retention basins where it was held up for a short period of time to allow thermal and radiological cooling before being released through the outfall structure to the Columbia River. These pipelines carried radioactive effluent from the 100-F Area Retention Basins to the 1904-F and 116-F-16 outfalls and spillways.

During periods of reactor fuel cladding ruptures, some effluent was diverted to an open trench. Cooling of the 105-F Reactor during operation required that a large volume, approximately 380,000 liters/minute (100,000 gallons/minute) of high quality water be continuously supplied to the reactor on a single pass basis. This water was obtained from the Columbia River and, after chemical treatment and filtering in the water treatment plant, was directed through the reactor process tubes. As it passed through the reactor, the cooling water became radioactive to a degree due to irradiation of the remaining impurities and the pick-up of corrosion products from within the piping and process tubes. Upon exiting from the reactor, the coolant was conveyed to the 107-F Retention Basin by gravity flow via a large diameter pipe, the effluent water line. After being retained in the 107-F Retention Basin long enough to permit decay of the short half-life radioactive elements, the water flowed through another large diameter pipe to the 116-F-8 (1904-F) Outfall Structure.

Occasionally during reactor operation, failure of the protective cladding on one of the fuel elements would occur. The reactor coolant would then pick up debris from this failure and, for a limited time, be contaminated with long half-life radionuclides. On these occasions, the effluent would not be permitted to return directly to the river, but would be diverted from the 107-F Retention Basin to the 107-F Liquid Waste Disposal Trench which was located near the retention basin. The trench functioned as a large filter with the highly radioactive particulate matter being retained in the soil below the trench and the purified water eventually finding its way back to the river.

**Waste Type:** Misc. Trash and Debris

**Waste Description:**
The waste was radioactively contaminated steel piping, concrete and soil. Reactor cooling water became radioactively contaminated as it passed through the reactor core. Activation products created in the water included calcium-41, chromium-51, and zinc-65. Activation products from the reactor core that were picked up and transported by the cooling water included tritium, carbon-14, cobalt-60, nickel-63, and europium-152/154/155. Fuel element fission products such as strontium-90, and cesium-137, as well as transuranics such as plutonium-239/240 were introduced into cooling water due to fuel cladding failures. Concentrations of radionuclides in cooling water during normal reactor operations were approximately 0.2 microcuries/liter. Concentrations of radionuclides have built up in rust.
flakes and scale on the inner surfaces of the pipelines and in sludge in the diversion and
junction boxes. Average beta-gamma concentrations for the effluent line scale and
junction/diversion boxes are 83,000 and 120,000 picocuries/liter, respectively. Average
plutonium-239/240 concentrations are 66 picocuries/gram for the effluent line scale and 720
picocuries/gram for the sludge at the bottom of the diversion and junction boxes. Direct
readings of the bottom of the effluent lines averaged approximately 40,000 counts/minute with
a Geiger-Mueller probe. Additional chemicals were added to the effluent for purposes of water
treatment. These included aluminum sulfate (alum), with excess hydrated calcium oxide,
sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the
free chlorine residual was approximately 0.2 milligrams/liter.

**Description:** The 100-F-19:1 has been remediated and Interim Closed Out. The North Pipelines subsite included piping that ran north-northwest from the north side of the 116-F-14 Retention Basin to the 116-F-8 Outfall Structure and also included a second underground effluent pipeline that extended northwest from the 116-F-14 Retention Basin to a junction box and to the 116-F-16 Outfall Structure. The pipelines in this area have been removed including miscellaneous co-located pipelines that were within the excavation boundary.

**Location:** These pipelines were in the northeast section of the 100-F Area, near the 146-F biology facilities, the 100-F Retention Basins, and the 100-F Outfalls.

**Process Description:** These pipelines carried radioactive effluent from the 100-F Area Retention Basins to the 1904-F and 116-F-16 outfalls and spillways.

**Waste Type:** Chemicals

**Waste Description:** The waste was radioactively contaminated steel piping, concrete and soil.

**Closure Info:** The 100-F-19:1 North Pipelines, 100-F-19:3 West Pipelines, 100-F-34 Biology Facility French Drain, and the 116-F-12 French Drain were remediated as a group, documented in CVP-2001-00002. The group is referred to as the 100-F-19:1 site. The 100-F-19:1 site remedial action began on August 7, 2001. Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Shallow zone excavation occurred both in the vicinity of the 100-F-19:3 West Pipelines and in the vicinity of the 100-F-19:1 North Pipelines, with a maximum depth of 4.6 meters (15 ft). The deep zone excavation occurred in the southern half of the 100-F-19:1 North Pipelines section of the remedial action, with a approximate maximum depth of 5.0 meters (16 ft).
the bottom of the excavation varied, but averaged approximately 119.6 m (392.4 ft). At the completion of remedial action in August 2001, the excavation was approximately 25,710 sq. meters (276,740 sq. ft.) in area. Approximately 56,335 metric tons (62,099 tons) of contaminated materials from the site were disposed of at the ERDF.

These sites meet the cleanup standards specified in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and Operable Units (ROD). Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Shallow zone excavation occurred both in the vicinity of the 100-F-19:3 West Pipelines and in the vicinity of the 100-F-19:1 North Pipelines, with a maximum depth of 4.6 m (15 ft). The deep zone excavation occurred in the southern half of the 100-F-19:1 North Pipelines section of the remedial action, with an approximate maximum depth of 5.0 m (16 ft). The elevation of the bottom of the excavation varied, but averaged approximately 119.6 m (392.4 ft).

The results showed that the materials from the 100-F-19:3 subsite containing COCs at concentrations exceeding RAGs have been excavated and disposed of. Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. All cleanup verification samples for the 100-F-19:3, 100-F-34 and 116-F-12 sites are listed under 100-F-19:1.

The SubSite is Part Of:

Type: Radioactive Process Sewer

Status: Inactive

Description: The 100-F-19:2 Reactor Cooling Water Effluent Pipeline and co-located sites, (116-F-11 Cushion Corridor French Drain, UPR-100-F-1 Sewer Line Leak, and the 100-F-29 Experimental Animal Farm Pipelines), were remediated as a group and documented in CVP-2001-00003.

Location: This group of effluent lines exited the reactor building, extending to the east, and to the north where they discharged to the 107-F Retention Basin. A portion of these pipelines were above ground before emptying into the retention basin. Another section of pipe in this subsite ran from the north side of the reactor and emptied into Lewis Canal.

Waste Type: Misc. Trash and Debris

Waste Description: The waste was radioactively contaminated steel piping, concrete and soil.

Closure Info: Remedial Action ran from August 2001 until December 2002. The 100-F-19:2 Reactor Cooling Water Effluent Pipeline and co-located sites, (116-F-11 Cushion Corridor French Drain, UPR-100-F-1 Sewer Line Leak, and the 100-F-29 Experimental Animal Farm Pipelines), were remediated as a group and documented in CVP-2001-00003. The group is referred to as the 100-F-19:2 site. The unplanned release was within the footprint of the 100-F-29 pipeline excavation. The elevation of the bottom of the excavation was approximately 124.7 meters (409 ft) upon...
Remediation included excavation of overburden, piping, debris and contaminated underlying soil. Approximately 39,347 metric tons (43,373 tons) of material including soil, debris and piping were removed and disposed at ERDF.

The SubSite is Part Of:

| Code: 100-F-19 |
| Names: 100-F-19; 1904-F Process Sewer; Contaminated Underground Lines; Effluent Water System; 100-F Reactor Cooling Water Effluent Underground Pipelines |

| Code: 100-F-19:3 |
| Classification: Accepted |
| Names: 100-F-19:3; 100-F Reactor Cooling Water Effluent Underground Pipelines (West Group) |
| Reclassification: Interim Closed Out (5/22/2002) |
| Type: Radioactive Process Sewer |
| Start Date: |
| End Date: |

Waste Type: Misc. Trash and Debris

Waste Description: The waste was radioactively contaminated steel piping, concrete and soil.

Closure Info: The 100-F-19:1 North Pipelines, 100-F-19:3 West Pipelines, 100-F-34 Biology Facility French Drain, and the 116-F-12 French Drain were remediated as a group, documented in CVP-2001-00002. The group is referred to as the 100-F-19:1 site. The 100-F-19:1 site remedial action began on August 7, 2001. Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Shallow zone excavation occurred both in the vicinity of the 100-F-19:3 West Pipelines and in the vicinity of the 100-F-19:1 North Pipelines, with a maximum depth of 4.6 meters (15 ft). The deep zone excavation occurred in the southern half of the 100-F-19:1 North Pipelines section of the remedial action, with a approximate maximum depth of 5.0 meters (16 ft). The elevation of the bottom of the excavation varied, but averaged approximately 119.6 m (392.4 ft). At the completion of remedial action in August 2001, the excavation was approximately 25,710 sq. meters (276,740 sq. ft.) in area. Approximately 56,335 metric tons (62,099 tons) of contaminated materials from the site were disposed of at the ERDF.

These sites meet the cleanup standards specified in the Amendment to the Interim Action.
Record of Decision for the 100-BC-1, 100-DR-1, and Operable Units (ROD). Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Shallow zone excavation occurred both in the vicinity of the 100-F-19:3 West Pipelines and in the vicinity of the 100-F-19:1 North Pipelines, with a maximum depth of 4.6 m (15 ft). The deep zone excavation occurred in the southern half of the 100-F-19:1 North Pipelines section of the remedial action, with a approximate maximum depth of 5.0 m (16 ft). The elevation of the bottom of the excavation varied, but averaged approximately 119.6 m (392.4 ft).

The results showed that the materials from the 100-F-19:3 subsite containing COCs at concentrations exceeding RAGs have been excavated and disposed of. Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. All cleanup verification samples for the 100-F-19:3, 100-F-34 and 116-F-12 sites are listed under 100-F-19:1.

The SubSite is Part Of:

<td>Closure Info:</td>
<td>Remedial action began and ended on April 12, 2003. At the completion of remedial action, the total excavation was approximately 113 square meters (1,216 square feet) in area with a depth greater than 2.7 meters (8.9 feet). Approximately 259 metric tons (286 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The pipeline structure associated with the site was entirely within the footprint of the excavation and removed during remediation. Since the Remaining Sites DQO (BHI-01249) COPC lists were originally established, remediation of contaminated soil associated with the Experimental Animal Farm facilities in the 100-F Area, such as the 116-F-9 Experimental Animal Farm Animal Waste Leaching Trench (CVP-2001-00008), has provided potential contaminant information based on sampling and analysis. Cleanup verification sampling at the 116-F-9 site indicated that the COCs identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22) (carbon-14, cesium-137, cobalt 60, europium-152, strontium-90, and hexavalent chromium) are appropriate for waste sites associated with Animal Farm activities studying the effects of radiation. The 100-F-24 French drain is believed to have received liquid wastes from 145-F Animal Monitoring Laboratory. Based on verification sampling results from remediation of the 116-F-9 site, and with concurrence from the regulators, the COCs selected for the 100-F-24 site are the same as those identified in the SAP (DOE/RL-96-22) for the 116-F-9 site (CVP-2001-00008).</td>
</tr>
</tbody>
</table>

The 100-F-25 French drain is believed to have received liquid wastes from 145-F Animal Monitoring Laboratory. Based on verification sampling results from remediation of the 116-F-9 site, and with concurrence from the regulators, the COCs selected for the 100-F-24 site are the same as those identified in the SAP (DOE/RL-96-22) for the 116-F-9 site (CVP-2001-00008).
associated with the 146-F and 146-FR Aquatic Biology and Fish Ponds Laboratories, which both housed research on the effects of ionizing radiation on fish. The drywells may have been removed or covered with backfill during site cleanup in 1975. The 146-FR Slab located near the french drains was removed in 1975.

**Location:** The site was located approximately 75 meters (246 feet) south-southwest of the 116-F-8 Outfall Site and 15 meters (49 feet) east of Well # 1-F5-6. The 100F Area coordinates for the drywells are N80511.5, W29327.9 (center) and N80521.5, W29327.9.

**Related Sites/Structures:** The site was related to the 146-FR and 146-F Buildings, both housed research on the effects of ionizing radiation on fish.

**Process Description:** The french drains are believed to have received liquid wastes from 146-F and 146-FR research laboratories and ponds.

**Waste Type:** Oil

**Waste Description:**

**Closure Info:** The 100-F-25, 146-FR Drywells were a pair of french drains associated with the 146-F and 146-FR Aquatic Biology and Fish Ponds Laboratories, which both housed research on the effects of ionizing radiation on fish. The french drains are believed to have received liquid wastes from 146-F and 146-FR research laboratories and ponds. The UPR-100-F-3 Mercury Spill, is an unplanned release that occurred at the northeast corner of the 146-FR Building. The UPR-100-F-3 waste site falls entirely within the footprint of the 100-F-25 site remedial excavation. These wastes sites consisted of only a shallow zone decision unit.

Remedial actions were conducted on April 12, 2003. At the completion of remedial action, the total excavation was approximately 243 square meters (2,615 square feet) in area with a depth of approximately 4.0 meters (13 feet). Approximately 809 metric tons (892 tons) of material (structures and soil) from the site were disposed at the Environmental Restoration Disposal Facility.

**Code:** 100-F-26

**Classification:** Accepted

**Reclassification:** Interim Closed Out (2/13/2012)

**Names:** 100-F-26; 100-F Water Treatment Facility Underground Pipelines

**Type:** Process Sewer

**Start Date:** 1/1/1945

**End Date:** 1/1/1965

**Description:** The 100-F-26 waste site was divided into 16 subsites based on intended use of the pipe, expected sources of contamination, and potential remedial actions. All of the subsites were individually evaluated. They were either remediated and Interim Closed Out or designated No Action sites. Therefore the parent site is also considered to be Interim Closed Out.

The 100-F-26 waste site includes the underground process and sanitary sewer pipelines associated with the 100-F Area pre-reactor cooling water treatment facilities. These pipelines include all underground water lines used to transport reactor cooling water between water treatment facilities and the 105-F Reactor Building. This pipeline list also includes all underground lines running between buildings, to drainage facilities, and to the emergency cooling high tanks (water towers). Lines downstream from the reactor building (100-F-19) and the underground pipelines associated with the Experimental Animal Farm (100-F-29 and 100-F-33) and the clean water pipelines (100-F-41) were excluded.

The 16 subsites are as follows:
100-F-26:1 North process sewer collection pipelines
100-F-26:2 Process water pipelines to the aquatic biology and strontium gardens
100-F-26:3 184-F Powerhouse pipelines
100-F-26:4 South process pipelines
100-F-26:5 190-F bypass pipelines
100-F-26:6 190-F Reservoir pipelines
100-F-26:7 Sodium dichromate and sodium silicate pipelines
100-F-26:8 1607-F1 sanitary sewer pipelines
100-F-26:9 1607-F2 sanitary sewer pipelines
100-F-26:10 1607-F3 sanitary sewer pipelines
100-F-26:11 1607-F4 sanitary sewer pipelines
100-F-26:12 1.8-meter (72-in.) main process sewer pipeline
100-F-26:13 108-F drain pipelines
100-F-26:14 116-F-5 influent pipelines
100-F-26:15 Miscellaneous pipelines associated with the 1608-F sump
100-F-26:16 Reactor cooling water pipelines.

Location: The location is described as underground lines running from the 181-F River Pumphouse to the 182-F Reservoir, the 183-F Basins and Clearwells, the 184-F Powerhouse, the 190-F Buildings, 108-F Biology Laboratory, and to the 105-F Reactor Building. Also, the drainage lines running from the water treatment buildings to the junction with the 100-F-19 Effluent Pipeline at the Animal Farm are included in this waste site. Septic sewer system pipelines are included only where they are co-located with the other pipelines in this site.

Related Sites/Structures: Structures associated with 100-F-26 include the 181-F River Pumphouse, the 182-F Settling Basin, the 183-F Basins and Clearwells, the 184-F Powerhouse, the 190-F Water Treatment Building, the 105-F Reactor, 185-F, the 108-F Biology Laboratory, and the several 1700-series support buildings.

Process Description: Reactor cooling water was pumped from the Columbia River, settled and treated to remove minerals, and pumped to the reactor core at a rate of 1.93E+05 liters (51,000 gallons) to 2.69E+05 liters (71,000 gallons) per minute. Historical research indicates that several buildings and waste sites were associated with sodium dichromate use. Originally, from the startup of F-Reactor in 1945 until 1949, the receiving, mixing, and transfer of sodium dichromate and other water treatment chemicals occurred in the 108-F Building, which was constructed to receive and store bulk water treatment chemicals. The chemicals were unloaded from railcars in either bags or barrels. Sufficient sodium dichromate was added to reactor cooling water so that the instantaneous concentration was 2.0 ppm as required by the reactor cooling water specifications.

Waste Type: Chemicals
Waste Description: The waste consists of contaminated pipelines made of various materials (i.e. steel piping, concrete and soil). Chemical additives to the reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine residual was approximately 0.2 milligrams/liter.

This Site has the Following SubSites:
Code: 100-F-26:1
Names: 100-F-26:1; North Process Sewer Collection Pipelines

Hanford Site Waste Management Units Report
February 2015
The 100-F-26:1 subsite was evaluated and determined to require No Action. The subsite is a network of reinforced concrete and vitrified clay process sewer pipelines that received flow from the 182-F Reservoir and 183-F Clearwells. The pipelines were separated into five service areas based on the contributing discharges to pipeline segments from each of the two facilities. These pipelines are adjacent to the 182-F Reservoir and 183-F Clearwell.
**Waste Type:** Process Effluent  
**Waste Description:** The waste was pipeline sediment/scale and underlying soil.  

**Closure Info:** 100-F-26:1 is a network of reinforced concrete pipe (RCP) and vitrified clay pipe (VCP). The pipelines were separated into five service areas based on the contributing discharges to pipeline segments from each of the two facilities (182-F and 183-F). Confirmatory sampling of the subsite was conducted between December 1, 2004, and January 10, 2005. In each service area, a test pit was excavated and a section of the pipeline was removed. A stratified sampling design with focused sampling of pipeline sediment/scale and underlying soil was implemented in each of the five service areas. The invert of the pipelines were identified at depths of 4 to 4.9 meters (13 to 16 ft) below ground surface (bgs) at the locations excavated, with the exception of the sewer line southwest of the 182-F Reservoir. It had a junction box was located at 1.5 meters (5 ft) bgs. Soil samples beneath the pipe and samples of the scale/sediment inside the pipe were collected. The confirmatory sampling results supported a reclassification of this site to No Action. The results demonstrated that residual contaminant concentrations supported future unrestricted land use that can be represented (or bounded) by the rural-residential scenario. These results also indicated that contaminant levels remaining in the soil were protective of groundwater and the Columbia River.

**The SubSite is Part Of:**
**Code:** 100-F-26  
**Names:** 100-F-26; 100-F Water Treatment Facility Underground Pipelines

<tr>
<td>100-F-26:2</td>
<td>Accepted</td>
<td>Interim No Action (5/26/2005)</td>
</tr>
</tbody>
</table>

**Type:** Process Sewer  
**Status:** Inactive  
**Description:** The subsite was evaluated and determined to be a No Action site. It consisted of a 5.1-centimeter (2-inch) diameter carbon steel pipeline that exited the east side of the 190-F Pumphouse. Drawings indicated it split and conveyed filtered water to both the Aquatic Biology Fish Ponds and the Strontium Gardens. However, field excavation of test pits and exploratory trenches did not reveal the pipeline to the Strontium Gardens, nor did it reveal any indication that the Strontium Gardens pipeline split from the Aquatic Biology pipeline. The Aquatic Biology pipeline was opened and found to contain enough residual scale/sediment for the collection of one sample.

**Location:** These pipelines ran diagonally across the 100-F Area, from the 190-F Pumphouse northeast to the 146-F biology facilities, and southeast to the Strontium Gardens.

**Waste Type:** Chemicals  
**Waste Description:** The waste is the pipeline and any contaminated soil that may have occurred because of leaks in the pipeline.

**Closure Info:** Confirmatory sampling of the subsite was conducted from November 17 through 18, 2004. Since no manholes or junction boxes were indicated on site drawings, three test pits were excavated to located the two 5.1 cm (2 in) process water pipelines that conveyed water to the
Aquatic Biology Fish Ponds and the Strontium Gardens. According to historical information, the pipeline split at the location of test pit 1, and one 5.1 cm (2 in) pipe traveled southwest to the Strontium Gardens while the other 5.1 cm (2 in) carbon steel pipe traveled northeast to the Aquatic Biology Fish Ponds. However, excavation of test pits and exploratory trenches at the locations of test pit 1 and test pit 3 did not reveal the pipeline to the Strontium Gardens. They did not reveal any indication that there was a pipeline to the Strontium Gardens that split from the Aquatic Biology pipeline. Further excavation of exploratory test trenches in the vicinity of test pits 1 and 3, between test pits 1 and 3, and between test pit 1 and the 190-F Pumphouse also did not reveal any indication that the Strontium Gardens pipeline split from the Aquatic Biology pipeline, nor that it existed in its presumed location. Consequently, as it could not be located, no confirmatory samples from the Strontium Garden pipeline were collected.

Since the field excavation did not locate a split in the Aquatic Biology pipeline at or in the vicinity of test pit 1, it was determined by the field sampling task lead that test pit 1 was no longer a defensible focused sampling location. Test pit 2 was located at a 90 degree bend in the pipeline. No other pipelines contributed flow upstream or downstream of test pit 2. It was determined that residual contamination at test pit 2 was representative of the residual contamination throughout the pipeline. Therefore, test pit 2 was identified as a defensible worst case focused sampling location for the Aquatic Biology pipeline. Confirmatory samples of the residual scale/sediment in the 5.1 cm (2 in) carbon steel pipe and soil beneath the pipe were collected at the 90 degree elbow in the pipe at test pit 2.

The No Action decision for the 100-F-26:2 subsite is supported based on current reviews of the site history and confirmatory sampling results. The analytical results from soil samples collected were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

These results indicated that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future land uses of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

The SubSite is Part Of:

Code: 100-F-26
Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:3
Names: 100-F-26:3; 184-F Powerhouse Pipelines
Type: Process Sewer
Status: Inactive
Description: The 100-F-26:3 pipeline subsite was evaluated and determined to be a No Action site. The 100-F-26:3 pipeline subsite consisted of a network of process sewer pipelines that serviced the 184-F power house and 188-F ash disposal basin. The 184-F power house was primarily a boiler house, containing four boilers and one small turbine generator for emergency power generation. The 188-F ash disposal basin was an open rectangular-shaped pit used for the disposal of ashes from the 184-F Power House. Ash from the power house was combined with raw river water and pumped directly from the sluice pit in the power house to the ash disposal basin. This subsite was evaluated and reclassified as an analogous site of the 100-B-14:6 subsite (184-B Power House pipelines).
Location: The Subsite location is the network of pipelines running from the 184-F power house to the 188-
F ash disposal basin.

**Waste Type:** Chemicals  
**Waste Description:** The waste was the remaining pipelines and any potentially contaminated soil.  
**Closure Info:** The pipeline was determined to require No Action.

**The SubSite is Part Of:**  
**Code:** 100-F-26  
**Names:** 100-F-26; 100-F Water Treatment Facility Underground Pipelines

**Code:** 100-F-26:4  
**Names:** 100-F-26:4; South Process Pipelines  
**Type:** Process Sewer  
**Status:** Inactive  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (2/3/2012)

**Description:** This subsite has been remediated and Interim Closed Out. It was a network of process sewer pipelines that received flow from the 105-F Reactor, the 190-F Pumphouse, the 1717-F Combined Shops Buildings and the 108-F Biology Laboratory in the 100-F Areas. The 100-F-26:4 pipelines consisted of sewer lines from the service buildings that flowed north where they connected to the 100-F-26:12 pipeline. The pipelines in 100-F-26:4 were divided into six "service areas" for the confirmatory sampling effort. The service areas were:

Service Area 1 (105-F Reactor Building process sewer) included 39.6 meters (130 ft) of 0.2-meter (8-in.) vitrified clay pipe (VCP) and 62 meters (203 ft) of 0.3 meter (12-in.) VCP.

Service Area 2 (108-F Biology Laboratory process sewer) included 96 meters (315 ft) of 0.15-meter (6-in.) VCP and 32 meters (105 ft) of 0.15-meter (6-in.) cast iron pipe.

Service Area 3 (190-F Pumphouse process sewer) included 21.3 meters (70 ft) of 0.76-meter (30-in.) reinforced concrete pipe (RCP).

Service Area 4 (189-F Refrigeration Building process sewer) included 54.9 meters (180 ft) of 1.4-meter (54-in.) RCP.

Service Area 5 (1717-F Combined Shops Building process sewer) includes 120.4 meters (395 ft) of 0.15-meter (6-in.) VCP.

Service Area 6 (central process sewer collection line) includes 285 meters (935 ft) of 1.5-meter (60-in.) RCP, 53.3 meters (175 ft) of 0.91-meter (36-in.) RCP and 72 meters (236 ft) of 0.3-meter (12-in.) VCP.

**Location:** The pipelines in this subsite are located in the center of the 100-F Area, east of the 105-F Reactor and the 190-F Pumphouse and west of the 108-F Biology Laboratory and the 1717-F Combined Shops Building.

**Process Description:** Discharges from the 105-F Reactor Building into the 100-F-26:4 process pipelines are expected to have consisted only of nonradioactive process wastes. The 108-F Building was originally used as a reactor laboratory facility from 1945 to 1950 before being converted to a biology laboratory that operated until 1976. Process chemicals used at this facility were discharged to sewers, sumps, and french drains. The 108-F facility also contained a heavily shielded cobalt-60 source room. The 190-F Pumphouse was used for process water supply with water treatment.
The subsite has been evaluated and determined to be a No Action site.

The subsite included the underground pipelines that serviced the 185-F Building and the 190-F Pumphouse Building. They were constructed of 1.2-meter (48-inch) reinforced concrete pipe (RCP) and 0.46-meter (18-inch) vitrified clay pipe (VCP). The effluent discharged to the 100-F-19:3 [100-F Reactor Cooling Water Effluent] underground pipelines that acted as a bypass system to the 116-F-1 (Lewis Canal) site.

The pipeline ran from the 185-F and 190-F Facilities to the south before the pipeline turned west to discharge to one of the 100-F-19:3 [100-F Reactor Cooling Water Effluent] underground pipelines that acted as a bypass system to the 116-F-1 (Lewis Canal) site.
Underground Pipelines (West Group)

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The waste includes the pipelines, the contaminated scale and sediment which may be contained within them, and the underlying soils.

**Closure Info:** The subsite included the underground pipelines that serviced the 185-F Building and the 190-F Pumphouse Building, they were composed of 1.2-meter (48-inch) reinforced concrete pipe (RCP) and 0.46-meter (18-inch) vitrified clay pipe (VCP). The historic design flow direction consisted of discharges from the 185-F and 190-F Facilities traveling generally south before the pipeline turned west to discharge to one of the 100-F-19:3 [100-F Reactor Cooling Water Effluent Underground Pipelines (West Group)]. A discrepancy as to the termination point of the 100-F-26:5 pipeline was found, the CVP for the 100-F-19:3 waste site indicated that the 100-F-26:5 pipeline was approximately 63 meters (207 feet) longer at the southwest end of the subsite than was shown on Drawing 0100F-DD-C0189.

For characterization activities this pipeline subsite was divided into three service areas, based on the facilities pipelines serviced prior to confluencing to a general pipeline. One test pit in each service area was excavated to expose either the 1.2-meter (48-in.) RCP (service areas 1 and 3) or the 0.46-meter (18-in.) VCP (service area 2). Sediment or scale samples were collected from inside of the pipes, and soil under the pipes was also collected for analysis. Test pit 1 was excavated to a depth of 4.05 meters (13.3 ft) and was the only test pit where samples were taken from the shallow zone (samples J022P4, J022M5, J022P0, and the duplicate sample J022P1). Test pits 2 and 3 were excavated to depths of 5.8 meters (19 ft) and 7.9 meters (26 ft), respectively.

Mercury levels in test pit 2 (805 milligrams/kilograms) were significantly higher than the direct exposure remedial action goal (RAG) of 24 milligrams/kilograms. However, the sample that contained the high mercury concentration was taken at a depth of 5.5 meters (18 feet) below ground surface in the deep zone, and therefore direct exposure RAGs were not applicable. The results demonstrated that residual contaminant concentrations support future land use that can be represented (or bounded) by the rural-residential scenario. These results also showed that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. However, because mercury concentrations in deep vadose zone soil exceed direct exposure, institutional controls are required for the 100-F-26:5 waste site to prevent excavation or drilling into the deep vadose zone soils.

The No Action decision for the 100-F-26:5 pipeline subsite is supported based on reviews of the site history, field observations, and the confirmatory investigation and sampling results. The analytical results from the 100-F-26:5 pipeline subsite soil and pipe sediment samples were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection with the exception of mercury. Because mercury concentrations in the deep vadose zone soil exceed RAGs, institutional controls are required for the 100-F-26:5 waste site to prevent excavation or drilling into the deep vadose zone.

**The SubSite is Part Of:**

- **Code:** 100-F-26
- **Names:** 100-F-26; 100-F Water Treatment Facility Underground Pipelines

---

**Code:** 100-F-26:6

**Names:** 100-F-26:6; 190-F Reservoir Pipelines

**Type:** Process Sewer

**Classification:** Accepted

**Reclassification:** Interim No Action (12/3/2004)

**Start Date:**
Status: Inactive

Description: The subsite was evaluated and determined to be an analogous site of the 100-B-14:7 pipeline site. It was reclassified to No Action. 100-F-26:6 includes cast iron pipe servicing the 190-F Pumphouse Building.

Location: The location is described as underground lines running from the 190-F Building to the 105-F Reactor Building.

Process Description: The subsite received flow via a cast iron pipeline (CIP) with lead joints, from the re-use water reservoir portion of the 190-F Pumphouse. Waste water from the steam jet condensers was collected in the re-use water reservoir and pumped back to the main reservoir (182-F Building) during the winter months to maintain the temperature of the process water.

Closure Info: The 100-F-26:6 subsite (190-F re-use water reservoir and pipeline) are analogous to the 100-B-14:7 (190-B Sump and Pipelines) site. They had a similar source of water and supported a similar process. The 190-F Reservoir Pipelines subsite (100-F-26:6) meets the Remedial Action Objectives specified in the Remaining Sites ROD, U.S. Environmental Protection Agency, Region 10, Seattle, Washington. The 190-F re-use water reservoir and pipeline are analogous to the 190-B Sump and Pipelines (100-B-14:7), as they had a similar source of water and supported a similar process. Historical sampling indicated that no unacceptable levels of residual ICP metals, mercury, or hexavalent chromium exist in the 190-B sump or the 100-B-14:7 cast iron pipeline. The 100-F-26:6 pipeline is composed of cast iron pipe (CIP) with lead joints, as was the 100-B-14:7 pipeline. The lead contained in the pipeline does not present a direct exposure risk to human health, and an exposure pathway to groundwater does not exist. There is no history of radiological contamination associated with the 190-F Reservoir Pipelines and no radiological contamination was detected during decommissioning of the 190-F complex. There were no known process incidents at 105-F Reactor that would have introduced radiological contamination from the reactor into the 190-F Reservoir Pipelines. The 100-B-14:7 pipeline subsite has been determined to meet the cleanup criteria, consequently the 100-F-26:6 subsite also meets the cleanup criteria and the remaining contaminant levels are protective of human health, groundwater and the Columbia River.

The lead contained in the pipeline did not present a direct exposure risk to human health, no exposure pathway to groundwater existed. There was no history of radiological contamination associated with the 190-F Reservoir Pipelines and no radiological contamination was detected during decommissioning of the 190-F complex. There were no known process incidents at 105-F Reactor that would have introduced radiological contamination from the reactor into the 190-F Reservoir Pipelines. The 100-B-14:7 pipeline subsite was determined to meet the cleanup criteria. Consequently the 100-F-26:6 subsite also has met the cleanup criteria and the remaining contaminant levels were protective of human health, groundwater and the Columbia River. The site has been reclassified to No Action.

This subsite has been remediated and Interim Closed Out. The subsite consisted of two parallel, 0.07 meter (3 inch) steel pipelines that conveyed sodium dichromate and sodium silicate, respectively, from the 108-F Chemical Pumping Building to the 190-F Water Treatment Building.

Note from the WIDS Administrator: After the original reclassification form (2005-010) was approved in 2005, a portion of this remaining pipeline subsite was punctured during the 100-F-26:9 overburden removal. Sodium dichromate was still present in the pipeline. Plans were developed to remediate the entire pipeline. The reclassification status listed on the reclassification form was no longer valid, so the reclassification status for this subsite was removed in the WIDS database on 6/10/2010. Reclassification form 2011-088 was issued to track the second remediation activity.

Based on historical information, the sodium silicate pipeline conveyed only chemicals with low inherent toxicity or that readily degrade to compounds of low inherent toxicity. Therefore it is not considered hazardous/dangerous or to present a risk to human health or the environment. Because the sodium silicate pipeline was within 0.8 meters (2 ft) of the sodium dichromate pipeline along their entire lengths, the two were treated as twin pipelines for confirmatory sampling. In 2005, samples were taken of the soil beneath a 90-degree bend in the sodium dichromate pipeline and from a section of the pipe.

The pipelines ran from the 108-F Chemical Pumping Building to the 190-F Water Treatment Building.

The waste is contaminated steel piping and underlying soils.

In January 2005, one test pit was excavated and the soil beneath the pipelines was sampled and analyzed. An additional sample was taken from within the sodium dichromate pipeline. The maximum detected results from the soil and pipe sediment/scale were used to support a waste site reclassification to Interim Closed Out in 2005. However, during overburden removal of the 100-F-26:9 pipeline in February 2007, a portion of the 100-F-26:7 pipeline was unearthed and punctured. Approximately 3.75 to 7.5 liters (1 to 2 gal) of liquid from within the pipe spilled to the ground and was quickly contained. Samples taken of this liquid demonstrated that concentrations of total chromium and hexavalent chromium exceeded cleanup criteria. As a result, the original 100-F-26:7 waste subsite reclassification of Interim Closed Out was withdrawn. The pipeline remedy was changed to remove, treat and dispose.

Remedial action of the 100-F-26:7 waste subsite was initiated on January 12, 2011. Remediation activities consisted of removal and stockpiling of overburden soil to expose the pipelines, tapping, draining, and collecting the pipeline contents, removal and size reduction of the pipelines, and excavation of approximately 0.3 meters (1 ft) of soil directly below the pipelines including stained and contaminated soil that was identified during remediation. Two small staging pile areas, that were used for contaminated pipe and soil material, were later loaded out and also disposed at the ERDF.

During excavation, both ends of each pipeline were found to be open. The sodium dichromate pipeline was found to contain approximately 990 liters (300 gal) of liquid, which was emptied into large 954 liter (250 gal) tubs. The liquid in these tubs was then pumped into drums for storage until sampling and disposal could occur. This liquid was sampled on February 15, 2011, and found to exceed cleanup criteria for hexavalent chromium.

<td>Waste Description</td>
<td>The waste is any potentially contaminated pipelines and associated soils.</td>
</tr>
<tr>
<td>Description</td>
<td>Confirmatory sampling was performed at the 1607-F1 septic tank waste site on October 7, 2004. Three sample locations were identified in the work instruction for this site. One sample was collected from soil under the septic tank. Two samples were collected from the septic drain field. No sample of tank contents was collected, as the inside of the tank was previously cleaned and backfilled. At the 1607-F1 septic tank site, contaminants in the drain field and in the soil beneath the septic tank were below the remedial action goals (RAGs). Confirmatory sampling of the 100-F-26:8 waste site was conducted on January 5, 2005. Samples of the scale inside the pipe and the soil beneath the pipe were collected. A pipe matrix calculation was prepared using the analytical results of the pipe scale sample. An evaluation of the pipe matrix calculations showed that benzo(a)pyrene exceeded the direct exposure RAG. Concentrations of some polychlorinated biphenyl (PCB) congeners, pesticides, and semivolatile organic compounds (SVOCs) also exceeded the groundwater and river protection RAGs. These confirmatory sample results indicated that the 100-F-26:8 waste site required remedial action due to benzo(a)pyrene present at levels exceeding remedial action goals for direct exposure. Remediation of the 1607-F1 and 100-F-26:8 waste sites were performed from January 8 to April 3, 2007. Remedial activities included removal of the septic tank and the associated piping. Both sites were excavated to approximately 3.4 meters (11 feet) below grade resulting in a combined volume of approximately 464 cubic meters (607 cubic yards) of material stockpiled for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 266 meters (872 feet) of pipeline were removed during remediation. During pipeline excavation, a french drain was discovered on the west side of the former 1709-F facility. Although this french drain was independent of the pipelines, it was removed.</td>

Type: Process Sewer  
Status: Inactive  

Location: The collection pipelines were located at 105-F, 108-F, 184-F, 185-F, 190-F, 1704-F, 1707-F, 1707-FA, 1713-F, 1717-F, 1719 F, and 1722-F Buildings, and ran to the south and east to the 1607-F2 septic tank.

Waste Type: Demolition and Inert Waste
Waste Description: The waste includes the pipelines and the contaminated scale and sediment which may be contained within them, and any contaminated soil associated with leaks from the pipelines.

Closure Info: For Confirmatory sampling activities, the waste site was divided into eleven Service Areas. Test pits were dug and sampled at along the pipelines where junction boxes, bends or pipe joints were located. The contaminants found at seven of the service areas (1, 3, 4, 5, 6, 7 and 8) were found to be at concentrations protective of human health, groundwater, and the Columbia River. A remedial action requirement was determined for service areas 2, 9, and 10. Service Area 11 was remediated because it was downstream of service areas 2 and 10. Remediation of Service Areas 2, 9, 10 and 11 of the 100-F-26:9 pipeline subsite was performed from February 8 through October 30, 2007.

Remediation of these service areas was performed from February 8 through October 30, 2007. The site was excavated to a depth of approximately 3.7 meters (12 ft) below grade, resulting in approximately 1,360 bank cubic meters (BCM) (1,780 bank cubic yards [BCY]) of material disposed of at the Environmental Restoration Disposal Facility. Approximately 6,340 BCM (8,290 BCY) of overburden and layback soil was removed and stockpiled for use as clean backfill.

Type: Process Sewer  
Status: Inactive  
Description: The 100-F-26:10 underground pipeline subsite has been remediated and Interim Closed Out. It consisted of underground sanitary sewer pipelines that received effluent from the 182-F, 183-F, and 151-F Buildings and discharged to the 1607-F3 septic system. These pipelines were constructed of 6 and 8-inch vitrified clay.

Location: The pipelines and septic systems were about one-quarter mile northwest and north of the 105-F Reactor.

Waste Type: Process Effluent
Waste Description: The waste was contaminated pipelines and associated soils.
Waste Description: The waste was contaminated pipelines and associated soils.

Closure Info: In preparation for the site remediation, two road crossings were excavated, sampled, and immediately backfilled in January 2007. Remedial action was performed from March 7 through March 12, 2007. The site was excavated between 2.4 meters (8 feet) and 4.3 meters (14 feet) below grade, resulting in approximately 1,900 bank cubic meters (BCM) (2,500 bank cubic yards [BCY]) of material disposed at the Environmental Restoration Disposal Facility, including removal of approximately 600 meters (1,970 feet) of pipeline. Approximately 4,200 BCM (5,500 BCY) of overburden soil was removed and stockpiled for use as clean backfill. Samples were collected at a test pit in each service area from the contents of the junction boxes and from the soil underneath the junction boxes.

The portion of the north-south vitrified clay pipeline (VCP) line that serviced the 182-F Pump Station and a portion of the 183-F Water Treatment Plant VCP line were removed during decommissioning of those buildings, leaving two separate sections of pipeline. The 1607-F3 septic tank, drain field, and associated contaminated soil were removed in September 2005. Remedial action objectives for the 1607-F3 waste site were met after the additional excavation of contaminated soil in 2006 and were addressed in RSVP-2006-047.

The 100-F-26:10 subsite was divided into three decision units for verification sampling. The first decision unit consisted of the excavation footprint of the pipeline, the second decision unit consisted of the overburden stockpiles, and the third decision unit consisted of the pipeline excavations underlying the haul road (road-crossing area) and the overburden stockpiles used to backfill in the road crossings. Statistical and judgmental sampling to verify the completeness of remediation was performed, and analytical results were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

A 30.1 cm (12 in) diameter pipeline discovered during confirmatory sampling of the 100-F-26:10 test pit #2. It was added to 100-F-44:3 for dispositioning. A 76 centimeter (30-inch) pipe entering the foundation of the 189-F Refrigeration Building was added to 100-F-44:6 for dispositioning.

The SubSite is Part Of:
Code: 100-F-26
Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:11
Names: 100-F-26:11; 1607-F4 Sanitary Sewer Pipelines
Type: Process Sewer
Status: Inactive
Description: The subsite was evaluated and determined to be a No Action site. The subsite consisted of a 0.15-meter (6-inch) diameter vitrified clay pipe (VCP) encased in concrete. It received effluent from the 115-F Gas Recirculation Building. The VCP originated at the southwest corner of the 115-F Gas Recirculation Building and carried flow west approximately 53.6 meters (178 feet). The pipeline terminated at the inlet to the 1607-F4 septic tank.
Location: The 100-F-26:11 subsite is located approximately 139 meters (456 feet) west of the 105-F Reactor Building.
Waste Type: Chemicals
Waste Description: The waste was the pipeline interior scale and the soil underneath the pipe.

Closure Info: During excavation of test pit 1, the 0.15-meters (6-in.) VCP was discovered at 1.2 meters (4 ft) below ground surface (bgs) and found to be encased in 0.2 meters (8 in.) of concrete. A section of the VCP was removed by means of a rock hammer (hydraulic hammer attached to an excavator) and samples of the scale sediment inside and soil beneath the pipe were collected. Test pit 2 was excavated to the concrete-encased influent VCP at a depth of 1.2 meters (4 ft) bgs. A section of the VCP was removed via a rock hammer and found to contain no residual sediment in the pipe. A pipe scale sample was scabbled from the VCP. A soil sample from beneath the pipe was also collected. Field radiological surveys and volatile organic constituent field screening were conducted during excavation.

Confirmatory sampling of the subsite was conducted on November 22, 2004, in accordance with the WCH work instructions. A focused sampling approach was selected using the probable worst-case locations for sampling. Confirmatory samples of the 0.15-m (6-in.) influent VCP were collected via excavation of two test pits, one at either end of the pipeline. Samples were taken of the pipeline interior scale and the soil underneath the pipe. Analytical results of pipe scale and underlying soil samples for the subsite were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection, excluding the soil sample for lead and the pipe scale sample for aroclor-1260.

The No Action decision for the 100-F-26: 11 subsite is supported based on reviews of the site history and confirmatory sampling results. The analytical results from pipe sediment and underlying soil samples collected were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

</tr>
<tr>
<td>Waste Description:</td>
<td>The waste was the sewer pipe and surrounding soils.</td>
</tr>
</tbody>
</table>

Remediation of the pipeline subsite was performed from January 11 through October 4, 2007. The subsite was excavated between 4.0 meters (13 ft) and 6.0 meters (20 ft) below grade, resulting in approximately 2,900 bank cubic meters (BCM) (3,800 bank cubic yards [BCY]) of
material disposed of at the Environmental Restoration Disposal Facility that including removing of approximately 308 meters (1,011 ft) of pipe. Approximately 23,340 BCM (30,530 BCY) of overburden was stockpiled for use as clean backfill.

Radiological field measurements and staining discovered during excavation of the 100-F-19 pipeline in August 2001 indicated that contamination was present within the 100-F-26:12 sewer pipe and its surrounding soils. The site was referred for remedial action without requiring additional confirmatory sampling.

The portion of the pipeline that ran beneath the railroad crossing (near the coal conveyor structure) was encased in concrete to support the additional load. The pipeline encased in concrete was removed. The coal conveyor structure was evaluated and found to be absent of hydraulic systems. The large concrete monolith associated with the coal conveyor was abandoned in place.

<td>Description</td>
<td>The 100-F-26:13 subsite was remediated and Interim Closed Out. It consisted of one 0.15 meter (6 inch), two 0.2 meter (8 inch), and one 0.31 meter (12 inch) diameter vitrified clay pipe (VCP) segments encased in concrete. The pipelines discharged effluent from the former 108-F Biological Laboratory, which was originally built in 1944 to support treatment of cooling water for use in the 105-F Reactor to the 188-D Ash Disposal Area (126-F-1). In 1949, the 108-F Building was completely remodeled for use in life-science studies to test the effects of radiation and contamination on plant and animal life. In 1999, the 108-F Building was decontaminated, demolished, and removed; however, the 100-F-26:13 pipeline segments were left in place.</td>

<tr>
<td>Closure Info</td>
<td>Remediation of this subsite was performed in two stages because a portion of the pipelines were located under the main access road to the 100-F Area. The first stage was performed between February 5 and March 27, 2007, and consisted of excavating and removing all pipeline segments except the portion underlying the main access road. The second stage included excavation and removal of the pipeline segment under the access road and was performed on August 24, 2007. Approximately 580 bank cubic meters (BCM) [760 bank cubic yards (BCY)] of pipeline material and suspect contaminated adjacent and underlying soils were removed and stockpiled in the staged waste area for later disposal to ERDF. The staged waste area footprint will be addressed with the 100-F-26:9 subsite. Excavation depths at the subsite ranged from 4.3 meters to 5.2 meters (14 feet to 17 feet) below ground surface.</td>

Hanford Site Waste Management Units Report
February 2015
The SubSite is Part Of:
Code: 100-F-26
Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:14
Names: 100-F-26:14; 116-F-5 Influent Pipelines
Type: Process Sewer
Status: Inactive
Classification: Accepted
Reclassification: Interim Closed Out (2/29/2008)
Start Date: Interim Closed Out (2/29/2008)
End Date: Interim Closed Out (2/29/2008)

Description: The subsite has been remediated and Interim Closed Out. It consisted of underground pipelines located southwest of the 105-F Building (a 10.2-centimeter (4-inch) influent pipeline that ran from the 105-F Reactor Building to the 116-F-5 ball washer crib, two process pipelines (30.48-centimeter [12-inch] and 15.24-centimeter [6-inch]) that connected to a previously remediated process pipeline (100-F-19:2); and a short 15.24-centimeter [6-inch] cast-iron pipe). These pipelines were associated with the 116-F-5 Ball Washer Crib and remnants of process pipelines on the west side of the 105-F Building.

The 30.48-cm (12 in) process line ran from the 115-F seal pit to the 60.96 cm (24 in) process sewer south of the fuel storage basin (W-73174). The 15.24 cm (6 in) process line received effluent from the tunnel eductor discharge (H-1-70185) and joined with the process line from the 115-F seal pit prior to entering the process sewer. The process sewer was remediated between August 2001 and December 2002 (CVP-2001-00003). The remedial design drawings also show a short 15.24 cm (6 in) cast-iron pipeline off the end of the ball washer influent line near the 105-F Building (0100F-DD-C0032). A possible reference to this pipeline is made on drawing M-1904 F sheet 5. The pipe is referenced by the notation "6 [inch] V.P. BELOW 12 [inch] V.P." with an arrow pointing to the 30.48 cm (12 in.) process line from the 115-F seal pit. No additional historical information is available regarding this pipe.

Location: The 100 F 26:14 pipeline subsite consists of underground pipelines associated with the 116-F-5 Ball Washer Crib and remnants of process pipelines on the west side of the 105-F Buildings. The 100-F-26:14 subsite is an influent pipeline that runs from 118-F-8 (105-F) Reactor Building to 116-F-5 trench.

Related Sites/Structures: The pipelines are associated with the 116-F-5 crib.

Waste Type: Chemicals
Waste Description: The waste was contaminated pipelines and associated soils.

Closure Info: Remediation of this subsite was performed from February 1 through April 24, 2007. The excavation cut through the middle of the 118-F-8:4 Fuel Storage Basin area, that had been previously remediated. The total depth of the 118-F-8:4 excavation (8 meters [26 feet] below ground surface) was below the deepest (6 meters [20 feet]) segment of the 100-F-26:14 pipeline. Portions of pipeline that overlapped the 118-F-8:4 site were included in the 118-F-8:4 remediation report. The only pipeline discovered during remediation was a 15.24-cm (6-in.) vitrified clay pipe in a location where the 15.24-cm (6-in.) cast-iron pipe was expected. It was encased in concrete its entire length. The other pipelines are presumed to have been removed during previous remedial actions. There were no anomalies or stained soil discovered during remediation.

Approximately 700 BCM (916 BCY) of contaminated soil was disposed at the Environmental Restoration Disposal Facility and 900 BCM (1,177 BCY) of overburden and layback soil were
stockpiled for use as clean backfill.

**The SubSite is Part Of:**

<td>The 100-F-26:15 waste site includes the remnant portions of underground process effluent and floor drain pipelines that originated at the 105-F Reactor that drained into the 1608-F sump and pumphouse.</td>
</tr>
</tbody>
</table>

**Location:** The 100-F-26:15 pipelines in the vicinity of the southeast corner of the 105-F Reactor.

**Waste Type:** Chemicals

**Waste Description:** The waste was radioactively contaminated piping and associated soils.

**Closure Info:** The only pipelines encountered during remediation of the 100-F-26:15 subsite were to the immediate west of the former 132-F-6, 1608-F site. All of the other pipelines included in the 100-F-26:15 subsite are believed to have been removed during previous remediation activities. The 100-F-26:15 subsite was remediated from January 29 through January 31, 2007. Two distinct areas were excavated resulting in disposal of approximately 82 cubic meters (107 cubic yards) of contaminated materials to the Environmental Restoration Disposal Facility. Only 3 of the 16 pipeline segments (numbers 2, 4, and 15 in Table 1 of the RSVP) were found during the excavation. Excavations for the remaining pipeline segments were performed to native soil to verify their previous removal. Eight of the pipeline segments (numbers 7, 8, 9, 10, 11, 12, 14, and 16) were associated with the remediation of the 100-F-19:12, reactor cooling water effluent pipelines, in 2002 (CVP-2001-00003). The five remaining pipeline segments (numbers 1, 3, 5, 6, and 13) were not found during either of the pipeline removal activities in 2002 or 2007. These were most likely removed during previous demolition activities or historical pipeline replacement projects.

For the five pipeline segments that were not found during either remediation (numbers 1, 3, 5, 6, and 13), excavations at the locations shown on historical drawings were performed until native soil was encountered to verify their previous removal. Additional verification was available for pipeline segments 1 and 6 as these were associated with the 1608-F building. The below grade portion of the 1608-F building was present in the subsurface. It was used as a guide to verify these pipeline segments were no longer present. Excavation was performed next to the 1608-F building for pipeline segments 1 and 6 and continued until the bottom of the structure was reached. This activity verified the pipeline segments were no longer present.
Type: Process Sewer
Status: Inactive

Description: The 100-F-26:16 subsite has been evaluated and determined to be a No Action site. It consisted of pipelines inside the Cooling Water Pipe Tunnels that ran between the 190-F Pumphouse and the 105-F Reactor. The 100-F-26:16 Reactor Cooling Water Pipelines are analogous to the 100-B-14:4 and 100-C-9:4 105-B and 105-C Cooling Water Pipelines.

Location: The process water tunnels were located due west of the 105-F Reactor (between 190-F and 105-F).

Closure Info: The process water piping had been contained inside the concrete tunnels. As part of decommissioning activities during 1987, the process water tunnels were filled to grade with clean soil. WHC-EP-0478 indicates the pipelines inside the tunnels were removed and salvaged at the time of decommissioning of the water tunnels.

There was no history of radiological contamination associated with the 100-F Cooling Water Tunnels and no known process incidents at 105-F Reactor that would have introduced contamination from the reactor into the tunnels. Historical sampling of concrete and soil underlying the 105-C Cooling Water Tunnels (BHI-01050) and pipe scale sampling inside the cooling water pipelines at the 100-B Reactor valve pit indicate that residual contamination associated with the 105-B and 105-C Cooling Water Tunnels meets the cleanup criteria.

The 100-F-26:16 105 F Reactor pipelines have been removed, the tunnels have been backfilled, and the analogous sites have been determined to meet the cleanup criteria. A through evaluation the 100-F-26:16 Reactor Cooling Water Pipelines found they are analogous to the 100-B-14:4 105-B Reactor Cooling Water Tunnels and 100-C-9:4 105-C Reactor Cooling Water Tunnels. Per Waste Site Reclassification form 2004-120, the 100-F-26:16 105 F Reactor pipelines meet the cleanup criteria and the residual contaminant levels are protective of human health, groundwater and the Columbia River and support a Reclassification to No Action.

The SubSite is Part Of:
Code: 100-F-26
Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-29
Names: 100-F-29; 100-F Experimental Animal Farm Process Sewer Pipelines

Type: Radioactive Process Sewer
Status: Inactive

Description: The site has been remediated and Interim Closed Out. The site consisted of contaminated sewer pipelines that serviced the 100-F Experimental Animal Farm (EAF) facilities.

Location: The location consisted of parts of process sewers (underground pipelines) between various Experimental Animal Farm (EAF) buildings and Junction Box P-24F (H-1-13850).

Related Sites/Structures: The sewer is associated with UPR-100-F-1. The related structures included all the facilities within the 100-F Area animal farm, such as the 146-FR Aquatic Biology Laboratory, the 141-H Isolation Building, the 141-F Sheep Barn, the 141-N Retention Basin Building, the 141-C Hog Barn, and the Junction Box JB-P-23F. Because the 108-F Biology Laboratory was not near the rest of the animal farm, its pipelines were included with 100-F-26.
Pipline sites in the 100-F Area include the Process Effluent Pipelines in site 100-F-19, the Water Treatment Pipelines in site 100-F-26, the river effluent lines are site 100-F-39, the clean water pipelines were 100-F-41, the experimental animal farm pipelines in site 100-F-29 and miscellaneous pipelines in 100-F-44.

**Process Description:** Various Experimental Animal Farm (EAF) research projects yielded liquid waste effluents that were disposed of through the EAF process sewers. Research projects studied the effects of ionizing radiation on living plant and animal organisms. Radioisotopes were introduced to laboratory animals through inhalation, inoculation, ingestion, and absorption. Resulting wastes were flushed down floor drains into the process sewers. Contaminated animal straw bedding was placed over drains to allow drainage into the process sewer. The process sewers also received drainage when animal pens were hosed out to remove contaminated urine and feces and when fish tanks were drained.

**Waste Type:** Oil

**Waste Description:** The waste is mixed (chemically and radiologically) contaminated piping (concrete, steel and vitrified clay) and contaminated soil. Several radioisotopes were used in varying concentrations. These included iodine-131, strontium-90, cesium-137, and isotopes of plutonium and uranium. All such research generated contaminated urine and feces. Other wastes resulted from cleaning contaminated pens and cages with water.

**Closure Info:** Remedial Action ran from August 2001 until December 2002. The 100-F-19:2 Reactor Cooling Water Effluent Pipeline and co-located sites, (116-F-11 Cushion Corridor French Drain, UPR-100-F-1 Sewer Line Leak, and the 100-F-29 Experimental Animal Farm Pipelines), were remediated as a group and documented in CVP-2001-00003. The group is referred to as the 100-F-19:2 site. The unplanned release was within the footprint of the 100-F-29 pipeline excavation. The elevation of the bottom of the excavation was approximately 124.7 meters (409 ft) upon completion. The excavation area was approximately 19,000 square meters (205,000 sq. ft) with a maximum depth of approximately 5 meters (16 ft) and an average depth of approximately 3.7 meters (13 ft). Removal of the 100-F-29 pipelines near the northwest corner of the 116-F-14 (107-F Retention Basin) required shallower excavation, averaging approximately 1 meter (3 ft) in depth. Little evidence of the 116-F-11 french drain site was found during excavation of the 100-F-19:2 pipelines. The location of the french drain was excavated and sampled to the design elevation 4.6 meters (15 ft).

Remediation included excavation of overburden, piping, debris and contaminated underlying soil. Approximately 39,347 metric tons (43,373 tons) of material including soil, debris and piping were removed and disposed at ERDF.

**Code:** 100-F-31  
**Classification:** Accepted

**Names:** 100-F-31; 144-F Sanitary Sewer System  
**Reclassification:** Interim Closed Out (8/24/2006)

**Type:** Septic Tank  
**Start Date:**

**Status:** Inactive  
**End Date:** 1/1/1977

**Description:** The site has been remediated and Interim Closed Out The site consisted of a septic tank and drain field. The area has been restored to match the surrounding terrain.

**Location:** The site was located in the 100-F Area within the former Pacific Northwest Laboratory's Experimental Animal Farm site. The 144-F Building was located between the 141-C Animal Barn, Large Animal Barn & Biology Laboratory, Hog Barn Building and the 116-F-14 (107-F Retention Basin) site. The septic system was located directly south of 132-F-2 (144-F Building) and approximately 20 meters (65 feet) west of the 107-F Retention Basin Fence.
Reclassification: 100-F-33; 146-F Aquatic Biology Fish Ponds

Unplanned Release

Status: Inactive

Description: The site has been remediated and Interim Closed Out. The waste site is also referred to as the 146-F Aquatic Biology Fishponds and the fish laboratory. It was designed to conduct tests on fish. The ponds were removed in 1975. There was no visual evidence remains of their original location. The fish ponds were constructed of unlined reinforced concrete. Originally, there were 6 small rectangular ponds. Each pond was divided into two sections. There was also one large circular pond and one large rectangular pond. The waste site is the area where unplanned releases likely occurred from the fish ponds.

Location: The site was located approximately 610 meters (2,000 feet) northwest of the 105-F Reactor Building. Well 199-F5-6 was located just west of the site. The fish ponds were located west of 146-F Aquatic Biology Laboratory, which has been demolished.
Process Description: The studies involved exposing fish to varying concentrations of reactor cooling water effluent to assess possible effects of effluent discharge on aquatic life in the Columbia River. In addition to hatchery troughs, there were six rearing ponds located next to the laboratory. Effluent water was continuously circulated through the troughs at a rate of about 0.2 to 0.3 liters per second (3 to 5 gallons per minute) and was discharged to the Pacific Northwest Laboratory Outfall (116-F-16) via the 147-F Pump House. Testing began in 1945 and was conducted using various mixtures of river and effluent water to determine effects on fish. The effluent water contained a variety of chemicals that included process cooling water, sludge from the water purification area, condenser water, refrigeration cooling water, floor drainage containing radioactive substances and substances that inhibited corrosion, such as materials used for purging the tubes in the pile. From 1947 through 1950, salmon eggs, rainbow trout, carp, and crayfish were tested under several conditions. Testing included unrefrigerated effluent water, effluent treated with five parts of river water from the 107-F Retention Basin, charcoal filtered and unfiltered river water with 2 parts per million (ppm) dichromate added, pre-pile process water, 5 ppm sodium silicate, and copper sulfate. The testing was designed to determine the accumulation of activity in bone, liver, skin, and the gastrointestinal tract. Some of the feed supplied to the fish was algae and snails. Document HW-20266-RD stated that some of the feed was grown in effluent from the 107-F Retention Basin. The fish ponds were constructed of unlined reinforced concrete. The configuration of the fish ponds were 6 small rectangular ponds, in a 2 by 3 matrix, one large circular pond located due south of the smaller ponds. Two larger rectangular ponds may have been located between the 6 smaller ponds and the circular pond. There is a note on Drawing H-1-2898 Sheet M-1, Mechanical Plot Plan, Aquatic Biology Laboratory that says that these larger rectangular ponds were not built during 1951-1952 construction. These ponds may never have been constructed. Later drawings show only the six smaller rectangular ponds and the one large circular pond. The six pairs of small rearing ponds were numbered 1 through 12. The structures had outer dimensions of 3.35 meters (11 feet) by 2.90 meters (9.5 feet). Each had a center dividing wall separating it into two halves. If the outer walls and dividing walls were 15 centimeters (6 inches) thick, the dimensions of each half would have been 1.2 meters (4 feet) by 3.0 meters (10 feet) by 0.9 meters (3 feet) which is the size of a liquid waste disposal facility documented in both HW-43121 and HW-33305. Pond 13 was the largest, measuring 16 meters by 2 meters (51 feet by 6 feet). It also contained a circular pond that measured 9 meters (30 feet) in diameter. Drawing H-1-2898, Architectural Plot Plan, Aquatic Biology Laboratory, showed the addition of 3 additional ponds. Hanford Drawing, H-1-2898, Sheet 17, Rectangular Ponds - Aquatic Biology Laboratory shows a pair of the pond structures that were 5.8 meters (19 feet) by 3.5 meters (11.5 feet). Each of the ponds were split lengthwise down the middle by a divider. The divider was removable and did not extend the full length of the pond. The ponds sloped towards the end of the structure containing the drains (2 drains per structure). The depth of the ponds was 0.91 meters (3 feet) sloping to 1 meter (3.3 feet). There was a note on Drawing H-1-2898 Sheet M-1, Mechanical Plot Plan, Aquatic Biology Laboratory that stated these larger rectangular ponds were not built during 1951-1952 construction. These ponds may never have been constructed. Later drawings show only the six smaller rectangular ponds and the one large circular pond. Hanford Drawing H-1-2898, Sheet 18, Circular Pond - Aquatic Biology Laboratory shows the large circular pond to be 9.1 meters (30 feet) in diameter and about 0.87 meters (34 inches) high. The pond slopes to the middle toward a center drain.

Waste Type: Chemicals
Waste Description: If the fish ponds or supporting pipelines had leaked, the waste would contain the same contaminants as the radioactive process effluent. A pipeline containing radioactive process effluent came from the reactor to this site. The waste was the pipelines and contaminated soil. Contaminants of potential concern were Co-60, Ce-137, Eur-152, Eu-154, Eu-155, Pu-238, Pu-239/240, Sr-90, U-234, U-235, Cr6, Hg, Pb, and polycyclic aromatic hydrocarbons (PAHs).

Closure Info: In 2004, three test trenches were dug and confirmatory samples collected from the trenches. Based on field observations during confirmatory sampling and the results of laboratory analysis of samples collected from trench 1 and trench 2, it was decided that the northern portion of the site required remediation. The confirmatory sample results for the southern portion of the site, collected in the area of the circular fish pond (test pit 3), did not indicate that residual contaminants were present exceeding cleanup criteria. It was decided that this portion of the site did not require remedial action. Site personnel noted that 10 meters (33 ft) of the process sewer leading to the circular pond in the south half of the site appeared to be outside of the excavation. The drain at the head end of this sewer was sampled (J01TF8) as part of 100-F-33 test pit 3. It did not require remedial action.

Remedial action of the northern portion of the site was initiated on August 5, 2005, and continued through August 8, 2005, with excavation of 2,024 metric tons (2,231 U.S. tons) of material including concrete debris, piping, and soil. Excavated soil and debris were staged at the site until disposal of the materials to the Environmental Restoration Disposal Facility (ERDF) occurred from September 19 to September 21, 2005. Radiological surveys were performed over the excavation and staging pile areas using a mobile sodium iodide detector.

Code: 100-F-34  Classification: Accepted
Name: 100-F-34; Biology Facility French Drain  Reclassification: Interim Closed Out (5/22/2002)
Type: French Drain  Start Date:
Status: Inactive  End Date:
Description: The site has been remediated and Interim Closed Out. The french drain was removed during the 100-F Area cooling water effluent pipeline remediation activity in 2002 (100-F-19:1).
Location: The drain was located due south of the demolished 1705-F Experimental Gardens. The drain location is noted on Hanford Drawing H-1-13850. There is a label titled "Greenhouse and Slab (Removed) June 6, 1975" and behind and between the "o" and the "v" of "Removed" is a small circle.
Related Sites/Structures: The site is believed to be associated with one of the Biology Facilities that were part of the Experimental Animal Farm.
Process Description: It was not known what purpose this site served. The pipeline that connected the french drain to a facility has not been located on any of the numerous drawings that have been researched for this area.
Closure Info: The 100-F-19:1 North Pipelines, 100-F-19:3 West Pipelines, 100-F-34 Biology Facility French Drain, and the 116-F-12 French Drain were remediated as a group, documented in CVP-2001-00002. The group is referred to as the 100-F-19:1 site. The 100-F-19:1 site remedial action began on August 7, 2001. Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Shallow zone excavation occurred both in the vicinity of the 100-F-19:3 West Pipelines and in the vicinity of the 100-F-19:1 North Pipelines, with a maximum depth of 4.6 meters (15 ft). The deep zone excavation occurred in the southern half of the 100-F-19:1 North Pipelines section of the remedial action, with a approximate maximum depth of 5.0 meters (16 ft). The elevation of
the bottom of the excavation varied, but averaged approximately 119.6 m (392.4 ft). At the completion of remedial action in August 2001, the excavation was approximately 25,710 sq. meters (276,740 sq. ft.) in area. Approximately 56,335 metric tons (62,099 tons) of contaminated materials from the site were disposed of at the ERDF.

These sites meet the cleanup standards specified in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and Operable Units (ROD). Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Shallow zone excavation occurred both in the vicinity of the 100-F-19:3 West Pipelines and in the vicinity of the 100-F-19:1 North Pipelines, with a maximum depth of 4.6 m (15 ft). The deep zone excavation occurred in the southern half of the 100-F-19:1 North Pipelines section of the remedial action, with an approximate maximum depth of 5.0 m (16 ft). The elevation of the bottom of the excavation varied, but averaged approximately 119.6 m (392.4 ft).

The results showed that the materials from the 100-F-19:3 subsite containing COCs at concentrations exceeding RAGs have been excavated and disposed of. Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. All cleanup verification samples for the 100-F-19:3, 100-F-34 and 116-F-12 sites are listed under 100-F-19:1.

<tr>
<td>Location:</td>
<td>The site was located approximately 100 meters (330 feet) east of the 105-F Reactor Building.</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The initial intended use of the 108-F Building was to provide chemical treatment of the 105-F Reactor cooling water. Site 116-F-15 was a sump with an associated trench in the middle of the building. During excavations and sampling in Winter 2002, the 6 inch (15 centimeter) cast iron pipe at this location had radiation readings of 3000 disintegrations per minute (dpm) alpha and 250,000 dpm beta-gamma. The excavation was closed up without removing any material. French drains on the perimeter of the building included 100-F-4, 100-F-11, 100-F-15, and 100-F-16.</td>
</tr>
</tbody>
</table>
| Process Description: | The 108-F building was constructed in 1944 as part of the original Hanford site construction. It was originally a chemical makeup facility that supported the 105-F reactor. In 1949, the 108-F building was completely remodeled for use in life-science studies for the effects of radiation and contamination on plant and animal life. The original 108-F building was a four-story steel frame, concrete block structure with reinforced concrete foundation, and a total floor space of about 1,858 square meters (20,000 square feet). The roof was constructed of concrete tile with a built-up tar and gravel surface. In 1949, and again in 1962, the 108-F building was remodeled, and the floor space increased by the addition of a 1,022 square meter (11,000 square foot) annex. This addition was a three-story concrete block structure adjoining the older building. The interior of the building contained 39 offices, 47 laboratories, and a heavily
shielded cobalt-60 source room, 18 rooms for handling small animals, a large conference room, an administrative section, a library, lunch and locker rooms. Since radioactive materials were used in the work performed within the building, the laboratories and storage rooms were maintained in a controlled status until 1973 when the laboratory activities were phased out and transferred to 300 Area facilities. From 1983 through 1984, the first floor of the 108-F Building was used for office space.

**Waste Type:** Ash

**Waste Description:** Friable asbestos insulation, asbestos cement, pipe wrapping and suspected asbestos-containing floor tiles were in the building before demolition. The 108-F closeout report reported contaminants of concern as mercury, PCBs, lead, asbestos, sodium dichromate, and miscellaneous low radiological contamination.

**Waste Type:** Ash

**Waste Description:** Oil in the elevator motor, compressor motors, water coolant system and hoist equipment was suspected to contain polychlorinated biphenyl (PCB) and Resource Conservation and Recovery Act of 1976 (RCRA) metals.

**Waste Type:** Ash

**Waste Description:** On the first floor there are exposed sheets of lead, approximately 0.64 centimeters (0.25 inches) thick under the wallboard. All paint within the facility is suspected to contain lead.

**Waste Type:** Ash

**Waste Description:** The main drain trench and sump were posted as a radiological contamination area. Potential contaminants of concern for this facility were plutonium-238, strontium-90, cobalt-60, and cesium-137.

**Closure Info:** The 108-F facility became inactive in 1973. From 1977 through 1983, contaminated material was removed from inside the building and disposed in 200 Area burial grounds. The 108-F building was demolished in 1999. The contaminated cast-iron pipe found during the February 2002 excavation was not located during this remedial action. Therefore, an additional test pit was excavated on November 29, 2005, in an attempt to locate the contaminated 15-cm (6-in.) diameter cast-iron pipe. The additional excavation was unsuccessful, and the excavated material was placed back in the pit. Additional efforts in July 2006 to locate the contaminated pipe using a metal detector were also unsuccessful. However, the contaminated 15-cm (6-in.) diameter cast-iron pipe (100-F-26:4) was found during test pitting activities in December 2006. The contaminated pipe is associated with the 100-F-26:4 pipeline site and is not a part of the 116-F-15 sump as previously indicated. Remediation and sampling activities for the 100-F-26:4 pipelines site will be included in a separate verification package.

Remediation of the 116-F-15 waste site was performed on September 26, 2005. It consisted of the removal of approximately 86 metric tons (95 US tons) of material, including concrete debris, piping, and soil being disposed at the Environmental Restoration Disposal Facility. The soil was excavated and field surveyed to a depth of approximately 2.6 meters (8.5 feet).

Following the remediation of 116-F-15, confirmatory sampling at the 100-F-36 waste site was performed on December 5, 2006 and verification sampling of the 116-F-15 waste site was performed on December 12, 2006.

The 100-F-36 waste site was evaluated and confirmatory samples collected. It was determined to require No Action.

**Code:** 100-F-37  
**Classification:** Accepted
Rev. 24

DOE/RL-88-30

Reclassification: 100-F-37; French Drain Discovered Near Hydrant F-2

French Drain

Inactive

Start Date: Interim No Action (8/11/2004)

End Date:

The site was evaluated and determined to require No Action. The waste site consisted of an abandoned french drain found while digging an electrical conduit trench. The soil around the drain structure was discolored.

Location: The site was about 235 meters (760 feet) east-northeast of the 100-F Reactor. It was in the northeast corner of the intersection of the F Area perimeter Road and the north-south road that ran on the east side of the 1716-F, 1713-F, 1717-F, and 1707-F facilities.

Waste Type: Demolition and Inert Waste

Description: The analytical results showed a high level of lead at 214 ppm.

Closure Info: Sampling of the discolored stained soil associated with the french drain was performed on November 3, 2000 to support disposal of the concrete pipe that was removed during excavation of the electrical conduit trench. The sample was submitted for inductively coupled plasma metals (ICP metals), mercury, and semi-volatile organic analysis (SVOA). Radiological surveys during excavation and sampling did not identify any field detectable radiological activity. Since the site was not associated with historical radiological processes, the sample was not analyzed for radionuclides.

Code: 100-F-38

Classification: Accepted

Reclassification: Interim Closed Out (3/13/2006)

Names: 100-F-38; Yellow Stained Soil Near Hydrant F-2

Unplanned Release

Description: The site has been remediated and Interim Closed Out. The waste site consisted of yellow soil discovered during the excavation of a trench for electrical conduit in November 2000. The trench ran diagonally through the parking lot from the subcontractor trailer to Hydrant F-2.

Location: The site was located approximately 235 meters (760 feet) east-northeast of the 100-F Reactor. It was in the northeast corner of the intersection of the F Area perimeter road and the north-south road that ran on the east side of the 1716-F, 1713-F, 1717-F, and 1707-F facilities.

Related Sites/Structures: A small unidentified structure north of this site can be seen in aerial photos shown in the 100-F Area Technical Baseline Report. The yellow stained soil was found immediately north of Hydrant F-2, and south of the unearthed rust coated rocks and french drain (100-F-37), discovered in the same excavation. Their relationship, however, was not known.

Waste Type: Water

Description: The stained soil showed high levels of chromium and lead. No radioactivity was detected with field instruments.

Closure Info: Remedial action occurred in September 15, 2005. Approximately 5.4 metric tons of material was disposed at ERDF. The depth of the excavation was approximately 0.9 meters (3 feet). There were no stockpile areas associated with this site. Verification sampling occurred in November 21, 2005.

Sampling of the yellow soil at the site was performed during November 2000 when the
discolored soil was first encountered while trenching at that location for the placement of underground utilities. At the time of discovery, the yellow soils were assumed to be associated with the disposal or spilling of unused paint. Therefore, inductively coupled plasma (ICP) metals were identified as the potential contaminants associated with the yellow soil. Lead and chromium values were 8850 parts per million (ppm) and 2080 ppm, respectively. The soil was then placed back into the trench and covered.

Although the excavation of the utility trench was not performed within a radiologically controlled area, a radiological control technician was directed to perform a field survey to verify that radiological contamination was not present. Radiological contamination was not detected during this survey.

In August 2004 a remove, treat, and dispose (RTD) report was done to provide documentation to support the remedial action decision for the site, as required by the Sampling and Analysis Plan for the 100 Area Remaining Sites. The 2000 soil sampling results indicated that a remedial action was necessary due to the presence of barium, chromium and lead in concentrations exceeding the Rags. The 100-F-38 waste site is located in a building parking lot, prone to high traffic volumes posing a potential safety hazard. Because of the potential hazard associated with an open excavation in parking lot, three focused verification samples were collected and the excavation backfilled.

Code: 100-F-39
Names: 100-F-39; 100F River Effluent Pipelines; 100F River Lines
Type: Radioactive Process Sewer
Status: Inactive
Description: This site consists of the river effluent pipelines (river lines) that extend from 1904-F outfall (116-F-8) in the 100F area into the main channel of the Columbia River.
Location: The river lines are located in the Columbia River, adjacent to the 100F area. The lines extend north into the main channel of the river from the 1904-F outfall (116-F-8). The river effluent pipelines extend from, and are perpendicular to, the discharge (river side) face of the 116-F-8 outfall structure for 91 meters (300 feet) into the main channel of the river.
Release Description: No recorded releases were found.
Related Sites/Structures: The site is associated with the 116-F-8 outfall, the process effluent lines (100-F-19), the water treatment facility pipelines (100-F-26), the 107-F Retention Basin (116-F-14), the animal barn (141-C), the 100F Experimental Animal Farm Process Sewer Pipelines (100-F-29), the aquatic biology fish ponds (100-F-33), the PNL outfall (116-F-16), the PNL spillway (100-F-43), and the 100-F-42 spillway. Pipeline sites in the 100-F Area include the Process Effluent Pipelines in site 100-F-19, the Water Treatment Pipelines in site 100-F-26, the river effluent lines are site 100-F-39, the clean water pipelines were 100-F-41, the experimental animal farm pipelines in site 100-F-29 and miscellaneous pipelines in 100-F-44.
Process Description: Reactor cooling water was discharged from the 105-F Building through 152 centimeter (60 inch) diameter effluent lines to temporary storage in 116-F-14 (the 107-F Retention Basin), before being pumped to the river via 116-F-8 and two associated 107 centimeter (42 inch) pipelines (100-F-39). In the event the lines became plugged or had to be removed from service during operation, the effluent overflowed the outfall and entered the river via an attached spillway (100-F-42). The two river lines were constructed of 107-centimeter (42-inch) diameter reinforced concrete/steel pipes with 1.3-centimeter (0.5-inch) thick walls. The two parallel lines were originally 91 meters (300 feet long). During a survey in 1994, the pipes
were found to extend about 24 meters (80 feet) offshore, protruding 1.2 to 2.4 meters (4 to 8 feet) above the riverbed. No buried or exposed pipelines could be found further offshore using geophysical instruments. The pipelines may have been obscured by large pieces of debris or rip rap. In 1946, damaged sections of pipe were removed from the river and buried in the riverbank. The broken pipe sections were buried in the riverbank just upstream of the outfall and marked with stakes.

Waste Type: Demolition and Inert Waste

Waste Description: The waste includes the pipelines and the contaminated scale and sediment which may be contained within them. Contaminants of concern/potential concern are based on those for 116-F-8 Outfall Structure. Contaminants of concern include cobalt-60, europium-152, europium-154, europium-155, and hexavalent chromium. Contaminants of potential concern include carbon-14, cesium-137, nickel-63, and strontium-90.

Code: 100-F-42

Names: 100-F-42; 1904-F Spillway; 100-F-39:1 Flume

Type: Outfall

Status: Inactive

Description: The site has been remediated and Interim Closed Out. The site consisted of a reinforced concrete spillway (also referred to as a flume). The spillway extended from the 116-F-8 Outfall to the Columbia River shoreline and into the river.

Location: The spillway was located approximately 214 meters (700 feet) north of the 116-F-14 Retention Basin. The upper end of the spillway began at the west face of the outfall and terminated in the river.

Related Sites/Structures: The site was associated with the 100-F-39, 100-F River Effluent Pipelines, the 116-F-8 Outfall Structure, the 116-F-16 (PNL) Outfall, and 100-F-43 (PNL) Spillway.

Process Description: The spillway was an alternate discharge point for the 116-F-8 Outfall Structure. It was to be used only if the 100-F-39 river effluent pipelines were blocked, damaged, or undergoing maintenance. There was no corroborated physical or historical evidence that the spillway was ever used. The flume was constructed of reinforced concrete and was 4 by 0.6 meters (14 by 2 feet) deep and about 40 meters (130 feet) long. It was an open concrete structure with a flat bottom and two sidewalls. An engineered erosion barrier composed of heavy riprap was constructed at the discharge end of the concrete structure. The spillway was designed to prevent excessive backwater at the 107-F Retention Basin during high water or in the event of a blockage of the outfall lines.

Waste Type: Soil

Waste Description: If ever put into service, the COPCs for the 100-F-42 spillway would be the same as those for the 116-F-8 outfall structure. The contaminants of concern include Cobalt-60, Europium-152/154/155, and hexavalent chromium.

Closure Info: The 100-F-42 Spillway was administratively separated from the 116-F-8 Outfall for inclusion within the Remaining Sites ROD by agreement among the Tri-Parties. It was subsequently determined that sufficient evidence existed to warrant remedial action during remediation of the 116-F-8 waste site, therefore both waste sites were remediated and evaluated as a single unit.

Remedial action activities at the waste sites were conducted from August 31, 2004, to September 22, 2005. Remediation involved excavation and staging of clean overburden material and removal of the demolished concrete outfall structure, the concrete spillway.
structure above the Columbia River ordinary high water mark, and contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs. The residual 100-F-39 effluent pipelines will be sealed with concrete prior to backfill of the remediation footprint. Contaminated materials were disposed at the ERDF. Approximately 1,325 square meters (14,260 square feet) of plan area was excavated, including excavation within the deep zone (greater than 4.6 meters [15 feet] below ground surface) up to 8 meters (26 feet) below ground surface. Approximately 4,900 metric tons (5,400 U.S. tons) of material from the sites was removed and disposed at the ERDF.

| Description: | | |
|--------------|-----------------------------------------------|
| All ten subsites have been addressed and reclassified to Rejected, No Action or Interim Closed Out. Therefore, the parent site is considered Interim Closed Out. The waste site consisted of a compilation of pipelines and pipeline segments not previously addressed in any closure documents. Some subsites required remedial action and others were evaluated and determined to require No Action. Some segments were reclassified to Rejected. |

| Location: | | |
|-----------|-----------------------------------------------|
| The underground pipeline segments are located throughout the 100-F Area and co-located with those described in waste site 100-F-26 (100-F Water Treatment Facility Underground Pipelines with 16 subsites). |

| Related Sites/Structures: | | |
|---------------------------|-----------------------------------------------|
| Segments of pipelines were identified within the areas of the following buildings: 105-F, 1717-F, 190-F, 1608-F, 141-C, 187-F1 elevated water tower and 189-F. Pipeline sites in the 100-F Area include the 100-F-19 Process Effluent Pipelines, the 100-F-26 Water Treatment Pipelines, the 100-F-39 river effluent lines, the 100-F-41 clean water pipelines, the 100-F-29 experimental animal farm pipelines and the 100-F-44 miscellaneous pipelines. |

**Reclassification:** Interim No Action (4/26/2007)  
**Start Date:** Interim No Action (4/26/2007)  
**End Date:**

**Type:** Process Sewer  
**Status:** Inactive

**Description:** The 100-F-44:1 pipeline subsite has been evaluated and determined to require No Action. It was discovered during confirmatory sampling at the 100-F-26:1 test pit 5. The test pit contained a junction box with two 76 centimeters (30-inches) reinforced concrete pipes and a previously unidentified 20-centimeter (8-inch) carbon steel pipe. The smaller pipe was just west of the 182-F Reservoir and ran north from the junction box an undetermined distance at a depth of 2.1 meters (7 feet) below the ground surface. The only building in the vicinity was the former 182-FA Pump Test Stand.

The Pump Test Stand was built in 1959 to test new designs for impellers and prototype pumps for future use at the 190 Pumphouse. It was located west of the 182-F reservoir. The pumps, instrument panels and suction piping were housed inside an army surplus prefabricated building. Apparently the project was of a short duration. Therefore sanitary and steam utilities were not constructed. The only underground piping installed from the pump test stand was between the 182-F reservoir and the process sewer. Water from the 182-F reservoir was recirculated through a suppression tank with constant makeup and bleed to control temperature rise.

**Location:** The pipeline runs north-south and west of the 182-F reservoir. The junction box was sampled at coordinates N148179 E580343 where the pipeline starts, before continuing north for an undetermined distance at a depth of 2.1 meters (7 ft) below ground surface.

**Related Sites/Structures:** This subsite is associated with the remediation of 100-F-26:1.

**Waste Type:** Construction Debris  
**Waste Description:** The waste is piping, scale/sediment, concrete, and soil (if contaminants are present).

**Closure Info:** The Remaining Site Verification Package for 100-F-26:1 North Process Sewer Collection Pipelines (Attachment to Waste Site Reclassification Form 2005-008) documented that the process sewer that joined the 182-FA discharge pipe at the junction box was sampled as part of confirmatory sampling for the 100-F-26:1 pipelines site. Based on these results, No Action is required for this segment of pipeline. Evaluation of the confirmatory sample results for the 100-F-26:1 satisfied the remedial action objectives and the site was reclassified to "No Action". The water carried by the 100-F-44:1 pipeline was essentially the same water as that carried by the...
100-F-26:1 pipeline. Therefore no remedial action for the 100-F-44:1 subsite was needed and it was reclassified on WSRF form 2007-05.

Type: Process Sewer
Status: Inactive

Description: The subsite has been evaluated and determined to require No Action. The 100-F-44:2 subsite is a 0.05 meter (2-in.) steel pipeline that was discovered in a junction box during confirmatory sampling of the 100-F-26:4 pipeline in December 2004. The 100-F-44:2 pipeline fed into the 100-F-26:4 subsite, the 0.15 meter (6-in.) vitrified clay pipe process sewer pipeline from the 108-F Biology Laboratory at the junction box. Historical and drawing research supports the conclusion that the 100-F-44:2 pipeline is associated with the former 1,140,000 L (300,000-gal) 187-F1 elevated water tower. This information includes the proximity of the junction box location (where the pipeline was discovered) to the 187-F1 elevated water tower and the geophysical results that demonstrate that the pipeline's path is to the water tower.

Location: This pipeline is on the east side of the 187-F1 water tower.

Waste Type: Equipment
Waste Description: The waste includes the pipelines and any contaminated soil associated with these pipelines.

Closure Info: Historical and drawing research supports the conclusion that the 100-F-44:2 pipeline is associated with the former 1,140,000 L (300,000-gal) 187-F1 elevated water tower. This information includes the proximity of the junction box location (where the pipeline was discovered) to the 187-F1 elevated water tower and the geophysical results that demonstrate that the pipeline's path is to the water tower.

The geophysical survey of the 100-F-44:2 subsite was conducted in January 2007 using ground-penetrating radar. Two east-westerly trending linears were identified that appear to originate or pass through the former junction box location. The linear that extends to the east is consistent with the location and depth of the 100-F-26:4 pipeline. The linear that extends to the west is consistent with the location and orientation of the pipeline of interest (100-F-44:2). The assumed 100-F-44:2 pipeline linear is interpreted to be between 1 and 1.5 meters (3 and 5 ft) deep.

Confirmatory sampling at the 100-F-44:2 subsite was performed on January 16, 2008. A test pit was excavated beneath the pipe, to a depth of approximately 2 meters (7 feet). The pipe was located and uncovered eastward toward the 100-F-26:4 excavation boundary. The pipe was cut open at coordinates N147618, E580542. No interior pipe sample could be taken because there was no sediment or scale inside the pipe. Confirmatory sampling has shown that the site meets the cleanup objectives for direct exposure, groundwater protection, and river protection. Accordingly, a No Action reclassification is supported for the 100-F-44:2 subsite.

<td>Description:</td>
<td>The 100-F-44:3 subsite has been evaluated and reclassified to Rejected. In 2007, the pipeline subsite was originally identified by visual observation during confirmatory sampling within the manhole at 100-F-26:10 test pit #2. The test pit was located at coordinates E580259, N148001 and east of the 183-D Filter Plant. The 0.3 meter (1-foot) diameter steel or cast iron pipe within the manhole was recorded in logbook EL 1578-4. The pipeline was listed as a discovery site and became 100-F-44:3. The entire manhole, associated VCP piping and surrounding soil were removed during the 100-F-26:10 remediation. No other pipeline was encountered during the excavation. There was no evidence to support the existence of the 100-F-44:3. Therefore, 100-F-44:3 was reclassified as Rejected from consideration as a waste site. The 100-F-44:3 subsite does not pose a risk to human health or the environment and will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario, and no institutional controls are required.</td>

<tr>
<td>Description:</td>
<td>The 100-F-44:4 subsite has been evaluated and determined to require No Action. It consisted of a steel pipe discovered October 17, 2004, during trenching to locate the 118-F-4 Silica Gel Pit. The 110-F Gas Storage Tanks consisted of two low-pressure (carbon dioxide) storage tanks, 33 high-pressure (helium) storage tanks, an unloading platform, and a rail tank-car spot. The area is believed to have remained essentially unchanged from the time of the reactor's construction in 1944 until the demolition of nearby structures [i.e., 132-F-3 (115-F Gas Recirculation Facility)] in 1984. There were no pipelines indicated on historical drawings for the area. Water, sewer, fire, and steam lines were all north of the 110-F structure and entered the northwest corner of 132-F-3. The nearest waste site was the 118-F-4 Silica Gel Pit. According to historical records silica gel was deposited once in 1949. No installation of pipelines was involved.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The pipeline was located 122 m (400 ft) west southwest of 105-F, at coordinates N147522 E580298.</td>
<td></td>

</tr>
</tbody>
</table>
Waste Type: Construction Debris
Waste Description: The waste was pipeline sediment-scale and underlying soil.

Closure Info: A phased approach was used to evaluate the pipeline and collect samples in support of the sampling objectives. Confirmatory sampling began on February 13, 2008. An exploratory test trench, approximately 5 to 6 meters (15 to 20 ft) long, was excavated. However, the pipe was not found at that location. On February 21, 2008, another trench was dug approximately 6 meters (20 ft) due east of the first trench and of approximately the same length. This time the pipe was found and observed to be approximately 5 cm (2 in.) in diameter and 0.9 m (3 ft) below grade. The pipe length was determined to be 6 meters (20 ft).

The visual evidence indicated this pipe was a piece of electrical conduit debris and not a process pipeline or sewer pipeline. Though the pipe was identified as non-hazardous conduit debris, part of the confirmatory samples planned for the waste site was collected. On February 25, 2008 the pipe was cut and a sample of about 250 milliliters of soil was taken from inside the pipe.

The SubSite is Part Of:
Code: 100-F-44
Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:5
Names: 100-F-44:5; Process Sewer Pipelines
Type: Process Sewer
Status: Inactive

Classification: Accepted
Reclassification: Interim No Action (4/22/2009)

Description: The 100-F-44:5 subsite has been evaluated and determined to require No Action. It is a network of reinforced concrete and steel pipelines that received process flow from the 190-F Building and discharged to a 1.07 meter (42-in.) diameter pipeline associated with the 100-F-19:3 reactor cooling water effluent pipelines (CVP-2001-00003), which have been remediated. This pipeline subsite includes reinforced concrete pipe (RCP) and steel pipe consisting of the following:

- Two 0.9 m (36-in.) diameter RCP, 14 m (46-ft) long process sewers
- Two 0.15 m (6-in.) diameter steel, 14 m (46-ft) long process sewers
- One 1.2 m (48 in.) diameter RCP, 38 m (125 ft) long process sewer
- One 0.15 m (6-in.) diameter steel, 25 m (82 ft) long process sewer
- One 1.2 m (48 in.) diameter RCP, unknown length (up to 54 m [177-ft] long) process sewer.

In 1956, an annex was added to the south side of the 190-F Pump House to increase the process water flow throughout the system. It is assumed, based on the 190-F Annex construction photographs and site drawings, that in the process of excavation for the 190-F Annex below-grade pump room, approximately 54 meters (177 ft) of the original 1.2 meters (48 in.) diameter RCP running east to west was removed and replaced with the 1.2 meters (48 in.) diameter RCP that elbows to the south in a path around the 190-F Annex. However, an unknown length of the original pipeline could remain, and therefore has been included in the 100 F-44:5 subsite decision.

Location: It is located directly north of the 105-F Reactor and south of the 190-F Building Annex.

Waste Type: Equipment

Hanford Site Waste Management Units Report
February 2015
The waste is potentially contaminated soil.

Confirmanoty sampling at the site was conducted on January 17, 2008. Samples of soil underlying the below-grade concrete floor of the pump room that previously contained the 100-F-44:5 pipelines were collected. The two 0.9 meter (36-in.) diameter reinforced concrete pipe, 14 meter (46-ft) long process sewer pipelines were not in the pump room; however, it was confirmed that the location was consistent with the design drawing (H-1-26685). Evidence to that effect included two portals in the south vertical wall and two portals in the north vertical wall. The sampling logbook (WCH EL-1601) documents that the excavator operator confirmed a low spot in the floor that may have indicated a sump between the walls. A section of the floor was rubblized and removed, and the excavator collected soil from beneath the floor location as soil sample material.

One test pit (test pit #1) was excavated at the junction of the 0.15 meter (6-in.) diameter steel pipeline and the 1.2 meter (48-in.) diameter RCP pipeline. The 0.15 meter (6-in.) diameter steel pipeline intersects with the west side of the manhole at 0.91 meter (3 ft) to 2.7 meter (9 ft) bgs, per drawing H-1-26706. According to the sampling logbook, at test pit #1 a square manhole (approximately 1.2 meter (4 ft) on each side) was encountered approximately 0.3 meter (1 ft) bgs. However, the excavation extended to 5 meters (16 ft). This was 2.3 meter (7 ft) below the 0.15 meter (6-in.) diameter steel pipeline anticipated intersection, on the south and west sides of the manhole without intercepting the steel pipeline. As shown in the photographs taken during the excavation, the concrete room at the base of the manhole is visible at approximately 5 meters (16 ft), without evidence of a pipeline or visible point of entry for a pipeline within the concrete side of the manhole. To the south and west of the manhole, the roof of the 190-F cooling water tunnel was encountered at 3 meters (10 ft), and the base of the 190-F cooling water tunnel was encountered at 5 meters (16 ft).

Confirmanoty sampling at the 100-F-44:5 site, test pit #2, was performed on January 17, 2008. Field volatile organic compound and radiological surveys were conducted during the sampling. No elevated detections were noted in the logbook. The historical knowledge of the 190-F Annex demolition in 1977 does not include the condition of the below-grade pump rooms following the post-demolition clean up and grading of the site. Therefore, an observational approach was used during excavation of the test pit to identify potential worst-case media for focused sampling. The excavation continued to the below-grade concrete floor surface, approximately 4.0 meter (13 ft) bgs, to expose the contents of the pump room. The two 0.9 meter (36-in.) diameter, 14 meter (46-ft) long pipelines were not in the pump room. However, it was confirmed that the location was consistent with the design drawing.

- The 76 centimeter (30 inch) pipe entering the foundation of the 189-F Refrigeration Building was discovered during excavation of a test pit for confirmatory sampling at the 100-F-26:4 site.
on December 17, 2004. The origin of the pipeline was investigated as part of the 100-F Orphan Sites Evaluation task. Initially, the pipeline was thought to be an abandoned 107-centimeter (42-inch)-diameter raw water line for the 189-F Refrigeration Building, associated with 100-F-41 (100-F Service Water Pipelines, 100-F Clean Water Pipelines) and became 100-F-41:2. Because its former use was uncertain, the pipeline was reassigned to 100-F-44 (Miscellaneous Pipelines) and designated 100-F-44:6.

Location: This pipeline ran from the 181-F River Pumphouse to the 189-F Refrigeration Facility in the north-central part of the 100-F Area.

Process Description: The pipe has been identified as a raw water pipeline that supplied water to the condenser units in the 189-F Refrigeration Building. The pipeline also supplied backup raw water to the 182-F and 183-F facilities. The information discovered during the review substantiated the initial finding that the pipeline was the abandoned 107-centimeter (42-inch) raw water line for the 189-F Refrigeration Building. It varied in diameter from 76 centimeters (30 inches) to 107 centimeters (42 inches) and is 908 meters (2,979 feet) in total length, including laterals.

Waste Type: Soil

Waste Description: The waste is the old buried pipes from the raw water pipeline system.

The SubSite is Part Of:
Code: 100-F-44
Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:7
Names: 100-F-44:7; 1717-F Blowdown Pipeline
Type: Process Sewer
Status: Inactive
Classification: Accepted
Reclassification: Rejected (8/27/2007)
Start Date: End Date:

Description: The subsite has been evaluated and reclassified to Rejected. The reclassification was based on the absence of potential chemical or radionuclide contamination within the pipelines.

The subsite was originally thought to be one pipeline. It actually consists of two 10 centimeter (4 in.) diameter cast-iron pipelines, each 27 meters (88 ft) long. The existence of the pipelines was confirmed by geophysical methods. During decommissioning and demolition of the 1717 F Maintenance Shop structure in 1983, short sections of both pipelines had been removed.

The two pipelines had been used to connect the 1717-F auxiliary boiler system to the 1717-F Building Drywell for safety reasons. As a rule the blowdown valve on a boiler was plumbed into a dedicated pipeline or drain. These pipelines discharged into the 100-F-5, 1717-F Building Drywell. Conflicting construction drawings indicated there may be a drain line of identical size and length running in parallel to this line.

Location: The segment consisted of one or two pipelines extending 23 meters (76 feet) from N147757/E580622 to N147757/E580645. The two 10 centimeter (4 inch) diameter pipelines were identified, in historical construction drawings, on the west side of the former 1717-F Maintenance Shop.

Process Description: Both pipelines connected from an auxiliary boiler system in the 1717-F Building to the 100-F-5, 1717-F Building Drywell. Water carried in the pipelines consisted of sanitary (potable) water. The Blowdown pipe served to prevent an explosion if the boiler pressure got too high, hot liquids and vapors would not be able to backflow, and possibly damage other locations or...
personnel in or around the boiler system. Having a dedicated pipeline also ensured that the carrying capacity of that pipeline would not become restricted over time due to incidental use. Therefore, each of the boilers in the heating system required a separate dedicated blowdown pipeline.

Steam condensate, from the heating systems serviced by the 1717-F auxiliary boiler system, was not returned to the boiler system for reuse. Therefore, water would not have contained chemical or radiological contaminants from the laboratories or other facilities serviced by the 1717-F auxiliary boiler (heating) system. Only unregulated concentrations of water treatment chemicals, used to produce potable water, would be present in the boiler system and, therefore, in the water carried by the pipelines.

The SubSite is Part Of:

Code: 100-F-44
Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:8
Names: 100-F-44:8; 1717-F Fuel Oil Supply and Return Pipelines
Type: Process Sewer
Status: Inactive
Description: This subsite has been remediated Interim Closed Out. It was also known as Segment DS-100-F-009 that consisted of two 3.8 centimeter (1.5 inch) diameter black steel pipelines. They extended 36 meters (118 feet) from N147753/E580610 to N147753/E580637 to N147756/E580645. They were fuel oil supply and return pipelines that serviced the three underground fuel oil tanks (WIDS site 100-F-32) and the 1717-F building. Evidence was found that the tanks were offered for sale and photographs showed a disturbance where the tanks were previously located. It is possible these pipelines were removed as part of the tank removal.
Location: These pipelines were located about 240 meters (787 feet) northeast of the 105-F Reactor.
Process Description: The pipelines allowed fuel oil to be supplied to the 1717-F maintenance shop and office buildings.
Waste Type: Animal Waste
Waste Description: The waste includes the pipelines and any contaminated soil associated with these pipelines.

Closure Info: In 2008, the pipelines were located. Confirmatory sampling determined that liquid with a strong diesel odor was still present in the lines. Remedial action at the 100-F-44:8 pipelines began on October 27, 2010, and continued through January 4, 2011, to a depth of approximately 0.7 meters (2.3 ft) across the entire excavation footprint. Due to the shallow nature of the excavation, no overburden was associated with this site. The excavation resulted in approximately 80 bank cubic meters (BCM) (104.6 bank cubic yards [BCY]) of contaminated soil and debris being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 72 meters (238 ft) of 3.81 centimeters (1.5 inch) diameter steel pipe, along with contaminated soil, piping, conduit, wires, concrete, and used personal protective equipment was excavated from this waste site and disposed at the ERDF. Following the verification sample analysis, it was determined that additional remediation was needed due to sample locations that exceeded cleanup criteria. A second remediation was conducted on June 9, 2011, with the removal of 126.4 BCM (165.3 BCY) of contaminated soil. With agreement from the U.S. Environmental Protection Agency (EPA), additional soil was removed from areas...
that exceeded direct exposure and/or groundwater and river protection RAGs in the excavation and staging pile area footprint.

The SubSite is Part Of:

Code: 100-F-44
Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:9 Classification: Accepted
Names: 100-F-44:9; 105-F Process Sewer Pipeline Reclassification: Interim Closed Out (9/14/2011)
Type: Process Sewer Start Date:
Status: Inactive End Date:
Description: The pipeline has been removed and Interim Closed Out. The pipe segment was a 46 centimeter (18 inch) steel process sewer pipeline approximately 42 meters (140 feet) in length.
Location: The 100-F-44:9 waste site was located in the 100-FR-1 Operable Unit of the Hanford Site. It was east of the former 105-F Reactor Building, within the 105-F Exclusion Area fenceline. The pipeline was 42.5 meters (140 feet) long, extending from N147620/E580460 to N147620/E580473 to N147618/E580475, and ending at N147591/E580475.
Related Sites/Structures: 100-F-44:9 was associated with the 100-F-19:2 cooling water pipeline.
Process Description: The pipeline conveyed effluent from the east side of the 105-F Reactor Building and appeared to discharge to a 1.07-m (42-in.)-diameter pipeline associated with the 100-F-19:2 Reactor cooling water effluent pipelines that have since been remediated.
Waste Type: Misc. Trash and Debris
Waste Description: Possible chemical and/or radionuclide contaminated pipelines and underlying soils.
Closure Info: A geophysical survey of the site was conducted in January 2007. The geophysical survey findings agreed with historical documentation for the pipeline that shows a north-south trending, 18-in.-diameter steel pipeline paralleling the 105-F Reactor footprint along the east side. The pipeline turns to the west near the northern side of the reactor. Remedial action at the 100-F-44:9 pipeline subsite began on November 3, 2010, and continued through January 5, 2011, to a depth of approximately 3 meters (10 ft). One staging area was developed during the excavation for storing soil prior to disposal at the ERDF. Contaminated soil, pipe, asphalt, clay pipe, concrete, and rebar were removed from the 100-F-44:9 excavation for shipment and disposal to the ERDF. The post-excavation surveys, conducted on January 10, 2011, identified no residual radioactivity above twice background within the site.

An anomaly was discovered within the excavation of the 100-F-44:9 subsite that appeared to be a large metal valve. A sample of the anomaly not collected after the object was found to be empty. Industrial Hygiene and radiological readings did not detect contamination present within the anomaly.

The SubSite is Part Of:

Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:10 Classification: Accepted

Hanford Site Waste Management Units Report
February 2015
Reclassification: Rejected (10/11/2007)

Names: 100-F-44; 141-C Sewer Pipelines; 100-F Experimental Animal Farm Sewer Pipelines

Type: Process Sewer

Status: Inactive

Start Date:

End Date:

Description: The subsite has been evaluated and reclassified to Rejected. The subsite is described as two 20.3-centimeters (8-inch)-diameter sewer pipeline segments exiting the 141-C building. It has been determined through the excavation results that there is no evidence to support the existence of the site. The pipelines were likely removed during earlier demolition activities. The subsite does not pose a risk to human health or the environment and will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario, and no institutional controls are required.

Historical review determined that during Decontamination and Decommissioning activities of the 141-C Building (between August and December 1979), the building, concrete pad, foundation and contaminated soils were removed. The only remaining structure was a temporary steel post that marked the location of a 6-inch gate valve. The valve and 36.5 meters (120 feet) of potentially contaminated 20 centimeter (8-inch) steel pipe that extended from the valve to the decommissioned waste lift station (141-N) was capped and abandoned in place.

Documentation in the Cleanup Verification Package-2001-0003 for sites 100-F-19:2, 116-F-11, 100-F-29, and UPR-100-F-1 stated that pipelines were excavated on March 22, 2002 that extended from just east of the former 141-C Building to the former 141-N waste lift station. A geophysical survey was performed in April 2004 to locate and map any buried remains from the demolished 141-C Building. The geophysical survey narrative stated that the entire site appeared to have been disturbed from operational or deactivation activities. There were no obvious anomalous features detected that had the characteristics of remnants of the infrastructure from the original site (e.g., foundation footings, buried debris, pipelines, utilities).

In August 2005 during the 141-C Building remediation, exploratory trenches were dug to confirm that the sewer lines formerly servicing the 141-C Building had been removed during previous deactivation activities. No sewer lines were located by these excavations and field instrumentation did not detect any beta-gamma or alpha activity above background levels. There was no evidence to support the existence of the pipe segments in the vicinity of the 141-C Building.

Location: The waste site was located within the 100-F Experimental Animal Farm area. The subsite consisted of two 20.3-centimeters (8-inch)-diameter sewer pipeline segments exiting the 141-C building. It has been determined through the excavation results that there is no evidence to support the existence of the pipelines.

The SubSite is Part Of:

Code: 100-F-44

Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-45

Classification: Accepted

Names: 100-F-45; Buried River Effluent Pipelines

Reclassification: Interim Closed Out (12/15/2011)

Type: Radioactive Process Sewer

Status: Inactive

Start Date:

End Date:

Description: The waste site was remediated and Interim Closed Out. It consisted of a piece of pipeline that was buried in the river bank after it floated loose from the river effluent pipeline.
**Location:** The site is located on a steep river bank approximately 10 meters (33 feet) from the Columbia River, approximately 670 meters (2,200 feet) northeast of the 105-F Reactor Building and about 15 meters (50 feet) upstream from the 116-F-16 PNL Outfall.

**Related Sites/Structures:** These suspected pipeline sections are believed to have resulted from the failure of the 100-F-39, 100-F River Effluent Pipelines which are also co-located with 116-F-8 Outfall Structure, and the 100-F-42, 1904-F Spillway/Flume.

**Process Description:** The 100-F Area process sewers discharged via the 1904-F (116-F-8) Outfall to the Columbia River through two 106 centimeter (42 inch) steel lines (BHI-01141). Soon after the 105-F Reactor started up in 1945, these pipelines began to experience a problem common to all of the early reactors, floating river effluent lines. More than 100 feet of each of these lines were bent and broken. Historical documentation suggested that these broken sections were removed from the river and buried somewhere along the shoreline, although the exact location was not recorded. In 1946, the original pipelines were replaced with much shorter ones, causing confusion over time.

**Waste Type:** Soil

**Waste Description:** Contaminants of concern/potential concern are based on those for the 1904-F outfall (116-F-8). Contaminants of concern include Co-60, Eu-152, Eu-154, Eu-155, and Cr+6. Contaminants of potential concern include C-14, Cs-137, Ni-63, and Sr-90.

**Closure Info:** Remedial action at the 100-F-45 waste site began on March 14, 2011, and continued through March 21, 2011, to a depth of approximately 0.5 to 2.0 meters (1.7 to 6.6 ft). The excavation resulted in approximately 160.0 bank cubic meters (BCM) (208.0 bank cubic yards [BCY]) of contaminated soil and debris being removed, including 15.3 meters (50.0 ft) of the 42 inch diameter steel pipe, for disposal at the Environmental Restoration and Disposal Facility (ERDF). Approximately 217.0 BCM (283.8 BCY) of overburden material was stockpiled southwest of the excavation for use as clean backfill. A small staging pile area was used for contaminated soil and pipe material, which was later loaded out and disposed at the ERDF. No anomalous materials or stained soil were encountered during the excavation.

Upon completion of remedial activities, high river flow caused water seepage into the excavated area. This seepage caused some of the surrounding bank to fall into the finished excavation area. Prior to verification sampling, this soil material was removed at the specified sampling locations.

No elevated radiological readings were detected during the excavation of the 100-F-45 waste site; therefore, no Global Positioning Environmental Radiological Surveyor (GPERS) surveys were conducted.

---

**Code:** 100-F-46  **Classification:** Accepted

**Names:** 100-F-46; 119-F Stack Sampling French Drain  **Reclassification:** Interim No Action (8/8/2008)

**Type:** French Drain  **Start Date:**

**Status:** Inactive  **End Date:**

**Description:** The site has been evaluated and determined to require No Action. It consisted of the 119-F french drain, a gravel-filled vertical pipe, and the pipeline from the 119-F Stack Sampling Building to the french drain.

**Location:** The french drain was located about 7.5 meters (25 feet) northwest of the west wall of the 119-F Stack Sampling Building. The influent end of the pipeline was at E580382.2 N147614.2. The pipeline depth was above the top of the 117-F air tunnels such that it was likely removed during the decontamination and decommissioning (D&D) activities for the 117 F Building and air
tunnels.

**Related Sites/Structures:** The site was associated with the 118-F-8 Reactor Building 116-F Stack, 119-F Stack Sampling Building, 117-F Filter Building and Air Tunnels.

**Process Description:** The 116-F reactor stack exhaust gases were sampled by pulling moist stack offgases through a steam-heated pipe to the 119-F Stack Sampling Building where the gas stream was sampled. The condensate from the stack offgases drained via a 2 inch cast iron pipeline to the 119-F french drain. A 5 centimeter (2 inch) cast iron pipe drained condensate from the 119-F Stack Sampling Building into the french drain. The drain pipeline is included as part of this waste site.

**Waste Type:** Soil

**Waste Description:** The site may contain contaminated soil from condensate entering the french drain. The waste includes the french drain and the pipelines. However, remediation of these structures is not documented in a cleanup verification package. The condensate from the 116-F stack potentially contained the same contaminants of concern identified for the 116-F stack during the characterization sampling performed for the allowable residual contamination level (ARCL) evaluation completed in 1985. Low levels of tritium-3, carbon-14, strontium-90, cobalt-60, cesium-13, europium-152, and plutonium-239 were reported for the 116-F stack. Potential Contaminants of Concern: Low levels of tritium-3, carbon-14, strontium-90, cobalt-60, cesium-13, europium-152, and plutonium-239 were reported for the 116-F stack.

**Closure Info:** Both the 100-F-46 French drain and the condensate pipeline were presumed to have been removed during decommissioning and demolition of the 117-F Filter Building (132-F-5) and associated air tunnels in 1983. These structures had been decontaminated, removed to a depth of 1 meter (3 feet) below grade, and backfilled to grade. The confirmatory sampling results supported a reclassification of the site to No Action.

**Code:** 100-F-47

**Classification:** Accepted

**Names:** 100-F-47; 151-F Substation

**Reclassification:** Interim Closed Out (12/15/2011)

**Type:** Electrical Substation

**Start Date:** 1/1/1945

**Status:** Inactive

**End Date:** 1/1/1965

**Description:** The waste site has been remediated and Interim Closed Out. The substation consisted of a fenced, gravel-bed yard measuring 92.4 meters (303 feet) by 137.2 meters (450 feet), with the 151-F Switch House along the eastern fence line. A railroad spur entered the yard from the south and paralleled the east fence line.

The 151-F Substation distributed power to transformers located at the 181-F River Pump House, 182-F Head House, 183-F Filter House, 184-F Power House, 190-F Pump House, and the 105-F Reactor, each of which, in turn, distributed power to associated facilities.

**Location:** The 151-F Building and associated switch yard were located approximately 350 meters (1148 feet) northwest of the 105-F Reactor Building. The 151-F Building was centered along the east fence line of the switch yard.

**Related Sites/Structures:** The 151-F Building and associated switch yard were located approximately 350 meters (1148 feet) northwest of the 105-F Reactor Building. The 151-F Building was centered along the east fence line of the switch yard.

**Process Description:** The 151-F Substation was fully energized in January 1945 and supplied 13.8 KV electrical power to the 100-F Area.
More than 100 concrete footings and pads of various sizes protruded from the crushed gravel bed throughout the yard, supporting a variety of electrical equipment, including two 31,250 KVA, 220/13.8 KV transformers, one 37.5 KVA transformer, three oil circuit breakers, and several power line towers and stands. Underground concrete-encased "Korduct" ducts connected the switch house with the transformers and oil circuit breakers.

The single-story concrete block switch house was 24.4 meters (80 feet) long by 9.1 meters (30 feet) wide and 3.4 meters (11 feet) high. A 3.4 meter (11 foot) wide by 3.4 meters (11 feet) high by 21.9 meters (72 feet) long reinforced concrete cable pit ran beneath the block house.

Waste Type: Misc. Trash and Debris

Waste Description: There have been no reported unplanned discharges of oil containing PCBs. Since leak/spill reporting is inconsistent for the entire period of operation of the substation, it is prudent to assume unplanned discharges of oil may have occurred at locations where transformers or oil circuit breakers were positioned, or where the railroad tanker was located. Confirmatory sampling around these locations should be considered. There may be more than 2,744 meters (9,000 feet) of underground electrical cable, generally housed in fiber or transite conduit, and encased in at least 7.6 centimeters (3 inches) of concrete. It is suspected that much of this copper cabling is encased in an asbestos wrap and an outer lead sheath. Also, depending on the extent of unplanned releases, these lines may be contaminated by PCB-containing oil. This same cabling may also still remain in the cable pit of the 151-F Building. Potential Contaminants of Concern: PCBs, lead, and asbestos.

Closure Info: Remediation of the 100-F-47 waste site was performed from October 20, 2010, through June 27, 2011, to a depth between 1 and 4.35 meters (3 and 14.3 ft) across the entire excavation footprint. Due to the shallow nature of the contamination, no overburden was associated with this site. Approximately 14,500 cubic meters (19,000 cu. yd.) of contaminated soil, concrete, rebar, wire, steel cable, asphalt, asbestos, wood, steel, porcelain, and glass were removed from the 100-F-47 excavation and were directly loaded for shipment and disposal at the Environmental Restoration Disposal Facility. No anomalous materials were encountered during the excavation. Two small transformers were found during the excavation, and will be characterized for disposal at a later date.

Code: 100-F-48

Classification: Accepted

Reclassification: Interim Closed Out (12/15/2011)

Names: 100-F-48, 184-F Coal Pit Debris

Type: Dumping Area

Status: Inactive

Description: The waste site ha been remediated and Interim Closed Out. It consisted of an area of debris that was identified in an aerial photograph and a historical literature search. The debris has been removed and disposed into the Environmental Restoration Disposal Facility.

Location: The coal pit debris is located immediately north of the 184-F Power House site (removed), about 500 meters (1,650 feet) northeast of the 105-F Reactor Building.

Related Sites/Structures: The associated structures included the 184-F Power House and 184-F Coal Handling Facilities.

Process Description: Inert demolition debris was commonly disposed on site in the large operations support storage facilities such as the coal storage bins and the water treatment and storage basins. The criteria for what was allowed to be disposed on site are not documented but generally are thought to include nonradioactive solid debris such as building materials (e.g., siding, roofing, structural, concrete/concrete block, fencing) removed during demolition of administrative and ancillary support facilities between 1967 and 1990. Some unacceptable solid waste forms such as
Closure Info: The 100-F-48 waste site anomalies included two deteriorated, leaking drums and a single intact, non-leaking drum. The single intact, non-leaking drum was found to be empty. The two deteriorated, leaking drums were sampled. One drum was found to contain high concentrations of TPH and lead.

Confirmatory sampling failed to meet remedial action objectives. Analytical results from the confirmatory samples indicated that the material in the drum, found in the geophysical anomaly area, exceeded shallow-zone direct exposure Remedial Action Goals (RAGs) for thorium-230, uranium-233/234, uranium-238, and arsenic. The material also exceeded groundwater and river protection RAGs for copper, lead, mercury, and zinc. Based on the confirmatory sampling results, the 100-F-48 waste site was recommended for remediation.

Remediation of the 100-F-48 waste site was performed from September 21, 2010, to January 11, 2011. The coal scrape area was remediated to a depth of approximately 0.3 meters (1 ft), while the main excavation area had a final depth that ranged from approximately 0.2 meters (0.7 ft) to 3.5 meters (11.4 ft). The 100-F-48 waste site excavation resulted in approximately 13,922 BCM (18,209 BCY) of material being removed for disposal at the Environmental Restoration Disposal Facility (ERDF).

Soil and debris from the main excavation area were direct-loaded to ERDF, while material removed from the coal scrape area was staged at the east stockpile area before eventual removal to ERDF. Types of debris uncovered include: concrete, steel pipe, rebar, porcelain, clay pipe, bricks, wire, cable, suspect ACM, and asphalt. No overburden soil stockpiles were associated with the waste site.

---

Code: 100-F-49
Names: 100-F-49; 1716-F Maintenance Garage Lubrication Pit
Type: Foundation
Status: Inactive
Description: The waste site has been remediated and Interim Closed Out. The waste site consisted of components of the 1716-F Maintenance Garage, including the foundation, the lubrication pit, and the contaminated drain(s). The foundation of the former garage building was T-shaped with overall dimensions of approximately 15 by 17 meters (50 by 55 ft).
Location: The building was located in the northwest corner of the Service Building group approximately 1,101 meters (3,612 feet) north of the 100-FR-2 east-west perimeter road. The building was on the west side of F Avenue, about 13 meters (43 feet) from the road.
Process Description: The 1716-F facility provided automotive repair, light vehicle maintenance, and lubrication service for the 100 F Area vehicles.
Waste Type: Soil
Waste Description: There may have been oil spills in the lubrication pit and battery acid spills in the high bay area. The Geophysical team identified this area as a potential new waste site due to the probable oil spills (polychlorinated biphenyls [PCBs], total petroleum hydrocarbons [TPH]) in the lube pit, potential battery acid in the high bay area, potential unknown pipelines, and the potential asbestos shake siding debris.
Closure Info: Confirmatory Sampling failed. The results of confirmatory sampling indicated that test trench 1 met all remedial action goals. The results from the remainder of the site indicated contamination

---

Hanford Site Waste Management Units Report
February 2015
with lead and polychlorinated biphenyls (PCBs) above direct exposure RAGs. In addition, the remainder of the site also exceeded groundwater and river protection RAGs for numerous metals, semivolatile organic analytes, pesticides, and total petroleum hydrocarbons (TPH). In all, 29 different contaminants exceeded groundwater and/or river protection RAGs. Asbestos was also confirmed at the site. Based on these results, the entire 100-F-49 waste site, except for suspect utility lines associated with test trench 1, was recommended for remediation.

The 100-F-49 waste site was remediated between January 11 and April 12, 2011. During the 100-F-49 remedial activities, a steel tank was discovered at Washington State Plane (WSP) coordinates N147891, E 580666. The tank was not expected to be present at this location, and therefore, the excavator had slightly broken into the tank, causing some of the liquid from the tank to spill into the surrounding soils. The spilled liquid from the tank and soil was sampled (J1F1N1) and determined that the tank was used for oil storage purposes. The tank and its location were carefully observed and determined to be the same oil tank that 2008 confirmatory sampling expected to find. The liquid and sludge contents were pumped from the tank prior to its disposal. The steel tank structure, oil saturated soils, and additional underlying soil were removed from the 100-F-49 excavation and disposed at the Environmental Restoration Disposal Facility (ERDF).

Remediation included removal of the 1-in.-diameter steel pipe, 20 cubic meters (21.3 cu. yd.) of concrete, a 1,325-L (350-gal) steel storage tank and approximately 1,325 L (350 gal) of fuel, oil and sludge from the tank. Miscellaneous debris such as concrete and rebar were removed from the excavation and stockpiled adjacent to the site for disposal at the ERDF. The deepest part of the 100-F-49 excavation extended to approximately 2.7 m (8.9 ft). Approximately 2,727 bank cubic meters (3,567 bank cubic yards) of soil and debris was excavated from the 100-F-49 waste site. Roughly half of the materials were stockpiled adjacent to the excavation prior to disposal at the ERDF. The other half of the excavated materials was directly loaded for disposal at the ERDF.

Following the load out of stockpile materials, the staging pile area was scraped to 0.3 meter (1 ft) below ground surface. A very small green/yellow stain was observed at 0.3-meter (1-ft) depth at WSP coordinates N 147943.3, E 580631.1. It was determined that the stain was not caused by the stockpile. The stain was present at this location prior to any 100-F-49 stockpiling activities. The stained soil was sampled (J1FHT7). The sample data of the stained soil indicates that all individual contaminant of potential concern concentrations are below RAGs.

<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The laboratory sat on a curved, concrete pad, the laboratory was 5 meters (16 feet) wide by 24 meters (80 feet) long. The floor sloped toward a central trough that was 15.8 meters (52 feet) long by 0.4 meters (1.5 feet) wide by 0.2 meters (0.5 feet) deep, which in turn drained out the</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
north end of the building and directly east into the 147-F Pump House pit. The laboratory contained ten pairs of elevated, open-top, wooden fish troughs, each 3.7 meters (12 feet) long by 0.3 meters (1 feet) wide by 0.2 meters (0.75 feet) deep, as well as three head tanks and associated piping to the troughs.

River water was pumped to the Fish Laboratory through a 15 centimeter (6 inch) line from the 181-F River Pump House; process water was pumped to the building through a 5 centimeter (2 inch) line from the 190-F Main Process Pump House and Annex; and process effluent was pumped to the facility (where it was cooled before use), via the 148-F Pump House from the 107 F Retention Basin. Spills and overflows from the troughs and head tanks drained to the 147-F Pump House pit, which pumped to the 1904-F Outfall and discharged to the Columbia River.

There were removable wooden walkways between the troughs. In addition, the building contained a process water refrigeration system, fish food bins, refrigerator and freezer, electric heater and swamp cooler, an office, and a bathroom. Immediately to the east of the building were the outdoor rearing ponds and the 149-F Biology Warehouse, and immediately to the south was the 146-FR Radioecology and Aquatic Biology Laboratory that was built in 1952.

Waste Type: Chemicals
Waste Description: No reports were found of unplanned discharges to the soil from this building. However, because of the open-trough operations within the building it is prudent to assume such discharges may have occurred. A partial geophysical survey of the area recorded mixed subsurface debris that could be a portion of the original foundation. Contaminants of concern/potential concern are based on those for the 1904-F Outfall (116-F-8). Contaminants of concern include cobalt 60, europium 152, europium 154, europium 155, and hexavalent chromium. Contaminants of potential concern include carbon 14, cesium 137, nickel 63, and strontium 90.

Closure Info: In November 2007 and February 2008, confirmatory sampling of the 100-F-51 waste site was carried out during the excavation of two test pits, at the north end and southeast corner of the laboratory. Confirmatory sampling results failed to meet remedial action goals (RAGs) and indicated the need for remedial action at the 100-F-51 waste site. Confirmatory sampling was not performed for the 100-F-63 waste site. 100-F-63 was added to the 100-F Area remove, treat, and dispose scope in 2010.

Remedial action at the 100-F-51 and 100-F-63 waste sites began on December 20, 2010, and continued through January 20, 2011. Excavation depth ranged from 0.5 to 1.5 meters (1.6 to 4.9 ft) below ground surface and resulted in approximately 253 bank cubic meters (BCM) (331 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility. Approximately 330 BCM (432 BCY) of overburden soil was stockpiled to be used as backfill. The 100-F-51 and 100-F-63 waste sites debris included concrete, clay pipe, steel pipe, and asphalt. The verification sampling results support a reclassification of the 100-F-51 and 100-F-63 waste sites to interim closed out.

<tr>
<td>Description: The waste site was evaluated and determined to require No Action. The 100-F-53 waste site was created when research of historical information identified an early pre-construction drawing (HEW 1 944b) that depicts what appeared to be an undocumented septic system and drain field. The waste site included the septic drain field, a potential septic tank, and septic...</td>
<td></td>
</tr>
</tbody>
</table>
pipelines. The septic system was suspected to be associated with the 108-f Biology Laboratory, due to its proximity to the laboratory facility. The site represented what was thought to be a septic system.

**Location:** The site was located approximately 190 meters (625 feet) east of the 105-F Reactor Building.

**Release Description:** Releases unknown.

**Related Sites/Structures:** Any liquid waste discharges to this suspect site would have originated from the 100-F-36 (108-F Chemical Pump House, 108-F Biological Laboratory) site.

**Process Description:** Gravity drain sewer system, either sanitary or chemical, discharged to the soil column via a drain field.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The waste potentially consists of the pipelines, the septic tank, the drain field and any contaminated soil around them. Geophysical measurements were inconclusive. No clear evidence was found of a septic tank, a septic line, or a drain field. Since the septic system (if it existed) would have been associated with 108-F Building and the activities within the building (before 1949 and the addition of the biology facilities to 108-F), the contaminants of potential concern may have been hexavalent chromium or mercury.

**Closure Info:** Phase I and Phase II confirmatory sampling, the 100-F-53 septic system was determined not to have been associated with the 108-F Biological Laboratory, but instead serviced a temporary construction building. Confirmatory sampling activities determined that the septic tank had previously been removed and sampling results indicate that the residual concentrations of COPCs at this site meet the remedial action objectives for direct exposure, groundwater protection, and river protection.

An aerial photograph P-1888 taken during construction of the 100-F Area showed that the Crafts Office was one of the first buildings constructed in the 100-F Area. This building did not appear on photographs taken during operation of the 100-F Area, indicating it was removed early in the operations time period. Based on the historic aerial photographs, the 100-F Area Plot Plan drawing (Drawing C-3231), and the building description in DuPont (1945), it was concluded that the TC-32 Crafts Office was the Layout building and that this is the building seen in the historic photographs. It follows that the drain field shown on the drawing (and found in the 100-F-53 test trench) serviced this temporary construction building. Thus, the septic tank associated with the 100-F-53 septic system was a wood framed box buried 0.3 m (1 ft) below grade and located somewhere between the drain field and the "Layout" building.

A geophysical survey was performed at the site in August 2005 (Bergstrom and Mitchell 2005) to locate evidence of a septic tank, underground pipelines, and a drain field based on the historical drawing (HEW 1944). Ground-penetrating radar and an electromagnetic induction (EM-61) metal detector were the geophysical methods used for the investigation. The results found no features that would have been characteristic of a typical septic tank. Several linears were detected that could be characteristic of underground pipelines and/or utilities, but the results were inconclusive. Also, scattered anomalies throughout the surveyed area were likely buried remnants from decommissioning of the 108-F Building. It should be noted the geophysical methods used have only a limited capability to detect wood septic tanks and vitrified clay pipes (characteristic of drain fields and sanitary sewer piping).

Based on historical and photographic evidence, including field observations during Phase I and Phase II confirmatory sampling, the 100-F-53 septic system was determined not to have been associated with the 108-F Biological Laboratory, but instead serviced a temporary construction building. Confirmatory sampling activities determined that the septic tank had previously been
removed and sampling results indicated that the residual concentrations of COPCs at this site meet the remedial action objectives for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the confirmatory sampling results supported a reclassification of the site to No Action.

145-F Buildings. The second sample area was within a pasture north of the former 141-T Building. Nine soil samples were collected from these areas.

**Code:** 100-F-55  
**Classification:** Accepted

**Names:** 100-F-55; 1607-F7 Contaminated Ash Layer  
**Reclassification:** Interim Closed Out (12/22/2011)

**Type:** Unplanned Release  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The waste site has been remediated and Interim Closed Out. The ash layer was discovered during 1607-F7 sampling activities. The site consisted of a black layer of ash approximately 0.3 meters (1 foot) below the ground surface north of the 1607-F7 septic system, near the former 141-M building. The ash was found to be above cleanup limits for hexavalent chrome.

**Location:** The ash layer was observed in a trench near the 1607-F7 Septic System, approximately 0.3 meters (1 foot) below grade.

**Related Sites/Structures:** The ash layer is unrelated to the 1607-F7 Septic System.

**Waste Type:** Construction Debris

**Waste Description:** The waste is a contaminated ash layer. The only known contaminant of potential concern is hexavalent chromium.

**Closure Info:** Remedial action at the 100-F-55 waste site was performed from September 16 to October 7, 2010 to a depth of 0.7 meters (2.3 ft). Remedial action at the 100-F-62 waste site was performed from December 2010 to March 2011. The 100-F-62 north pipeline excavation included the removal of the pipelines to the former 1607-F7 septic tank and contained the 100-F-55 waste site excavation. From the north excavation, approximately 2 meters (7 ft) of the 4 inch diameter vitrified clay pipe were removed, and approximately 5 meters (16 ft) of 4 inch diameter steel pipe with lead bells were removed. Verification sample results indicated additional remediation was required. Additional remediation was performed from July 29 to August 9, 2011. The center section of the north excavation was further remediated, and the entire south excavation was further remediated and expanded to the south. The final north excavation depth is 2.3 meters (7.6 ft), and the final south excavation depth is 4.4 meters (14.5 ft). Additional remediation also occurred at the east staging pile area and the northeast quadrant of the south staging pile area.

**Code:** 100-F-56  
**Classification:** Accepted

**Names:** 100-F-56; 100-F Surface Debris/Stains  
**Reclassification:** Interim Closed Out (12/15/2011)

**Type:** Dumping Area  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The waste site was miscellaneous discarded/abandoned materials across the 100-F Area. The waste site was divided into two subsites, 100-F-56:1, 100-F Garnet Sand Areas and 100-F-56:2, Other 100-F Surface Debris Areas. Both subsites have been remediated, so the parent site is also Interim Closed Out.

**Location:** The subsite areas were located throughout the 100-F Area.

**Related Sites/Structures:** Temporary and permanent 100-F Area facilities removed by remedial action or decontamination/decommissioning activities are listed in the Buildings section of the OSE report for 100-F.
Process Description: Various sizes and forms of hazardous (CERCLA) and/or dangerous (MTCA) surface debris were left during the construction, operation, decontamination and decommissioning (D), and remedial action (RA) activities at the 100-F Area.

Waste Type: Sanitary Sewage

Waste Description: The solid waste types addressed here are typically transite, lead battery residues, and treated wood including isolated railroad ties, treated power pole, and wood posts. Railroad ties in railroad beds are not addressed here. The contaminants of potential concern relate to waste characterizaton for disposal of the debris. There are no significant environmental contaminants of concern for this site since the debris is expected to leave no residue during removal.

This Site has the Following SubSites:

</table>

Location: One area was located 200 meters (656 ft) north of the 105-F Reactor Building and the other located was 300 meters (984 ft) south of the 105-F reactor.

Process Description: The exact process that caused the garnet sand to be located at these locations is unknown. However, garnet sand was used in sandblasting operations to clean rust, paint, and contamination from the surface of metal components. The garnet material is not a hazardous substance. However, there is contamination potential due to the paint and other materials removed by sandblasting.

Closure Info: Remediation of the 100-F-56:1 waste subsite occurred from March 1 to April 4, 2011. Soil was excavated to a depth of 0.2 meters (9 inches) below ground surface resulting in 440 cubic meters (575 bank cubic yards) of soil and debris being disposed at the ERDF. Following remediation, verification sampling was conducted in July and August 2011. Results showed that a single sample taken from the northern excavation contained contaminant concentrations in excess of the cleanup criteria for hexavalent chromium. Further remediation was performed to excavate an additional meter in depth at that location. A new sample was collected from the original failed location in August 2011. The garnet sand was mixed with soil, therefore, no clean soil in the immediate vicinity was available for backfill.

The SubSite is Part Of:

### 100-F-56:2

**Classification:** Accepted  
**Reclassification:** Interim Closed Out (8/23/2012)  
**Status:** Inactive  
**Start Date:**  
**End Date:**  

**Description:** This subsite has been remediated and Interim Closed Out. It consisted of twenty locations having stained soil and/or debris across the 100-F Area. Seventeen of the sites were the result of treated wood debris. Two of the sites had oil filters and one site had lead debris. The surface debris was removed.

**Location:** The debris was located throughout the 100-F Area. The GPS coordinates are provided in the 100-F Orphan Sites Evaluation Report (OSR-2005-0001) and are associated with the 100-F-56:2 waste site in the WCH GIS database using the OSE-ID field.

**Closure Info:** The WCH Field Remediation (FR) project performed remedial action and housekeeping activities at the 100-F Area from July 2005 to March 2008. During these activities, Field Remediation crews found that many of the previously identified 100-F-56 waste site components appeared to have been at other sites that were remediated after the orphan sites evaluation. Thirteen areas did not require any remediation. A total of seven locations containing wood debris (i.e., railroad ties and a wooden utility pole) at the 100-F-56:2 subsite were remediated on March 1 and 2, 2011. Remedial action activities included surface pick up only, generating less than 20 bank cubic meters (26.16 bank cubic yards) of wood debris. This debris was directly loaded for disposal at the Environmental Restoration Disposal Facility.

### 100-F-57

**Classification:** Accepted  
**Reclassification:** Interim Closed Out (8/23/2012)  
**Status:** Inactive  
**Start Date:** 1/1/1945  
**End Date:** 1/1/1965  

**Description:** The waste site was of the remaining, below grade foundation of the demolished 190-F Process Water Pump House. The waste site was split into two subsites in October 2011, to allow separate remediation activities on the eastern and western portions of the waste site. Both subsites have been remediated and Interim Closed Out, so the parent site is also considered Interim Closed Out.

**Location:** The pump house and annex were directly north of the 105-F Reactor.

**Related Sites/Structures:** The 190-F Process Water Pump House was associated with the 100-F-36, 108-F Biological Laboratory, the 183-F Filter Plant, the 185-F Water Treatment Plant, the 189-F Refrigeration Building, 126-F-2, 183-F Clearwells and the 105-F Reactor Building.

**Process Description:** The 100-F Area water treatment facilities were operated from 1945 until 1965 to provide large volumes of high quality cooling water to the 105-B Reactor. The 190-F Process Water Pump House was the final in a series of facilities that treated the raw river water before it was pumped to the 105-F Reactor. The water was transferred to underground clearwells (four 6.6 million L (1.75 million gal) tanks) located in the 190-F Process Water Pump House, where sodium dichromate was added to inhibit corrosion of the 105-F Reactor process tubes. The treated water was temporarily stored in the 190-F Process Water Pump House and pumped to the 105-F Reactor.
Reactor as needed.

Water was pumped from the Columbia River at the 181-F River Pump House and stored temporarily in the 182-F Reservoir. From 182-F, the water was pumped to the 183-F Filter Plant where it was treated for use as process cooling water for the 105-F Reactor. Additives for treatment of the water included chlorine, sulfuric acid (often contaminated with lead and mercury), and coagulants. The treatment process included flocculation and sedimentation process, chemical treatment, and filtration. Following coagulation and settling, the water was filtered, lime was added, and the water stored temporarily in underground clearwells.

The 190-F Process Water Pump House was the last facility in a series of facilities that treated the raw river water. Water arrived at 190-F after a flocculation and sedimentation process, chemical treatment, and filtration. At 190-F, the treated water was temporarily stored in four 6.6 million L (1.75 million gal) tanks (Clearwells), and sodium dichromate was added prior to pumping it through the F Reactor for cooling of the core and fuel. A several thousand gallon sodium dichromate storage tank was located within the facility. The facility shared a common wall on the north with the 185-F Water Treatment Plant, which later became a shop and storage facility. In 1956, an annex was added to the south of the pump house to increase the process water throughout the system. Both the pump house and the annex contained below-grade pump rooms.

Waste Type: Sanitary Sewage
Waste Description: Concrete foundations, demolition debris, and surrounding soil is potentially contaminated by hexavalent chromium.

This Site has the Following SubSites:

Code: 100-F-57:1
Names: 100-F-57:1; Eastern 190-F Process Water Pump House Debris
Type: Foundation
Status: Inactive
Classification: Accepted
Reclassification: Interim Closed Out (4/10/2012)

Description: The subsite has been remediated and Interim Closed Out. The 100-F-57:1 site consisted of the eastern half of the remaining below-grade pump room facilities and foundation of the 190-F Process Water Pump House.

Location: The 190-F pump house and annex were approximately 100 meters (330 ft) directly north of the 105-F Reactor building.

Closure Info: Confirmatory sampling of the 100-F-57 waste site was conducted in 2007. Results from the confirmatory samples failed to meet the direct-exposure remedial action goal (RAG) for benzo(a)pyrene. The subsequent design and remediation plan called for removal of the pipe cradles at the waste site.

Remediation of the 100-F-57 waste site pipe cradles began December 6, 2010. On December 9, 2010, during exploration for the 100-F-57 northern pipe cradles, discolored (i.e., green-stained) concrete was discovered. High concentrations of hexavalent chromium were noted in the
concrete. The discovery of the hexavalent chromium contamination resulted in a design change from the original plan to remediate only the pipe cradles. The waste site was split into two subsites in October 2011, to allow separate remediation activities on the eastern and western portions of the waste site. Remediation of the 100-F-57:1 waste subsite was completed September 7, 2011 and resulted in 2,969 bank cubic meters (BCM) (3,883 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility. The verification sampling failed to pass the Remedial Action Goal levels. This resulted in an additional 33 BCM (43 BCY) of soil and concrete, which was completed January 31, 2012. A total 3,002 BCM (3,926 BCY) was removed from the 100-F-57:1 waste subsite. Additional verification sampling was conducted at the 100-F-57:1 waste subsite on February 1, 2012.

No overburden material was stockpiled from the 100-F-57:1 waste subsite. The material in the overburden stockpile came from the 100-F-57:2 waste subsite, but was sampled for cleanup verification in conjunction with the 100-F-57:1 waste subsite.

Closure Info: A discrepancy between the 100-F-57 sample design and the excavation findings resulted in an evaluation that supported a revised trench location, approximately 9 meters (30 ft) south of the original coordinates. Excavation was done at test trench #2 in January 2008. Samples of tar-like material, suspect asbestos found in pipe cradles at test trench #1, scabbled concrete and soil below test trench #2 were collected and analyzed. Based on the confirmatory sampling results, it was determined that remedial action was necessary at this waste site. The excavation exposed concrete slab walls approximately 1 meter (3 ft) apart, with debris filling the area between the walls. The debris was removed to reveal a trench, approximately 1.2 meters (4 ft) below ground surface (bgs), with pipe cradles along the length of the trench. The floor of the pump room was cleared of debris, exposing the pump pads and a grate covering the trench along the north wall. The pump room was examined for the potential location of a sump. It was concluded that no sump was present. Sample material was scabbled from each of the four pieces of concrete brought out of the trench. Soil samples were also collected from below the trench.

The excavation of the 100-F-57 waste site pipe cradles began on October 15, 2010, to collect waste characterization samples. Remediation of the 100-F-57 waste site began on December 6, 2010. On December 9, 2010, during exploration for the 100-F-57 northern pipe cradles, discolored (green-stained) concrete was discovered. The discolored concrete was surveyed using x-ray fluorescence (XRF) and high concentrations of chromium (>900 mg/kg) were detected. The discovery of the high hexavalent chromium concentrations in the in-process soil samples resulted in a design change from the original plan, which had only required...
remediation of the pipe cradles at the 100-F-57 waste site. October 2011, the project split the site into the 100-F-57:1 and 100-F-57:2 subsites to allow continued remediation of the western portion of the site and to facilitate closure of the eastern portion of the site and the overburden stockpile. The green stain became WIDS site 100-F-65, Green Stained Area Along Railroad Tracks Immediately West of 190-F. It was located approximately 20 meters (66 ft) west of the northwest side of the 190-F Building foundation.

Remediation of 100-F-65 was performed on July 25, 2011. The site was excavated to a depth of 1 meter (3.3 ft) bgs and resulted in approximately 84 BCM (109.9 BCY) of soil being removed and disposed at ERDF.

During the excavation, an underground injection control well was discovered on May 25, 2011 within the 100-F-57:2 subsite (at N147737.93, E580363.59). The underground injection control well was removed and disposed at ERDF. No other anomalies were noted during remediation.

The 100-F-57:2 waste subsite was excavated to groundwater levels in two locations.

Remediation of the 100-F-57:2 waste site was completed on April 9, 2012. The excavation reached a maximum depth of 12.8 meters (42 ft) bgs and resulted in approximately 55,701 BCM (72,854 BCY) of material being removed and disposed at ERDF. The debris included concrete, rebar, steel pipe, transite pipe, miscellaneous steel, wire, steel cable, and non-friable asbestos, unlike the friable asbestos discovered during confirmatory sampling.

Description:
The waste site consisted of twenty two areas that potentially included asbestos containing material (ACM) discarded or abandoned in the 100-F Area. A total of eight of the twenty two locations identified with potential Asbestos Containing Material (ACM) in the 100-F-58 waste site were remediated on March 2, 2011. Fourteen of the twenty-two 100-F-58 waste site locations did not require remediation.

Location:
Twenty two locations have been provided as a table that includes the date found, an identification (ID) number and northing and easting coordinates in Washington State Plane, South Zone.

ID 5 - N147742.1 E580488.0
ID 6 - N147770.2 E581392.2
ID 7 - N146923.3 E580058.8

ID 18 - N147379.5 E580333.7
Surface debris waste (hazardous and/or dangerous) was tabulated for the 100-F Orphan Sites Evaluation (OSE) report to document the field results and guide cleanup. A WIDS submittal (100-F-58) is required pending implementation of a waste control plan for the cleanup of surface debris/stains. Various sizes and forms of hazardous (CERCLA) and/or dangerous (MTCA) surface debris waste materials were left during the construction, operation, decontamination and decommissioning (D&D), and remedial action (RA) activities at the 100-F Area. During fiscal year 2005, a field walkdown of the area was conducted as a site closure screening activity. Surface debris identified as potential dangerous/CERCLA waste was precisely located and recorded using Global Positioning Satellite technology and a field logbook. For some features, additional information was obtained using digital photography. Subsequent evaluation of the collected data yielded four generic groupings of wastes: potentially asbestos containing material, lead, oil filters/oil stains, garnet (sand blasting material), and treated wood.

Originally, there were five categories of waste that were part of 100-F-56. At the request of the Remaining Sites Project, a separate WIDS site (100-F-58) was created for the potential asbestos containing material (ACM). The type of surface debris identified as either hazardous or dangerous waste materials according to CERCLA or MTCA was potentially asbestos containing material (including transite). Whereas this waste was created as a result of either operations or a site cleanup (i.e., D&D) activity, it would seem appropriate to dispose of them at the Environmental Restoration Disposal Facility under a project waste control plan. The concept for handling scattered surface debris under the Investigation Derived Waste (IDW) Strategy was presented at the June 2005 Unit Managers Meeting (UMM) and accepted at the July 2005 UMM meeting for implementation by the RA Project.

Various sizes and forms of hazardous (CERCLA) and/or dangerous (MTCA) surface debris waste materials were left during the construction, operation, decontamination and decommissioning (D&D), and remedial action (RA) activities at the 100-F Area. During fiscal year 2005, a field walkdown of the area was conducted as a site closure screening activity. Surface debris identified as potential dangerous/CERCLA waste was precisely located and recorded using Global Positioning Satellite technology and a field logbook. For some features, additional information was obtained using digital photography. Subsequent evaluation of the collected data yielded four generic groupings of wastes, including potentially asbestos containing material, lead, oil filters/oil stains, garnet (sand blasting material), and treated wood.

Waste Type: Process Effluent
Waste Description: The solid waste consists of scattered debris mainly in the form of transite. The debris is thought to potentially contain asbestos.
Closure Info: Remedial action and housekeeping activities occurred from July 2005 through March 2008.
Fourteen of the twenty-two 100-F-58 waste site locations did not require remediation. The locations associated with site ID numbers 20 and 75 encompassed small areas with scattered potential ACM where no ACM was visible. It is believed these areas had been scraped during road blading activities or during soil stockpile moving, such that the scattered ACM that had been present was no longer visible. Because there is no human health or environmental threat from the scattered miscellaneous concrete debris, locations that contained cement and/or grout did not require remediation. The cement/grout debris is suspected to be associated with former pre-Hanford farmsteads and is likely residual remnants of former building foundations. Larger accumulations of concrete will be removed via Miscellaneous Restoration.

A total of eight of the twenty two locations identified with potential Asbestos Containing Material (ACM) in the 100-F-58 waste site were remediated on March 2, 2011. Remedial action activities included non-mechanical surface pick-up (picked up by hand) only, generating less than 1 bank cubic meter (1.3 bank cubic yards) of potential ACM that was directly loaded for disposal at the Environmental Restoration Disposal Facility.

---

### Code: 100-F-59

**Classification:** Accepted  
**Recategorization:** None

**Names:** 100-F-59; Riparian Area Contamination Originating from 128-F-2

**Type:** Burn Pit  
**Status:** Inactive  

**Description:** The 100-F-59 is a non-radiological waste site created after the remediation of the 128-F-2 Burn Pit. It is two riparian areas known to contain contaminants above soil remedial action goals (RAGs). The first riparian area is located adjacent to the Columbia River. It was remediated, as part of 128-F-2, to an elevation below the ordinary high water mark (OHWM) of the river. The second riparian area is located below the OHWM, east and southeast of the 128-F-2 waste site. Sediment sampling showed metal contamination in excess of soil RAGs was present. These areas became 100-F-59. During the burn pit remediation, this area was known as Area C. The portion of the 100-F-59 site located outside of the 128-F-2 remediation boundary represents the riparian area with relatively elevated metals concentrations in sediment.

**Location:** The site is located in the northeast corner of the 100-F Area; approximately 30.5 meters (100 feet) east of the northeast corner of the 100F Area perimeter road which runs along the riverbank and directly east of the 107-F Retention Basin; and along the Columbia River, in the nearby riparian area which is occasionally under water.

**Related Sites/Structures:** 128-F-2 Burning Pit

**Process Description:** The 128-F-2 Burn Pit was an irregularly shaped depression that was used for incinerating nonradioactive, combustible materials (e.g., vegetation, office waste, paint waste, and chemical solvents). During Hanford Site cleanup operations in the late 1970s, unknown quantities of debris were removed from the burn pit and the site was backfilled (UNI-1488).

**Waste Type:** Transformer  
**Waste Description:** Contaminated soil, The contaminants of concern are ICP metals, mercury, hexavalent chromium, polychlorinated biphenyl (PCBs), and pesticides.

---

### Code: 100-F-60

**Classification:** Accepted  
**Recategorization:** Interim No Action (3/2/2011)

**Names:** 100-F-60; Cast Iron Pipe

---

*Hanford Site Waste Management Units Report*  
February 2015  
375
**Type:** Product Piping  
**Status:** Inactive

**Description:** The 100-F-60 site was evaluated and determined that No Action was required. It was a 10 centimeter (4 inch) diameter cast iron pipe, buried approximately 1.2 meters (4 feet) below ground surface. Confirmatory sampling for 100-F-60 was performed in September 2010.

**Location:** This feature is located approximately 75 meters east of the 185-F Building, at coordinates E580556 N147780. It was discovered laying in a northwest direction leading towards a sanitary sewer junction box (100-F-26:9). The junction box was removed during confirmatory sampling of 100-F-26:9 and is no longer present.

**Related Sites/Structures:** The 100-F-60 pipe was found while sampling 100-F-26:9.

**Closure Info:** Confirmatory sampling for 100-F-60 was performed in September 2010. Two focused samples from the excavated test pit were used to evaluate the 100-F-60 waste site. The cast iron pipe was uncovered 3 meters (9.8 feet) to the northwest of the expected location at coordinates N 147783, E 580552. The pipe was 1.3 meters (4 feet) below ground surface and appeared to be intact. One focused sample was collected from the pipeline contents. There was not enough soil and sediment present inside the pipeline; therefore, the duplicate was collected from the soil underlying the pipeline. Field surveys for radiological contamination and volatile organic compounds (VOCs) were conducted during sampling. No radiological activity or VOCs were detected. Confirmatory sampling determined that environmental contamination was not present at this waste site. Based on confirmatory sampling at the 100-F-60 waste site, remedial action was determined to be unnecessary.

The 100-F-60 waste site has been evaluated in accordance with the 100 Area Remaining Sites ROD and the Remedial Design Report/Remedial Action Work Plan. Confirmatory sampling was performed, and the analytical results indicate that the residual concentrations of COPCs at this site meet the RAGs and associated RAOs for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the verification sampling results support a reclassification of the 100-F-60 waste site to No Action.

---

**Code:** 100-F-61  
**Classification:** Accepted

**Names:** 100-F-61; Stained Soil near 100-F-12  
**Reclassification:** Interim Closed Out (12/22/2011)

**Type:** Unplanned Release  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The waste site has been remediated and Interim Closed Out. It consisted of an area of stained soil discovered while excavating the 100-F-12 french drain, near 105-F.

**Location:** The site was located northeast of the 105-F Reactor, approximately 30 centimeters (12 in.) east of the Electrical Equipment Room Number 1 at (E) 580460, (N) 147631 Washington State Plane.

**Related Sites/Structures:** 100-F-61 is associated with 100-F-12.

**Closure Info:** Demolition activities at this location had removed the upper portion of the 100-F-12 french drain. The french drain was then investigated by digging a test pit on October 11, 2004, to determine what structure remained and if the site was contaminated. Wood debris was uncovered just beneath the gravel surface and was identified as pieces of a power pole. A dark stain was uncovered approximately 1 meter (3.3 ft) below ground surface (bgs), along with
power pole debris and asphalt. The stained soil was observed outside the red gravel exterior of the french drain and, as a result, was determined to be a discovery site (becoming sitecode 100-F-61) and not associated with the 100-F-12 french drain.

Remediation of the 100-F-61 waste site began February 7, 2011, to remove the stained soil contamination. The stained soil associated with the confirmatory sampling description was located and removed. A layer of coal ash beneath the surface was removed with the excavation. Debris removed from the excavation consisted of asphalt, steel cable, steel conduit, and parts of steel pipe. All waste material was directly loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). No overburden was associated with the waste site. An underground injection chamber associated with the No Action 100-F-12 french drain was removed with the excavation. Through in-process sampling of the excavated area, the 100-F-61 soil contamination was determined to extend north of the original stained soil location toward an active utility pole with overhead power lines. Remediation continued north of the existing excavation during an electrical power outage on March 24, 2011, removing contaminated soil, ash, and associated debris. The excavation was expanded toward the power pole area to the extent possible without affecting the stability of the pole. Due to remaining contamination indicated by in-process samples around the power pole, the decision was made to remove the pole and expand the excavation. The power pole was removed June 22, 2011, and the surrounding contaminated soil was excavated. On August 11, 2011, soil removal targeted the area around the electrical equipment room and extended the excavation on the north side. The final excavation was approximately 3 meters (10 ft) deep.

</tr>
<tr>
<td>Process Description:</td>
<td>The 1607-F7 septic tank and drain field received sanitary sewage from the 141-M Building. The building was constructed in 1949 to provide office space and to serve as a change room for Animal Farm personnel working in the 100F Area. The EAF operations were discontinued in 1976. The 141-M building was also demolished in 1976. A sample of the 1607-F7 septic tank contents was collected on October 6, 2004. The results indicated that the site required remediation. The septic tank and drain field was excavated between August 8 and November 30, 2005. Remediation of the 1607-F7 site was successful and it was reclassified as interim closed out. The post excavation civil survey (0100F-DD-C0309) shows the area excavated to remove the septic tank and drain field. The influent piping was not removed during the 2005 remedial action activities.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The 100-F-31 septic tank and drain field received animal and human septic waste from the 144-F Building. The building was constructed about 1960 as an L-shaped addition to the south end of the 141-F Sheep Barn. It contained an office, several laboratories, and a series of...
indoor/outdoor kennels. It was used for Pu-239 and Ra-226 inhalation studies first with mice, and then with dogs (BHI-00031). The 144-F facility was decontaminated and removed in 1978.

Samples of the 100-F-31 septic tank contents and stained soil were collected on October 15, 2004. The results indicated that the site required remediation. The septic tank and drain field was excavated in October 2004. Additional excavation was performed on February 6, 2006. Remediation of the 100-F-31 site was successful and it was reclassified as interim closed out. The post excavation civil survey (0100F-DD-C0309) shows the area excavated to remove the septic tank and drain field. The influent piping does not appear to have been removed by the remedial action activities. A portion of the influent piping was removed previously during the Group 4 Remedial Action (100-F-29) as shown in 0100F-DD-C0140. Approximately 13 meters (43 ft) of the influent piping was in an undisturbed area between the two excavations.

**Closure Info:** Remedial action at the 100-F-55 waste site was performed from September 16 to October 7, 2010 to a depth of 0.7 meters (2.3 ft). Remedial action at the 100-F-62 waste site was performed from December 2010 to March 2011. The 100-F-62 north pipeline excavation included the removal of the pipelines to the former 1607-F7 septic tank and contained the 100-F-55 waste site excavation. From the north excavation, approximately 2 meters (7 ft) of the 4 inch diameter vitrified clay pipe were removed, and approximately 5 meters (16 ft) of 4 inch diameter steel pipe with lead bells were removed. Verification sample results indicated additional remediation was required. Additional remediation was performed from July 29 to August 9, 2011. The center section of the north excavation was further remediated, and the entire south excavation was further remediated and expanded to the south. The final north excavation depth is 2.3 meters (7.6 ft), and the final south excavation depth is 4.4 meters (14.5 ft). Additional remediation also occurred at the east staging pile area and the northeast quadrant of the south staging pile area.

**Code:** 100-F-63  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (9/26/2011)

**Names:** 100-F-63; Animal Farm Radioactive Effluent Lines  
**Type:** Radioactive Process Sewer  
**Status:** Inactive  
**Start Date:**  
**End Date:**

**Description:** The waste site has been remediated and Interim Closed Out. It included radioactive effluent piping and process sewers at the north end of the Experimental Animal Farm (EAF).

**Location:** The EAF complex was located approximately 500 meters (0.3 miles) northeast of the 105-F Reactor.

**Related Sites/Structures:** The pipelines were associated with 146-F, 147-F and 1705-F.

**Process Description:** Radioactive effluent was supplied to the EAF beginning in 1945 from the 147-F pump house. The effluent was used to perform studies by exposing fish to varying concentrations of reactor cooling water effluent (BHI-00031). Radioecology experiments also took place at the EAF. Greenhouses located in the 1705-F Building were used for growing potted plants. Samples of piping and soil were collected at the 146-F Aquatic Biology Fish Ponds site (100-F-33) in September 2004 (118428). The results indicated that the northern portion of the site required remediation. Excavation of contaminated concrete, piping and soil was performed between August 5 and 8, 2005. Remediation of the 100-F-33 was successful and it was reclassified as interim closed out (129492). Portions of the effluent pipelines and process sewer that ran between the 146-F and 147-F buildings appear to be outside of the excavated area. In addition, portions of the process sewer from drains in the 1705-F building appear to be outside the excavated area. Lastly 10 m (33 ft) of the process sewer leading to the circular pond in the
south half of the 100-F-33 site appears to be outside of the excavation. The drain at the head end of this sewer was sampled (J01TF8) as part of 100-F-33 test pit 3 and did not require remedial action. It is assumed that this segment was closed in place using the same information. Two other remedial action events took place in the vicinity of the piping. Portions of the piping were likely removed by these activities. Refer to CVP-2001-00002 and CVP-2001-00010 for a description of the cleanup activities.

**Closure Info:** In November 2007 and February 2008, confirmatory sampling of the 100-F-51 waste site was carried out during the excavation of two test pits, at the north end and southeast corner of the laboratory. Confirmatory sampling results failed to meet remedial action goals (RAGs) and indicated the need for remedial action at the 100-F-51 waste site. Confirmatory sampling was not performed for the 100-F-63 waste site. 100-F-63 was added to the 100-F Area remove, treat, and dispose scope in 2010.

Remedial action at the 100-F-51 and 100-F-63 waste sites began on December 20, 2010, and continued through January 20, 2011. Excavation depth ranged from 0.5 to 1.5 meters (1.6 to 4.9 ft) below ground surface and resulted in approximately 253 bank cubic meters (BCM) (331 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility. Approximately 330 BCM (432 BCY) of overburden soil was stockpiled to be used as backfill. The 100-F-51 and 100-F-63 waste sites debris included concrete, clay pipe, steel pipe, and asphalt. The verification sampling results support a reclassification of the 100-F-51 and 100-F-63 waste sites to interim closed out.

---

**Code:** 116-F-1  
**Classification:** Accepted  
**Names:** 116-F-1; Lewis Canal  
**Type:** Trench  
**Status:** Inactive  
**Start Date:** 1/1/1953  
**End Date:** 1/1/1965

**Description:** The site has been remediated and Interim Closed Out. The waste site was an unlined trench that carried cooling water effluent to the Columbia River.

**Location:** The site was located approximately 160 meters (525 feet) west-northwest of the 105-F Building then turned north to the Columbia River.

**Release Description:** Contaminated coolant from the reactor front and rear faces were known to have drained into the unit. This included reactor cooling water diverted to the Columbia River via this waste site during the Ball 3X Project in 1953. It also received reactor coolant that was diverted to the trench during reactor process tube chemical scaling activities (i.e., when chemicals were flushed through the process tubes to remove scale that had built up on their inner surfaces and during the H-558 Increased Cooling Water Flow Project and other reactor upgrade projects).

**Related Sites/Structures:** The site was related to 105-F, 182-F, 183-F, and 190-F and 189-F Buildings. The pipelines associated with the canal became part of 100-F-19:2 and 100-F-19:3.

**Process Description:** The 116-F-1 Trench was commonly known as Lewis Canal. The 105-F Reactor cooling water was diverted to the Columbia River via this trench. The water flowed west from the headwall, turned northward where it intersected with the Columbia River. Two additional ditches entered the main trench laterally from the east. The north lateral ditch was 194.5 meters (638 feet) long. The south lateral ditch was 219 meters (718 feet) long. Water from the main trench entered the Columbia River without an outfall structure. The water ran across a cobble-covered beach and into the river.

**Waste Type:** Ash
Waste Description: The site received liquid wastes from the 105-F, 182-F, 183-F, and 190-F Buildings and decontamination wastes from the 189-F Building. Reference RHO-CD-827 lists a calculated contaminated soil volume of 2.066E+05 cubic meters (7.3E+06 cubic feet) for the 914-meter (3000-foot) length of Lewis Canal (the length described in most of the documentation for the site). Estimated radionuclide inventories are available in Stenner (1988). Soil sample results are available in Dorian and Richards (1978). The hazardous chemical inventory included sodium dichromate and sulfamic acid. Surface soil and vegetation samples were collected from the areas adjacent to 116-F-1, analyzed for radionuclide concentrations (cobalt-60, strontium-90, cesium-137, plutonium-238, plutonium-239/240), and compared with the results from 1981 through 1986 (Jacques 1986).

Closure Info: The selected remedial action included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

Remedial action began in June 2002. Excavation involved removing overburden, buried sludge, the contaminated structure and underlying contaminated soil. Two, parallel, lateral ditches did not require remediation and were not excavated. The main excavation was completed in December 2002. An additional small portion was excavated in January 2003. The maximum depth of excavation was 4.5 meters (14.8 feet).

At the completion of remedial action, the total excavation was approximately 24,820 square meters (267,000 square feet) in area with a depth of approximately 4.5 meters (14.8 feet). Approximately 77,696 metric tons (70,634 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

The remedial action at the 116-F-1 site has achieved the RAOs and corresponding RAGs established in the ROD (EPA 1997) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at ERDF. These results also indicate that residual concentrations at the site, including overburden, will support future land uses that can be represented (or bounded) by a rural-residential scenario, and are protective of groundwater and the Columbia River. The 116-F-1 site is verified to be remediated in accordance with the ROD (EPA 1997) and may be backfilled.

<td>Description:</td>
<td>The waste site has been remediated and Interim Closed Out. It was an open liquid waste trench. A 15-centimeter (6-inch), 12-gauge steel distribution pipe ran from the north end of the 107-F Basin to the north end of the trench. The length of piping inside the trench was unknown since piping was added as the trench was used and later backfilled. This site was also fed by two emergency bypass ditches that connected the 116-F-2 trench to the effluent line connected to the south end of the 107-F Basin. The first emergency bypass ditch, about 90 meters (295 feet) long, ran from the west center side of the 116-F-2 Trench to the gate valve on the 1.7 meter (5.6 feet) pipeline that ran to the 107-F Basin Inlet Distribution</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Box at the south end of the 107-F Retention Basin. A second emergency ditch bypass trench connected the 116-F-2 trench to a valve on the 107-centimeter (42-inch) diameter 105-F effluent pipeline. These ditches are also considered to be part of 116-F-2. The trench is shown on Hanford drawings H-1-70185, H-1-1522 and H-1-1540. The liquid waste and bypass trenches are visible in Hanford aerial photo 91062128-8.

**Location:** The site was located approximately 670 meters (2200 feet) east of the 105-F Reactor Building and approximately 60 meters (197 feet) east-southeast of the southeastern corner of 107-F Retention Basin.

**Related Sites/Structures:** The site was related to the 116-F-14 (107-F) Retention Basin and the 1.7-meter (5.6-foot) diameter pipeline exiting the south end of the Retention Basin and the 100-F-19, 100-F Reactor Cooling Water Effluent Underground Pipelines, Contaminated Underground Lines, Effluent Water System.

**Process Description:** The original trench was excavated June 4-5 1948 and used to dispose of the contaminated reactor effluent from the first Hanford site fuel failure (HW-10284).

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The site received cooling water effluent from the 107-F Retention Basin during reactor outages due to fuel ruptures. During deactivation of the 105-F Reactor, the unit received overflow water from the 105-F Storage Basin via the retention basin. RHO-CD-827 lists the calculated volume of contaminated soil to be 2.5E+05 cubic meters (9E+06 cubic feet). Radionuclide inventory for 116-F-2 from Stenner (1988) lists, 0.37 curies of tritium, 0.8 curies of cobalt-60, 0.07 curies of strontium-90, 0.76 of cesium-137, 0.007 curies of plutonium-239, and 6.05 curies of europium-152. The site also has a hazardous chemical inventory that includes 60,000 kilograms (1.3E+05 pounds) of sodium dichromate. The results of four soil sample sites in the trench and four samples taken in the connecting ditch can be found in Dorian and Richards (1978).

**Closure Info:** Remedial action began on November 22, 2000, and was completed on April 17, 2002. Excavation involved removing the overburden materials and underlying soil. On May 21 through May 29, 2002 cleanup verification samples from the shallow zone, deep zone and overburden were collected and analyzed for the established contaminants of concern.

At the completion of the remedial action, the total excavation was approximately 15,352 square meters (50,367 square feet) in area with a depth of approximately than 4.6 meters (15 feet). Approximately 113,007 metric tons (124,534 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility.
The trench received reactor cooling water during a 1947 fuel rupture occurrence. In 1951, the trench received sludge from the 105-F fuel storage basin.

The site received reactor effluent from the 105-F Reactor Building during an early fuel failure outage. In 1951, the site received sludge from the 105-F Storage Basin. During test pit activities in 1993, a buried pipe measuring 150 millimeters (6 inches) in diameter was found buried in the trench at approximately 1.8 meters (6 feet) below surface grade. The pipe was radiologically contaminated reading 500 counts per minute (5000 disintegrations per minute). The contaminants of concern (COC) for this site consist of Europium-152, Europium-154 and Hexavalent chromium.

Remedial action at the 116-F-3 site began in October 2002. The majority of the excavation was completed in January 2003. However, an additional remedial excavation occurred in February 2003. Excavation of the site involved removing the overburden materials and underlying contaminated soil. Contaminated materials were disposed of at the ERDF. At the conclusion of excavation activities in February 2003, the elevation of the bottom of the excavation was at 121.7 meters (399.3 feet). Site excavation and waste disposal are complete, and the exposed surfaces have been sampled and analyzed to verify attainment of the Remedial Action Goals (RAG). At the completion of the remedial action, the total area of the excavation was approximately 843 square meters (9,074 square feet) with a depth of 4.7 meters (15.4 feet). Approximately 5,205 metric tons (5,738 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

Field screening was used to guide the excavation to quickly assess for the presence and level of contamination. Field screening for the 116-F-3 site included using a radiological data mapping system survey, hand-held sodium iodide (NaI) detectors, and gamma energy analyses. The radiological mapping survey is performed over more than 50% of the site excavation surface area. The hand-held NaI detector is used to screen excavated waste material and to screen for potential excavation wall and floor hot spots. Gamma energy analyses were used to support waste characterization and to corroborate the radiological mapping survey and hand-held sodium iodide (NaI) detector data.

Remedial action objectives and goals for the 116-F-3 site were established by the U.S. Environmental Protection Agency and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL 2002). The RAGs were developed to support a rural-residential exposure scenario. This scenario involves exposures to soils less than 4.6 meters (15 feet) deep only.

The selected remedial action for the 116-F-3 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.
Description: The waste site has been remediated and Interim Closed Out. The unit consisted of a French drain-type distribution system. A 0.61-meter (2-foot) riser was attached to a bottomless 208-liter (55-gallon) drum that drained into a cobble leach field.

Location: The unit was located approximately 40 meters (130 feet) southwest of the southwestern corner of the 105-F Reactor Building.

Process Description: The 116-F-4 Pluto Crib was an inactive waste site that operated from 1950 to 1952 receiving contaminated reactor cooling water from the 105-F Reactor building. The purpose of the crib was to receive liquid wastes from the 105-F Reactor Building during outages due to fuel ruptures. Cooling water was diverted from the affected tube through a valve known as a "pluto valve" or "pluto cap" and through a rubber hose to the crib. The hose ran above ground from the rear face of the reactor to the crib.

Waste Type: Misc. Trash and Debris

Waste Description: The site received coolant water from pressure tubes containing ruptured fuel elements. It was estimated that 280 curies of fission products were discharged to the crib during its operation (Dorian and Richards 1978). It was also assumed that the contaminated soil occupied a volume of 6 by 6 by 7.6 meters (20 by 20 by 25 feet).

Closure Info: The 116-F-4 site was excavated from September to November 1993 during a soil treatability study. Before excavation activities commenced, the vertical extent of contamination was estimated using February 1993 borehole data taken from a location next to the crib riser.

The crib excavation proceeded in 0.6 meter (2-ft) deep increments, or "lifts," over a 6 meter by 6 meter (20 ft by 20 ft) survey/sample grid. Each lift of soil was surveyed using a Geiger-Mueller detector (GM) and portable alpha meter to segregate contamination areas from uncontaminated areas. Excavation at each lift consisted of an initial phase in which uncontaminated soil was removed, followed by a second phase in which contaminated soil was removed. The contaminated soil was transported to a container for storage prior to disposal at ERDF. Overburden materials, identified as potentially clean, were placed in stockpiles for possible use as backfill. On the ninth lift, at a depth of 5.5 meters (18 ft), radiation levels were below detection limits of the GM survey instruments. Additional in situ monitoring equipment indicated cesium-137 levels just above background in the immediate vicinity of the February 1993 borehole. As a result of an onsite decision by DOE/RL, EPA, and Ecology, a 7.9 meter (26 ft) deep (2.4 meters [8 ft] below bottom of excavation) test pit (Test Pit 1) was excavated at the bottom of the site excavation. An additional test pit (Test Pit 2) was also excavated at the bottom of the site excavation. The elevation of the excavation floor was 123.2 meters (404.2 ft) upon completion, with a maximum depth of approximately 5.5 meters (18 ft). The resulting final excavation yielded 2,980 cubic meters (3,900 cu. yd) of non-contaminated overburden soil and 410 cubic meters (540 cu yd) of contaminated soil. Approximately 700 metric tons (772 tons) of material from the site were disposed of at ERDF.

Cleanup verification sampling was conducted on November 10, 1993 from the bottom of the test pits.

Remedial action objectives and goals for the 116-F-4 site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 2000).
The site has been remediated and closed out. The 116-F-5 Crib has been fully backfilled and appeared as an unmarked, gravel-covered field. No vent pipes or other appurtenances remain.

The crib was fed by a 76-meter (250 foot) long vitrified clay pipeline that ran from the 105-F Reactor Building, at which point a 10.2-centimeter (4-inch) schedule 40 steel pipe was used. The pipeline was about 1.2 meters (4 feet) below grade. The vitrified clay pipe consisted of 1.2-meter (4-foot) sections. The bell ends were sealed with lead rings. The pipeline ended in a 3 by 3 by 2.7-meter (10 by 10 by 9-foot) excavation filled with cobble. Approximately 36.5 meters (120 feet) of the pipe, from 116-F-5 to the north end of the 116-F-4 excavation, was removed in 1993 during the 100 Area Excavation Treatability Test. The remaining 39.5 meters (130 feet) of pipe is part of site 100-F-26 for remedial action.

The site was located approximately 50 meters (140 feet) southwest of the 105-F Reactor Building.

The site was associated with the 105-F Reactor Building ball washer assembly and the 100-F-26:14 Influent Pipeline.

The site was used to dispose of liquid decontamination wastes from the 105-F Reactor ball washer assembly. It served to clean and decontaminate small, steel-jacketed boron balls used in the Ball 3X safety system. The ball washer assembly was located in the transfer basin area of the 105-F Reactor Building.

Misc. Trash and Debris

The site received liquid waste associated with the decontamination of boron steel balls. Contaminants included strontium-90, cesium-137, europium-154, and europium-155. The waste also included nitric acid that was used for decontamination. However, sampling done in 1997 found only cobalt-60 and europium-155 to be above background levels. The Cleanup Verification Package lists the final contaminants of concern (COCs) based on the Sampling and Analysis Plan (DOE/RL-96-22) as cesium-137 and cobalt-60.

A large test pit was excavated at the 116-F-5 site on July 30, 1997. Field screening and sampling of soil were conducted during excavation. The test pit excavation was an ellipse approximately 6.1 meters by 7.3 meters (20 feet by 24 feet) by 3.4 meters (12 feet) in depth. During test pit excavation, the entire 3-meter (10-foot) by 3-meter (10-foot) by 2.7-meter (9-foot)-deep crib structure (gravels) was excavated, field screened, and sampled. A total of 20 verification samples were collected from four intervals within the test pit on July 30, 1997.

No contaminated materials or soil were encountered.

The site has been remediated and Interim Closed Out. The site was an open excavation used to receive reactor cooling water. The waste site was an unlined trench used intermittently to dispose of cooling water while maintenance and repairs were being performed on the effluent.
The site was located about 55 meters (180 feet) southeast of the southeastern corner of the 105-F Building.

The site intermittently received cooling water from the 105-F Reactor Building.

The site was used intermittently to dispose of cooling water while maintenance and repairs were being performed on the effluent system.

Dorian and Richards (1978) refer to the 116-F-6 Trench as the "1608-F Liquid Waste Disposal Trench", suggesting that the 1608-F Pumping Station wastes were disposed at this site. Several other documents, including Gano and Hall (1987), Hanford Drawing H-1-15244, and Kiser (1988) also use this nomenclature for 116-F-6. Hanford drawing H-1-70185 shows a "crib" pipe emerging from the east side of 1608-F and angling south toward 116-F-6. A ground penetrating radar (GPR) survey done in 1993 identified a linear anomaly that may represent this pipe.

The site received water diverted during reactor shutdowns when maintenance was necessary on the effluent system. This practice was used during several reactor upgrades. Contaminants would include, europium-152, cobalt-60, europium-154, cesium-137, and sulfamic acid (3,000 kilograms [6600 pounds]).

The selected remedial action for the 116-F-6 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

The remedial action began in October 2002. The majority was completed in November 2002, with a small addition excavation occurring in January 2003. A pipe was encountered on the north part of the excavation. It was removed and disposed at ERDF. At the completion of the remedial action, the total excavation was approximately 5,272 square meters (56,747 feet) in area with a depth of 5.1 meters (17 feet). Approximately 32,156 metric tons (35,446 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

The subsite components were evaluated and determined to require No Action. The waste site consisted of the seal pit crib and pipeline.

The site was located 137 meters (450 feet) south of the southwestern corner of 105-F Building.

The site was associated with 132-F-5 (117-F Filter Building) and 116-F-7 Seal Pit Water Crib.
Process Description: The crib was used to dispose water collected in exhaust system filter seal pits in the 117-F Ventilation Exhaust Filter Building (132-F-5). The 117-F facility filtered ventilation air from the confinement zone of the 105-F Reactor Building prior to its discharge to the atmosphere through the 105-F Reactor Building Stack.

Waste Type: Water

Waste Description: The site received drainage from confinement exhaust system filter seal pits in the 117-F Building. UNI-946 states that boring 7-A appears to have been drilled very close to the center of the crib and a sample was collected at a depth of 3 meters (10 feet). Analysis of this material shows concentrations of 0.032 picocuries/gram for cesium-137, 0.057 picocuries/gram for strontium-90, 0.1 picocuries/gram for plutonium-239/240, and 0.26 picocuries/gram for europium-152.

This Site has the Following SubSites:

Subsite 1 was evaluated and determined to require No Action. It consisted of the 116-F-7 Seal Pit Water Crib. The crib was marked by a 122 centimeter (48 in) diameter steel vent pipe.

Location: The site was located 137 meters (450 ft) south of the southwestern corner of 105-F Building.

Process Description: The crib was used to dispose water collected in exhaust system filter seal pits in the 117-F Ventilation Exhaust Filter Building (132-F-5). The 117-F facility filtered ventilation air from the confinement zone of the 105-F Reactor Building prior to its discharge to the atmosphere through the 105-F Reactor Building Stack.

Waste Type: Asbestos (friable)

Waste Description: The waste would be the crib structure and soil contaminated from the material entering the crib via the pipeline.

Closure Info: A site evaluation was conducted as part of the Remaining Sites Verification Package (RSVP) attached to the Reclassification Form 2004-128 through field observations and focused sampling and analysis for the purpose of determining if hazardous or radiological contaminants were present. One test pit was excavated to the bottom of the seal pit water crib structure to a depth of 5.8 meters (19 feet). Soil was collected from the pit sample and combined into a composite sample. Four samples were collected at the site on October 12, 2004. A sample of pipe scale from the nonfriable asbestos-cement pipe (subsite 116-F-7:2), a crib soil composite sample, a duplicate sample in the native soil below the gravel, and an equipment blank sample. Confirmatory sample results found the values of all of the contaminants of potential concern were below remedial action limits. Therefore, nor remedial action was required.

<tr>
<td>Description:</td>
<td>The 132-F-5 (117-F Filter Building) was reclassified as &quot;No Action&quot; based on a ResRad evaluation of the Allowable Residual Contamination Level (ARCL) information. The 132-F-5 Filter Building and the 116-F-7 Seal Pit Water Crib and pipeline waste sites have been evaluated and reclassified to &quot;No Action&quot;. The fine soil at the top of the crib soil column had greater sorption capabilities for the contaminants of potential concern than either the 4 inch to 6 inch cobble fill in the crib or the asbestos-cement piping. The 116-F-7 influent pipeline was made of asbestos-cement, which had less surface area than surface soils and did not adsorb ionic contaminants nor filter as effectively as fine soil particles. The soil analyses showed the crib and its internal piping met the cleanup standards. Because the pipeline was composed of the same material as in the crib and was exposed to the same waste stream. Therefore, a reclassification to &quot;No Action&quot; WIDS is appropriate for the pipeline subsite. The absence of either detectable radiation reading or pipeline scaling indicates a low risk of significant contamination within the pipeline. The influent pipe is deemed to be a lower risk for contamination than within the crib since it has a lower sorptive or filtering capability. As such, the influent pipeline was recommended for reclassification to a &quot;No Action&quot;, as a subsite of the 116-F-7 crib. The reclassification form 2005-044 was signed in November 2005.</td>

</table>
Type: Outfall  
Status: Inactive

**Description:** The site has been remediated and Interim Closed Out. This site consisted of an open-topped, compartmentalized, reinforced concrete outfall structure. A 183 centimeter (72 inch) diameter steel retention basin pipeline entered the south face and two 107 centimeter (42 inch) pipelines exited the north face to the river.

**Location:** The site was located approximately 214 meters (700 feet) northeast of the 107-F Retention Basin, near the shore of the Columbia River.

**Related Sites/Structures:** The site was associated with the 116-F-14 (107-F Retention Basin) and the 116-F-16 Pacific Northwest Laboratory (PNL) Outfall Structure. The outfall discharged effluent to the 100-F-39 River Effluent Pipelines and/or 100-F-42 Flume.

**Process Description:** The outfall was designed as an open concrete structure for discharging reactor effluent cooling water from the 116-F-14 (107-F Retention Basin) to the center of Columbia River via 100-F-39 river pipelines. The outfall was constructed of a reinforced, compartmentalized concrete weir box, with walls extending from 7.6 meters (25 feet) below grade and 0.3 meters (1 foot) above grade. This unit was also connected to the Pacific Northwest Laboratory (PNL) Outfall (116-F-16) by a distribution box. The north effluent discharge consisted of two 107 centimeter (42-inch) diameter pipes. The second was a spillway flume (100-F-42) that ran from the outfall chamber, down the riverbank, and emptied into the river. The flume was constructed of reinforced concrete and was 4 by 0.6 meters (14 by 2 feet) deep and about 40 meters (130 feet) long. The spillway was designed to prevent excessive backwater at the 107-F Retention Basin during high water or in the event of a blockage of the outfall lines. Piping for the 116-F-8 outfall included two 107 centimeter (42 inch)-diameter by 139 meter (455 feet) steel effluent pipelines that exited the northeast side of the outfall and extended into the Columbia River. Two pipelines entered the south side of the outfall from the 107-F Retention Basin. One was a 152 centimeter (60 inch) diameter pipe. The other was a 91 centimeter (36 inch)-diameter pipe.

**Waste Type:** Water

**Waste Description:** Reactor water from the 107-F Basin was piped to the outfall structure that discharged into the Columbia River. The outfall could have also received reactor water that had been diverted for fish studies and other process wastes from the Experimental Animal Farm. Contaminants of concern include cobalt-60, europium-152, europium-154, europium-155, and hexavalent chromium. Other contaminants of potential concern include carbon-14, cesium-137, nickel-63, and strontium-90.

**Closure Info:** The 100-F-42 Spillway was administratively separated from the 116-F-8 Outfall for inclusion within the Remaining Sites ROD by agreement among the Tri-Parties. It was subsequently determined that sufficient evidence existed to warrant remedial action during remediation of the 116-F-8 waste site, therefore both waste sites were remediated and evaluated as a single unit.

Remedial action activities at the waste sites were conducted from August 31, 2004, to September 22, 2005. Remediation involved excavation and staging of clean overburden material and removal of the demolished concrete outfall structure, the concrete spillway structure above the Columbia River ordinary high water mark, and contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs. The residual 100-F-39 effluent pipelines will be sealed with concrete prior to backfill of the remediation footprint. Contaminated materials were disposed at the ERDF. Approximately 1,325 square meters (14,260 square feet) of plan area was excavated, including excavation within the deep zone (greater than 4.6 meters [15 feet] below ground surface) up to 8 meters (26 feet) below ground surface. Approximately 4,900 metric tons (5,400 U.S. tons) of material from the sites was removed and disposed at the ERDF.
Type: Trench
Status: Inactive

Description: The site has been remediated and Interim Closed Out. The site was a leaching trench that received waste water from the cleaning of animal pens in the Experimental Animal Farm. The pipelines that originated at the 141-C Building and terminated at the trench are documented in sitecode 100-F-29.

Location: The site was located approximately 46 meters (150 feet) northeast of the 107-F Retention Basin.

Release Description: An unplanned release that occurred in 1955 created what was known as the "basin leak ditch" (see UPR-100-F-2). This release formed a ditch that crossed the animal waste trench site from west to east.

Related Sites/Structures: The site received wash waste water from the 141-C Animal Barn and the 141-N Animal Waste Collection Facility. Pipelines to the trench are included in site 100-F-29 100 F Experimental Animal Farm Process Sewer Pipelines.

Process Description: During the time that Experimental Animal Farm was active, animal pens housed the animals used for experimental purposes. When the pens were cleaned, waste water containing animal wastes was flushed to the 116-F-9 Animal Waste Leaching Trench.

Waste Type: Water
Waste Description: The site received wash waste water from the cleaning of animal pens.

Waste Type: Water
Waste Description: Contaminants found during sampling in 1979 included cesium-137, cobalt-60, europium-152, europium-154, europium-155, strontium-90, plutonium-238, plutonium-239/240. The total estimated radioactive inventory (1979) of the 116-F-9 Animal Leach Trench contaminated soil column was 4.1 curies (See Memorandum from V. R. Richards to J. J. Dorian).

Closure Info: Remedial action objectives and goals for the 116-F-9 site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17).

Remedial action at the 116-F-9 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

Remedial action at the 116-F-9 site began on September 4, 2001. Excavation of the site involved removing the overburden materials and underlying contaminated soil. Contaminated materials were disposed of at the ERDF. On March 25, 2002, the excavation was completed. The elevation of the bottom of the excavation was 120.3 meters (394.7 ft) upon completion. The excavation was approximately 5,484 square meters (59,029 sq ft) in area with a depth of approximately 5.7 meters (19 ft). Approximately 49,405 metric tons (54,460 tons) of material from the site were disposed of at ERDF.

<tr>
<td>Waste Description:</td>
<td>The site received radioactive water rinses and spent nitric acid from the decontamination of fuel element spacers and other reactor hardware, primarily pressure tube caps. In addition, the site received liquid waste containing 2000 kilograms (4400 pounds) of sodium dichromate, 2000 kilograms (4400 pounds) of sodium oxalate, and 2000 kilograms (4400 pounds) of sodium sulfamate. The site may have received other chemicals as well. Known decontamination solutions at 100-F included chromic acid, citric acid, oxalic acid, sulfamic acid, sulfuric acid, and sodium fluoride. Other chemicals, including organic solvents, were also used for some decontamination processes. Three soil borings were drilled in the vicinity of the drain in 1975 (Dorian and Richards 1978). Boring 10-A was drilled next to the tile pipe, and borings 10-B and 10-C were completed approximately 3 meters (10 feet) and 9 meters (30 feet) east of the tile pipe respectively. Samples were collected from these borings at depths ranging from 3.8 to 8.2 meters (12.5 to 27 feet). Analytical results indicated elevated concentrations of cobalt-60 (610 picocuries/gram), europium-152 (250 picocuries/gram), europium-154 (31 picocuries/gram), europium-155 (100 picocuries/gram), and cesium-137 (7.4 picocuries/gram) in boring 10-B. Elevated concentrations were not detected in the samples from borings 10-A and 10-C.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The selected remedial action for the 116-F-10 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to the average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. At the completion of remedial action, the total excavation was approximately 195 square meters (2,100 square feet) in area with a depth of approximately 4.4 meters (14.4 feet). Approximately 848 metric tons (935 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The site also included a 10-centimeter (4-inch)-diameter steel pipeline that discharged into the</td>

</tbody>
</table>
french drain about 1.2 meters (4 feet) below grade. This pipeline originated at the wash pad located in the southeast corner of the 105-F Building Fuel Storage Basin. The pipe ran to the northwest 9 meters (30 feet) and then entered the 116-F-3 excavation. The 10 centimeter (4 inch) diameter steel pipeline was removed without excavation during remediation of the fuel storage basin and the 116-F-10 French Drain and 116-F-3 Storage Basin Trench waste sites. Field screening indicated there was no contamination in the pipeline, and the area was not included in the final cleanup verification sampling design. Because the two associated waste sites (116-F-3 and 116-F-10) were verified clean as shallow zone sites, and the ends of the pipes originally terminated within the boundaries of these excavations, it can be concluded that the short distance between was also clean. This strategy was approved by the regulators.

</tr>
<tr>
<td>Closure Info:</td>
<td>Remedial Action ran from August 2001 until December 2002. The 100-F-19:2 Reactor Cooling Water Effluent Pipeline and co-located sites, (116-F-11 Cushion Corridor French Drain, UPR-100-F-1 Sewer Line Leak, and the 100-F-29 Experimental Animal Farm Pipelines), were remediated as a group and documented in CVP-2001-00003. The group is referred to as the 100-F-19:2 site. The unplanned release was within the footprint of the 100-F-29 pipeline excavation. The elevation of the bottom of the excavation was approximately 124.7 meters (409 ft) upon completion. The excavation area was approximately 19,000 square meters (205,000 sq. ft) with a maximum depth of approximately 5 meters (16 ft) and an average depth of approximately 3.7 meters (13 ft). Removal of the 100-F-29 pipelines near the northwest corner of the 116-F-14 (107-F Retention Basin) required shallower excavation, averaging approximately 1 meter (3 ft) in depth. Little evidence of the 116-F-11 french drain site was found during excavation of the 100-F-19:2 pipelines. The location of the french drain was excavated and sampled to the design elevation 4.6 meters (15 ft).</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Remediation included excavation of overburden, piping, debris and contaminated underlying soil. Approximately 39,347 metric tons (43,373 tons) of material including soil, debris and piping were removed and disposed at ERDF.

<td>This drain would have received minimal amounts of leakage or spillage from two pumps located in the facility that were used to supply reactor cooling water to the fish studies facilities. Although Stenner, et al (PNL-6456) states that the site received recovered effluent pump prime, drawings (H-1-459-VOID and H-1-1518) indicate that the site could not have received any effluent except leakage or spillage from maintenance activities on the pumps.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>The 100-F-19:1 North Pipelines, 100-F-19:3 West Pipelines, 100-F-34 Biology Facility French Drain, and the 116-F-12 French Drain were remediated as a group, documented in CVP-2001-00002. The group is referred to as the 100-F-19:1 site. The 100-F-19:1 site remedial action began on August 7, 2001. Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Shallow zone excavation occurred both in the vicinity of the 100-F-19:3 West Pipelines and in the vicinity of the 100-F-19:1 North Pipelines, with a maximum depth of 4.6 meters (15 ft). The deep zone excavation occurred in the southern half of the 100-F-19:1 North Pipelines section of the remedial action, with a approximate maximum depth of 5.0 meters (16 ft). The elevation of the bottom of the excavation varied, but averaged approximately 119.6 m (392.4 ft). At the completion of remedial action in August 2001, the excavation was approximately 25,710 sq. meters (276,740 sq. ft.) in area. Approximately 56,335 metric tons (62,099 tons) of contaminated materials from the site were disposed of at the ERDF. These sites meet the cleanup standards specified in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and Operable Units (ROD). Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Shallow zone excavation occurred both in the vicinity of the 100-F-19:3 West Pipelines and in the vicinity of the 100-F-19:1 North Pipelines, with a maximum depth of 4.6 m (15 ft). The deep zone excavation occurred in the southern half of the 100-F-19:1 North Pipelines section of the remedial action, with a approximate maximum depth of 5.0 m (16 ft). The elevation of the bottom of the excavation varied, but averaged approximately 119.6 m (392.4 ft).</td>
</tr>
</tbody>
</table>
The results showed that the materials from the 100-F-19:3 subsite containing COCs at concentrations exceeding RAGs have been excavated and disposed of. Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. All cleanup verification samples for the 100-F-19:3, 100-F-34 and 116-F-12 sites are listed under 100-F-19:1.

### 116-F-14; 107-F; 107-F Retention Basin

- **Code:** 116-F-14
- **Names:** 116-F-14; 107-F; 107-F Retention Basin
- **Type:** Retention Basin
- **Status:** Inactive
- **Classification:** Accepted
- **Reclassification:** Interim Closed Out (7/12/2002)
- **Start Date:** 1/1/1945
- **End Date:** 1/1/1965

**Description:**
The site has been remediated and Interim Closed Out. The retention basin was a rectangular, concrete-lined, open-top reservoir designed to retain reactor cooling water prior to being discharged to the Columbia River. The basin had an estimated capacity of 5.67E+08 liters (1.5E+08 gallons). It was divided into two equal sections by weir walls running lengthwise from inlet to outlet end. Each section was subdivided by a series of wooden baffles. The site was surrounded by sprinklers (Hanford Drawing H-1-14321) installed on the top of the wall to keep the sludge from drying out during those times when effluent was not being discharged to the basin.

**Location:**
The site was located approximately 530 meters (1488 feet) east-northeast of the 105-F Reactor Building.

**Release Description:**
Numerous instances of retention basin and pipeline leakage occurred during the operation of the basin resulting in areas of soil contamination. The basin leaked at many locations along its walls and bottom. Hanford Drawing H-1-70247 (Retention Basin Leak Repair) shows some of the many types of repairs performed on the basin, including repairs of vertical cracks in the basin walls, removal of spilled concrete, rebuilding of expansion joint and repairs of cracks in the floor of the basin. The largest recorded leak extended roughly 7.6 meters (25 feet) from the foot of the unit wall. The leak, discovered in the summer of 1952, occurred in the effluent lines leading from the basin to the 148-F Pumphouse. Another release of contamination occurred at a large manhole located north of the 107-F basin (identified as P-22F on Hanford Drawing H-1-13850). Effluent overflowed intermittently for an extended period during the early 1950's before it was stopped. In 1955, water overflowed from the basin and contaminated the soils adjacent to the basin and a narrow path between the basin and the Columbia River. This release was identified as UPR-100-F-2. Contamination levels were 20,000 to 60,000 counts per minute with a maximum of 350 millirads/hour. HW-54636 contains information regarding the ground contamination size and shape. At least once during reactor operations, an unknown quantity of sludge was removed from the bottom of the basin and buried approximately 30.5 meters (100 feet) southeast of the southeastern corner of the basin. An estimated 1.8E+06 kilograms (2,000 tons) of sludge remained in the retention basin (Dorian and Richards 1978). In 1952, a hole was dug adjacent to the basin inlet pipe to drain the pipe. The hole and associated soil contamination were stabilized by covering it with clean soil, gravel, and cobbles. In 1964, high winds spread contamination when the basin was emptied and dry for maintenance. Known leakage from the 116-F-14 basin appears to have occurred primarily along the south and west sides. Estimates of leakage rates are not well documented, but the presence of a groundwater mound beneath the basin extended as high as 3 meters (10 feet) above the pre-existing water table elevation, suggests that significant leakage had occurred (Dorian and Richards 1978). The extent of these releases were contained within the AC-5-40 permanent Underground Radioactive Material posting.

**Related Sites/Structures:**
The site was associated with the 105-F Reactor Building, the 100-F-19 pipeline and the 116-F-2 overflow trench.
**Process Description:** The site was used as a retention basin to hold the discharged reactor water for a brief period of time, allowing radioactive decay and thermal cooling to occur before the water was discharged to the Columbia River. Effluent was discharged to the basin by way of pipelines that were partially underground and partially above ground. The site received essentially all reactor cooling water passing from the reactor to the Columbia River. The total volume has not been estimated, but the flow rate ranged between 1.55E+05 and 2.95E+05 liters (41,000 and 78,000 gallons) per minute. Water flowed from the north end of the basin through a concrete pipeline to the 116-F-8 Outfall. The site is shown on Hanford drawings H-1-1522, M-1600-F, W-73199, W-69714 and Photo 9005316-1cn.

**Waste Type:** Equipment

**Waste Description:** This site received cooling water effluent from the 105-F Reactor and held it to allow radioactive decay and thermal cooling prior to releasing the effluent to the Columbia River. Approximately 10 curies of radioactivity had leached into the concrete floor and walls.

**Waste Type:** Equipment

**Waste Description:** This site received cooling water effluent from the 105-F Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Seventy percent of the total radionuclide inventory was contained within the soil adjacent to the basin.

**Closure Info:** Remedial action began on July 27, 2000. The excavation included removing the overburden, debris and underlying contaminated soil. The majority of the site was completed in September 2001, with additional excavation occurring in October 2001, December 2001 and January 2002.

Site excavation and waste disposal were completed on January 16, 2002, and the exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 20,039 square meters (215,698 sq. ft.) in area with a depth greater than 4.6 meters (15 ft). Approximately 212,015 metric tons (233,707 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

**Code:** 116-F-15  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (5/24/2007)

**Names:** 116-F-15; 108-F Radiation Crib  
**Start Date:**

**Type:** Sump  
**End Date:**

**Status:** Inactive  
**Description:** The site has been remediated and Interim Closed Out. The site consisted of 0.9 1 by 0.9 inch (3 by 3-ft) concrete sump near the center of the former 108-F building first floor. The sump system connected to a subgrade (under the building foundation) pipe trench that ran north and south beneath the first floor. The trench was approximately 0.9 meter (3 ft) deep, 0.3 meter (1 ft) wide, and 61 meters (200 ft) long, and drained from both ends into the sump. Many laboratory floor and hood drains were connected to the trench and sump. A 15-cm (6-in.) earthenware pipeline exited the sump and the building to the south. The pipe trench and sump were reportedly removed during D&D activities of the 108-F Biological Laboratory.

Location: The site was located under the excavation of the 108-F Building (site 100-F-36).

**Related Sites/Structures:** The sump received effluent from the 100-F-36 site glove boxes and floor and hood drains. The sump then emptied into a trench that had the same WIDS site code.

**Process Description:** The trench drained from both ends into a sump located in approximately the center of the trench. Many laboratory floor and hood drains were connected to the trench and sump. The trench and sump were covered with plywood and posted as radioactive. A 15-centimeter (6-inch) earthenware (vitrified clay) pipeline exited the sump and the building to the south. A
continuation drawing (W-2934, sheet 5) that would show the route and destination of the pipeline was no longer available.

Hanford Drawing H-1-2037 showed a 20-centimeter (8-inch) vitrified clay tile pipe that ran south, then east, from the western side of 108-F to the ash pit. Although there was no clear connection between the sump and the pipelines known to run to the ash pit, there was a strong possibility they were interconnected.

Several documents, including Herman, Stenner et al, (1988), Kiser (1988), and Clukey (1954, 1956), discussed sites like this one. If it was a crib, they did not reference as a crib. The noted omission from these documents casts doubt on the existence of this waste site as a crib.

**Waste Type:** Process Effluent

**Waste Description:** Prior to 1996, the unit had not been sampled for radiological or chemical contamination. It was known that alpha contamination experiments were conducted in the 108-F Building. The sump was reported to have received liquid wastes from the 108-F Building sinks, glovebox drains, and ventilation hoods. Alpha contamination experiments were conducted at the 108-F Building, therefore the potential for alpha contamination of this waste site exists.

**Closure Info:** The 108-F facility became inactive in 1973. From 1977 through 1983, contaminated material was removed from inside the building and disposed in 200 Area burial grounds. The 108-F building was demolished in 1999. The contaminated cast-iron pipe found during the February 2002 excavation was not located during this remedial action. Therefore, an additional test pit was excavated on November 29, 2005, in an attempt to locate the contaminated 15-cm (6-in.) diameter cast-iron pipe. The additional excavation was unsuccessful, and the excavated material was placed back in the pit. Additional efforts in July 2006 to locate the contaminated pipe using a metal detector were also unsuccessful. However, the contaminated 15-cm (6-in.) diameter cast-iron pipe (100-F-26:4) was found during test pitting activities in December 2006. The contaminated pipe is associated with the 100-F-26:4 pipeline site and is not a part of the 116-F-15 sump as previously indicated. Remediation and sampling activities for the 100-F-26:4 pipelines site will be included in a separate verification package.

Remediation of the 116-F-15 waste site was performed on September 26, 2005. It consisted of the removal of approximately 86 metric tons (95 US tons) of material, including concrete debris, piping, and soil being disposed at the Environmental Restoration Disposal Facility. The soil was excavated and field surveyed to a depth of approximately 2.6 meters (8.5 feet).

Following the remediation of 116-F-15, confirmatory sampling at the 100-F-36 waste site was performed on December 5, 2006 and verification sampling of the 116-F-15 waste site was performed on December 12, 2006.

The 100-F-36 waste site was evaluated and confirmatory samples collected. It was determined to require No Action.

**Code:** 116-F-16 **Classification:** Accepted

**Names:** 116-F-16; PNL Outfall **Reclassification:** Interim Closed Out (9/14/2006)

**Type:** Outfall **Start Date:**

**Status:** Inactive **End Date:**

**Description:** The site has been remediated and Interim Closed Out. This site consisted of an open-topped, compartmentalized, reinforced concrete outfall structure.

**Location:** The site was located approximately 670 meters (2200 feet) northeast of the 105-F Reactor
Building and about 15 meters (50 feet) upstream of 116-F-8 outfall.

Related Sites/ Structures: The site was associated with 100-F-29 (100-F Experimental Animal Farm Process Sewer Pipelines), 100-F-19, 100-F Reactor Cooling Water Effluent Underground Pipelines, Contaminated Underground Lines, Effluent Water System, 1904-F Process Sewer (See Subsites), the 116-F-8 Outfall Structure, 100-F-43 Flume and 100-F-39 River Lines.

Process Description: Animal Sewage and low-level contamination resulting from various Experimental Animal Farm projects, were pumped to the river via the 116-F-16 outfall structure and associated 100-F-43 spillway (flume). The site was a concrete outfall structure that received effluent from the experimental animal farm and aquatic biology laboratory. The Outfall emptied into the 100-F-43 Spillway via direct discharge then into the Columbia River. This unit was connected to the 116-F-8 Outfall Structure by a distribution box. A 183 centimeter (72 inch) diameter pipe extended from the north side of the 107-F Retention Basin, through a diversion box and connected to the south side of the outfall.

Waste Type: Animal Waste

Waste Description: The unit received animal sewage from various Experimental Animal Farm projects, 107-F Retention Basin water from fish studies, and low-level contamination. The COPCs include Plutonium-239/240, Strontium-90, Cesium-137, Lead, and hexavalent chromium.

Closure Info: The 100-F-43 waste site was administratively separated from the 116-F-16 waste site for future inclusion within the Remaining Sites Record of Decision by agreement among the Tri-Parties. It was subsequently determined that sufficient evidence existed to warrant remedial action of both waste sites as a single unit. All samples collected during remediation are listed under 116-F-16.

During decommissioning work performed during the 1980’s, the portion of the spillway above the river level was demolished and covered with soil. Remedial action activities at the sites were conducted from August 31, 2004, to September 8, 2005. Remediation involved excavation and staging of clean overburden material and removal of the outfall, the concrete spillway structure above the Columbia River ordinary high water mark, and contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs.

Approximately 384 square meters (4,130 square feet) of plan area was excavated, with all remedial activities restricted to the shallow zone (less than 4.6 meters [15 feet] below ground surface). Approximately 2,090 metric tons (2,300 U.S. tons) of contaminated material was removed from the site and disposed at the ERDF.

<td>Description:</td>
<td>The waste site has been remediated and Interim Closed Out. It consisted of two covered, reinforced concrete basins (east and west). Originally, the basins were used as part of the cooling water treatment train for the 105-F Reactor from 1944 to 1965. In the late 1970s, the eastern clearwell was used for the disposal of inert debris generated in the demolition of various 100-F Area buildings. Part of the concrete cover on both clearwells had been demolished to permit dumping into the clearwell cavity. The pump room was reinforced concrete and largely below grade. The above-ground portion of the pump room had been demolished, and the below-ground portion was filled with pump room rubble and backfilled. Approximately 25% of the eastern clearwell basin contained building</td>

Hanford Site Waste Management Units Report
February 2015 396
demolition waste from the 183-F, 185-F, 189-F, 190-F, 115-F and the 108-F buildings.

**Location:**
The site was located north of the 105-F Reactor Building, at the site of the 183-F Water Treatment Facility (demolished).

**Related Sites/Structures:**
The clearwells were associated with the 183-F Water Treatment Facility.

**Process Description:**
Originally, the basins were used as part of the cooling water treatment train for the 105-F Reactor from 1944 to 1965. The basins had a capacity of about 3.7E+07 liters (1E+07 gallons), they were separated in the center by a pump room. Chemical addition to this point in the treatment train was limited to coagulants (alum and hydrated calcium oxide), pH adjustment (sulfuric acid), and chlorination. Beginning in the 1970's, this site received demolition rubble and inert waste from building demolitions. It received rubble from the 183-F, 190-F, 189-F, 185-F and 171-F buildings.

**Waste Type:**
Sanitary Sewage

**Waste Description:**
The unit now contains demolition waste from demolished facilities. This waste includes rubble from the uncontained portion of 115-F as well as rubble from such noncontaminated facilities as 183-F, 190-F, 189-F, 185-F, 171-F. The rubble is believed to include asbestos siding tiles from several buildings. The site has been included in the Remaining Sites Record of Decision, and is listed as having "possible low-level radioactive waste."

**Closure Info:**
Site remediation was performed from July to September 2005 and consisted of the removal of debris within the eastern clearwell structure down to the concrete floor. Radiological surveys and visual inspection of the remediated clearwell structure revealed no residual contamination on the concrete floor or sidewalls and no indication of possible contaminant migration beyond the boundaries of the clearwells. No remediation or investigation was performed at the western clearwell, as no waste materials were disposed there, and the roof of the facility remains intact. Samples of excavated material were collected during remediation to support waste characterization. Following remedial activities, radiological surveys were performed.

Approximately 28,986 metric tons (31,952 U.S. tons) of material was removed and staged at an area adjacent to the clearwells before disposal at the Environmental Restoration Disposal Facility.

**Code:**
128-F-2

**Classification:**
Accepted

**Reclassification:**
Interim Closed Out (12/1/2008)

**Names:**
128-F-2; 100-F Burning Pit

**Type:**
Burn Pit

**Start Date:**
1/1/1945

**End Date:**
1/1/1965

**Description:**
The wastes site has been remediated and Interim Closed Out. The burn pit was an irregularly shaped depression that was used for burning wastes. Prior to remediation, the site had been covered and appeared as a flat surface with no sign of the burn pit or its contents. An area appeared to have been filled and leveled in preparation for the installation of well 199-F5-42.

**Location:**
The site was located approximately 30.5 meters (100 feet) east of the northeast corner of the 100-F Area perimeter road which runs along the riverbank. The site is located directly east of the 107-F Retention Basin.

**Related Sites/Structures:**
An area of residual contamination in Area C remaining after the burn pit remediation was designated as a new site, 100-F-59 Riparian Area Contamination.
Process Description: The 128-F-2, 100-F Burning Pit waste site was an irregularly shaped depression that was used for incinerating nonradioactive, combustible materials (e.g., vegetation, office waste, paint waste, and chemical solvents) from 1945 to 1965.

During Hanford Site cleanup operations in the late 1970s, unknown quantities of debris were removed from the burn pit and the site was backfilled. Historical documentation suggested that multiple burn pits were present at the site, with each pit having the dimensions of 31 by 31 by 3 meters (100 by 100 by 10 ft) deep. According to documentation the waste site was 46 meters (151 ft) by 18 meters (60 ft) and was situated on a steep grade near the shoreline of the Columbia River.

Waste Type: Soil

Waste Description: The results of confirmatory sampling were used to determine the COCs and contaminants of potential concern (COPCs) for verification sampling. Metals (including hexavalent chromium and mercury), SVOCs (inclusive of the PAHs detected in confirmatory samples), chlorinated pesticides, TPH, PCBs, and asbestos were considered COCs/COPCs for verification sampling. Additionally, because radiological activity was detected above background levels during confirmatory sampling, laboratory radiological analysis was performed on verification samples to verify the absence of radiological contamination.

Closure Info: Confirmatory sampling from four test trenches was done in December 2004. Remediation of the site was initially performed August through October 2005, with 21,900 metric tons (24,100 US tons) of material excavated and disposed at the Environmental Restoration Disposal Facility (ERDF). Scrap metal, concrete debris, bottles, laboratory glassware, ash, potentially contaminated soil, asbestos debris, and other miscellaneous materials were removed from the waste site.

Additional debris and ash related to the burn pit waste site was still visible on the Columbia River shoreline beyond the original waste site boundary. Further remediation was conducted in October 2006 that removed material on the riverbank slope. A soil berm was created to protect the area from any water encroachment from the river. In process sample results from October and November 2006 showed residual metal concentrations in the excavated area and soil berm exceeded soil (RAGs). After meeting with the regulatory agency, it was agreed that additional excavation would be conducted on the shoreline below the ordinary high water mark (OHWM). This excavation was completed in February 2007 and was followed by immediate collection of verification samples and gravel stabilization, prior to the onset of higher spring river levels. An agreement with the lead regulatory agency allowed this portion of 128-F-2, along with surrounding sediments with elevated levels of contaminants, to be designated as a new waste site, 100-F-59 (aka Area C).

Excavated materials were sorted and segregated based on visual inspection and location of origin and then staged onsite before disposal at ERDF. Samples of soil and debris were collected as needed to support waste characterization.

On August 19, 2005, soon after the onset of remediation, an area of cultural significance was discovered in the northwestern end of the riverside excavation. The first discovery was a thin concentration of mussel shell and bone fragments in the wall of the excavation. Additional artifacts (subsistence bone, chipped stone tools, knives, several rough stone tools, and trade beads) were discovered on the surface in nearby recently scraped areas on August 22, 2005. During a follow-up inspection on August 29, 2005, a hearth was discovered. The area of cultural significance was excluded from disturbance during remediation activities and was backfilled between February 20 and February 28, 2008.

During the initial 2005 remediation activities, it was observed that debris and ash material extended beyond the excavation design boundaries of the site toward the river shoreline and
appeared to be present below the OHWM. Further excavation was delayed until October 2006 to take advantage of lower flows of the Columbia River and avoid impacts to endangered Upper Columbia River (UCR) spring Chinook salmon and steelhead. Remediation continued as Phase II with the excavation of the soil containing debris and ash within the slope extending to the OHWM in October 2006. The remediation proceeded to the shoreline, leaving a low berm to protect against site flooding in the event of higher river stages. Soil samples were collected from the berm to evaluate if it could be left in place or required removal. The data showed individual samples contained levels of hexavalent chromium and lead that exceeded direct exposure RAGs and levels of barium, cadmium, chromium, copper, manganese, mercury, nickel, silver, zinc, PAHs, and PCBs that exceeded the criteria for protection of groundwater and the Columbia River.

| Code: 132-F-1 | Classification: Accepted |
| Names: 132-F-1; 132-F-1 Chronic Feeding Barn; 141-F; 141-F 100-F Experimental Animal Farm Sheep Barn | Reclassification: Interim Closed Out (8/23/2006) |
| Type: Laboratory | Start Date: |
| Status: Inactive | End Date: |
| Description: The site has been remediated and Interim Closed Out. The barn has been demolished. When in use, it was an L-shaped concrete block building with a concrete floor and concrete animal pens located both inside and outside of the building. The 141-F building was demolished in 1977. | |
| Location: The 141-F (132-F-1) barn site was located in the northeast corner of the 100-F Experimental Animal Farm area. The building site was northwest of the 107-F Retention Basin (116-F-14) and south of the 1904-F Outfall Structure (116-F-8) and the Pacific Northwest Laboratory (PNL) Outfall Structure (116-F-16). | |
| Related Sites/Structures: Drawings indicate that the effluent discharged into the process sewer system (100-F-29) until 1963 then wastewater was diverted to the 116-F-9 Animal Leach Trench. | |
| Process Description: Studies involving sheep began in the late 1940's. Up to 1,000 head of sheep were kept in 132-F-1 Barn (141-F) for use in dose studies using iodine-131, strontium-90, plutonium-239, and cesium-137. Most of the work performed involved 20-year lifetime exposure studies. The 141-F Building was one of the main facilities used to house the animals. Animal pens in the building had concrete floors and were connected to the special sewer (100-F-29) for contaminated animal wastes. Contaminated manure and sawdust that could not be shoveled out of the animal pens were washed into the sewer which went to the 141-N Sump. When the sump became full, the wastewater was pumped through a screen to the Columbia River via the PNL Outfall (116-F-16). The solids trapped by the screen were dried and sent to the 118-F-5 Sawdust Pit. The Remedial Investigation/Feasibility Study Work Plan for the 100-FR-1 Operable Unit, Hanford Site, Richland, Washington states that wash water from this facility went to the 1607-F6 septic system. A review of Hanford Site historical drawings H-1-13850 (sheets 2 and 3) and M-1904-F (sheet 5) and conditions encountered during remediation of the 132-F-1 site do not indicate piping between the 132-F-1 site and the 1607-F6 septic system. The drawings show that the only outgoing line (a 15 centimeter (6 inch) vitrified clay pipe) from the building discharged into the process sewer system (100-F-29) until 1963, when wastewater was diverted to the 116-F-9 Animal Leach Trench. | |
| Waste Type: Misc. Trash and Debris | |
| Waste Description: Residual strontium-90, cesium-137, and plutonium-239 contamination may remain in any buried debris. | |
| Closure Info: Confirmatory samples were collected from a test trench in September 2004. Only Strontium-90 |
was detected above remedial action goals. Low levels of polycyclic aromatic hydrocarbons were detected.

Remedial excavation began August 9, 2005 and continued through August 12, 2005. The concrete foundation, debris and piping were removed to a depth of approximately 1 meter (3 feet). A total of approximately 3,400 bank cubic meters (4,400 bank cubic yards) of soil and debris was excavated and staged onsite before disposal at the Environmental Restoration Disposal Facility. Strontium-90 was detected above remedial action goals in the cast iron piping. After remediation, the site existed as a shallow (approximately 1 meter [3 feet] deep) excavation. Excavation southeast of the former building footprint depth was extended up to 2.4 meters (8 feet) below ground surface (bgs) before native material was encountered, and no debris.

**Description:** The site has been evaluated and determined to require No Action. This site was the below grade remaining material from the decommissioning of the 115-F Gas Recirculation Facility. The building was demolished in-situ using Allowable Residual Contamination Level (ARCL) methodology. At present, the site looks like a gravel parking lot that is free of any debris.

**Location:** The site was located approximately 61 meters (200 feet) due west of 105-F Building.

**Process Description:** The gas recirculation facility was a single-story concrete building that housed the reactor inert gas processing and recirculation system. The gas system continuously recirculated a large volume of gas at very low pressure. The recirculation cycle included cooling, drying, and filtering of the gas prior to reentry into the reactor. The purpose of the reactor inert gas system was to provide a closed-loop nonreactive gas environment in the graphite core that would remove moisture and gases from the core and serve as a heat transfer medium between the graphite core and the process tubes. The system also served to detect water leaks within the reactor core. When a leak was detected, the gas was routed to the ventilation exhaust system. Filters, gas coolers, blowers, condensers, and silica gel drying towers were located within the 115-F Building. The system was designed to maintain gas pressure in the reactor at a slightly positive value with respect to the ventilation air so that the air could not make contact with the graphite core. Contamination of the 115-F Building occurred on the inside surfaces of ducts, concrete surfaces, machinery, and filters, as indicated by analysis of smear samples taken from these surfaces. The tunnels that connected the 115-F Building to the 105-F Reactor Building were also radioactively contaminated. When in operation, the site was a single-story, reinforced concrete structure, 6.1 meters (20 feet) high. The unit's dimensions were 51.2 meters (168 feet) long, 29.9 meters (98 feet) wide, with 4.0 meters (13 feet) below grade. An operating gallery extended down the center and was flanked on either side by cells that contained the gas processing equipment. The equipment cell walls and floors were 0.9 meters (3 feet) thick. At right angles to the operating gallery and extending across the full width of the west end was the service section, which contained the ventilation fan, air compressor, office, locker room, etc. A pipe tunnel 11.0 meters (36 feet) wide by 2.4 meters (8 feet) high ran beneath the full length of the building. The main gas lines to and from the 105-F Building entered through this tunnel.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The resident radionuclides are tritium, carbon-14, cobalt-60, strontium-90, cesium-137.

**Surface smears taken in the facility over a 100-square centimeter (15.5-square inch) area...**
revealed alpha contamination of less than 200 disintegrations per minute (dpm) on all surfaces tested. The maximum direct reading of 15,000 counts per minute (cpm) was recorded in the east end of the piping tunnel that connected the gas recirculation facility to the reactor (Chattin and Powers 1985).

Closure Info: The 115-F Gas Recirculation Facility decommissioning activities began in July 1984 and were completed in October 1984. The above ground debris and rubble were trucked to the 100-F Clearwell for disposal. The below grade perimeter walls, which extended 4.0 meters (13 feet) below grade, were demolished to 0.9 to 1.2 meters (3 feet to 4 feet) below grade. The remaining walls and piping tunnel were left intact and served as containment for the building rubble. Equipment was removed from the drier/blower cells, packaged, and buried in the 200 West Area Burial Ground. The entire area was covered with clean backfill material. This overburden averaged 1.2 to 1.5 meters (4 to 5 feet) in depth, which exceeded the ARCL requirements of 1 meter (3.3 feet) of clean fill. In addition, grading the final site to be compatible with the surrounding terrain added another 0.9 to 1.2 meters (3 to 4 feet) of clean backfill.

A "No Action" decision is supported based on reviews of the facility information, historical data, and modeling results (ARCL and RESRAD) as summarized below. As part of facility decommissioning activities, contaminated piping and equipment were removed from the facility and shipped to the Hanford 200 Area for disposal. Uncontaminated material and rubble was sent to the 183-F clear wells for disposal. Only the concrete floor surfaces of the facility were contaminated. In these areas, contamination did not penetrate the concrete surface more than 1 cm (0.4 in.). Using conservative inputs (e.g., highest activity sample results, uniform contamination levels over 100% of exposed surfaces), the ARCL and RESRAD outputs indicate that residual contamination levels do not present an unacceptable risk to the maximally exposed individual. In addition, the RESRAD model results indicate that the residual contamination levels are protective of groundwater and the Columbia River. Excavation of the site to collect more information is not cost effective and is not likely to result in a change to the no action interim closure decision for the 132-F-3 site.

the atmosphere.

**Waste Type:** Sanitary Sewage

**Waste Description:** The estimated radionuclide inventory for the 116-F Stack prior to demolition was 5.0 picocuries/gram. This amount was calculated from the concentration of nuclides over the interior of the stack to a depth of 1 centimeter (0.39 inches). The radionuclides found were tritium, carbon-14, cobalt-60, strontium-90, cesium-137, europium-152, and plutonium-239. Testing performed on several of the reactor stacks in the 100 Area prior to decommissioning showed that the stacks contained residual quantities of radionuclide materials on their interior surfaces. Standard smear testing performed over a 100-square centimeter (15.5-square inch) area on these surfaces showed the presence of tritium at concentrations of 400 to 13,000 picocuries per square centimeter and carbon-14 at concentrations of 200 to 2.1E+07 picocuries per square centimeter (Dorian and Richards 1978). Beta-gamma activity from other radionuclides was also identified.

**This Site has the Following SubSites:**

- **Code:** 132-F-4:1
- **Names:** 132-F-4:1; 116-F Reactor Stack Demolition Site
- **Code:** 132-F-4:2
- **Names:** 132-F-4:2; 116-F Reactor Stack Base Burial

- **Code:** 132-F-4:1  
  **Classification:** Accepted
- **Names:** 132-F-4:1; 116-F Reactor Stack Demolition Site  
  **Reclassification:** Interim No Action (12/8/2003)
- **Type:** Burial Ground
- **Status:** Inactive
- **Description:** The demolished 116-F Stack Demolition Site has been evaluated and determined to require No Action. It is the location of the buried rubble from the demolished stack. The stack a reinforced concrete structure, 61 meters (200 feet) high with a base diameter of 5.05 meters (16.58 feet) and a maximum thickness of 0.46 meters (18 inches) at the base. The interior of the unit contained 4.2 microcuries of radioactive materials. The stack was demolished by explosive demolition in 1983 and laid into a trench. It was then was broken into pieces smaller than 1 meter (3 feet) in diameter. All of the loose rubble was pushed into the trench and backfilled. The area was graded to match the surrounding terrain.

**Closure Info:** Radiological surveys were done in 1980 and 1983. Characterization concrete samples were collected in 1983. The contamination penetrated only a thin layer of the concrete. Prior to demolition, contaminated sand was vacuumed from the bottom of the stack. The interior of the stack was coated with a substance to adhere any residual contamination to the walls if the stack. The stack was demolished in September 1983 and buried in a trench located between the 117-F Building Site and the 115-F Building Site. The trench was backfilled and covered with a 1 meter (3 foot) layer of soil.

The "No Action" decision is supported based on reviews of the facility information, historical data, and modeling results (ARCL and RESRAD) showing that residual risk is within the bounds established for unrestricted land use. Results used in the ARCL and RESRAD modeling were from the pre-decontamination concrete sample collected at the elevation of the intake duct. The sample elevation was where the highest contaminant levels would be expected and where the highest direct readings were observed during pre-decontamination radiological surveys conducted in 1980. These contaminant levels were modeled over 100% of the inner surface area. Consistent with what would be expected, the contamination did not significantly penetrate the inner concrete surface of the stack. Based on the concrete samples, penetration of...
contaminants was estimated to be 0.1 to 0.2 cm (0.04 to 0.79 in.), while thickness of the stack wall was up to 46 cm (18 in). Conservative penetration depth of 0.95 cm (0.37 in.) was used to calculate the as-buried contaminated zone thickness. Excavation of the disposal trench to collect more information is not likely to result in a change to the no action interim closure decision for the 132-F-4 site.

The SubSite is Part Of:

- **Code:** 132-F-4
- **Names:** 132-F-4; 132-F-4 Reactor Stack Demolition Site; 116-F Reactor Exhaust Stack; 116-F Reactor Stack

---

**Code:** 132-F-4:2

- **Classification:** Accepted
- **Names:** 132-F-4:2; 116-F Reactor Stack Base Burial
- **Reclassification:** Interim No Action (11/14/2005)

**Type:** Burial Ground

**Status:** Inactive

**Start Date:**

**End Date:**

**Description:** The subsite has been evaluated and determined to require No Action. Subsite 2 consisted of the (116-F) Reactor Stack Base. The monolithic concrete stack base and foundation included an imbedded stack condensate drain line. The 116-F stack base burial site has a separate waste site boundary about 0.5 meters (1.5 feet) east of 116-F stack burial site. The reclassification of this site was based on the CVP-2005-00003 document for the 105-D Reactor stack base. The two waste sites are analogous.

**Closure Info:** The reclassification of this waste site is documented on form 2005-043. This stack base (132-F-4:2) is analogous to the stack base at 105-D reactor. The 132-D-4 (116-D) reactor stack concrete base and foundation including the imbedded cast iron drain line was closed with the 105-D Reactor Cleanup Verification Package (CVP-2005-00003). The analogues decision was based on reviews of the facility information, historical data, and modeling results (ARCL and RESRAD) showing that residual risk is within the bounds established for unrestricted land use. Results used in the ARCL and RESRAD modeling were from the pre-decontamination concrete sample collected at the elevation of the intake duct. The sample elevation was where the highest contaminant levels would be expected and where the highest direct readings were observed during pre-decontamination radiological surveys conducted in 1980. These contaminant levels were modeled over 100% of the inner surface area. Consistent with what would be expected, the contamination did not significantly penetrate the inner concrete surface of the stack. Based on the concrete samples, penetration of contaminants was estimated to be 0.11 to 0.2 cm (0.04 to 0.79 in.), while thickness of the stack wall was up to 46 cm (18 in). Conservative penetration depth of 0.95 cm (0.37 in.) was used to calculate the as-buried contaminated zone thickness. Excavation of the disposal trench to collect more information is not likely to result in a change to the No Action interim closure decision for the 132-F-4 site.

The 5.6 meters (18.5 feet) diameter octagonal stack base was removed to about 1 meter (3 feet) below grade and extended to 7.2 meters (23.5 feet) below grade. The vertical 15-centimeters (6-inches) cast iron condensate drain pipe in the center of the stack base exited the side of the concrete monolith about 1.6 meters (5.2 feet) below grade. The condensate drain line from the stack base to the 105-F Building process sewer was removed during the demolition activities for the 105-F Reactor below-grade structures.

The stack base included a 15 centimeter (6 inch) diameter cast iron drain pipe in the center of the base that exited the east side of the base at a depth of 1.5 meters (5 feet) below grade. The 15 centimeter (6 inch) cast iron drain pipe ran east from the stack base to the 105-F Building wall a distance of 1.9 meters (6.2 feet) and entered the 105-F Building at a depth of 1.9 meters (6.2 feet) below grade. The external piping and the upper 1 meter (3 feet) of internal piping was removed during the demolition of the 116-F stack and the adjacent 105-F Building walls. About
3.4 meters (11 feet) of cast iron drain pipe remains imbedded in the stack base.

The potential contamination within the imbedded pipeline is deemed negligible since the pipe was a free draining condensate line to the process sewer. The 116-F stack, which was closed with a No Action reclassification, represents the worst-case contamination potential for the drain line. The corresponding 105-D concrete base and foundation, including the imbedded cast iron drain line, was closed with no further action.

The SubSite is Part Of:

Code: 132-F-4
Names: 132-F-4; 132-F-4 Reactor Stack Demolition Site; 116-F Reactor Exhaust Stack; 116-F Reactor Stack

---

**Code:** 132-F-5  
**Classification:** Accepted  
**Names:** 132-F-5; 117-F Filter Building  
**Reclassification:** Interim No Action (12/8/2003)  
**Type:** Burial Ground  
**Start Date:** 1/1/1960  
**End Date:** 1/1/1965  
**Description:** The site has been evaluated and determined to require No Action. The exhaust filter building housed blowers and particulate and activated carbon filters used to treat the ventilation exhausted from the 105-F Reactor Building. The building was demolished in 1983.  
**Location:** The building was located west of 105-F.  
**Related Sites/Structures:** The building received exhaust fan discharge through an inlet duct from the 105-F Reactor and discharged the filtered air through a discharge duct and out the 116-F Stack.  
**Process Description:** The ventilation exhaust filter building housed blowers and particulate and activated carbon filters used to treat the ventilation exhausted from the F Reactor Building. The unit and duct work were all made of reinforced concrete, 0.3 to 0.6 meters (1 to 2 feet) thick. The building was 10.7 meters (35 feet) high with 2.4 meters (8 feet) above ground.  
**Waste Type:** Chemicals  
**Waste Description:** The radionuclides found in the 117-F Building are tritium, carbon-14, cobalt-60, cesium-137, strontium-90, europium-154, and europium-152. During the decommissioning of the facility, surface smears over 100-square centimeter (15.5-square inch) areas in the building revealed beta-gamma contamination of less than 200 counts/minute and alpha contamination less than 500 counts/minute.  
**Closure Info:** The 117-F Filter Building was released for unrestricted use based on the post-decontamination characterization results cited in a letter from J. J. Dorian with the subject Radiological Criteria for Decontamination and Decommissioning of the Retired 100 Area 117-F Filter Buildings dated May 18, 1983. Consequently, demolition and site grading were performed in November 1983 using conventional heavy equipment. The rubble was buried under at least 1 meter (3 feet) of clean fill and the site was graded to blend with the natural terrain.  
RESRAD modeling was performed in 2003 to provide another data point. The RESRAD modeling accounts for radioactive decay from 1983 (the year of building demolition) to 2003, and predicts that none of the contaminants detected in the paint will reach groundwater within 1,000 years. Residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario and pose no threat to groundwater or the Columbia River based on RESRAD modeling.

</tr>
</tbody>
</table>

**Description:** The site has been evaluated and determined to require No Action. The pumping station was demolished in 1987. The area where the demolished facility once stood is currently a cobble covered field.

**Location:** The site was located near the southeast corner of the 105-F Reactor Building.

**Related Sites/Structures:** This site was associated with 116-F-6 (1608-F Liquid Waste Disposal Trench) and the 105-F Reactor Building.

**Waste Type:** Ash

**Waste Description:** Before demolition, this site received water from reactor building drains containing trace amounts of low-level radionuclides and decontamination chemicals (primarily Turco). Radionuclides were primarily miscellaneous activation products, including tritium, carbon-14, cobalt-60, strontium-90, cesium-137, europium-152, and europium-154. The decontamination chemicals consisted of sodium fluoride, oxalic acid, and citric acid. Water was pumped from the reactor collection pits into the reactor effluent lines near the 105-F Reactor Building and became part of the 107-F effluent that was discharged to the Columbia River. During decommissioning of the facility in 1987, a survey of the walls, ceilings, and floor areas of the main floor, pump room, switch gear room, and valve room revealed direct beta-gamma contamination to less than 200 counts/minute (cpm). The maximum contamination levels recorded were for the floor areas of the sumps at 5,000 to 25,000 counts/minute (cpm) direct beta-gamma. During the Dorian and Richards (1978) study in 1975-1976, samples were collected from a soil boring identified as location 132-F-6. Analytical results of material collected in this boring at depths of 7.6 meters (25 feet) and 9 meters (30 feet) revealed elevated concentrations, with a maximum of 92 picocuries/gram for europium-152.

**Closure Info:** The 132-F-6 (1608-F) pumping station was demolished in August 1987. The excavation depth was approximately 5 meters (16 feet). 1.6 cubic meters of asbestos was taken to the Hanford Central Landfill. Pumps and piping were shipped to the 200 Area burial grounds for disposal. Approximately 27,500 gallons of residual water was trucked to 1325-N for disposal.

Concrete core samples and scale samples were collected and analyzed.

A "No Action" decision is supported based on reviews of the facility information, historical data, and modeling results (ARCL and RESRAD) and documented on reclassification form 2003-32.

Contaminated material (e.g., asbestos, pumps and associated piping, residual water from sumps, sump sediment, transformer oil) were removed during decommissioning activities and sent to appropriate disposal facilities (e.g., central landfill, 200 Area burial grounds, 1325-N Liquid Waste Disposal Facility, 100-N). The residual contamination exists in a thin concrete layer. Using conservative inputs (e.g., highest activity sample results, Uniform contamination levels over 100% of exposed surfaces), the ARC and RESRAD outputs indicate that residual contamination levels do not present unacceptable risk to the maximally exposed individual. In addition, the RESRAD model results indicate that the residual contamination levels are protective of groundwater and the Columbia River. Excavation of the site to collect more information is not likely to result in a change to the no action interim closure decision for the 132-F-6 site.
Reclassification: 182-F; 182-F Reservoir Dumping Area
Type: Inactive
Status: Interim Closed Out (9/12/2005)

Names: 182-F; 182-F Reservoir
Type: Dumping Area
Status: Inactive
Start Date: 1/1/1977
End Date: 1/1/1977

Description: The site has been remediated and Interim Closed Out. The 182-F reservoir was used to provide reserve water from the Columbia River for reactor cooling water and raw water for the 100 Area and had a storage capacity of 94.6 million liters (25 million gallons). The reservoir was later used as a landfill for disposal of decontaminated rubble from buildings that were decommissioned in the 100-F Area. In 1997, the site was covered with clean fill.

Location: Reservoir was located approximately 400 meters (1,312 feet) due north of the 105-F Reactor Building.

Related Sites/Structures: The site was related to the 183-F Water Treatment Plant, the 126-F-2 (183-F) Clearwells and the 105-F Reactor Building.

Process Description: The 182-F Reservoir received raw water from the Columbia River for reactor cooling water and raw water for the 100 Area supply system. The reservoir had a storage capacity of 94.6 million liters (25 million gallons). The reservoir was later used as a landfill for disposal of decontaminated rubble from buildings that were decommissioned in the 100 F Area. In 1997, the site was covered with clean fill.

Waste Type: Misc. Trash and Debris
Waste Description: This unit received demolition rubble from the 182-F Pumping Station and the 183-F Water Treatment Building and Sedimentation Basins, and debris from other building demolitions. Some of the debris was from 144-F, 144-R, 141-N, 141-P, 141-F, 141-H and 141-L. The unit was covered with fill from adjacent land.

Closure Info: Based on a review of the site historical process information and the results of the geophysical survey, the site appeared to be a disposal area for material that contained hazardous constituents at levels in exceedance of remedial action goals. Based on these determinations, and the implications of sampling a site of this magnitude, remedial action was recommended.

Excavation of the reservoir began on March 29, 2005, with removal and stockpiling of debris and soil. Visual observations of soil and debris removed from the southern and eastern portions of the reservoir indicated the presence of inert demolition debris (e.g., concrete, wood, rebar) with a limited amount of lead, asbestos, and some batteries. No hazardous materials other than a limited amount of lead, asbestos, and some batteries were found. Excavation of the western portion of the reservoir revealed essentially soil with no debris. Based on the results of the excavation and discussion with the U.S. Department of Energy and U.S. Environmental Protection Agency, it was decided that excavation would stop and sampling would be performed to support a decision if additional excavation was necessary.

Reclassification: 1607-F2; 1607-F2 Sanitary Sewer System; 1607-F2 Septic Tank; 124-F-2
Type: Septic Tank
Start Date: 1/1/1944
End Date: 1/1/1988

Description: The site has been remediated and Interim Closed Out. It was a septic tank, tile field and associated pipeline. The unit was 4.6 meters (14.9 feet) deep, constructed of reinforced...
concrete, and had a 522 person capacity (130 liters [35 gallons] per capita) with an average detention period of 24 hours. The walls and floor were 25 centimeters (10 inches) thick. The tile field was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a minimum of 2.4 meters (8 linear feet) per capita. The laterals were open jointed, spaced 2.4 meters (8 feet) apart. The tile field was irregularly shaped, measuring approximately 90.3 meters (296 feet) by 54.0 meters (177 feet).

Location: The septic tank was located approximately 67 meters (220 feet) west and 15 meters (50 feet) south of the 116-F-14 (107-F Retention Basin). The tile field was located approximately 61 meters (200 feet) south of the septic tank, within the 126-F-1 Ash Pit.

Related Sites/Structures: This site received effluent from 184-F, 185-F, 190-F, 105-F, 108-F, and the 1700 Administration and Service Buildings.

Waste Type: Misc. Trash and Debris

Waste Description: This unit received unknown amounts of sanitary sewage from the 184-F Powerhouse, the 185-F Chemical Treatment Building, the 190-F Pumphouse, the 105-F Reactor Building, the 108-F Building, and the 1700 Administration and Service Buildings. The unit now services the 105-F and 108-F Buildings only. The other buildings have been demolished. Since the site serviced both the 105-F and 108-F Buildings, there is the potential to have received hazardous contaminants. The sludge in the septic tank was measured and sampled as part of the Group 4 Remedial Design Field Investigations. The sludge volume was estimated to be 49,970 liters (13,200 gallons). Sample numbers B0LC76, B0LC77, B0LC78 and B0LC82 were analyzed for metals, volatile organics and semi-volatile organics. Radionuclides were determined by Gamma Spectroscopy. Polyaromatic hydrocarbons were identified as well as elevated levels (above background) of cobalt-60, cesium-137, strontium-90, europium-154/155, radium-226, plutonium-238,239/240 and uranium-234, 235/238. The estimated dose rate from the tank sludge is 157.2 millirem per year.

Closure Info: The selected remedial action for the 1607-F2 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to the average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

During remediation of the 1607-F2 site, in-process sampling and analysis of the sludge in the septic tank, septic system, and tile field (sampling conducted to guide remediation and for waste characterization) indicated that strontium 90, the uranium isotopes, mercury, and arsenic were not COCs for the 1607-F2 site. Therefore, these contaminants are not addressed further in this CVP. In process sampling indicated that strontium-90, the uranium isotopes, and mercury were at levels less than the Hanford Site background (DOE-RL 1996) of 0.18 pCi/g for strontium-90, 1.1 pCi/g for uranium 234, 0.11 pCi/g for uranium-235, 1.1 pCi/g for uranium-238, and 0.33 mg/kg for mercury. Because a large portion of the 1607-F2 drain field was within the footprint of the 126-F-1 Ash Pit and based on agreement between the Tri-Parties, europium-152 was included in the final list CVP COC list for the 1607-F2 site. The COC list for the 126-F-1 Ash Pit is included in the Sampling and Analysis Instruction for Confirmatory Sampling of the Southern Portion of the 126-F-1 Ash Pit.

At the completion of the remedial action, the total excavation was approximately 6,679 square meters (7,988 sq. ft.) in area with a depth of 4.6 meters (15 ft). Waste site cleanup was conservatively evaluated to meet shallow zone criteria. Approximately 35,099 metric tons (38,690 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.
Results of the sampling, laboratory analyses, and data evaluations for the 1607-F2 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

</tr>
<tr>
<td>Closure Info:</td>
<td>Remediation of the waste site began in September 2005 and consisted of the removal of the septic system, drain field, associated piping, and overburden material. During remediation approximately 2,798 metric tons (US 3,085 tons) of material was excavated, staged onsite, and subsequently disposed of at the Environmental Restoration Disposal Facility, (ERDF). Verification sampling of the excavation and staging area footprint was conducted in March 2006 to verify the completeness of remediation. The results indicated that the excavation contained residual arsenic and lead concentrations exceeding cleanup criteria. Additional remediation of the excavation was performed in December 2006 and consisted of removing an additional 3,791 metric tons (4,179 US tons) of material. A second set of verification samples was collected from the excavation and analyzed for arsenic and lead.</td>

Hanford Site Waste Management Units Report
February 2015

408
Related Sites/Structures: This unit received effluent from the 115-F Gas Recirculation Building.

Process Description: The walls of the reinforced concrete septic tank were 20 centimeters (8 inches) thick, and the floor was 15 centimeters (6 inches) thick. It had a capacity of 794.94 liters (210 gallons). The system could support 6 persons assuming input of 132.49 liters (35 gallons) per capita per day and a one day retention period. The drainfield was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a total of 14.6 linear meters (48 linear feet) of piping (2.4 linear meters [8 linear feet] per capita). The laterals were open jointed and spaced 2.4 meters (8 feet) apart. The system supported the 115-F building.

Waste Type: Demolition and Inert Waste

Waste Description: This unit received an unknown amount of sanitary sewage from the 115-F Gas Recirculation Building. There is the potential for the site to have received hazardous contaminants from the 115-F Building.

Closure Info: Confirmatory sampling was conducted on October 6, 2004. During excavation in sample area 1, the septic tank was discovered but was found to have been previously decommissioned and backfilled. The backhoe bucket used in the excavation was too large to enter the opening in the top of the tank. In addition, the septic tank was constructed of reinforced concrete and could not be penetrated with the excavation equipment. As a result, confirmatory samples of material inside the tank were not collected. Instead, a soil sample was collected underneath the septic tank at 2.9 meters (9.5 feet) below ground surface.

Remediation of the waste site was performed from April 3 through April 5, 2007, and included removal of the septic tank, the drain field, and the associated piping. Overburden material and other soils presumed to contain no residual contamination above cleanup levels were stockpiled south of the excavation for post remediation verification sampling. Approximately 707 cubic meters (925 yards) of piping, concrete material, and suspect contaminated adjacent soils were removed and disposed at the Environmental Restoration Disposal Facility. The excavation depth ranged from 2.6 meters (8.5 feet) to 3.2 meters (10 feet).

Code: 1607-F5

Classification: Accepted

Reclassification: Interim Closed Out (9/14/2006)

Names: 1607-F5; 1607-F5 Sanitary Sewer System; 1607-F5 Septic Tank; 124-F-5

Type: Septic Tank

Start Date: 1/1/1944

End Date: 1/1/1965

Status: Inactive

Description: The site has been remediated and Interim Closed Out. The system consisted of a septic tank, drainfield, and associated pipeline.

Location: The site was located approximately 122 meters (400 feet) east of the northeast corner of the old 182-F Reservoir. The drainfield was located just southeast of the septic tank.

Related Sites/Structures: The site received effluent from the 181-F Pumphouse.

Process Description: The septic tank was constructed of reinforced concrete; the walls are 20 centimeters (8 inches) thick, and the floor was 15 centimeters (6 inches) thick. The septic tank had a capacity of 794.94 liters (210 gallons). The system could support 6 persons assuming input of 132.49 liters (35 gallons) per capita per day and a one day retention period. The drainfield was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a total of 14.6 linear meters (48 linear feet) of piping (2.4 linear meters [8 linear feet] per capita). The laterals were open jointed and spaced 2.4 meters (8 feet) apart. Piping for the system included a 15
This unit received an unknown amount of sanitary sewage from the 181-F Pumphouse.

Closure Info: Confirmatory sampling performed in November 2004. It was determined that the waste site required remedial action. However, the influent pipeline connecting the 181-F Pumphouse to the septic tank did not require remedial action. A portion of the piping was removed with the 181-F pump house. The remedial action was conducted on August 30 and 31, 2005, with excavation of 2,250 metric tons (2,480 US tons) of soil and debris, including the septic tank and drain field, being disposed at the Environmental Restoration Disposal Facility. The depth of the excavation was approximately 2.8 meters (9.2 feet).

Classification: Accepted
Reclassification: Interim Closed Out (11/8/2001)

Start Date: 1/1/1945
End Date: 1/1/1975

Description: The site has been remediated and Interim Closed Out. The 1607-F6 Sanitary Sewer System included two septic old tanks, a new septic tank, a tile field, and pipelines. The old "tanks" were constructed of two 0.91-meter (3-foot) lengths of 91-centimeter (36-inch) concrete pipe connected in series. The pipes were sealed to a wood planking base with asphalt and had wood plank covers. The new tank was constructed of a 1.91-meter (6-foot 3-inch) section of 183-centimeter (72-inch) diameter steel pipe installed vertically with an attached bottom and two layers of tongue and groove planking for the top. The tank is shown on drawing H-1-1518 to have a 61-centimeter (24-inch) by 61-centimeter (24-inch) square access hole at the surface.

Location: The site was located in the Experimental Animal Farm area of the 100F Area. Hanford drawings show the old tanks being located under what was the east side of the 1705-F Building. The new tank is shown to be located 3 meters (6.8 feet) east of 1705-F Building. The tile field is located 40 meters (112 feet) east of the septic tank.

Related Sites/Structures: Currently no associated structures remain. The site received sanitary sewage from the former 1705-F, 146-F and 146-FR Buildings.

Process Description: This septic system operated from 1945 to 1975, receiving sanitary sewage from area buildings. The site is in close proximity to the 100-F-19 Reactor cooling water effluent pipelines, with a portion of the septic system drainfield located directly over one of the large cooling water effluent pipelines.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: Waste site contaminants of concern (COCs) and contaminants of potential concern (COPCs) identified through process knowledge are listed in the SAP. Because a portion of the septic system drainfield piping was located over the 100-F-19 Reactor cooling water effluent pipelines, the COC/COPC lists for both sites were combined for the CVP. The COCs listed below are attributed to the 100-F-19 Reactor cooling water effluent pipelines, while the COPCs are attributed to the 1607-F6 site. Waste site COCs include: Carbon-14, Cesium-137, Cobalt-60, Europium-152, Europium-154, Europium-155, Nickel-63, Strontium-90. COPCs include: Lead, Polychlorinated biphenyls (PCBs), Semivolatile organic compounds.

Waste Type: Barrels/Drums/Buckets/Cans
Waste Description: This unit received sanitary sewage from the 146-F and 146-FR Buildings. The amount of waste received is unknown. Since the site serviced both the 146-F and 146-FR Buildings, there is the potential to have received hazardous contaminants.

Closure Info: Remedial action at the 1607-F6 site began on July 28, 2000. Excavation of the site involved removing the overburden materials, septic system structure (tank and associated influent and drainfield piping), and underlying contaminated soil. On April 25, 2001, the excavation was completed. There was a large gap between the excavation beginning date and completion date because the north-south septic pipeline was excavated at a later date, following the excavation of the septic tank and drain/tile field. The waste site description referred to three septic tanks. However, during remedial excavation of the site, only one tank was encountered and removed. The other two older septic tanks were likely removed and replaced with the newer septic tank during construction of the 1705-F Building. The two older tanks were formerly located under what was the east side of the former 1705-F Building. The animal farm buildings were demolished in 1975. The third and newer tank that was removed during site excavation was located approximately 3 meters (6.8 ft) east of the former 1705-F Building.

The third (and newer) tank was removed during this remedial action. It was located approximately 3 meters (6.8 ft) east of the former 1705-F Building. The drainfield was located east of the septic tank and was located partly over one of the 100-F-19 Reactor cooling water effluent pipelines.

The final excavation and removal of the 1607-F6 site included the removal of one septic tank, the north-south-oriented septic pipeline that served the 146-FR Building, the east-west oriented septic pipeline that served the 146-F Building, the septic system drain/tile field, and underlying contaminated soil. The general average elevation of the bottom of the overall site excavation was at 123.5 meters (405.2 ft) upon completion. The excavation was approximately 5820 square meters (1,908 sq. ft) in area with a maximum depth of approximately 3.5 meters (11.5 ft). Approximately 1,726 metric tons (1,898 tons) of material from the site were disposed of at ERDF.

Code: 1607-F7
Names: 1607-F7; 124-F-7; 141-M Building Septic Tank
Type: Septic Tank
Status: Inactive
Start Date: 1/1/1945
End Date: 1/1/1975
Classification: Accepted
Reclassification: Interim Closed Out (10/19/2006)
Description: The site has been remediated and Interim Closed Out. The site consisted of a septic tank, tile field, and interconnecting pipeline located under an area that was historically used for animal grazing (i.e., pasture). The septic tank received sanitary sewage from the former 141-M Building and had a volume of 3,800 Liters (1,000 gallons).
Location: The site was located within the 100-F Experimental Animal Farm area just off the northwest corner of the former 141-M Building and east of the 132-F-1 (The Chronic Feeding Barn) site. A walkway to the former 141-M Building was visible near three living juniper trees located south of the septic tank.
Related Sites/Structures: There were no associated structures remaining at the site. Before remediation, the site received sanitary sewage from the former 141-M Building and runoff from the pasture use. The barns in the area were used for animals being tested with radioactive substances.
Waste Type: Equipment
Waste Description: The site received sanitary sewage from the 141-M Building.
Closure Info: Confirmatory sampling was done in 2004. No stained soil or suspected asbestos-containing material was encountered during confirmatory sampling activities.

The site excavation began on August 8, 2005, and was completed November 30, 2005. Remediation of the waste site involved layback of overburden and removal of the septic tank, drain field, the interconnecting pipeline, and associated soils around and below those structures. Some of these materials were staged just south of the site before disposal. However, most of the waste was excavated using direct loadout and shipment to the Environmental Restoration Disposal Facility (ERDF). The overall depth of the excavation for the septic tank was approximately 3 meters (10 feet) below ground surface and approximately 1.5 meters (5 feet) below ground surface for the drain field. The excavation depths also included removal of 0.6 meters (2 feet) of soil below these structures. A total of approximately 1,088 metric tons (1,200 US tons) of contaminated material was disposed at ERDF.

Code: UPR-100-F-1
Names: UPR-100-F-1; 141 Building Sewer Line Spill; 141-C to 141-M Sewer Line Leak; UN-100-F-1
Classification: Accepted
Reclassification: Interim Closed Out (9/15/2003)
Type: Unplanned Release
Start Date: 1/1/1971
Status: Inactive
End Date:
Description: The site has been remediated and Interim Closed Out. An unplanned release of sewer effluent associated with the Hog Barn occurred on March 13, 1971. The main sewer line became plugged and release approximately 17,000 gallons of contaminated animal pen wash out water to the ground.
Location: The site was located between the 141-C and 141-M Buildings northeast of the 105-F Reactor and west of 116-F-14 (107-F Retention Basin).
Release Description: The release was a spill of wash water containing contaminated animal waste.
Related Sites/Structures: The site was related to the sewer line from the 141-C to the 141-M Buildings which have since been demolished.
Waste Type: Chemicals
Waste Description: The spill consisted of wash water used to clean out animal pens. The water contained 4.0E-5 curies of strontium-90 and 1.06E-6 curies plutonium-239.
Closure Info: Remedial Action ran from August 2001 until December 2002. The 100-F-19:2 Reactor Cooling Water Effluent Pipeline and co-located sites, (116-F-11 Cushion Corridor French Drain, UPR-100-F-1 Sewer Line Leak, and the 100-F-29 Experimental Animal Farm Pipelines), were remediated as a group and documented in CVP-2001-00003. The group is referred to as the 100-F-19:2 site. The unplanned release was within the footprint of the 100-F-29 pipeline excavation. The elevation of the bottom of the excavation was approximately 124.7 meters (409 ft) upon completion. The excavation area was approximately 19,000 square meters (205,000 sq. ft) with a maximum depth of approximately 5 meters (16 ft) and an average depth of approximately 3.7 meters (13 ft). Removal of the 100-F-29 pipelines near the northwest corner of the 116-F-14 (107-F Retention Basin) required shallower excavation, averaging approximately 1 meter (3 ft) in depth. Little evidence of the 116-F-11 french drain site was found during excavation of the 100-F-19:2 pipelines. The location of the french drain was excavated and sampled to the design elevation 4.6 meters (15 ft).

Remediation included excavation of overburden, piping, debris and contaminated underlying soil. Approximately 39,347 metric tons (43,373 tons) of material including soil, debris and
The Basin Leak Ditch was formed in 1955 following an overflow of the 107-F Retention Basin. The ditch was enlarged by repeated overflows from an effluent manhole located near the north end of the 107-F Retention Basin.

**Waste Type:** Sanitary Sewage

**Waste Description:** The waste was radioactive process liquid effluent from the 107-F Retention Basin.

**Closure Info:** Site excavation and waste disposal began on February 6, 2001 and were completed on July 28, 2001. The exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. The maximum excavation depth of 4.2 meters (13.8 ft) occurs in the western portion of the waste site, with a surface elevation of 124.5 meters and a bottom excavation elevation of 120.3 meters. The actual excavation depth throughout the remainder of the site varies, as does the surface elevation. Generally both decrease as the site approaches the river. At the completion of the remedial action, the total excavation was approximately 2,388 square meters (7,834 square feet) in area with a depth greater than 11 meters (36 feet). Approximately 670 metric tons (739 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility (ERDF). Results of the sampling, laboratory analyses, and data evaluations for the UPR-100-F-2 site indicated that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

---

**Code:** UPR-100-F-3  
**Classification:** Accepted

**Names:** UPR-100-F-3; Mercury Spill  
**Reclassification:** Interim Closed Out (8/14/2003)

**Type:** Unplanned Release  
**Start Date:** 1/1/1977

**Status:** Inactive  
**End Date:**

**Description:** The site has been remediated and Interim Closed Out. The site was an unplanned release that occurred at the northeast corner of the demolished 146-FR Fish Laboratory.

**Location:** The site was located at the northeast corner of the 146-FR Fish Laboratory.

**Release Description:** In 1977, an unknown quantity of mercury was spilled on the floor in the 146-FR Fish Laboratory and was "squeeeed" across the floor and out the door onto the ground at the northeast corner of the building. The mercury contaminated an area approximately 3.05 meters
by 3.05 meters (10 feet by 10 feet). Personnel who remember the incident are unable to specify the volume of mercury, its chemical composition, or the exact area of soil which was contaminated (employee interview).

<table>
<thead>
<tr>
<th>Related Sites/Structures:</th>
<th>The spill was originally in the 146-FR Fish Laboratory then &quot;squeeged&quot; out the door near the 146-FR Drywells (100-F-25).</th>

</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The site was related to the Experimental Animal Farm and radiological experiments conducted by Pacific Northwest Labs (PNL).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The site was established to study the behavior of plants grown in soil containing cesium-137 and strontium-90, under controlled conditions of soil tillage, irrigation, cropping and abandonment. Uptake of the radionuclides was measured in alfalfa, barley, radishes, beans, cheatgrass, and tansy mustard. The screened enclosure was designed to exclude mammals and birds, but not insects. Each plot was edged with wooden planks to reduce the transfer of contaminants among the soil plots. An article, written in 1971 by J.F. Cline and W.H. Rickard (published in 1972 in the Health Physics Pergamon Press), describes how the experiments were conducted and indicates the active experiment dates were 1954 -1964. It lists the sample results from the active experiment, collected from 1954 through 1963. Although the plot may have been established in 1952, a total of 180 inches of strontium contaminated irrigation water was used on these plots over the 1954 -1964 time period. This article also states that, in 1970, dry litter and soil samples were collected and analyzed. This seems to be the conclusion of the experiment.</td>

extending above grade. The above grade pipe was 10 centimeters (4 inches) in diameter with a 180 degree bend at its top. The top points downward at its tip which is fitted with a vent assembly. Steel fence posts surrounded the vent pipe. During a April 1999 visit, several soil gas probes were observed. The area was fairly level with sandy soil and had a moderate cover of grasses. A concrete foundation pad (6 meters x 9 meters [20 ft x 30 ft]) is 13.7 meters (45 ft) east of the site.

Location: The vent was located north of the northeast corner of 118-F-1 Burial Ground and approximately 244 meters (800 feet) southwest of the southwest corner of the 105-F Reactor Building. The unit was 13.7 meters (45 feet) west of a concrete floor pad that remains from a demolished carpenter shop.

Related Sites/Structures: The site was probably related to the 100-F Carpenter Shop.

Waste Type: Misc. Trash and Debris

Waste Description:

Closure Info: A site evaluation was conducted as part of the Remaining Sites Verification Package attached to the Reclassification Form 2004-127. Historical data, process knowledge, geophysical survey results, site walkdown observations, and aerial photographs were used to develop a site-specific sample design.

A focused sampling approach was selected for the site, biased towards potential worst-case contaminant locations. Because the site walkdown observations and aerial photographs indicated that the site may have been a decontamination facility, the crib beneath the vent pipe was chosen as the suspected location for the terminus of the drain pipe that discharged liquid effluent from the floor drain.

The evaluation included a focused sampling approach consisting of excavating a test pit into the 3 by 3 meter (10 by 10 feet) subsurface anomaly located beneath the vent pipe. At 0.9 meters (3 feet) below ground surface, a plastic vapor barrier was discovered, followed by the 0.15-meter (6-inch) lateral drain pipe that conveyed effluent from the concrete pad floor drain at 1.2 meters (3.9 feet) below ground surface. The drain pipe appeared to consist of nonfriable asbestos-cement material. A sample of the pipe material was taken.

The rock crib structure was revealed beneath the drain pipe. A sample of the crib material was taken at 1.7 meters (5.6 feet) below ground surface. Native soil was discovered at 2.2 meter (7.2 feet). A representative sample, consisting of 15 aliquots distributed across the bottom of the test pit, was collected. Results of the confirmatory sampling were used to make reclassification decisions for the site in accordance with the TPA-MP-14 (DOE-RL 1998) process.

Code: 100-F-15
Names: 100-F-15; 108-F Building Ventilation French Drain
Type: French Drain
Status: Inactive
Description: The site has been remediated and Interim Closed Out. The french drain was constructed of concrete, buried to a depth that placed the upper drain surface at grade level. A highly degraded wooden cover was in place over the drain. The bottom of the drain consisted of soil and large gravel, which supported a five-gallon carboy container. A copper tube connected the exhaust
duct from the 108-F third floor, room # 302, to the carboy.

Location: The unit was located next to the east wall of the 108-F Building.

Related Sites/Structures: This site was associated with the 108-F Building (site 100-F-36).

Waste Type: Demolition and Inert Waste

Waste Description: The drain received condensate that formed inside several large hood ventilation ducts mounted externally on the east wall of the building. Condensate formed during cold weather and ran through 2.5-centimeter (1-inch) stainless steel lines to the drain. The quantity of waste received is not known. A bottle containing 3 gallons of liquid from the 100-F-15 french drain was characterized between 05/07/96 and 08/08/96. A radiological survey of the bottle was conducted using field detection equipment and the resulting readings showed less than detectable. A sample from the liquid was collected and sent to the laboratory for chemical and radiochemistry analysis. The resulting analysis was received on 08/28/96 and indicated the liquid contained above threshold amounts of radiological and hazardous material (i.e., plutonium and chromium). Specifically, the chemical constituents analyzed for were TCLP Metals, Inorganic Ions, and Total Cyanide, and the radiological constituents were GEA, Gross Alpha, Gross Beta, Strontium-90, Isotopic Plutonium, and Total Uranium.

Closure Info: Site excavation was completed as reported in the 108-F Biological Laboratory D&D Project Closeout Report. The 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains were removed during decommissioning and demolition activities and backfilled with clean material. The CVP report documents that the 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 362.2 square meters (3898.7 square feet) in area with a depth of 4.6 meters (15.0 feet). No material from the sites was disposed of at the Environmental Restoration Disposal Facility as a result of the Remedial Action Project activities described here. Verified clean materials were used as backfill at the completion of the remedial action.

Code: 100-F-20

Names: 100-F-20; PNL Parallel Pits

Type: Trench

Status: Inactive

Description: The has been remediated and Interim Closed Out. The site consisted of two earthen pits or trenches, both oriented northeast to southwest. The pits were observed on aerial photographs (#7620 and #6451-5) dated 1962. The photos show the site to be actively in use, with refuse material visible in the pit bottoms. The access roads appear well used, suggesting frequent motor vehicle access to the pit locations.

Prior to remediation, the area was covered with cheat grass and rabbit brush vegetation. Evidence of surface disturbance was visible. Bricks and subsidence were observed at the site, but the exact location of the trenches is not visually discernible from the surface. Blue wooden stakes remain at the site from geophysical surveys. Between March 31, 1995 and April 4, 1995, a radiological survey was conducted over the general area of the Pacific Northwest Laboratory (PNL) parallel pits. Counts as high as 12,000 counts per minute (cpm) were collected over the surface of the site.

Location: The site was located about 30.5 meters (100 feet) west of the eastern 100-F Perimeter Road and immediately north of a dirt road that connects the 100-F Perimeter Road with the main reactor site access road, running along the southern boundary of the ash pit.
The site was believed to have been used to dispose of both radioactive and nonradioactive material from the experimental animal farm. The Burial Ground ROD reported that the northern trench may have contained non-radioactive animal farm wastes, including hardware, lumber, and soft materials. The southern pit may have received radioactively contaminated animal feces and pen sweepings.

A retired Hanford employee was interviewed in 1995. He clearly remembered delivering waste to the pits. The southern pit may have received radioactively contaminated animal feces (mostly sheep) and pen sweepings, small quantities of animal tissue, and miscellaneous Experimental Animal Farm wastes. The northern pit may have received non-radioactive Experimental Animal Farm wastes including hardware, lumber, and soft materials. Neither of these pits was used as a burn pit. Potential contaminates included: Co-60, Sr-90, Pu-239/240.

Remedial action began on December 5, 2005, with load out of waste material completed on August 8, 2006. Excavation of the site involved removing demolition debris that contained concrete, metal piping, steel sheeting, and wood. Approximately, 14 small laboratory-type containers were encountered throughout the burial ground. No asbestos-containing material was identified during waste excavation and no areas of the burial ground were identified for focused sampling.

After removal of all debris, radiological field screening was used to determine that excavation activities were complete. At the conclusion of the excavation activities, the remediation footprint was approximately 4.3 meters (14 ft) below the ground surface and at the deepest point the elevation at the bottom of the excavation was 117 meters (384 ft) above sea level. An estimated 11,953 metric tons (13,176 U.S. tons) of material was excavated from the 100-F-20 burial ground and disposed at ERDF.

The remaining soils at the site have been sampled, analyzed, and evaluated. The results of this effort indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The site had no deep zone; therefore, no institutional controls were required. The site was verified to be remediated in accordance with the ROD and may be backfilled.

---

**Code:** 100-F-35  
**Classification:** Accepted

**Names:** 100-F-35; Soil Contamination Area Inside the 105-F Exclusion Area  
**Reclassification:** Interim Closed Out (6/16/2003)

**Type:** Unplanned Release  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site has been remediated and Interim Closed Out. The site had been a posted Soil Contamination Area with no distinguishing features.

**Location:** The site was located southwest of the 105-F Reactor Building, inside the Exclusion Area.

**Release Description:** An area of contamination was found inside the 105-F Exclusion Area on April 29, 1997. The area was initially found with the Mobile Surface Contamination Monitor (MSCM-II) Tractor (report #MSCMR243). A more detailed survey with an Electra reported 60,000 disintegrations/minute over an area approximately 3 by 3 meters (10 by 10 feet). A
conversation with Steve Demers indicates that the source of contamination was a large
container (commercial name "Terra-Store") that had been sitting on this area during the
evacuation of the 116-F-4 Pluto Crib. The Terra-Store container was filled with contaminated
soil from the excavation and then transported to the Environmental Restoration Disposal
Facility (ERDF). The 3 by 3-meter (10 by 10-foot) contaminated area is residual contamination
from the container of contaminated soil (Terra-Store).

Related Sites/ Structures: The site was associated with 116-F-4 Crib.

Waste Type: Chemicals

Waste Description: An area of radiologically contaminated soil, reading 60,000 disintegrations/minute was
identified within the 105-F Exclusion Area. The ground contamination was the result of a large
container placed in this area to hold contaminated soil removed from 116-F-4 Crib. Soil
samples from 116-F-4 Crib identified strontium-90 and cesium-137 as the major contaminants.

Closure Info: Remedial action at the 100-F-35 site began in October 2002 and was completed in December
2002. The excavation was approximately 51.2 square meters (551 square feet) in area with a
depth of 0.9 meters (3 feet). Approximately 75.4 metric tons (83 tons) of material from the site
were disposed at the Environmental Restoration Disposal Facility (ERDF).

Code: 100-F-50

Classification: Accepted

Names: 100-F-50; Storm Water Run Off Culvert; 100-F Railroad French Drain

Reclassification: Interim No Action (4/15/2008)

Type: French Drain

Start Date:

Status: Inactive

End Date:

Description: The waste site was evaluated and determined to require No Action. It consisted of a circular
concrete basin and a steel culvert (pipe). The basin, approximately 1 meter (3 feet) in diameter,
collected surface water runoff that drained via a 36-centimeter (14-inch) diameter steel
diversion culvert under one of the railroad grades and flowed down an embankment to the flat
terrain below.

Location: The concrete retaining wall at the top of the french drain was located about midway between
the two sets of track that were about 10 meters (30 feet) apart.

Release Description: Evidence of water erosion on the hillside below the culvert and vegetation in aerial photographs
suggested water runoff.

Related Sites/ Structures: The site was associated with railroad tracks and rail cars.

Process Description: The purpose of the French drain and drain pipe was unknown. It appeared to have been
installed as a water collector and drain for the land between the two tracks. Aerial photographs
during Hanford operations show the presence of an unusually large amount of vegetation below
the drain culvert, suggesting that water solutions were discharged. No water piping sources
were found on drawings in this area, so it does not appear that rinsing processes were
performed at the site. The French drain appeared to be located at a low point in the area
between the two railroad tracks. A drain pipe ran east under one set of railroad tracks to
discharge from a soil bank above a low area in the adjoining land. There was a line of
vegetation below the drain pipe in older photographs, but there was only dead vegetation found
during the field walkdown in 2005. Since radioactive solutions were not typically discharged to
soil surfaces (to avoid airborne contamination and spreading), it does not appear that any
dumping of radioactive solutions was involved at the site. Cask car drainage and flushing was
typically done at the shipping or receiving areas that had process sewers. Chemical dumping

Hanford Site Waste Management Units Report
February 2015
was not suspected for this site. There was soil washout on the bank below the culvert east of the railroad tracks. There was evidence of dead vegetation and/or some darkening of the soil in the low area. There was no sign of soil stains that might indicate chemical solution dumping.

**Waste Type:** Process Effluent

**Waste Description:** There is evidence of soil erosion below the culvert from the french drain. The concrete ring (french drain) is filled with soil.

**Closure Info:** The site evaluation included investigation by confirmatory sampling conducted on November 19, 2007. The contaminants of concern included: hexavalent chromium, gamma-emitting radionuclides (cesium-137, cobalt-60, europium-152, europium-154), and strontium-90. Additionally, based on drainage, the following COPCs were: the expanded list of inductively coupled plasma metals, mercury, semivolatile organic compounds, pesticides, polychlorinated biphenyls, herbicides, total petroleum hydrocarbons, and alpha- and beta-emitting radionuclides. All confirmatory samples were analyzed in accordance with the 100 Area Remedial Action Sampling and Analysis Plan (SAP).

<tr>
<td>Burial Ground</td>
<td>The waste site has been remediated and Interim Closed Out. It consisted of a combination of two burial locations formerly called Minor Construction Burial Ground No. 2 and Solid Waste Burial Ground No. 2. The burial ground received radioactive equipment and other miscellaneous wastes from the 100-F Reactor operations. There were three unlined trenches and a pit present at the site. The trenches were oriented north-south and were typically 91 meters (300 feet) long by 6.1 meters (20 feet) wide. The site appeared as a cobble-covered, open field after remediation.</td>
</tr>
</tbody>
</table>

| Location          | The site was located approximately 300 meters (1000 feet) southwest of the 105-F Reactor Building. |

| Process Description | The 118-F-1 Burial Ground combined two locations formerly called Minor Construction Burial Ground No. 2 and Solid Waste Burial Ground No. 2. Solid waste from 105-F Reactor Building construction work was put into two holes in 1954 and covered with soil to grade in late 1955 or early 1956. Adjacent to this site, on the south side, a solid waste burial ground was opened in 1955 and extended on two subsequent occasions. Miscellaneous solid waste was buried in the 2 trenches, oriented north and south, and covered to grade with a minimum of 0.6 meters (2 feet) of soil. West of these trenches a number of pits containing irradiated process tubing and dummy elements were similarly covered. A third trench on the east side of the burial ground was used during July and August 1965, for burial of gun barrel tips, steel sleeves, and metal chips removed from the reactor. Filter boxes containing reactor graphite chips were also buried in the trench which was then backfilled to grade with 1.2 meters (4 feet) of soil cover. A pit near the west side of the site was used during the same period for burial of miscellaneous surface contaminated waste and was subsequently backfilled with approximately 1.8 meters (6 feet) of soil cover. The boundary of the burial ground had been marked with posts numbered F-65-1 through F-65-21. |

| Waste Type | Soil |
Waste Description: This site received radioactive reactor components and hardware (dummy elements, process tubing, etc) and other miscellaneous radioactive solid wastes. Potential contaminates include: Co-60, Sr-90, Pu-239/240.

Closure Info: Remedial action began on December 27, 2005. All remedial activities (excavation, sorting, and load-out) were completed by June 22, 2007. Wastes encountered in the 118-F-1 Burial Ground included reactor related waste including aluminum fuel spacers, splines, reactor hardware, equipment, piping, graphite dust, sheet metal, concrete, cardboard, wood timbers, other miscellaneous debris, and eight pieces of suspect spent nuclear fuel (SSNF).

The excavation area had a maximum depth of approximately 5.5 meters (18 feet), which included a shallow zone and a deep zone. Approximately 88,800 metric tons (97,900 U.S. tons) of waste and contaminated soil from the site was disposed at ERDF and approximately 13,400 bank cubic meters (BCMs) of soil (overburden/below contaminant level [BCL] stockpile material) was segregated for use as clean backfill material. At the conclusion of excavation activities, the elevation at the deepest part of the remedial excavation was 117 meters (384 feet) above sea level. The remediation excavation was approximately 11,600 square meters (125,000 square feet) in area with a maximum depth of approximately 5.5 meters (18 feet).

Code: 118-F-2  
Classification: Accepted  
Reclassification: Interim Closed Out (2/8/2008)

Names: 118-F-2; Burial Ground No. 2; Solid Waste Burial Ground No. 1

Type: Burial Ground  
Start Date: 1/1/1945  
End Date: 1/1/1965

Description: The waste site has been remediated and Interim Closed Out. It consisted of a solid waste burial ground that served as the original solid waste disposal site for the 100F Area. It was formerly called Solid Waste Burial Ground No. 1.

Location: The site was located approximately 450 meters (1,475 feet) west-southwest of the 105-F Reactor Building. Prior to remediation the burial ground boundary had been marked by posts numbered F-65-22 through F-65-37.

Process Description: Eight trenches contained miscellaneous solid waste from 105-F and one trench contained solid waste from the biology facilities. According to historical documentation, these trenches were covered to grade prior to 1956. The individual trenches were oriented north and south and were typically 76 meters (250 feet) long by 6.1 meters (20 feet) wide. Several cylindrical sleeves, measuring 5.5 meters (18 feet) long and 1.8 meters (6 feet) in diameter, were used for disposal of animal carcasses and liquid waste from 108-F, and were covered with approximately 1.8 meters (6 feet) of soil in 1955. GPR data from the northern portion of the site indicate considerable disturbed areas which precludes easy and accurate delineation of possible trenches. A 2002 Geophysical Investigation identified nine smaller caissons, measuring one meter (3 feet) in diameter, roughly at grade, on the northwest side of the burial ground. These caissons were located in a mound of soil, approximately 1.5 meters (5 feet) high, running north-south. Uncertainty existed whether these caissons could be the same as the cylindrical sleeves mentioned above because the sleeves measure 1.8 meters (6 feet) in diameter. Additionally, the co-ordinates for the sleeves from HW-33305 (Clukey 1954) places them 90 meters to the west of the caissons.

Waste Type: Water

Waste Description: The burial ground contains several long metal pipes with wooden lids used to dispose of contaminated animal carcasses.

Waste Type: Water
Waste Description: The site contains miscellaneous radioactive solid wastes, reactor components and hardware. Potential contaminants include: Co-60, Ni-63, Sr-90, Cs-137, Eu-152, Eu-154, U-238, Pu-238, Pu-239/240, chromium, lead, mercury.

Closure Info: Remedial action began on January 17, 2006, and was completed on August 8, 2007. Excavation of the site involved removing the uncontaminated overburden, the buried contaminated debris, and the underlying contaminated soil over an area approximately 14,197 square meters (152,815 square feet). Approximately 4,020 bank cubic meters (BCM) (5,260 bank cubic yards [BCY]) of uncontaminated overburden soil was removed and stockpiled near the excavation for subsequent use as backfill. Approximately 16,100 BCM (21,100 BCY) of waste, including contaminated soil and debris, was disposed at the Environmental Restoration Disposal Facility. At the conclusion of remediation activities, the elevation at the deepest part of the excavation was approximately 117.4 meters (385 feet) above mean sea level with a maximum depth of approximately 4.6 meters (15 feet) below original surrounding ground surface.

</table>
overburden material was excavated from the waste site and stockpiled for potential reuse as backfill.

The interim action ROD, based on a limited ecological risk assessment, established the soil cleanup levels. Although not required by the ROD, a screening comparison against ecological risk screening levels was made for the site COCs, as identified in the RDR/RAWP. The highest exceedance values were observed in the focused sample collected of the black surface ash located north of the site.

</tbody>
</table>

A stratified sampling design with focused sampling was implemented on October 16, 2004. One test pit and one test trench were excavated. The test pit was excavated to explore the area of the waste site described by WIDS and a linear anomaly identified through GPR believed to be a pipe. The test trench was excavated to explore three other areas identified through GPR as containing a high concentration of subsurface anomalous features near the waste site. At the southern end of the test trench three composite samples were collected from the bottom of the excavations, and one sample was collected from an area of ashy oil-stained surface soil. The results of the confirmation sampling were used to make reclassification decisions for the site in accordance with the TPA-MP-14 (DOE/RL 1998) process.

| Description: | The waste site has been remediated and Interim Closed Out. It consisted of a single, unlined trench that received radioactive sawdust from the floors of animal pens in the 100F
Experimental Animal Farm. The site appeared as a large raised mound. Prior to backfilling, the site consisted of several trenches oriented north and south.

**Location:**
The site was located approximately 305 meters (1000 feet) southeast of the 107-F Retention Basin outside the old perimeter road, and east of the 188-F Ash Disposal Area.

**Related Sites/Structures:**
The site was associated with the 100F Experimental Animal Farm.

**Process Description:**
According to the Technical Baseline Document, WHC-SD-EN-TI-169, past employees remember that sawdust from the Experimental Animal Farm was placed in boxes or 208-liter (55-gallon) metal drums before burial at this site. The material was transported to the sawdust pit in light trucks and the packaged waste was thrown into the pit by hand. A GPR survey conducted in January 2002, identified a large disturbed area but no evidence of buried containers (boxes or drums).

**Waste Type:**
Chemicals

**Waste Description:**
The site contains low-level activity sawdust and other solids from floors of dog kennels and swine pens. A facsimile sent from W. D. Richmond to M. R. Schneller on March 31, 1971 contains an estimate that the site had received 15 curies of strontium-90 and 0.3 curies of plutonium-239. The site was active and still receiving waste when the facsimile was sent. The facsimile is included in Appendix D of WHC-EP-0087.

**Closure Info:**
Remedial action of the 118-F-5 Burial Ground began on November 28, 2005, and was completed on August 29, 2007. Excavation of the site involved removing the uncontaminated overburden and the underlying contaminated soil. Sawdust was evident throughout the area excavated. There was no evidence of containers (i.e., boxes or metal drums) that reportedly been used for disposal of sawdust. A small area (given a field designation of 118-F-5A), northwest of the main 118-F-5 excavation, was also remediated. The area had been identified by the geophysics investigation as a disturbed zone distinct from the larger area. During remediation of this area, no evidence of sawdust or other buried waste was discovered.

Collectively, the sites had approximately 7,100 bank cubic meters (BCM) (9,287 bank cubic yards [BCY]) of uncontaminated overburden soil that would be reused as backfill. A total of approximately 25,500 BCM (33,354 BCY) of contaminated soil was excavated and disposed at the Environmental Restoration Disposal Facility. At the conclusion of remediation activities, the elevation at the deepest part of the excavation was approximately 119.5 meters (392 feet) above mean sea level with a maximum depth of approximately 5.5 meters (18 feet) below ground surface. The remediation excavation covered an area of approximately 7,392 square meters (79,535 square feet).

**Code:** 118-F-6  
**Classification:** Accepted

**Names:** 118-F-6; PNL Solid Waste Burial Ground  
**Reclassification:** Interim Closed Out (9/23/2008)

**Type:** Burial Ground  
**Start Date:** 1/1/1965

**Status:** Inactive  
**End Date:** 1/1/1973

**Description:** The waste site has been remediated and Interim Closed Out. It was an unlined burial ground that received animal and laboratory wastes related to the 100F Experimental Animal Farm. A 2002 Geophysical investigation of this burial ground identified six north south trending trenches. Prior to remediation the burial ground was designated by HPS-AC-5-40 concrete markers.

**Location:** The site was located southwest of the 105-F Reactor Building and adjoined the southern border of 118-F-1, Minor Construction Burial Ground No. 2, Burial Ground No. 1, Solid Waste Burial
Ground No. 2.

**Related Sites/Structures:** The site was associated with the 118-F-1, Minor Construction Burial Ground No. 2, Burial Ground No. 1, Solid Waste Burial Ground No. 2 and the 100F Experimental Animal Farm.

**Process Description:** The large buried railroad tank cars were used for incineration of animal tissue and carcasses. The carcasses were dropped through a manhole and lime was placed on them to facilitate decomposition. When a tank was full, 1,500 to 1,900 liters (400 to 500 gallons) of fuel oil were added to the tank and ignited. The residual ash was left in a tank after each incineration.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** This unit contains animal and laboratory wastes including plutonium-238 contaminated animal ash. The site did not receive reactor related waste.

**Closure Info:** Remedial action at the site began on December 12, 2005, and was completed on December 13, 2007. Remedial action activities involved removing the uncontaminated overburden, the buried contaminated debris, and the underlying contaminated soil. Wastes encountered in the 118-F-6 Burial Ground included a railroad tank car, laboratory equipment and bottles, cylinders and crushed drums, biological and animal wastes and carcasses, and limited reactor hardware. Some of these items contained small amounts of liquids. All liquid mixed waste was sent for off-site treatment and disposal.

Approximately 13,100 bank cubic meters (BCM) of material and contaminated soil was disposed at ERDF. Approximately 12,000 BCM of soil (overburden/layback stockpile material) was segregated for use as clean backfill material. At the conclusion of excavation activities the remediated area was approximately 7,075 square meters (76,155 square feet) with a maximum depth of approximately 6.5 meters (21 feet). The deepest part of the remedial excavation (trench 4) was at an elevation of 115.5 meters (379 feet) above sea level.

All areas identified by geophysical survey as potentially containing debris or waste were excavated. An area north of trench one showed subsurface disturbance in the geophysical survey, however, this portion of the burial ground did not contain waste or contamination. It is likely that it was excavated for the purpose of waste disposal but was never used.

<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The site was located just south of the 105-F Reactor Building south security fence, west of 116-F-10 and east of the rail line that connected to the 105-F Reactor Building.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>This site was an inactive solid waste storage vault used from 1945 to 1965 for temporary storage of slightly contaminated reactor parts that could be recovered and reused for the 100-F Area reactor operations. The storage vault was a partially buried, light-colored concrete box that extended approximately 46 centimeters (18 inches) above grade. The vault was approximately 23 meters squared (247.5 square feet) and 2.4 meters (8 feet) deep. It was covered with a wooden lid.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Waste Type:** Oil

**Waste Description:** This site served as temporary storage for miscellaneous reactor hardware. In 1965, contamination levels within the box were 200 to 300 counts-per-minute. There was some confusion in existing documentation as to whether equipment still remained in the vault. Table 11 of Miller and Wahlen (WHC-EP-0087) reported that 134,700 kilograms (148.3 tons) of lead of 5,600 kilograms (6.2 tons) of cadmium remains in the vault. Appendix A of the same report states that the vault contains only a small amount of radioactive material. DeFord (1993) reports that site personnel believe that the vault was empty.

**Closure Info:** The vault was a partially buried concrete box that extended 46 centimeters (18 inches) above grade and was covered with a wooden lid. Underground Radioactive Material signs had been posted on the wooden lid. Remedial action at the site began on January 31, 2006, with load out completed in April 2006. Excavation of the site involved removing the concrete vault structure, the wooden roof structure, and underlying contaminated soil. A single lead/cadmium reactor poison piece, measuring 15 centimeters (6 inches) in length and 3.8 centimeters (1.5 inches) in diameter, was discovered inside the vault during excavation.

At the conclusion of excavation activities, the elevation at the bottom of the excavation was 123 meters (403.5 feet). The excavation area was 138 square meters (1,487 square feet) with an approximate depth of 3.0 meters (9.8 feet). The total of an estimated 104 metric tons (115 U.S. tons) of material was disposed at ERDF.

**Code:** 120-F-1

**Names:** 120-F-1; Glass Dump

**Type:** Trench

**Status:** Inactive

**Classification:** Accepted

**Reclassification:** Interim Closed Out (6/27/2008)

**Start Date:**

**End Date:**

**Description:** The waste site has been remediated and Interim Closed Out. It consisted of two distinct disposal areas, one was a trench that ran east to west filled with fluorescent tubes, incandescent light bulbs, instrument vacuum tubes, small alkaline batteries, chemical bottles and laboratory apparatus. A second area of disturbed soil with plastic debris was located approximately 46 meters (150 feet) to the southeast.

**Location:** The site was located 275 meters (772 feet) south of 128-F-1, 100-F Burning Pit and south-southeast of the 105-F Reactor.

**Process Description:** The site was originally described as a single, open trench filled with fluorescent tubes, incandescent light bulbs, instrument vacuum tubes, small alkaline batteries, chemical bottles and laboratory apparatus. A second area of disturbed soil with plastic debris was located approximately 46 meters (150 feet) to the southeast. Due to its proximity, the probable source of the debris found at the 120-F-1 waste site is believed to be the 108-F Building, but the site may have contained debris from other locations within the 100-F Area.

**Waste Type:** Sanitary Sewage

**Waste Description:** The site is covered with approximately 0.61 meters (2 feet) of fluorescent tubes, incandescent light bulbs, instrument vacuum tubes, and small AAA, C, and D batteries. The site also contains an assortment of chemical bottles, both large and small.

**Closure Info:** Remedial action at the 120-F-1 waste site began in September 2007 and was completed in March 2008. Two distinct areas were excavated resulting in disposal of approximately 1,505 bank cubic meters of contaminated materials to the Environmental Restoration Disposal Facility.

On January 21, 2006, prior to remedial activities, an industrial hygiene investigation of the site...
was conducted to determine whether beryllium was present in the phosphor material used in the fluorescent tubes dumped at the 120-F-1 waste site. In preparation for remedial action at the site, a standard geophysical investigation was conducted in the vicinity of the glass dump. The second area of debris to the southeast proved to be larger than the glass dump. It contained concrete, wire debris, small drums with heavy oil-type petroleum hydrocarbons, and some stained soil with pesticides (dichlorodiphenyldichloroethylene [DDE] and dichlorodiphenyltrichloroethane [DDT]). The second area was remediated as part of the 120-F-1 Glass Dump Waste Site. When the previously interim-stabilized trench was opened using a front-end loader, it was discovered that the plywood barrier had failed and the fluorescent tubes were crushed. Pieces of the fluorescent tubes and accompanying soils were sampled.

Research indicated that prior to 1949 beryllium was used in the manufacture of fluorescent light bulbs, therefore, the samples were analyzed for metals, including mercury and beryllium. It was determined that the fluorescent tubes were not manufactured with beryllium and that beryllium would not be a health concern during remove, treat, and dispose (RTD). However, mercury and, to a much lesser extent, metals such as manganese, nickel, and cadmium were detected and determined to be possible airborne inhalation hazards.

</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The site was related to the 184-F Powerhouse.</td>
</tr>
<tr>
<td>Process Description:</td>
<td>The 126-F-1 site was created as a result of disposal of ash from the 184-F coal-fired steam plant that operated between 1944 and 1965. Large amounts of coal ash was sluiced to the ash pit with raw river water through a 20 centimeter (8 inch) ashcolite pipe. The ash pipeline originally terminated at a point between the aboveground reactor cooling water effluent lines that discharged to the 107-F Retention Basins. Leakage of reactor cooling water from the 107-F Retention Basins (116-F-14) flowed into the northern portion of the ash pit causing it to become radiologically contaminated. It was contained with an earthen dike. The coal ash sluice pipe was extended through the dike in the late 1940s to a point farther south, establishing coal ash discharge to the southern portion of the coal ash pit area.</td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Sanitary Sewage</td>
</tr>
<tr>
<td>Waste Description:</td>
<td>Unknown amounts of coal ash from the 184-F Powerhouse were sluiced to this unit with raw river water. The ash has been analyzed using the EP Toxicity Test in accordance with Washington Administrative Code (WAC 173-303), and no hazardous materials were found. This site also received low-level radionuclides from effluent system leakage. Radioactive contamination in excess of 50,000 counts/minute existed in the northwest corner of the pit.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Remedial action at the site began on October 5, 2001. Excavation of the site involved removing the overburden materials and underlying contaminated soil in the northern portion of the site</td>
</tr>
</tbody>
</table>
only. Based on field screening, overburden materials identified as potentially clean were placed in a stockpile for potential use as backfill.

The excavation of the northern portion of the site was completed on June 17, 2002, it measured approximately 10,689 square meters (115,052 square feet) in area with a maximum depth of approximately 4 meters (13 feet). The average bottom elevation of the excavation was 119.8 meters (393.0 feet). A total of approximately 100,964 metric tons (111,313 tons) of contaminated material was disposed at ERDF.

Portions of the Ash Pit were contaminated by unplanned releases of 105-F Reactor cooling water effluent. The northern portion of the site has been remediated and backfilled with clean soil to adjacent grade elevations. No remedial action was necessary in the southern portion of the 126-F-1 site, but this portion of the site could not be closed out until radioactive decay occurred from the original sampling date in 2001 to 2007 to meet the radiological dose limit of 15 milirem/year above natural background. The reclassification form was signed on 9/20/2007.

</tbody>
</table>

| Closure Info | Based on geophysical survey data and field observations, the site was stratified into two areas for focused sample collection at locations suspected of having the greatest potential for residual contamination. Results from the underlying soil would be used to represent residual contaminant concentrations for cleanup verification. The field activities included excavation of two test trenches in Area 1 and excavation of two test pits in Area 2. During the activities in each area, excavated material was observed for the presence of ash but none was identified. Screening instruments (NaI detector and OVM) were used to focus sample collection towards areas of elevated contamination. No samples were collected in Area 2, because no contamination or debris was observed during excavation activities. Samples collected from Area 1 consisted of 15 soil aliquots that were combined into a single composite for laboratory analysis. The remedial decision for the 128-F-1 site is supported based on reviews of site history, field observations, geophysical survey results, and characterization results. Maximum detected results from soil samples collected at locations suspected of having the greatest potential for residual contamination levels were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. |

</table>
Names: 128-F-3; PNL Burn Pit  
Reclassification: Interim Closed Out (10/20/2006)  
Type: Burn Pit  
Start Date:  
Status: Inactive  
End Date:  
Description: The waste site has been remediated and Interim Closed Out. The burn pit is believed to have received waste from the Experimental Animal Farm.  
Location: The site was located 25 meters (82 feet) south of the dirt access road that passed south of the 126-F-1 Ash Pit and approximately 70 meters (230 feet) west of the southeast corner of the ash pit.  
Waste Type: Misc. Trash and Debris  
Waste Description: It was not known what was burned at the site. However, Pacific Northwest Laboratory (PNL) and Westinghouse Hanford Company (WHC) employees verified that the site was used for burning. It was assumed the burned material came from the Experimental Animal Farm.  
Closure Info: A geophysical survey was performed in March 2003 and identified an anomalous area devoid of metallic debris. During confirmatory sampling and site evaluation in April 2003 to make a decision as to whether remedial action would be required at the site, two test trenches were excavated. Conclusive evidence of a burn pit could not be located. Additionally, significant matrix interference problems were encountered during analysis of coal ash samples. The surface had a thin layer of coal and coal ash mixed with fine sandy soil. Scraping the surface a few inches revealed black ash or coal dust. Nothing on the soil surface distinguished this site from other coal ash dumping sites found along the dirt road just south of the ash disposal pit. Remediation was performed on September 20, 2005. It consisted of the removal of coal ash and surrounding soil associated with excavation of the geophysical anomaly. The excavation was also performed to assure no residual debris or ash associated with historical burning was present at the site. During remediation, a limited amount of wood debris and ash associated with burning was found and removed. The excavation proceeded to a depth of approximately 1.1 meters (3.5 feet) within the site boundary. Approximately 690 metric tons (760 US tons) of coal ash, burn ash, debris, and soil was removed to Environmental Restoration Disposal Facility. The site has been evaluated and remediated in accordance with the Remaining Sites ROD and the RDR/RAWP. Statistical and judgmental sampling to verify the completeness of remediation was performed, and analytical results were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the verification sampling results support a reclassification to interim closed out.  
Code: 1607-F1  
Classification: Accepted  
Reclassification: Interim Closed Out (3/14/2008)  
Names: 1607-F1; 1607-F1 Sanitary Sewer System; 1607-F1 Septic Tank; 1607-F1 Septic Tank and Associated Drain Field; 100-F Experimental Animal Farm Septic Tank; 124-F-1  
Type: Septic Tank  
Start Date: 1/1/1944  
Status: Inactive  
End Date: 1/1/1965  
Description: The septic tank, drain field and associated have been remediated and Interim Closed Out. The septic tank was constructed of reinforced concrete. The walls and floor were 25 centimeters (10 inches) thick. The septic tank had a capacity of 16561.18 liters (4375 gallons). The system could support 125 persons assuming input of 130 liters (35 gallons) per capita per day and a one day retention period. The drain field was constructed of 10-centimeter (4-inch) vitrified...
pipe, concrete pipe, or drain tile with a total of 304.8 meters (1000 linear feet) of piping (2.4 linear meters [8 linear feet] per capita). The four laterals were open jointed, 38 meters (125 feet) long, and spaced 2.4 meters (8 feet) apart.

**Location:** The 1607-F1 Septic Tank was located south of the 105-F Reactor Building. The septic tank and drain field are approximately 91.4 meters (300 feet) west of the 1720-F Building.

**Related Sites/Structures:** The site was related to 100-F-26:8 Influent pipelines, 1701-F Badge House (security checkpoint), the 1709-F Fire Station, and the 1720-F Administrative Office and change room for security patrol personnel.

**Waste Type:** Chemicals

**Waste Description:** This unit received an unknown amount of sanitary sewage from the 1701-F Badge House (security checkpoint), the 1709-F Fire Station, and the 1720-F Administrative Office and change room for security patrol personnel. Since the site was connected to administrative and support facilities (security and fire protection), the site should not have received hazardous contaminants.

**Closure Info:** Confirmatory sampling was performed at the 1607-F1 septic tank waste site on October 7, 2004. Three sample locations were identified in the work instruction for this site. One sample was collected from soil under the septic tank. Two samples were collected from the septic drain field. No sample of tank contents was collected, as the inside of the tank was previously cleaned and backfilled. At the 1607-F1 septic tank site, contaminants in the drain field and in the soil beneath the septic tank were below the remedial action goals (RAGs).

Confirmatory sampling of the 100-F-26:8 waste site was conducted on January 5, 2005. Samples of the scale inside the pipe and the soil beneath the pipe were collected. A pipe matrix calculation was prepared using the analytical results of the pipe scale sample. An evaluation of the pipe matrix calculations showed that benzo(a)pyrene exceeded the direct exposure RAG. Concentrations of some polychlorinated biphenyl (PCB) congeners, pesticides, and semivolatile organic compounds (SVOCs) also exceeded the groundwater and river protection RAGs. These confirmatory sample results indicated that the 100-F-26:8 waste site required remedial action due to benzo(a)pyrene present at levels exceeding remedial action goals for direct exposure.

Remediation of the 1607-F1 and 100-F-26:8 waste sites were performed from January 8 to April 3, 2007. Remedial activities included removal of the septic tank and the associated piping. Both sites were excavated to approximately 3.4 meters (11 feet) below grade resulting in a combined volume of approximately 464 cubic meters (607 cubic yards) of material stockpiled for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 266 meters (872 feet) of pipeline were removed during remediation. During pipeline excavation, a french drain was discovered on the west side of the former 1709-F facility. Although this french drain was independent of the pipelines, it was removed.
100-HR-1

**Code:** 100-H-1  **Classification:** Accepted

**Names:** 100-H-1; Rod Cave  **Reclassification:** Interim Closed Out (3/26/2001)

**Type:** Storage  **Start Date:**

**Status:** Inactive  **End Date:**

**Description:** This site was a rod cave and has been remediated and closed out. Other rod caves, such as the 105-C Horizontal Control Rod Cave and the 100-K Area Horizontal Control Rod Caves, consisted of sections of metal culvert pipe on a concrete pad with an earthen mound. This rod cave was not as advanced a construction as other rod caves, but was similar in construction. End walls at other rod caves were formed of concrete, but the end walls at this site were made of lead bricks.

**Location:** The site is located inside the 105-H Exclusion Area west of the railroad tracks, approximately 23 meters (75 feet) southwest of the southwest corner of the 105-H Reactor building.

**Process Description:** The cave was used during the operation of the 105-H Reactor for temporary storage of irradiated reactor control rods as well as tools used in control rod removal and installation.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The site was contaminated from horizontal control rods and possibly other miscellaneous reactor facility components. The ends were constructed from lead bricks.

**Closure Info:** Remedial action at the 100-H-21 pipelines site began on October 19, 1999. Excavation of the site involved removing the overburden materials, pipelines (including miscellaneous small pipelines near the reactor building), the 100-H-1 rod cave structure, and underlying contaminated soil (100-H-22). Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. Approximately 2,500 lead bricks from the end walls of the rod cave were surveyed for radiological release to allow the lead to be recycled.

On July 21, 2000, the majority of the excavation was completed. Because of elevated lead levels in an area of the site excavation, additional soil was excavated in December 2000. The general average depth of the bottom of the excavation in the deep zone sampling areas was 5.6 meters (18.4 feet) below ground surface. The majority of the site excavation depth was 4.6 meters (15 feet) or less below ground surface, generally corresponding with the former pipeline invert depth. The excavation was approximately 17,629 square meters (189,660 square feet) in area. Approximately 32,725 metric tons (35,998 tons) of material from the site were disposed of at ERDF.

---

**100-HR-3**

**Code:** 100-H-3  **Classification:** Accepted

**Names:** 100-H-3; 1716-H Garage Fuel Tank Site  **Reclassification:** Interim Closed Out (6/1/2011)

**Type:** Storage Tank  **Start Date:** 1/1/1949

**Status:** Inactive  **End Date:**

**Description:** The site may contain one or more underground storage tanks (USTs) from the 1716-H Garage. The garage has been demolished. Some disturbance of the concrete pavement is visible at the site.

**Location:** The 1716-H Garage was located west of the 107-H Retention Basin (116-H-7) and north of the 1717-H Combined Shops.
Related Sites/Structures: The tanks supported the 1716-H Garage.

Closure Info: The 100-H-3 waste site was remediated between December 21 and 30, 2009. Approximately 894 bank cubic meters (1,170 bank cubic yards) of soil and debris were removed from the site and disposed at the Environmental Restoration Disposal Facility. Remediation included removal of the pump island as well as the fuel supply lines.

At the expected location of the tanks, the excavation continued until the approximate depth of 3.5 m (11.5 ft) was reached. The adjacent french drain and debris at the former tank location were also removed. No soil staining or anomalous hazardous debris was noted during excavation and loadout of material associated with the waste site.

<td>This waste site was remediated along with the 1717-H building. The french drain (FD13) was located northeast of the building footprint. It was excavated to a depth of approximately 4 meters (12 ft).</td>
</tr>
<tr>
<td>Location</td>
<td>The 1717-H Maintenance Shop was located west of the 107-H Basins and south of the 1716-H Service Station. The building has been demolished. An employee interview indicates a portion of the shop was used for working on very low-level radioactive materials. Drawing SK-1-7325 identifies two &quot;hot shops.&quot; Drawing SK-1-7328 proposed a building addition, also designated as a &quot;hot shop.&quot; Drawing P-9343 indicates an existing drywell.</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>This drain is also associated with waste site 100-H-49:3.</td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Asbestos (non-friable)</td>
</tr>
<tr>
<td>Waste Description:</td>
<td>Remedial action at the 100-H-4, 1717-H Hot Shop, French Drain, and Contaminated Storage Unit waste site was performed between January 4 and 18, 2010. The excavation resulted in approximately 3,148 bank cubic meters (4,117 bank cubic yards [BCY]) of contaminated soil. All material was direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). The footprint of the 1717-H Building, including the 1717-H Hot Shop and the foundation wall, was excavated to a depth of approximately 1 meter (3 ft) below ground surface. The excavation activities included remediation of former locations of decontamination tanks and exterior exhaust, as per approved excavation design. The french drain located northeast of the building footprint was excavated to a depth of approximately 4 meters (12 ft). A concrete floor trap with metal lid and insulation piece was uncovered and removed. All pieces including the drainpipe were excavated and loaded out in a void-space waste disposal can for grout filling at ERDF. The process sewer line and the sanitary sewer line were completely removed within the 1717-H Building footprint and excavation boundary. Other materials and debris such as concrete and asphalt were excavated and removed from the waste site.</td>
</tr>
</tbody>
</table>
Due to remediation exceeding the excavation design dimensions, two additional features were uncovered: a 6-in.-diameter cast iron (CI) pipeline running in the east-west direction to the northern side of the 1717-H footprint excavation and a Y-shaped concrete thrust block structure. These two features were left in place. Although not confirmed by historical drawings or historical aerial photographs, it is suspected that the 6 inch diameter cast iron pipeline is part of the 100-H-35, 100-H Clean Water Pipelines, 100-H Service Water Pipelines waste site. However, due to the lack of available historical information, this pipeline will be included with 100-H-56, H-Area Miscellaneous Pipelines. The Y-shaped thrust blocks do not encase any pipelines. These concrete thrust blocks do not appear on any historical drawings or historical aerial photographs.

<td>Description: This site has been remediated and Interim Closed Out. The trench was about 100 meters (328 feet) long, 16 meters (52 feet) wide, and 4.6 meters (15 feet) deep.</td>
<td></td>
</tr>
<tr>
<td>Location: According to the Technical Baseline Report, the location of the trench was not clear. Several employees were interviewed for information related to the location of this site. They identified several potential locations, including farther north, immediately adjacent to the 107-H Retention Basin or further south and east of the southeast corner of 107-H. (Note the references in the technical baseline report are inverted). In 1997, a Ground Penetrating Radar (GPR) scan was done to establish the location of the trench. The GPR scan placed the trench approximately 52 meters (170 feet) east of the southeast corner of the 116-H-7 Basin, in an area formerly used for orchards. (Washington State Plane Coordinates N152624.63 E578156.95; N152629.13 E578172.30; N152533.16 E578200.42; N152528.66 E578185.06.)</td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures: The 107-H Retention Basin (116-H-7) is related to this site.</td>
<td></td>
</tr>
<tr>
<td>Process Description: The site is a trench that received an unknown quantity of sludge removed from the 107-H Retention Basin during repair work in the Spring of 1953.</td>
<td></td>
</tr>
<tr>
<td>Waste Type: Barrels/Drums/Buckets/Cans</td>
<td>Waste Description: In 1975, samples of sludge from the basin floor had a maximum Geiger-Mueller (GM) probe reading of 20,000 counts/minute. Samples had an average concentration of 3.1E+04 picocuries/gram beta/gamma and 57 picocuries/gram of plutonium-239/240. The sludge buried in the trench would have similar characteristics.</td>
</tr>
<tr>
<td>Closure Info: The site was remediated to meet the cleanup standards and Interim Closed Out on December 12, 2000.</td>
<td></td>
</tr>
</tbody>
</table>

Remedial action at the 100-H-5 site began on September 27, 1999. Excavation of the site involved removing the overburden materials, buried sludge and debris, and underlying contaminated soil. Based on field screening overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at the Environmental Restoration Disposal Facility (ERDF). During site excavation, the area where buried sludge and debris were encountered at the south end of the site was not as wide as the estimated footprint of the sludge trench. To avoid unnecessarily excavating and disposing of uncontaminated soil, the excavation at the south end of the site narrowed from the original
estimated design site footprint. On April 28, 2000, the excavation was completed.

The elevation of the bottom of the excavation was at 121.4 meters (398.2 feet) upon completion. The surface reference elevation and design backfill elevation are 126.5 meters (415 feet). The excavation was approximately 3,308 square meters (35,589 square feet) in area with a maximum depth of approximately 5.1 meters (16.7 feet). Approximately 23,525 metric tons (25,877 tons) of material from the site were disposed of at ERDF.

The 100-H-5 site has been verified to be remediated in accordance with the ROD amendment.

---

**Code:** 100-H-7  
**Classification:** Accepted  
**Names:** 100-H-7; French Drain A  
**Reclassification:** Interim No Action (7/28/2009)  
**Type:** French Drain  
**Status:** Inactive  
**Start Date:**  
**End Date:**  
**Description:** The site has been evaluated and determined to require No Action. It consists of a french drain and an adjoining pipeline. It is a vertical, 76-centimeter (30-inch) diameter vitrified clay pipe with a metal lid. Its upper surface is at grade. A 6.3 centimeter (2.5 inch) steel pipe exits the reactor building at a point in line with the drain, suggesting the possibility of drainage from the 105-H Building to the drain. The drain had no markings.  
**Location:** The site was located south-southeast of the northeast corner of the 105-H reactor building.  
**Related Sites/Structures:** The drain was associated with the 105-H Reactor Building.  
**Waste Type:** Oil  
**Waste Description:**  
**Closure Info:** Prior to confirmatory sampling activities, it was not known if demolition and decommissioning of the 105-H Reactor Building also removed the 100-H-7 waste site. A geophysical survey was performed for the purpose of obtaining an excavation permit. The results did not detect the french drain, but did show the site to be an area of scattered buried debris and possible buried utilities. During confirmatory sampling activities, the french drain was found intact (minus the metal lid). The drain pipe from the 105-H building was also found in place, connected to the 100-H-7 french drain. No elevated volatile organic compounds or radiological readings were detected. The test pit excavation was approximately 3.7 meters (12 ft) deep.

---

**Code:** 100-H-8  
**Classification:** Accepted  
**Names:** 100-H-8; French Drain B  
**Reclassification:** Interim No Action (12/3/2009)  
**Type:** French Drain  
**Status:** Inactive  
**Start Date:**  
**End Date:**  
**Description:** The site has been evaluated and determined to require No Action. It consisted of as a 91-centimeter (36-inch) diameter concrete pipe with a steel lid. The drain was buried vertically with its upper surface at grade and was filled with gravel to within 20 centimeters (8 inches) of its top. Prior to site evaluation the drain was surrounded by a rope and posts and signs that read "Danger - Keep Out".  
**Location:** The unit is located east-southeast of the northeast corner of the 105-H Reactor Building.
During site evaluation, it was determined that this drain was designed and used to collect steam condensate from a former overhead steam line that serviced the emergency cooling water tower located on the northeast side of the 105-H Reactor Building. Sanitary river water was supplied to the 184-H power house, where it was converted to steam by the boiler and carried through aboveground steam lines to the 100-H Area facilities. Boiler water may have been treated with sodium sulfate, trisodium phosphate, and/or chromates.

**Process Description:**

Confirmatory sampling was performed in November 2008. Excavation of the site revealed the french drain was in place and largely intact. The metal lid was not in place. Inside the french drain were leach rocks that were stained red. There was no fine sediment inside the drain to sample. No elevated VOCs or radiological readings were detected on the french drain contents. Several pipes of various sizes were found during the excavation. None were intact or in service. Based on the location and size of the pipes they were determined to be either water or steam lines. No material was evident in the pipes to sample. No elevated VOCs or radiological readings were detected. The discovered pipes were left in the excavation when it was backfilled.

The vertical concrete pipe comprising the french drain was found to extend to a depth of approximately 3.7 meters (12-ft). Directly below the drain, red stained soil was visible extending to the bottom of the excavation. The red stain also extended horizontally in a thin layer around the sides of the excavation. The color of the stained soil beneath the french drain matched the stain on the rocks within the drain. A primary and duplicate sample was collected of the stained soil directly below the drain. The material present inside the drain consisted of only rock with no fine grained material and therefore was not amenable for sample collection.

**Code:** 100-H-9

**Classification:** Accepted

**Names:** 100-H-9; French Drain C

**Reclassification:** Interim Closed Out (6/22/2006)

**Type:** French Drain

**Start Date:**

**End Date:**

**Description:** The site has been remediated and Interim Closed Out along with 118-H-6:2 waste site. The waste site consisted of a vertical 61 centimeter (24 inch) diameter concrete pipe with a rusted metal lid. The drain had no markings.

**Location:** The unit was located east of the northeast corner of the 105-H Reactor Building, adjacent to the north wall.

**Related Sites/Structures:** This unit was associated with the 105-H Reactor Building (sitecode 118-H-6).

**Waste Type:** Equipment

**Waste Description:** Removal and disposal activities at the 105-H site (118-H-6:2, 118-H-6:3, 118-H-6:6 subsites) were completed in 2004. D&D activities, in preparation for the construction of the 105-H Reactor SSE, also resulted in the removal of 100-H-9, 100-H-10, 100-H-11, 100-H-12, 100-H-
13, 100-H-14 french drains and the 100-H-31 electrical transformer soil. All materials from the 105-H Reactor ISS Project were demolished and disposed at ERDF. The overburden piles produced during excavation were found to be contaminated. The overburden was deemed unsuitable for use as backfill of the site and was removed to ERDF.

The site was backfilled with clean soil aggregate from the 100-D Area Borrow Pit 21 and graded to match the surrounding terrain. This 105-H D&D activity generated approximately 4,863 bulk containers of low-level contaminated material that were shipped to ERDF, accounting for approximately 73,966 metric tons (81,365 tons).

Per the Sampling and Analysis Plan, the 105 H Reactor ancillary support areas and below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF). During the D&D activities, an additional evaluation was required to determine if the soils under the Fuel Storage Basin (FSB) floor (118-H-6:3) had achieved the RAGs. The evaluation of the FSB soils and deep zone side-slope soils (118-H-6:6) also evaluated the soils under the 100-H-11, 100-H-12, and 100-H-14 waste sites. Radiological surveys and verification sampling analysis were performed on the FSB underlying soils and deep zone side-slope soils. The data was used with the RESRAD computer model to verify that cleanup criteria were satisfied. Localized contamination was removed in preparation for clean demolition, and a fixative was applied as required. With one exception, no below-grade structures remaining. The exception is a portion of the FSB floor, at its northern end between the two access labyrinths to the D elevator. It was not removed with this activity.

Verification soil samples were collected from soils under the FSB floor. All demolition debris from excavations associated with the activity was sent to ERDF. Final cleanup verification samples for the FSB underlying soils and deep zone side-slope soils were collected following evaluation of field screening for radiological contaminants using global positioning environmental radiological surveyor (GPERS) and laser-assisted ranging and data system (LARADS) surveys. This field screening was performed in order to obtain an initial assessment of attainment of radiological cleanup levels.

The remaining soils at the 105-H Reactor site were either been deferred to the Field Remediation Closure Project or have been shown to meet the applicable RAGs through verification sampling, analysis, and RESRAD modeling. All excavated materials generated during the D activities were disposed at ERDF, and the area was backfilled to grade with clean backfill. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The three decontamination pads (118-H-6:5) and the Fuel Storage Basin shallow side-slope soils (118-H-6:4) were deferred to the Field Remediation Closure Project and remediated at a later date.

| Code: 100-H-10 | Classification: Accepted |
| Names: 100-H-10; French Drain D | Reclassification: Interim Closed Out (6/22/2006) |
| Type: French Drain | Start Date: |
| Status: Inactive | End Date: |
| Description: The site has been remediated and Interim Closed Out with 118-H-6:2. The unit consisted of a vertically buried 122-centimeter (48-inch) diameter vitrified clay pipe with a steel lid. It was suspected to be a french drain. The unit had no markings. |
Location: The unit was located north of the center point of the 105-H Reactor Building, adjacent to the north wall.

Related Sites/Structures: The drain was associated with the 105-H Reactor building (sitecode 118-H-6).

Waste Type: Equipment

Waste Description: Removal and disposal activities at the 105-H site (118-H-6:2, 118-H-6:3, 118-H-6:6 subsites) were completed in 2004. D&D activities, in preparation for the construction of the 105-H Reactor SSE, also resulted in the removal of 100-H-9, 100-H-10, 100-H-11, 100-H-12, 100-H-13, 100-H-14 french drains and the 100-H-31 electrical transformer soil. All materials from the 105-H Reactor ISS Project were demolished and disposed at ERDF. The overburden piles produced during excavation were found to be contaminated. The overburden was deemed unsuitable for use as backfill of the site and was removed to ERDF.

The site was backfilled with clean soil aggregate from the 100-D Area Borrow Pit 21 and graded to match the surrounding terrain. This 105-H D&D activity generated approximately 4,863 bulk containers of low-level contaminated material that were shipped to ERDF, accounting for approximately 73,966 metric tons (81,365 tons).

Per the Sampling and Analysis Plan, the 105 H Reactor ancillary support areas and below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF). During the D&D activities, an additional evaluation was required to determine if the soils under the Fuel Storage Basin (FSB) floor (118-H-6:3) had achieved the RAGs. The evaluation of the FSB soils and deep zone side-slope soils (118-H-6:6) also evaluated the soils under the 100-H-11, 100-H-12, and 100-H-14 waste sites. Radiological surveys and verification sampling analysis were performed on the FSB underlying soils and deep zone side-slope soils. The data was used with the RESRAD computer model to verify that cleanup criteria were satisfied. Localized contamination was removed in preparation for clean demolition, and a fixative was applied as required. With one exception, no below-grade structures remaining. The exception is a portion of the FSB floor, at its northern end between the two access labyrinths to the D elevator. It was not removed with this activity.

Verification soil samples were collected from soils under the FSB floor. All demolition debris from excavations associated with the activity was sent to ERDF. Final cleanup verification samples for the FSB underlying soils and deep zone side-slope soils were collected following evaluation of field screening for radiological contaminants using global positioning environmental radiological surveyor (GPERS) and laser-assisted ranging and data system (LARADS) surveys. This field screening was performed in order to obtain an initial assessment of attainment of radiological cleanup levels.

The remaining soils at the 105-H Reactor site were either been deferred to the Field Remediation Closure Project or have been shown to meet the applicable RAGs through verification sampling, analysis, and RESRAD modeling. All excavated materials generated during the D activities were disposed at ERDF, and the area was backfilled to grade with clean backfill. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The three decontamination pads (118-H-6:5) and the Fuel Storage Basin shallow side-slope soils (118-H-6:4) were deferred to the Field Remediation Closure Project and remediated at a
The site has been remediated and Interim Closed Out along with 118-H-6:3. The waste site was a french drain that had no markings.

Location: The unit was located next to the west wall of the south wing of the 105-H Reactor Building.

Related Sites/Structures: The site was associated with the 105-H Reactor Building (sitecode 118-H-6).

Process Description: This unit was a vertical 0.76 meters (30-inch) diameter steel manhole set in concrete that provided access to it. It appeared to be a french drain (drain) located at the bottom of a concrete expansion box in which a 1.52 meters (60-inch) steel effluent line made a 40-degree turn to the southwest. The 100-H-11 french drain provided drainage for any leakage that might have occurred from the effluent line within the expansion box.

Closure Info: Removal and disposal activities at the 105-H site (118-H-6:2, 118-H-6:3, 118-H-6:6 subsites) were completed in 2004. D&D activities, in preparation for the construction of the 105-H Reactor SSE, also resulted in the removal of 100-H-9, 100-H-10, 100-H-11, 100-H-12, 100-H-13, 100-H-14 french drains and the 100-H-31 electrical transformer soil. All materials from the 105-H Reactor ISS Project were demolished and disposed at ERDF. The overburden piles produced during excavation were found to be contaminated. The overburden was deemed unsuitable for use as backfill of the site and was removed to ERDF.

The site was backfilled with clean soil aggregate from the 100-D Area Borrow Pit 21 and graded to match the surrounding terrain. This 105-H D&D activity generated approximately 4,863 bulk containers of low-level contaminated material that were shipped to ERDF, accounting for approximately 73,966 metric tons (81,365 tons).

Per the Sampling and Analysis Plan, the 105 H Reactor ancillary support areas and below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF). During the D&D activities, an additional evaluation was required to determine if the soils under the Fuel Storage Basin (FSB) floor (118-H-6:3) had achieved the RAGs. The evaluation of the FSB soils and deep zone side-slope soils (118-H-6:6) also evaluated the soils under the 100-H-11, 100-H-12, and 100-H-14 waste sites. Radiological surveys and verification sampling analysis were performed on the FSB underlying soils and deep zone side-slope soils. The data was used with the RESRAD computer model to verify that cleanup criteria were satisfied. Localized contamination was removed in preparation for clean demolition, and a fixative was applied as required. With one exception, no below-grade structures remaining. The exception is a portion of the FSB floor, at its northern end between the two access labyrinths to the D elevator. It was not removed with this activity.

Verification soil samples were collected from soils under the FSB floor. All demolition debris from excavations associated with the activity was sent to ERDF. Final cleanup verification samples for the FSB underlying soils and deep zone side-slope soils were collected following evaluation of field screening for radiological contaminants using global positioning system (GPERS) and laser-assisted ranging and data system.
This field screening was performed in order to obtain an initial assessment of attainment of radiological cleanup levels.

The remaining soils at the 105-H Reactor site were either been deferred to the Field Remediation Closure Project or have been shown to meet the applicable RAGs through verification sampling, analysis, and RESRAD modeling. All excavated materials generated during the D activities were disposed at ERDF, and the area was backfilled to grade with clean backfill. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The three decontamination pads (118-H-6:5) and the Fuel Storage Basin shallow side-slope soils (118-H-6:4) were deferred to the Field Remediation Closure Project and remediated at a later date.

The three decontamination pads (118-H-6:5) and the Fuel Storage Basin shallow side-slope soils (118-H-6:4) were deferred to the Field Remediation Closure Project and remediated at a later date.
### Code: 100-H-14  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (6/22/2006)

### Names: 100-H-14; Surface Contamination Zone H

### Type: Unplanned Release

### Status: Inactive

### Description:
The site has been remediated and Interim Closed Out along with 118-H-6:3. The site consisted of an area of surface contamination located next to the south wall of the 105-H Reactor Building fuel storage basin (FSB). The area had been surface stabilized with 46 to 61 centimeters (18 to 24 inches) of gravel and cobbles.

### Location:
The site was located inside the exclusion area, on the southeast side of 105-H.

### Related Sites/Structures:
The site was associated with the 105-H Reactor Building (sitecode 118-H-6).

### Process Description:
Drawing P-1758 indicated the room behind the wooden door was a wash pad.

### Waste Type:
Equipment

### Waste Description:
No documentation has been found to identify the source of the contamination or describe the stabilization activity.

### Closure Info:
Removal and disposal activities at the 105-H site (118-H-6:2, 118-H-6:3, 118-H-6:6 subsites) were completed in 2004. D&D activities, in preparation for the construction of the 105-H Reactor SSE, also resulted in the removal of 100-H-9, 100-H-10, 100-H-11, 100-H-12, 100-H-13, 100-H-14 french drains and the 100-H-31 electrical transformer soil. Description: This site has been remediated and closed out.

Location: The site was located in a triangular area bounded by railroad tracks, south of the 116-H-2 Liquid Waste Disposal Trench.

Process Description: In 1953, the 116-H-2 (also known as 1608-H) Liquid Waste Disposal Trench overflowed and flooded the triangular area bounded by the railroad tracks.

Waste Type: Process Effluent

Waste Description: The technical baseline report lists 116-H-2 contaminants as including cobalt-60, cesium-134, cesium-137, europium-152, europium-154, europium-155, tritium, plutonium-239, plutonium-240, strontium-90, uranium-235, and uranium-238. Waste site COCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE-RL 1998). The COCs identified for this site in the CVP consist of plutonium-239/240, uranium-238, strontium-90, cesium-137, cobalt-60, europium-152, europium-154, and hexavalent chromium.

Closure Info: This area is located in an area that, prior to World War II and formation of the Hanford Site, was occupied by fruit tree orchards.

Remedial action at the 100-H-17 sites group (100-H-17, 100-H-30, 100-H-2 and 116-H-2) began on February 2, 2000. The sites were grouped together for remediation because of location and similar contaminants. Excavation of the area involved removing the overburden materials, miscellaneous debris, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. On February 10, 2000, the excavation was completed.

No evidence of buried waste was found during the excavation of the 100-H-2 site.

At the completion of the remedial action, the total excavation was approximately 6,240 square meters (67,170 square feet) in area with a maximum depth of approximately 2.6 meters (8.5 feet). Approximately 19,920 metric tons (21,960 tons) of material from the site were disposed.
This pipeline site has been remediated and was closed out in March 2001. The site was the underground 100-H Reactor cooling water effluent lines. It included the effluent lines that transported 105-H Reactor cooling water from the reactor to the 116-H-7 (107-H) Retention Basin, and from the basin to the 116-H-5 (1904-H) Outfall Structure and/or to the 116-H-1 Trench. This waste site included all associated expansion and valve boxes. It excluded the retention basin, outfall structure, and the effluent lines that are within the confines of the 105-H Reactor Building. It also excluded all reactor influent lines that are upstream of the reactor building. The site also included the pipeline(s) from the 1608-H Waste Water Pumphouse to 116-H-2 (1608-H Liquid Waste Disposal Trench).

Location: The site is the location of all underground reactor effluent lines running from the 105-H Reactor Building to the 1904-H Outfall Structure. This includes segments between the reactor building and the retention basin, and between the basin and the outfall structure. It excludes the reactor building, retention basin, and outfall structure, each of which is treated as a unique waste site. Also included are the underground lines that run from the retention basin to the 116-H-1 Trench (running on the west side of 116-H-7) and from the 1608-H Waste Water Pumphouse to the 116-H-2 Trench.

Process Description: Effluent water passed from the reactor rear face and flowed via gravity through the underground effluent lines, junction boxes and diversion boxes to the retention basins where it was held up for a short period of time to allow thermal and radiological cooling before being released through the outfall structure to the Columbia River. During periods of reactor fuel cladding ruptures, some effluent was diverted to an open trench.

Waste Type: Demolition and Inert Waste

Waste Description: The waste was contaminated steel piping, concrete, and soil. Reactor cooling water became radioactively contaminated as it passed through the reactor core. Activation products created in the water included calcium-41, chromium-51, and zinc-65. Activation products from the reactor core that were picked up and transported by the cooling water included tritium, carbon-14, cobalt-60, nickel-63, and europium-152/154/155. Fuel element fission products such as strontium-90, and cesium-137, as well as transuranics such as plutonium-239/240 were introduced into cooling water due to fuel cladding failures. Concentrations of radionuclides in cooling water during normal reactor operations were approximately 0.2 microcuries/liter. Concentrations of radionuclides built up in rust flakes and scale on the inner surfaces of the pipelines and in sludge in the diversion and junction boxes. Average beta-gamma concentrations for the effluent line scale and junction/diversion boxes were 83,000 and 120,000 picocuries/liter, respectively. Average plutonium-239/240 concentrations were 66 picocuries/gram for the effluent line scale and 720 picocuries/gram for the sludge at the bottom of the diversion and junction boxes. Direct readings of the bottom of the effluent lines averaged approximately 40,000 counts/minute with a Geiger-Mueller probe. Chemicals during water treatment included aluminum sulfate (alum), hydrated calcium oxide, sulfuric acid, chlorin, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine...
residual was approximately 0.2 milligrams/liter. The waste was any remaining process effluent and the contaminated pipelines.

**Closure Info:** Remedial action at the 100-H-21 pipelines site began on October 19, 1999. Excavation of the site involved removing the overburden materials, pipelines (including miscellaneous small pipelines near the reactor building), the 100-H-1 rod cave structure, and underlying contaminated soil (100-H-22). Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. Approximately 2,500 lead bricks from the end walls of the rod cave were surveyed for radiological release to allow the lead to be recycled.

On July 21, 2000, the majority of the excavation was completed. Because of elevated lead levels in an area of the site excavation, additional soil was excavated in December 2000. The general average depth of the bottom of the excavation in the deep zone sampling areas was 5.6 meters (18.4 feet) below ground surface. The majority of the site excavation depth was 4.6 meters (15 feet) or less below ground surface, generally corresponding with the former pipeline invert depth. The excavation was approximately 17,629 square meters (189,660 square feet) in area. Approximately 32,725 metric tons (35,998 tons) of material from the site were disposed of at ERDF.

### Classification: Accepted
### Reclassification: Interim Closed Out (3/19/2001)

#### Code: 100-H-22
#### Names: 100-H-22; Soil Contaminated by Effluent Line Leakage
#### Type: Unplanned Release
#### Status: Inactive
#### Start Date: 
#### End Date:

#### Description:
The release occurred from the reactor cooling effluent lines. Both the pipelines and the unplanned release to the soil have been remediated and cleaned up.

#### Location:
The 100-H-22 Effluent Pipeline Leakage site is associated with general underground leaks from the cooling water effluent pipelines.

#### Release Description:
Several sources indicate evidence of leaks in the underground 152-centimeter (60-inch) steel reactor cooling effluent lines. Dorian and Richards (UNI-946) indicates backhoe sampling was done in 1971. Excavated soil was less than detection levels with a Geiger-Mueller (GM) probe. UNI-946 documents 1975 characterization studies of the pipeline contents and borehole soil sample results for two holes drilled adjacent to the effluent lines.

#### Related Sites/Structures:
The 107-H Retention Basin, 105-H Reactor, and 100-H-21 Effluent Pipelines are related to this unplanned release.

#### Waste Type: Barrels/Drums/Buckets/Cans
#### Waste Description:
Contaminants at the 100-H Area included plutonium, strontium, europium, cobalt, cesium, uranium, nickel, hexavalent chromium, lead, and arsenic.

### Closure Info:
Remedial action at the 100-H-21 pipelines site began on October 19, 1999. Excavation of the site involved removing the overburden materials, pipelines (including miscellaneous small pipelines near the reactor building), the 100-H-1 rod cave structure, and underlying contaminated soil (100-H-22). Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. Approximately 2,500 lead bricks from the end walls of the rod cave were surveyed for radiological release to allow the lead to be recycled.

On July 21, 2000, the majority of the excavation was completed. Because of elevated lead
levels in an area of the site excavation, additional soil was excavated in December 2000. The

**Classification:** Accepted  
**Names:** 100-H-24; 100-H-24 Substation; 151-H Electrical Facilities; 151-H Substation  
**Reclassification:** Interim Closed Out (5/9/2001)  
**Type:** Electrical Substation  
**Start Date:** 1/1/1948  
**Status:** Inactive  
**End Date:** 1/1/1978  
**Description:** The site has been remediated and closed out. The waste site is the area surrounding the
demolished 151-H Substation. It included the 151-H Building and adjacent Switchyard. The
former switchyard area had a layer of crushed gravel with several remaining concrete structures
that had been used to support electrical equipment. Electrical conduit was observed protruding
up from under the ground near the concrete structures. Two manholes appeared to provide
access to the main electrical feeder cables that ran from the switchyard to the 151-H Building.
These features were removed during the remedial action excavation of the site.

In the area of the former 151-H Building, the southwest corner of the building appears to be
protruding through the ground surface and several pieces of rebar were visible to the north. An
area of subsidence was also visible near the former northeast corner of the building. An inactive
power pole structure exists off the northeast corner of the site. The railroad spur that serviced
the switchyard area has been removed. A former chain link fence, that has been cut off and
removed just above ground level, surrounds the site. Demolition debris, such as rebar and
broken concrete, was observed in the area of the former 151-H Building.

Note: In 1991 soil samples were located at oil stained sites, adjacent to existing concrete
transformer foundations. A site visit on 3/20/1996 observed that no oil spills or stains were
visible at the site.

**Location:** The 151-H Substation site was located approximately 200 meters (656 feet) west northwest of
the 105-H Reactor Building.

**Related Sites/Structures:** The site was related to 100-H Area electrical utilities.

**Process Description:** Two power transformers at the 151-H Substation provided 13.8 kV (rated at 31,250 kVA)
power to two distribution systems that serviced the 100-H Area from 1948 to about 1965.

**Waste Type:** Soil  
**Waste Description:** The site contains polychlorinated biphenyls (PCBs) contaminated soil. Seven samples were
taken from stained area around the transformer foundations. The sample results indicated the
presence of PCBs, however, the PCB levels were below Toxic Substance Control Act cleanup
levels.

**Waste Type:** Soil  
**Waste Description:** The 151-H Building was demolished in 1978. The demolition debris was placed in the
basement cavity and covered with earth.

**Closure Info:** Remedial actions began in November 1999 and were completed in December 2000. Excavation
of the site involved removing contaminated concrete, debris, and contaminated soil. Based on process knowledge and visual observation, the remaining portions (all below ground surface) of the 151-H Building concrete basement walls, foundation, and demolition debris did not require removal and were therefore left in place. The debris is from the demolition of the 151-H Building in 1978. Based on the history of operations at the H Area, the 151-H Building contained mechanical switchgear for control of electrical operations. Operational history, building demolition observations, and remedial action observations indicate that no hazardous materials were stored or used in the building and that there was no contamination associated with the building.

At completion the lowest elevation of the bottom of the excavation was at 121.9 meters (400 feet). The excavation was approximately 12,289.8 square meters (132,286.4 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 19,924 metric tons (21,268 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility (ERDF).

<tr>
<td>Status: Inactive</td>
<td></td>
</tr>
<tr>
<td>Description: The subsite has been evaluated and determined to require No Action. It consisted of a single 0.20 meter (8-in.) Ashcolite pipeline. It was used to sluice coal ash from the 184-H boiler house to the 126-H-1 ash pit. The total length of the pipeline was approximately 265 meters (870 ft), with an approximate depth of 1.5 meters (5 ft) below existing grade.</td>
<td></td>
</tr>
<tr>
<td>Location: This pipeline was located between the east side of the former 184-H boiler house and the east side of the 126-H-1 ash pit. The ash pit is located due west of the 184-H Power House. The subsite exits the former 184-H Power House on the east side, runs north for 56.8 meters (186.3 ft), turns west, runs approximately 192 meters (630 ft) into the ash pit.</td>
<td></td>
</tr>
<tr>
<td>Waste Type: Misc. Trash and Debris</td>
<td></td>
</tr>
<tr>
<td>Waste Description: The waste was ash that was transferred through the pipeline from the 184-H Power House to the 188-H Ash Pit.</td>
<td></td>
</tr>
<tr>
<td>Closure Info: During excavation, a 0.20 meter (8-in.) diameter, steel pipeline was encountered. It was broken at the end and filled with soil and gravel. Field observations of the end of the pipeline and the broken concrete slab determined the pipeline outfall had been demolished in place and backfilled. On September 24, 2008, at test pit 2, the excavator broke into the pipeline, no material was observed inside the pipeline. Therefore, no additional sampling was performed and the excavation was backfilled. To collect a soil sample, a decision was made to excavate below the concrete slab underlying the pipeline. Confirmatory sampling was performed on August 28, 2008, and September 24, 2008. A focused sampling design was selected for confirmatory sampling based on historical drawings, process knowledge, and other available information.</td>
<td></td>
</tr>
</tbody>
</table>
Due to the expected uniform distribution of residual material, no sampling location was preferred for collecting a focused sample within the pipeline. Therefore, a sample representative of pipeline contents was collected from a location selected based on access considerations at the outfall of the pipeline. The most appropriate focus location for characterization of potential impact to underlying soils was also selected at the outfall of the pipeline, as the pipeline terminus was a free discharge to soil.

**Names:** 100-H-28:6; 182-H Reservoir Sump Drains

**Reclassification:** Interim No Action (10/29/2009)

**Type:** Process Sewer

**Start Date:**

**Status:** Inactive

**End Date:**

**Description:** The subsite has been evaluated and determined to require No Action. The 100-H-28:6 subsite consists of approximately 190 meters (620 ft) of 20 cm (8-in.) vitrified clay pipeline north of the 182-H Reservoir. The pipeline was approximately 4.6 meters (15 ft) below ground surface.

**Location:** The 100-H-28:6 subsite runs from the north side of the 182 H Reservoir northeast to the upper river bank, approximately 1.8 meters (6 feet) down slope of the present embankment crest. The exact location of the pipeline was documented in drawings P-1215 and P-1216 (GE 1949a, 1953).

**Process Description:** The pipeline was installed during construction of the 182-H Reservoir. The water that traveled through the pipeline originated directly from the Columbia River via the 181-H Pump house, with the exception of steam condensate.

**Waste Type:** Sanitary Sewage

**Waste Description:** The waste was pipeline sediment/scale and underlying soil.

**Closure Info:** Confirmatory sampling was performed on September 2, 3, and 24, 2008. During test pit excavation and sampling, radiological field screening was performed as specified in the confirmatory sampling work instruction. No radiological contamination was detected above background levels. Field screening for the presence of volatile organic compounds (VOCs) was also negative. No anomalous media indicated by staining, evidence of burning, and/or debris were observed during test pit excavations. Samples were collected from the outfall in test pit 1 and a manhole structure and outlet pipe in test pit 2.

**Hanford Site Waste Management Units Report**

February 2015
Description: This subsite has been evaluated and determined to require No Action. It included the filtered/treated water supply lines originating at the 183-H Filter Plant, two 0.91-meters (36-inches) steel lines terminating at the 190-H building, a 0.76-meters (30-inches) line terminating at the 182-H Reservoir pumphouse, two 0.25-meters (10-inches) steel lines terminating at the 184-H Power House, and the former supply lines to the emergency cooling water high tanks at the 105-H Reactor Building.

Location: The 100-H-28:7 process water lines are part of the 100-HR-1 Operable Unit. These pipelines are located between the former 183-H Filter Plant Pump House, 184-H Boiler House, 190-H Pump House, the 187 Elevated Water Towers, and the 105-H Reactor. These pipelines are approximately 1.8 to 3 meters (6 to 10 ft) below existing grade.

Process Description: These pipelines were used to transfer treated water from the 183-H Filter Plant Pump House to the 182-H Reservoir Pumphouse, 184-H Boiler House, 190-H Pumphouse, and 105-H Reactor facilities (including the 187-H Emergency Cooling Water Tanks).

Waste Type: Sanitary Sewage

Waste Description: The waste would be any potentially contaminated soil and remaining pipeline components.

Closure Info: Confirmatory sampling of the 100-H-28:7 pipelines occurred over the period beginning September 3, 2008 and concluding on March 3, 2009. The pipelines were accessed and sampled via three test pits. Based on evaluation of the analytical results, it was determined that the 100-H-28:7 subsite does not require remedial action.

At Test Pit 1, two 25 centimeter (10 inch) diameter pipelines were excavated. Both of the 100-H-28:7 pipelines at test pit 1 contained a significant volume of water. Water within each pipe, as well as the soil underlying each pipe, were sampled on September 30 and October 1, 2008. The water contained slightly elevated concentrations of lead and manganese, but at levels which would allow this water to be used for dust suppression. With concurrence from the Washington State Department of Ecology, the water was removed from the pipeline and used for dust suppression. After the water was removed from the pipes, a second sampling of the pipe material at Test Pit 1 occurred on March 19, 2009. Limited scale material was available for collection. Therefore, scale from the north and south pipe sections was collected and combined into a single sample.

Test pit 2 excavation began September 3, 2008 and two pipes were located at approximately 2.1 to 2.4 meters (7 to 8 ft) below ground surface (bgs). The west pipe was 61 centimeters (24 in.) in diameter and the east pipe was 76 cm (30 in.) in diameter. The 61 centimeters (24 in.) diameter pipe was an unknown pipeline not related to the 100-H-28:7 pipelines and has since been included as part of 100-H-35, 100-H Service Water Pipelines. Scale inside the 100-H-28:7 pipe at test pit 2 and the underlying soil were sampled on October 13 and 15, 2008. Additionally, a sample of suspect Asbestos Containing Material from each pipe was sampled on October 1, 2008.

During excavation at Test Pit 3, on March 23, 2009, a french drain was discovered. Samples were taken both within and below the drain structure. The french drain was not related to the 100-H-28:7 pipelines and has since been included as part of the 100-H-49:1, 184-H Boiler House and 1717-H Hot Shop French Drains subsite. The 100-H-28:7 Test Pit 3 pipeline was also excavated and scale from inside the pipe and the soil underlying the pipe was sampled on March 23, 2009. The pipe contained no water and the scale inside had a similar appearance to that seen in the Test Pit 2 pipe.

The SubSite is Part Of: Hanford Site Waste Management Units Report
February 2015

<tr>
<td>Status</td>
<td>Inactive</td>
<td>End Date:</td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td>The subsite has been evaluated and determined to require No Action. The subsite consisted of four 0.61 meter (24-inch) diameter seamless welded steel pipelines located in two subsurface, reinforced concrete tunnels between the 190-H and 105-H facilities, as well as possible ancillary piping within the tunnels. The 100-H-28:8 pipelines were pressurized lines housed in subsurface tunnels, and have been completely removed by previous decommissioning and demolition activities.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location</td>
<td>These pipelines ran from the 190-H Pumphouse to the 105-H Reactor Building.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description</td>
<td>These pipelines were used during operations from 1949 to 1965 to provide final treated cooling water originating from the 190-H Pumphouse, limited to the residual portions of the 105-H Reactor Building supply lines within the reactor cooling water tunnels.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Closure Info</td>
<td>The 190-H Pumphouse was demolished in 1977. The tunnels between the 190-H footprint and the 105-H exclusion fence were excavated and collapsed in 1985. Piping in the tunnels north of the reactor exclusion fence was removed prior to demolition. No piping was observed south of the exclusion fence at the time of demolition activities. The remaining portions of the tunnels between the reactor block and the exclusion fence were excavated and removed during Interim Safe Storage (ISS) activities for the 105-H Reactor Building. Remaining portions of the tunnels and piping at the reactor block were sealed as part of ISS activities and will be addressed as part of closure of the reactor facilities (118-H-6 waste site). The cooling water tunnels were sloped downwards toward the 190-H Pumphouse; accordingly, any water entering the tunnel would accumulate at the pumphouse facility. There was no known record of any leaks occurring within the cooling water tunnels. Sampling of soils underlying the cooling water tunnels at the 105-C Reactor—where radioactive process water from the reactor back flowed into the tunnels—did not reveal any residual hexavalent chromium or uranium (the sole contaminants of potential concern) above remedial action goals.</td>

<td>The site has been remediated and Interim Closed Out. It was a sanitary sewer trench and feed pipeline.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location</td>
<td>The site was located south of the demolished 110-H Building and east of the 116-H-2 (1608-H) Crib.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Process Description: No additional information could be found concerning the site. However, the nearby 116-H-2 (1608-H) Crib is known to have overflowed. It is likely the overflow contaminated this septic trench with the same radionuclide and chemical contamination as the crib. This contributed to the confusion surrounding the 116-H-2 Crib's description and location in various documents.

Waste Type: Demolition and Inert Waste

Waste Description: The unit received unknown amounts of sanitary sewage from the 110-H Building.

Closure Info: This area is located in an area that, prior to World War II and formation of the Hanford Site, was occupied by fruit tree orchards.

Remedial action at the 100-H-17 sites group (100-H-17, 100-H-30, 100-H-2 and 116-H-2) began on February 2, 2000. The sites were grouped together for remediation because of location and similar contaminants. Excavation of the area involved removing the overburden materials, miscellaneous debris, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. On February 10, 2000, the excavation was completed.

No evidence of buried waste was found during the excavation of the 100-H-2 site.

At the completion of the remedial action, the total excavation was approximately 6,240 square meters (67,170 square feet) in area with a maximum depth of approximately 2.6 meters (8.5 feet). Approximately 19,920 metric tons (21,960 tons) of material from the site were disposed of at the ERDF.

Code: 100-H-31

Names: 100-H-31; Polychlorinated Biphenyl in Soil on North Side of 105-H Reactor Building

Type: Unplanned Release

Status: Inactive

Description: The site has been remediated and Interim Closed Out, along with 118-H-6:2 and 118-H-6:3. The site consisted of a surface gravel area near a former electrical substation. There were no visible oil stains or vegetation. The adjacent concrete pad had electrical conduit and wiring extending up to the surface where the electrical equipment was removed. The site was not marked or posted. The reactor exclusion fence was posted as Underground Radioactive Material, Danger, Restricted Area, Multiple Hazards, and No Entry Without Written Authorization.

Location: The site was located on the north side of the 105-H Reactor Building (inside the exclusion area fence) and off the southeast corner of a former electrical transformer pad. The site is 4 meters (11.2 feet) south of 100-H-10 French Drain site.
Release Description: Polychlorinated Biphenyls were detected in the soil.

Related Sites/Structures: The site is related to electrical transformers that were formerly located on the concrete pad near the site and the 105-H Reactor Building (sitecode 118-H-6).

Waste Type: Misc. Trash and Debris

Waste Description: The waste is polychlorinated biphenyl (PCB) contaminated soil.

Closure Info: Removal and disposal activities at the 105-H site (118-H-6:2, 118-H-6:3, 118-H-6:6 subsites) were completed in 2004. D&D activities, in preparation for the construction of the 105-H Reactor SSE, also resulted in the removal of 100-H-9, 100-H-10, 100-H-11, 100-H-12, 100-H-13, 100-H-14 French drains and the 100-H-31 electrical transformer soil. All materials from the 105-H Reactor ISS Project were demolished and disposed at ERDF. The overburden piles produced during excavation were found to be contaminated. The overburden was deemed unsuitable for use as backfill of the site and was removed to ERDF.

The site was backfilled with clean soil aggregate from the 100-D Area Borrow Pit 21 and graded to match the surrounding terrain. This 105-H D&D activity generated approximately 4,863 bulk containers of low-level contaminated material that were shipped to ERDF, accounting for approximately 73,966 metric tons (81,365 tons).

Per the Sampling and Analysis Plan, the 105 H Reactor ancillary support areas and below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF). During the D&D activities, an additional evaluation was required to determine if the soils under the Fuel Storage Basin (FSB) floor (118-H-6:3) had achieved the RAGs. The evaluation of the FSB soils and deep zone side-slope soils (118-H-6:6) also evaluated the soils under the 100-H-11, 100-H-12, and 100-H-14 waste sites. Radiological surveys and verification sampling analysis were performed on the FSB underlying soils and deep zone side-slope soils. The data was used with the RESRAD computer model to verify that cleanup criteria were satisfied. Localized contamination was removed in preparation for clean demolition, and a fixative was applied as required. With one exception, no below-grade structures remaining. The exception is a portion of the FSB floor, at its northern end between the two access labyrinths to the D elevator. It was not removed with this activity.

Verification soil samples were collected from soils under the FSB floor. All demolition debris from excavations associated with the activity was sent to ERDF. Final cleanup verification samples for the FSB underlying soils and deep zone side-slope soils were collected following evaluation of field screening for radiological contaminants using global positioning environmental radiological surveyor (GPERS) and laser-assisted ranging and data system (LARADS) surveys. This field screening was performed in order to obtain an initial assessment of attainment of radiological cleanup levels.

The remaining soils at the 105-H Reactor site were either been deferred to the Field Remediation Closure Project or have been shown to meet the applicable RAGs through verification sampling, analysis, and RESRAD modeling. All excavated materials generated during the D activities were disposed at ERDF, and the area was backfilled to grade with clean backfill. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The three decontamination pads (118-H-6:5) and the Fuel Storage Basin shallow side-slope soils (118-H-6:4) were deferred to the Field Remediation Closure Project and remediated at a
The 100-H-33 waste site has been evaluated and determined to require No Action. 100-H-33 was created to address the radionuclides associated with the former 183-H Solar Evaporation Basins (see sitecode 116-H-6 TSD). The basin had been used for solar evaporation of liquid wastes from the 300 area. The solar basins were remediated in 1985 and 1995. After remediation, the basins were completely demolished in the fall of 1996. The waste site was backfilled and re-vegetated in the spring of 1997. No radiological posting were associated with the backfilled basin.

The non-radiological, RCRA TSD component of the Solar Evaporation Basins (sitecode 116-H-6) was closed out on May 13, 1997, under a Modified Closure signed by Washington State Department of Ecology. The RCRA TSD closure did not address any radionuclide contaminants associated with the solar evaporation basins (gross alpha, gross beta, uranium-234, uranium-235, technetium-99, total uranium, and gamma energy analysis). Consequently, site 100-H-33 waste site was created to address the radionuclide component of the solar evaporation basins. Borehole C7860 (199-H4-84) was drilled in the waste site footprint in February 2011 as part of the Remedial Investigation. Strontium-90, Tc-99 and tritium were detected above background levels.

Location: The solar evaporation basins were located north of the 105-H Reactor and just north of the east 183-H Clearwell (WIDS Site 126-H-2).

Related Sites/Structures: Sitecode 116-H-6, the 183-H Solar Evaporation Basins, is the associated TSD component for this site.

Process Description: The basins were constructed in 1949 and used for 100-H Area water treatment until the mid-1960's. Beginning in July 1973, radioactive and dangerous (mixed) waste from the 300 Area fuel fabrication facilities was shipped to the basins for storage and treatment. Approximately 1.6E+06 kilograms (3.6E+06 pounds) of waste per year were treated by solar evaporation. The basins had an earthen berm around three sides and an asphalt-covered ramp on the north side to allow tanker truck unloading.

Waste Type: Sanitary Sewage

Waste Description: The facility received routine and nonroutine wastes. The routine wastes consisted of spent acid etch solutions (primarily nitric, sulfuric, hydrofluoric, and chromic acids) generated by the Nuclear Fuel Fabrication process. These acidic solutions were reacted with excess sodium hydroxide before being transported to the 183-H Basins. Metal constituents include copper, silicon, zirconium, nickel, aluminum, chromium, manganese, and uranium, which were in the form of precipitates. Nonroutine wastes consisted of unused chemicals and spent solutions from miscellaneous processes. Beginning in July 1973, radioactive and dangerous (mixed) waste from the 300 Area fuel fabrication facilities was shipped to the basins for storage and treatment. The waste has been designated an Extremely Hazardous Waste (EHW) because of toxicity, waste code (WT01). The basins also received various nonradioactive waste (listed discarded chemical products), resulting in designation for cyanide (P030), vanadium pentoxide (P120), and formic acid (U123). Additionally, Basin #2 was designated EP Toxic because of the presence of chromium (D007). More detailed descriptions of these wastes and quantities.
are contained in DOE/RL 88-04, Interim Status Closure/Post-Closure Plan 183-H Solar Evaporation Basins. Additional radionuclide contaminants of concern were identified in the Closure/Post Closure Plan.

**Closure Info:** This waste site was determined to be a No Action site on Waste Site Reclassification Form 2011-099.

The shallow zone samples from below the former (116-H-6) concrete basin floor and borehole samples from beneath each of the four basins indicate that the source of radiological contamination has been removed and only low concentrations of residual radionuclides are present in the deep vadose zone beneath the easternmost basin (Basin 1) at the 100-H-33 waste site.

As a part of the modified RCRA closure of the 116-H-6 waste site, four groundwater monitoring wells were drilled. Three wells were placed downgradient of the 183-H Basins in 1991 (199-H4-12C, 199-H4-12A, and 199-H4-3), and one was placed upgradient (199-H4-8). The 2010 results of the groundwater monitoring report show that technetium-99 and total uranium are present but are below the maximum contaminant level for each constituent. Borehole C7860 (199-H4-84) was drilled in the waste site footprint in February 2011 as part of the Remedial Investigation. Strontium-90, Tc-99 and tritium were detected above background levels.

The combination of borehole results and groundwater sampling indicate that source removal has occurred, and that residual radionuclide contamination warranting cleanup is not present in the deep vadose zone. Results of groundwater monitoring for technetium-99 and uranium show continued decline since monitoring was begun, indicating that residual contamination only remains in the groundwater and is slowly dissipating. Groundwater will continue to be monitored for uranium and technetium-99 in coordination with nonradionuclide monitoring performed by the U.S. Department of Energy as a part of the 183-H RCRA Postclosure Plan.

Ecology evaluated the data for this waste site against the WAC 173-340 (2007) cleanup levels for direct contact, groundwater protection and river protection. This evaluation is documented in the letter transmitting Ecology's approval of the waste site's interim reclassification to No Action on the WIDS Waste Site Reclassification form (2011-099).

---

**Code:**  100-H-34  
**Classification:**  Accepted  
**Names:**  100-H-34; 100H River Effluent Pipelines; 100H River Lines  
**Reclassification:**  None  
**Type:**  Radioactive Process Sewer  
**Start Date:**  
**Status:**  Inactive  
**End Date:**  
**Description:**  This site includes the river effluent pipelines (river lines) that extend from the outfall (116-H-5) into the main channel of the Columbia River. This site includes two 152 centimeter (60 inch) diameter (1.3 centimeter [0.5 inch] thick walls), steel river effluent pipelines that extend 229.5 meters (753 linear feet) from the face of 116-H-5 (the 1904 H outfall structure) into the main channel of the Columbia River.

**Location:**  The river lines are located in the Columbia River, adjacent to the 100H area. The lines extend east into the main channel of the river from the 1904-H outfall. The river effluent pipelines extend perpendicular from the discharge (river side) face of the 1904-H outfall structure for 20.3 meters (66.5 feet), then take a 19-degree downstream bend and continue on for another 209.2 meters (686.5 feet).
DOE/RL-88-30
Rev. 24

Related Sites/Structures: The site is associated with the 116-H-5 Outfall Structure, 100-H-36 Spillway (Flume), 116-H-7 Retention Basin and 184-H Power House. The site is associated with the 116-H-5 outfall structure, 116-H-7 (the 107-H Retention Basin), the lines (116-H-21) from the retention basin to the outfall structure, and 100-H-36 (the 1904-H spillway).

Process Description: The River Effluent pipelines discharged reactor coolant water to the river. Effluent was received from the 107-H Retention Basin and the area process sewer system to the outfall structure. In the event that the outfall line plugged, effluent would back up into the outfall structure and overflow into an underground concrete sluiceway (flume) that led to the river. Reactor (105-H) effluent cooling water was collected and temporarily stored in the 107-H Retention Basin. This cooling water, as well as process sewer wastes, were discharged to the river via the river effluent pipelines after passing through the 1904-H outfall structure. In the event the pipelines became plugged or were out of service for any reason, the discharge streams would overflow to an underground, emergency spillway (100-H-36), which was also routed to the river. The total drop from the face of the outfall structure to the discharge end of the pipeline is 8.5 meters (28 feet). The pipelines are separated by approximately 90 centimeters (35 inches) and are covered by a minimum of 1 meter (3 feet) of soil over their entire length, as well as large pieces of basalt riprap extending from the face of the outfall to the shoreline. The top portion of the outfall structure has been partially demolished, and backfilled with clean soil. It is not known what condition the outfall ends of the river effluent pipelines were left in following outfall demolition. During February and March 2005 visits to the site, it was noted that the bottom portion of the underground spillway (flume) (100-H-36) associated with the outfall structure is partially intact and visible. The total drop from the face of the outfall structure to the discharge end of the pipeline is 8.5 meters (28 feet). The pipelines are separated by approximately 90 centimeters (35 inches) and are covered by a minimum of 1 meter (3 feet) of soil over their entire length, as well as large pieces of basalt riprap extending from the face of the outfall to the shoreline. The top portion of the outfall structure has been partially demolished, and backfilled with clean soil. It is not known what condition the outfall ends of the river effluent pipelines were left in following outfall demolition. During February and March 2005 visits to the site, it was noted that the bottom portion of the underground spillway (flume) (100-H-36) associated with the outfall structure is partially intact and visible.

Waste Type: Demolition and Inert Waste

Waste Description: The waste includes the pipelines and the contaminated scale contained within them.

Contaminants of concern/potential concern are based on those for the outfall itself. Contaminants of potential concern include Co-60, Cs-137, Eu-152, -154, -155, Ni-63, Pu-238, -239/240, Am-241, C-14, H-3, Tc-99, Sr-90, U-234, -235, -238, Cr+6, Cr (total), Pb, and Hg.

Code: 100-H-35

Classification: Accepted

Reclassification: Interim No Action (2/28/2012)

Names: 100-H-35; 100-H Clean Water Pipelines; 100-H Service Water Pipelines

Type: Product Piping

Status: Unknown

Start Date:

End Date:

Description: Confirmatory sampling of the pipelines supported a No Action Reclassification. The 100-H-35 waste site consists of the underground service water pipelines upstream of the 105-H Reactor that carried water not treated with sodium dichromate. The service water pipelines are those that were used to transport raw water (RW), sanitary water (SW), and steam condensate (CW). The pipes generally ranged in size from 1.9 centimeters (0.75 in.) to 106.7 centimeters (42 in.) and were typically constructed of concrete, cast iron, or steel.

Pipelines excluded from this site include those within buildings, process and sewer pipes, pipes that carried water treated with sodium dichromate, and all lines that were downstream from the
reactor building, i.e., those lines that carried cooling water from the reactor to the retention basin, trench, and/or the river.

**Location:** The clean water (non-contaminated) underground pipelines were located across the 100-H Area, from the 181-H intake structure to the water treatment facilities, reactor (fire and potable water, not reactor cooling water), south to the fire and patrol headquarters near the 1607-H-3 Patrol Headquarters area, west to miscellaneous shops and warehouses, and the 184-H Coal Fired Powerhouse. The export water line entered the H Area from the 100 D/DR Area north of the coal storage area, it turned south along the road then east to the 182-H Reservoir. This line also continued further south and turned east where it entered the 105 H reactor on the north side.

**Related Sites/Structures:** The clean water and fire protection water pipelines ran to or near virtually all the facilities at the 100-H Area. The other pipeline sites at the 100-H Area are 100-H-21 (Reactor Cooling Water Effluent Underground Pipelines); 100-H-28 (Water Treatment Facilities Underground Pipelines); and 100-H-34, (River Effluent Pipeline).

**Process Description:** The site encompasses the clean water pipelines for the 100-H Area, including underground pipelines used to transport raw water from the river pumphouse to the water treatment facilities and to 100-H Area facilities and fire hydrants.

**Waste Type:** Oil

**Waste Description:** The waste is the old buried pipes from the clean water pipeline system.

**Closure Info:** Confirmatory sampling of the 100-H-35 waste site occurred primarily in September and October 2010 from test pits. A total of 11 test pits were excavated. Seven samples of underlying soil and four samples of pipeline contents (scale) were collected. Two locations that were sampled during a 2008 and 2010 were resampled in 2010. The confirmatory sampling results supported a reclassification of this site to No Action.

**Code:** 100-H-36

**Classification:** Accepted

**Reclassification:** None

**Names:** 100-H-36; 116-H-5 Spillway; 1904-H Spillway; 100-H-34:1 Flume (Spillway) for the 116-H-5 Outfall Structure

**Type:** Outfall

**Start Date:**

**Status:** Inactive

**End Date:**

**Location:** The site is located on the Columbia River shoreline north of the 116-H-7 Retention Basin. Assuming midline Washington State Plane coordinates, the underground spillway exits the south face of the 116-H-5 outfall. takes an immediate 45 degree turn in the upstream direction, and terminates.

**Related Sites/Structures:** The site is associated with the 100-H-34 River Effluent Pipelines and the 116-H-5 Outfall Structure.

**Process Description:** The spillway carried effluent overflow from the outfall (116-H-5) structure to the shoreline of the river for release. It was planned to be used only if the river effluent pipelines (100-H-34) were blocked, damaged, or undergoing maintenance. There is no corroborated physical or historical evidence that the spillway was ever used. The slope between the outfall and the river is covered with large basalt riprap boulders that have been mortared in place, extending about 73 meters (80 yards) north and south of 116-H-5. The exit end of the underground sluiceway has been covered with concrete rubble and is no longer visible. A shallow, dish-shaped...
concrete runoff pad extends across the beach from the spillway exit to the low water line.

**Waste Type:** Process Effluent  
**Waste Description:** Possible chemical and/or radionuclide contamination (see Contaminants of Potential Concern). The contaminants of potential concern are based on those for the 116-H-5 outfall, and include C-14, Cs-137, Sr-90, U-235, -238, and Pu-239/240.

<td>Interim Closed Out (3/15/2011)</td>
</tr>
</tbody>
</table>

**Names:** 100-H-41; Contaminated Area; Contaminated Vertical Pipe  
**Type:** Unplanned Release  
**Status:** Inactive  
**Description:** The waste site has been remediated and Interim Closed Out. The site consisted of soil inside a posted Contaminated Area (CA). Within the CA was a 35.6 centimeter (14 inch) diameter, vertical concrete structure. The posted area was as a flat, graded, gravel covered area with rabbit brush. Because the contamination was determined to be due to the presence of mud dauber nests, it was determined that the contamination should be identified as part of the 100-H-37 Mud Dauber Contamination Area waste site.

**Location:** The site was located 16.29 meters (53.44 feet) east of the 190-H building. It was also within the boundaries of the 100-H-28:2 sample area.

**Related Sites/Structures:** 100-H-41 is associated with other contaminated mud dauber nests found in 100-H-37 and 100-H-58. Associated structures include the 183-H and 190-H buildings. Associated WIDS sites include: 100-H-28, Water Treatment Facilities Underground Pipelines and 100-H-35, 100-H Service Water Pipelines, 100-H Clean Water Pipelines.

**Process Description:** The concrete structure inside the posted Contamination Area (CA) appeared to be associated with a filtered water line from the 183-H facility. The filter water line serviced the 190-H Building operations via a 60.96 centimeter (24 inch) cast iron pipe. The 35.6 centimeter (14 inch) diameter concrete structure may be related to the 100-H-28 Water Treatment Facilities Underground Pipelines. The basis for the radiological posting of the site as a CA was unknown. There was no process knowledge indicating radiological contamination would be present at the location. It is possible the radiological CA posting may have been associated with mud dauber contamination that was prevalent in the 100-H area (also see 100-H-37). Because process knowledge was inconclusive, WIDS information identified the site as an Unplanned Release.

**Closure Info:** Prior to performing the excavation, a radiological survey of the surface soil was performed with no radiological contamination detected above background. As the excavation proceeded, plastic sheeting was noted approximately 15 centimeter (6in.) below the ground surface, holding the soil above it from entering the pipe. The pipe was empty below the plastic to a depth of approximately 0.9 meter (3 ft). Mud dauber nests were found on the inside of the pipe. Field radiological surveys of the nests identified up to 450,000 disintegrations per minute beta-gamma contamination on the nests. Because the contamination was determined to be due to the presence of mud dauber nests, it was determined that the contamination was more appropriately identified as part of the 100-H-37 Mud Dauber Contamination Area waste site. Therefore, on November 12, 2009, the Field Remediation project excavated and removed the contaminated materials, including the pipe and soil, for disposal at the Environmental Restoration Disposal Facility as part of the ongoing 100-H-37 remediation effort.

Names: 100-H-42; 1906-H Drainage Lift Station

Reclassification: None

Type: Pump Station

Start Date:

Status: Inactive

End Date:

Description: The site consists of the following components:

- An underground reinforced concrete flume/reservoir filled with building rubble and clean soil. The concrete structure is in contact with underlying soil which may be contaminated from past leaks from the structure. There are no documented unplanned releases from this facility.
- A 183 cm (72 in) diameter, 37 m (121 ft) long, reinforced concrete pipeline exiting the east side of the underground structure and connecting to the 1904-H diversion box (outfall structure). The pipeline is in contact with underlying soil which may be contaminated from past leaks. There are no documented unplanned releases from this pipeline.
- A 15.2 cm (6 in) diameter, 67 m (220 ft) long, steel effluent sample line between the 1904-H outfall and the 1908-H effluent monitoring station. A 9.18 m (30.13 ft) section of this pipeline is drawn on drawing P-4407 with a different orientation than what is shown on drawing P-1220. Both versions of the pipe orientation are shown on the waste site drawing to ensure that it is not missed.
- A 20.3 cm (8 in) diameter, 94 m (308 ft) long, steel sample drain line from the 1908-H effluent monitoring station that empties into the 1904-H outfall. A 10.84 m (35.55 ft) section of this pipeline is drawn on drawing P-4407 with a different orientation than what is shown on drawing P-1220. Both versions of the pipe orientation were shown on the waste site drawing to ensure that it was not missed.

Location: The site is located in the 100-HR-1 Operable Unit and is approximately 75 m (246 ft) north of the 107-H retention basin. The approximate center of the remaining underground structure in Washington State Plane coordinates is E578058, N152819 (Washington State Plane coordinates).

Process Description: The 1906-H Drainage Lift Station was designed to receive process sewer discharges (primarily floor drains) from all of the non-radioactive buildings in H Area. The structure consisted of a rectangular-shaped reinforced concrete reservoir and by-pass flume, surmounted by a one-story concrete-block building over a portion of the reservoir section. The facility originally contained three 66,245 LPM (17,500 GPM) electric pumps, one 56,781 LPM (15,000 GPM) electric pump, and one 7,571 LPM (2,000 GPM) electric pump. A concrete dividing wall running the length of the structure separates the flume and reservoir sections. Two electrically operated gates controlled the flow into the structure, and flow between the bypass flume and the reservoir sections. A 15 cm (6 in) concrete slab cover supported the above grade building. This building contained the pump room, switch gear, and controls. A 183 cm (72 in) pipeline entered the facility on the west end of the flume, and exited the east end of the flume directly to the 1904-H Diversion Box (P-2091). Construction materials included 1,489 m3 (1,950 cubic yards) of concrete, 126 tonnes (139 tons) of reinforcing steel, 1.36 tonnes (1.5 tons) of structural steel, and 4,370 concrete blocks. In 1974 this above grade building was demolished into the reservoir and the site backfilled with clean soil (letter UNI-7231974). The entire below grade reservoir is made of 0.9 m (3 ft) thick reinforced concrete. The 1908-H Effluent Monitoring Station was used to sample and monitor cooling water process effluent which was being discharged to the river via the 1904-H Diversion Box. The 1904-H Diversion Box received process waste from the 107-H Retention Basin and the 1906-H Drainage Lift Station.

Waste Type: Sanitary Sewage
Waste Description: The waste associated with the 1906-H lift station includes piping and remaining equipment (pipeline and concrete reservoir), rubble and underlying soils associated. Potential contaminants of concern include sodium dichromate, total petroleum hydrocarbons (TPH), polychlorinated biphenyls (PCBs), sulfuric acid, lead, mercury, and paint solvents. The waste associated with the 1908-H Effluent Monitoring Station includes the piping and underlying soils associated. Potential contaminants of concern include Cs-137, Co-60, Eu-152, Eu-154, Eu-155, Ni-63, Pu-238, Pu-239/240, Sr-90, U-238, hexavalent chromium, total chromium, lead, mercury, paint solvents, sulfuric acid, TPH and PCBs.

|               | The center of the fuel island is E577972 N152683. |
|               | The center of the two northern french drains are (east and west respectively) E577989 N152709 and E577987 N152709. |
|               | The center of the southern french drain is E577997 N152673. |
| Related Sites/Structures: | The 100-H-3, 1716-H Garage Fuel Tanks were approximately 6.7 meters (22 feet) directly south of the building. Other associated structures include: 100-H-28, 100-H Water Treatment |
Facilities Underground Pipelines (See Subsites), and the 116-H-6, 183-H Solar Evaporation Basins.

Process Description: The 657 sq meter (7068 sq ft) maintenance garage was constructed between March and August 1949. The building was a one-story wood-frame structure with wood columns which supported the roof frame and trusses; the exterior concrete foundation walls extended four feet above the finished concrete floors of the building; and concrete footing pads carried the laminated columns which supported the high roof wood trusses (HW-24800-2). The building contained a repair shop, tire shop, battery room, compressor and oil storage room, mechanical equipment room, office, parts, toilet, locker, and lunch room.

The 1716-H Maintenance Garage was equipped as a service station, and for light maintenance and repair. At one point about half of the building was converted to shops for maintenance, calibration, and repair of electrical and electronic instruments (GEH-26434-100). Operations were discontinued at the 1716-H building when 105-H was deactivated in 1965 (BHI-00127). The building was dismantled prior to 1974. The footings and foundation were demolished, backfilled and the site was leveled in 1974 (letter UNI-7231974).

A past employee reported that he believes waste oil was commonly dumped on ground surface near auto shop as dust inhibitor (DC-0227).

Waste Type: Sanitary Sewage

Waste Description: Automobile wastes may include gasoline, diesel, motor oil, antifreeze, automatic transmission fluid, battery acid, engine and radiator flushes, brake fluid, engine and metal degreasers. Contaminants of potential concern include volatile organic compounds, semi-volatile organic compounds, sulfate, pH, lead, cadmium, mercury, chromium, hexavalent chromium, polychlorinated biphenyls, TPH-Gasoline Range, TPH-Diesel Range, and TPH-Oil Range.

Code: 100-H-44 Classification: Accepted
Name: 100-H-44; 183-H Neutralization Pit; H-016 Reclassification: None
Type: Process Unit/Plant Start Date:
Status: Inactive End Date:

Description: The site consists of the 183-H Neutralization Pit and its potentially contaminated soils, possibly a concrete structure (pit), acid brick and associated piping. There are no visible surface features that identifies the pit. The neutralization pit lies within the footprint of the 100-H-28 Process Sewer.

Location: The site is located in the 100-HR-1 Operable Unit. The Neutralization Pit was located 59 m (194 ft) west of the 183-H Head House (west of the railroad car spot) and 9 m (30 ft) north of the 183-H Flocculent Basin flume wall. The center coordinates are E577712.58, N152881.48.

Related Sites/Structures: The 183-H Neutralization Pit was associated with the 183-H Filter Plant, acid pipelines, railroad car spot and the North Process Sewer, which is located below and adjacent to the pit.

Process Description: The 183-H Filter Plant was designed to treat raw river water before it entered the 190-H building. Chemicals were added to the river water in the head house. The head house was used for the storage, preparation, and addition of alum, chlorine, and sulfuric acid for water treatment. Alum was used as a flocculating agent and sulfuric acid was used to control the acidity of the water. Chlorine was added to control algae. Concentrated sulfuric acid was received by railroad car and stored outside in horizontal storage tanks. Chemicals were delivered as bulk materials and unloaded from railroad cars by either bottom dumping or side unloading to conveyors. Concentrated sulfuric acid, received by railroad car, was stored outside in horizontal storage tanks. It was pumped from the storage tanks to the head tank through...
black iron pipelines. Pipelines used to transport lime slurry and acid solutions were encased in an underground concrete trench with a concrete cover. The interior surface of the trench was coated with AMERCO at #55 chemical resistance coating (H-1-5671). Along the length of the trench various pipelines made connection outside of the trench to above grade ancillary equipment including the acid pumps and the acid tanks. The concrete trench was sloped to allow drainage of liquids to the neutralization pit. The neutralization pit served as a structure to treat excess concentrated sulfuric acid (from acid tank cleanouts) prior to disposal through the north process sewer. In addition to receiving sulfuric acid the neutralization pit received lime slurry from the 183-H Head House. The building also contained rooms for chlorine storage, lavatories, janitor's room, electrical switchgear room, and a locker room (HW-74094). The neutralization pit served as a structure to treat excess concentrated sulfuric acid (from acid tank cleanouts) prior to disposal through the north process sewer. The Neutralization Pit received sulfuric acid from two storage tanks and one acid head tank, and lime slurry from the 183-H Head House. The surface elevation was 126.97 m (416.56 ft). In the center of the pit is a vertical orientated vitrified clay pipe (VCP) with a Vitrabond seal at approximately 0.9 m (3 ft) below grade surface (bgs). Vitrabond consists of a conventional glass ionomer, in conjunction with a light-curing resin and hydroxyethylmethacrylate. The pit was constructed on top of a concrete monolith and vertically drained with a 10.2 cm. (4 in) VCP into a 76.2 cm (30 in) reinforced concrete pipe (RCP) extra strength process sewer line (100-H-28:3 North Process Sewer). The process sewer pipe was at inverse elevation 123.52 m (405.26 ft). The pit drain line was perforated with the pit itself and within the drain line was a 2.54 cm (1 in) diameter (Hastelloy) rod which seated into a 7.62 cm. (3 in) diameter lead hemisphere. The lead hemisphere was seated in the floor of the pit in the acid proof brick layer. Hastelloy is a trademark for a series of high-strength, nickel based, corrosion resistant alloys produced by Haynes International (H-1-5671). Portions of the above described neutralization pit may remain. The piping included a sulfuric acid supply and drain lines, a lime slurry pipeline, sludge trap drains, filtered water and steam condensate drain lines. The pipelines were contained in a concrete trench extending from the Acid Head tank to the Neutralization Pit and then to the west wall of the 183-H Head House. Also included were short sections of pipelines connecting to ancillary equipment outside of the trench. Also included in the site are two french drains, a steam trap, and acid pump foundation. One 30.48 cm (12 in) french drain (E577728.89, N152882.85) was located adjacent to the covered car spot and was connected to a compressed air line. The second french drain (E577735.51, N152880.58) received steam condensate adjacent to the 183-H Head House Acid Facility Silica Tank. A steam trap was located between the silica tank and the 183-H Head House (E577732.5, N152876.2). The steam trap was the termination point for a silica tank condensate pipeline. Although the french drain and steam trap both supported the silica tank, the relationship of the two to each other is not known. The acid pump foundation (E 577721.0, N152883.2) held two pumps located to the north side of the trench. Portions of the foundation were below grade. Historical documentation does not indicate if the pumps were located above grade and were removed or are still within the below grade portion of the foundation. The foundation had a "Lead Fill" type cover measuring 1/16 of an inch thick.

Waste Type: Chemicals
Waste Description: The site received concentrated sulfuric acid which may have included lead and mercury. There may be contaminated equipment components, piping and soil that remain in place.

Description: The site has been evaluated and determined to require No Action. It was a suspect propane underground storage tank (UST) and associated below grade piping or features. It is unknown if the propane tank shown in the historical construction drawing (SK-1-7325) was ever installed.

Location: The suspect propane UST is located near the northeast corner of the 1717-H building. The tank's location is shown on SK-1-7325 at coordinates E578018, N152621.

Related Sites/Structures: The propane tank is associated with the 1717-H building and the 1717-H Hot Shop (sitecode 100-H-4).

Process Description: The 1717-H Building housed a machine shop, sheet metal shop, fabrication, shop, and carpenter shop that provided services for all of the 100 Area operations. The fabrication shop was outfitted for fabrication and repair of reactor system components, particularly those associated with water treatment and pumping systems. A portion of the 1717-H Building was also used as a hot shop, for work on very low-level radioactive materials.

Waste Type: Process Effluent

Waste Description: Potential contaminants include propane hydrocarbons in the soil.

Closure Info: Geophysical surveys did not identify any anomalies consistent with a buried tank. A test pit was excavated to a depth of 2.4 meters (8 ft). on November 10, 2009. Confirmatory sampling were collected from the test pit. No radiological contamination or organic vapors were observed.

<td>Description:</td>
<td>The waste site has been remediated and Interim Closed Out. It consisted of contaminated soils, concrete structures and drain pipes that were beneath 100-H Area sodium dichromate process equipment, piping, unloading dock and railroad spur. This site was within the footprint of the 190-H Pump house, which was demolished and removed to 1 meter (3 ft) below grade in 1977. The site was approximately the northern twenty percent of the facility with original elevation of 421.0 ft. The site consisted of several locations that existed along the northern and west sections of the 190-H building where sodium dichromate was handled, mixed and injected into the reactor process water system. There were 4 equipment pads which measured 3.04 meters (10 ft) by 1.34 meters (4.4 ft) by 0.61 meters (2 ft) high. There were 3 concrete trenches that formed a &quot;U&quot; shape which measured 7.66 meters (25.16 ft) by 10.56 meters (34.66 ft) by 1.52 meters (5 ft) depth. Each of the four process water storage tanks had concrete drain pits which measured overall 3.04 meters (10 ft) by 4.87 meters (16 ft) by 1.52 meters (5 ft) depth. A 15.24 cm (6 in) drain line which received fifteen percent sodium dichromate, in the form of overflow, exited the building towards the south process sewer at an elevation of 417.5 ft. There was a loading dock, which received the dry sodium dichromate, it was located adjacent to the railroad spur. And there was an elevator which was used to transport dry sodium dichromate to the upper floors.</td>

Process Description: The 190-H complex was a process water treatment plant which supplied the 105-H Reactor with nonradioactive cooling water. Sodium dichromate, in dry crystalline form, was added to filtered water as an anticorrosive agent. The fifteen percent sodium dichromate was injected into piping which fed to four 6,624 kL (1,750,000 gal) Process Water Storage Tanks within the 190-H facility. The sodium dichromate process consisted of a mixing tank, two feed tanks, two centrifugal pumps, eighteen proportioning pumps, piping, valves, and associated electrical and instrument equipment.

Bagged sodium dichromate was delivered to the 190-H building via railcar. An unloading dock, with adjacent elevator inside, was used to convey the material from the railcar to an upper level of the 190-H building (P-1315). The mixing and feed tanks each had a 3,236 L (855 gallon) capacity and were located on the second through fourth floors of the 190-H building (P-1315). There was one mixing tank located directly above the two feed tanks. At the top of the mixing tank were an agitator and a wooden cover with a bag hopper where the sodium dichromate was added. Water was added to the sodium dichromate and mixed to a fifteen percent concentration (HW-27270). A 7.62 cm (3 inch) diameter process pipe, with a three way valve for draining purposes, exited the base of the mixing tank to the feed tanks. Also, a 7.62 cm (3 inch) diameter overflow pipe exited near the top of the mixing tank and connected to the tank drain pipe. The 7.62 cm (3 inch) mixing tank pipe entered through the top of two sodium dichromate feed tanks located below the mixing tank. The feed tanks were 1.5 meter (5 ft) in diameter with a conical bottom. A 7.62 cm (3 in) diameter overflow pipe exited near the top of each tank. At the base of the feed tanks was a 3.8 cm (1 inch) diameter pipe that fed the liquid concentrate to four injection pump pads (P-1315). The sodium dichromate concentrate piping was located next to the north wall, elevated above the floor, and ran approximately the full length of the building servicing the four injection pump locations. The sodium dichromate liquid was added to the filtered water by injection pumps through chemical feed injection rings. The injection rings were located inline with 76 cm (30 inch) and 107 cm (42 inch) diameter pipes that entered the Process Water Storage Tanks through automatic control valves (P-1260, P-1874). The drain pipes from the mixing tank and the feed tanks entered a 15 cm (6 inch) drain pipe that fed to the process sewer system which exited north out of the building (P-1221).

Waste Type: Sanitary Sewage
Waste Description: The primary contaminate of concern is sodium dichromate. There may be buried debris, i.e., concrete, rebar, and piping below grade.
Closure Info: In November and December 2009, confirmatory samples were collected from Test Pits. The soil was analyzed for Hexavalent Chromium, ICP metals and mercury. In November and December 2009, confirmatory samples were collected from Test Pits. The soil was analyzed for Hexavalent Chromium, ICP metals and mercury. Remedial action at the 100-H-46 waste site began on February 5, 2013, and continued through July 16, 2013. Waste removed from the site included concrete and demolition debris, steel pipe, steel rebar, and chromium-contaminated soil. The original design included removal of material to a depth of approximately 3 meters (10 ft) bgs. However, green-stained concrete with concentrations of hexavalent chromium greater than RAGs was discovered in March 2013. The concrete originated from the western portion of the remediation. Several test pits were excavated with in-process samples collected as deep as 5.5 meters (18 ft) below the original surface grade. Due to the discovery of green-stained concrete and the test pit results, the remedial design was changed to allow removal of additional hexavalent chromium-contaminated material in the western portion of the former 190-H Building. Based on the remediation necessary to remove hexavalent chromium-contaminated soil at the 100-D-30, 185-D Sodium Dichromate Trench in the 190-D Complex, and at the 100-F-57, 190-F Process Water Pump House Debris waste sites, the updated 100-H-46 design conservatively allowed for remediation to the depth of groundwater in the area with hexavalent chromium-contamination.
Due to the increased remediation depth, additional overburden/layback material was removed and staged in a pile to the west of the remediation. The clean overburden pile contained approximately 62,000 bank cubic meters (BCM) (81,100 bank cubic yards [BCY]) of soil.

As remediation progressed, in-process samples were collected to measure hexavalent chromium and chromium (total) concentrations in 1.5 meters (5 ft) depth intervals. A sample collected May 16, 2013, from the southwestern corner of the excavation (J1RMF0) indicated hexavalent chromium concentrations in excess of RAGs extended past the design boundary. The remedial design was then expanded to allow additional removal of material in the southwest area of the excavation.

Remediation in the western portion of the waste site extended to the periodically rewetted zone (PRZ) at an elevation of approximately 117.0 meters (384 ft) above mean sea level (msl) (a depth of 12.5 meters [41 ft] bgs), effectively removing all of the vadose zone soil in this area. In-process sampling of the sidewalls surrounding the excavation floor in the PRZ indicated that the concentration of hexavalent chromium in the remaining soil was less than RAGs.

During the course of remediation, the portion of the 190-H Building foundation within the 100-H-46 WIDS boundary was totally removed. All 100-H-46 confirmatory sampling locations were removed. The only remaining portion of the 190-H Building foundation that remains lies outside of the 100-H-46 waste site boundary, along the southeast edge of the former building.

Approximately 61,300 BCM (80,200 BCY) of contaminated soil and debris was removed and staged at multiple staging pile areas (SPAs) pending loadout and disposal. The SPAs received waste beginning February 5, 2013. Waste loadout of 100-H-46 material with disposal at the Environmental Restoration Disposal Facility began on June 17, 2013, and was completed March 5, 2014. The SPAs were also used to receive waste from other 100-H remediation areas and were not included in the verification sampling of the 100-H-46 excavation and overburden. Verification sampling of the SPAs will be conducted with sampling of the other waste sites.

During remediation, a previously unidentified french drain was discovered at Washington State Plane (WSP) coordinates N152655/E577686. The base of the french drain extended to approximately 4.6 meters (15 ft) bgs. Red-stained soil and rock were present in the french drain and were sampled. The hexavalent chromium concentration in the sample (2.3 mg/kg), J1RMK3, slightly exceeded direct exposure and river protection RAGs. The french drain location was within the area of the site in which the vadose zone was removed during remedial action. No other anomalies were discovered.

| Description: The site has been remediated and Interim Closed Out. It consisted of potentially remaining fuel oil piping that was associated with two fuel oil underground storage tanks (UST's) that supported the 184-HA Boiler House Building. The two 45,651 liter (12,036 gallon) fuel oil tanks had been previously removed from the site in 1974. | |
| Location: The approximate location for the two fuel tanks was E577833, N152585. | |
| Related Sites/Structures: The piping is associated with the 184-HA boiler, the 190-HA Main Process Pump House Annex | |

Hanford Site Waste Management Units Report
February 2015
The 184-HA Boiler House Building and associated equipment was constructed in approximately 1965 to replace the 184-H boiler house that was being shutdown in conjunction with deactivation of the 100-H reactor (HW-82720). The reactor was shut down permanently in April of 1965. The boiler provided steam to the administration and Central Shops buildings, which consisted of 1703H, 1704H, 1716H, 1717H, 1719H, 1722H, 1760H, and 1761H.

Buildings 1703, 1760, and 1761 were on one supply line and the remaining buildings on another (HW-82720). These steam supply lines were all above grade features (H-1-14575). The 184-H building water/chemical equipment consisted of the following above grade features: (1) fuel oil fired package boiler, (1) brine tank, (2) water softener tanks, (1) chemical treatment tank w/pump, (1) de-aerator w/boiler feed pump.

Each tank had a 5.1 centimeter (2 inch) fuel oil supply (FOS) and fuel oil return (FOR) pipe line connected to it that comes from a pump pit on the south side of the building. The fuel oil piping, as it leaves the south end of the pump pit going to the tanks, is at 0.6 meters (2 feet) elevation (H-1-14579). The fuel oil piping consists of ASTM A-53 schedule 40 black steel covered with taping. This buried piping was required to have an exterior coat of coal tar enamel with bonded asbestos felt wrap, with the joints wrapped in coal tar tape (tapecoat). A U-shaped concrete trench in the floor of the 184-HA building contained fuel oil supply and return lines, a propane (PR) line (boiler pilot light connection - H-1-14579), the 5.1 centimeter (2 inch) influent sanitary water (SW), and (2) trench floor drains that connected to the 5.1 centimeter (2 inch) sanitary drain (SD) connected at the east end of the building drain field's (west of the building) 20.3 centimeter (8 inch) perforated concrete main line (H-1-14576 and H-1-14577). Steam line vent valves and a 1.9 centimeter (0.75 inch) soot blower drain valve also emptied effluent into the trench (H-1-14583).

Waste Type: Chemicals
Waste Description: Fuel oil potentially remains in the piping and the underlying soil.
Closure Info: Geophysical surveys were done in 2007. Confirmatory sampling was done from within Test Trenches in November 2009.

Remediation of the combined 100-H-48 and 100-H-52 waste sites was performed from July 25, 2013 through July 29, 2013 to a depth of approximately 4.6 meters (15 ft). A combined volume of approximately 1,576 bank cubic meters (BCM) (2,061 bank cubic yards [BCY]) of contaminated soil and debris was excavated and stockpiled for disposal at the Environmental Restoration Disposal Facility (ERDF). Debris waste included piping associated with the former underground fuel tanks and piping associated with the 100-H-52 drain field. Other concrete and steel debris was encountered at the former underground tank location. During remediation, field screening for VOCs was conducted and no elevated readings were detected. All waste material was stockpiled, prior to shipment and disposal at ERDF. All waste material from the 100-H-48 and 100-H-52 waste sites have yet to be loaded out to ERDF. The waste staging pile area will be sampled and closed out with a separate waste site at a later date.

**Description:** This site consists of sixteen french drains, the underlying soil of the potentially contaminated french drains, and their associated below grade piping components. The site has been divided into three subsites as follows:

100-H-49:1 is the 184-H Boiler House and 1717-H Hot Shop French Drains and the 105 H Reactor TP3 drain.
100-H-49:3 is the 183-H and 1717-H French Drains.

**Location:** Refer to the subsites for the detailed locations of each french drain.

**Process Description:** The french drains were discovered during the Orphan Site Evaluation (OSE) historical review. Each of the facilities that the french drains are associated with, were identified and the process or function of the buildings summarized. This information is incorporated into the list of french drains included in the site description for each of the subsites. Details of the inlet pipes sizes, depths of the french drains, and construction drawings are provided when available. Generally, french drains are a minimum of 4.6 meters (15 ft) from the edge of buildings. When exact locations were not available from construction drawings and these locations have been estimated by placing the location 4.6 meters (15 ft) away from building. In other cases, the piping to the french drains is a well defined location. Orphan sites field investigations were conducted on March 12th and 17th of 2008. Photographs of the present site conditions were obtained.

**Waste Type:** Process Effluent

**Waste Description:** The waste consists of the french drains, piping to the french drains, and potentially contaminated soil. The contaminants of potential concern will be evaluated during work planning and confirmatory sampling.

**This Site has the Following SubSites:**

**Code:** 100-H-49:1

**Names:** 100-H-49:1; 184-H Boiler House and 1717-H Hot Shop French Drains

**Code:** 100-H-49:2

**Names:** 100-H-49:2; 119-H, 181-H, 184-H and 183-H French Drains

**Code:** 100-H-49:3

**Names:** 100-H-49:3; 183-H and 1717-H French Drains

**Code:** 100-H-49:1

**Classification:** Accepted

**Reclassification:** None

**Type:** French Drain

**Status:** Inactive

**Start Date:**

**End Date:**

**Description:** This site consists of four french drains, the underlying soil of the potentially contaminated french drains, and their associated below grade piping components. The waste removed while remediating 100-H-49:1 french drains was placed in a combined waste staging pile area (SPA). This SPA will be addressed in the 100-H-43 work instruction and closure document. The drains included in this subsite are:

FD4 is a 0.9 meter (36 in) french drain with a 11 meter (36.1 ft) long, 0.1 meter (4 in)
condensate (CNDS) drain line from the 184-H Boiler House Reclaiming Hopper (P-1418) to the french drain. The pipeline enters the french drain 1.07 meter (3.5 ft) below grade. The 184-H building utilized steam from the boilers to heat the coal conveyor system and coal shack. It's unknown whether a non-contact form of steam heating was used. The resulting condensate was drained to 0.1 m (4 in) VCT piping 1.07 meter (3.5 ft.) below grade and was the inlet piping to the french drain. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil.

FD5 is a 0.6 meter (24 in) french drain with a 7.2 meters (24 ft) long, 0.1 meters (4 in) vitrified clay type (VCT) condensate (CNDS) drain line from the 184-H Boiler House Transfer House to the french drain. The pipeline enters the 1.9 meter (76 in) deep french drain at 1.07 meter (42 in) below grade. The 184-H building utilized steam from the boilers to heat the coal conveyor system and coal shack. It's unknown whether a non-contact form of steam heating was used. The resulting condensate was drained to 0.1 meter (4 in) VCT piping 1.07 meter (3.5 ft) below grade and was the inlet piping to the french drain. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil.

FD16 is a 0.9 meter (36 in) french drain with a 5.2 meter (17.1 ft) long, and a 11.0 m (36.1 ft) long pipeline; each is a 0.08 meter (3 in) diameter heating/steam return line from 1717-H Hot Shop (west side) to the french drain. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil.

The 100-H-28:7 french drain was added to subsite to 100-H-49:1. The french drain was discovered along the edge of a test pit that was excavated supporting confirmatory sampling for process water lines at the 183-H Filter Plant going to the 105-H Reactor (TP3) at coordinates E577853/N152563, The french drain is a 0.9 meter (36-in.) vitrified clay french drain at coordinates 577848 E/52567 N, on the northeast side of the 105-H Reactor.

**Location:**
The locations for each of the French Drains are listed below. Washington State Plane coordinates are provided for each french drain. The associated drawings were rectified to Washington State Plane coordinates to obtain the coordinates listed below.

FD4 - E577504.29/N153006.45
FD5 - E577553.28/N152996.60
FD16 - E577970.71/N152553.58
100-H-28:7 TP3 FD - E577848/N152567

**Process Description:**
The process description was inferred from the construction drawings and the function of the building that they were associated with. This information is provided for each of the french drains in the Site Description above.

**Waste Type:**
Water

**Waste Description:**
The waste is the french drain, piping to the french drain, and potentially contaminated soil.

**The SubSite is Part Of:**

**Code:** 100-H-49
**Names:** 100-H-49; Potentially Contaminated French Drains

**Code:** 100-H-49:2
**Names:** 100-H-49:2; 119-H, 181-H, 184-H and 183-H French Drains

**Type:** French Drain
**Classification:** Accepted
**Reclassification:** Interim No Action (10/26/2011)
**Start Date:**
Inactive

The subsite was evaluated and determined to require No Action. It consists of nine french drains, the underlying soil of the potentially contaminated french drains, and their associated below grade piping components. The drains include:

FD1 was a dry well that was associated with the 119-H Sample Building. A 5.1 cm (2 in) cast iron pipeline ran from the 119-H Sample Building to the dry well. During the Orphan Site's Walkdown the dry well could not be proven to exist or not exist from the view point outside the fence of the contamination area for the 105-H Reactor. No documents or records were obtained during historical research to indicate the end state of the dry well or underlying soil. Analogous sites include 100-D-24 and 100-F-46. (See orphan site photo # 031708-976).

FD2 was a 0.6 meter (24 in) french drain with a 4.5 meters (14.8 ft) long, 0.1 meters (4 in) cast iron soil line from the 181-H Battery Room to the french drain. During the Orphan Site's Walkdown, there was no evidence of a recent disturbance or french drain existing within a 5 meters (16.4 ft) diameter area. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo #03172008-973).

FD3 was a 1 meter (36 in) french drain with a 4.7 meters (15.4 in) long, 0.1 m (4 in) vitrified clay type (VCT) condensate (CNDS) drain line. The french drain is 1.9 meter (76 in) deep with the inlet pipeline at 1.1 meter (42 in) below grade. The pipeline comes from the 184-H Boiler House Coal Shack Track Hopper. The 184-H building utilized steam from the boilers to heat the coal conveyor system and coal shack. It is unknown whether a non-contact form of steam heating was used. The resulting condensate was drained via 0.1 m (4 in) VCT piping 1.07 m (3.5 ft.) below grade and was the inlet piping to the french drain. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo #03172008-974).

FD6 was a 1 meter (36 in) french drain with a 8.7 meter (28.5 ft) long, 0.1 m (4 in) diameter vitrified clay type (VCT) condensate (CNDS) drain line from the 184-H Coal Crusher House to the french drain. The pipeline enters the 1.9 m (76 in) deep french drain at 1.04 meter (42 in) below grade. The 184-H building utilized steam from the boilers to heat the coal conveyor system and coal shack. It's unknown whether a non-contact form of steam heating was used. The resulting condensate was drained to a 0.1 m (4 in) VCT pipe 1.07 m (3.5 ft.) below grade and was the inlet piping to the french drain. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil.

FD7 was a 0.6 meter (24 in) french drain with two pipe segments that are 0.1 meter (4 in) diameter vitrified clay type (VCT) condensate (CNDS) drain lines from the 184-H Coal Transfer Tower to the french drain. The pipeline enters the 1.9 meter (76 in) deep french drain at 1.07 meter (42 in) below grade. The french drain had a total below grade depth of 1.92 meter (76 in) with two 10.2 cm (4 in) diameter VCT inlet pipes 1.07 meter (42 in) below grade and located 4.5 m (15 ft) east from the transfer house and conveyor system. The piping appears to be condensate from a 15.25 cm (6 in) above grade steam main. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil.

FD8 was a 1 meter (36 in) french drain with a 5.9 meter (19.4 ft) long, 0.1 m (4 in) vitrified clay type (VCT) line. The inverse elevation at the french drain is 125.9 meters (413 ft). The pipeline runs from the 184-H Boiler House Battery Room floor drain to the french drain. There is a second inlet from an unknown source. No documents or records were obtained during
historical research to indicate the end state of the french drain or underlying soil. The location is estimated. (P-1413, P-1417).

FD9 is a 1 meter (36 in) french drain with a 5.6 meter (18.4 ft) long segment, a 6.6 meter (21.7 ft) long segment, and a 2.4 meter (7.9 ft) long segment of pipe; all are 10.16 cm (4 in) vitrified clay type (VCT) line. The french drain is 1.9 meter (76 in) deep with the line inlet at --1.04 m (42 in) below grade (P-1417). The line runs from the 184-H Boiler House laboratory and radiator heating system to the french drain. There is a second inlet pipe at the french drain from an unknown source. No documents or records were attained/obtained during historical research to indicate the end state of the french drain or underlying soil.

FD12 is a 1 meter (36 in) french drain with a 9.7 meter (37.8 ft) long, 0.1 m (4 in) diameter vitrified clay pipeline from the 1719-H First Aid Building (Laboratory Waste) to the french drain. (P-1235) No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil.

FD14 is a 0.9 meter (36 in) french drain with a 5.3 meter (17.4 ft) long, 0.08 m (3 in) diameter cast iron (CI) pipeline from 1717-H (northwest side) pipe shop radiator heater to the french drain (P-1436). The pipeline is 1.07 meters (3.5 ft) below grade. (P-1436) No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil.

Location: The locations for each of the French Drains are listed below. Washington State Plane coordinates are provided for each french drain. The associated drawings were rectified to Washington State Plane coordinates to obtain the coordinates listed below. Order is maintained with the listing in the site description.

FD1 - E577726.55, N152492.97
FD2 - E577523.25, N153473.24
FD3 - E577454.99, N153009.28
FD6 - E577503.89, N152994.26
FD7 - E577555.38, N152956.89
FD8 - E577537.92, N152954.51
FD9 - E577556.16, N152942.17
FD12 - E577927.32, N152676.63 (No french drain exists)
FD14 - E577970.58, N152592.89 (No french drain exists)

Process Description: The process description was inferred from the construction drawings and the function of the building that they were associated with. This information is provided for each of the french drains in the Site Description.

Waste Type: Sanitary Sewage

Waste Description: The waste consists of the french drain, piping to the french drain, and potentially contaminated soil. COPCs ICP metals, mercury, hexavalent chromium, polyaromatic hydrocarbons, polychlorinated biphenyls and total petroleum hydrocarbons.

Closure Info: Confirmatory sampling showed the site that did not need remediation.

The SubSite is Part Of:

Code: 100-H-49
Names: 100-H-49; Potentially Contaminated French Drains
The original waste site description indicated it consisted of four french drains, the underlying soil of the potentially contaminated french drains, and their associated below grade piping components. Based on historical research, field investigation and confirmatory sampling (performed in 2010), it was concluded that these four french drains were either previously remediated, removed or never constructed. The french drains were identified during the orphan sites evaluation historical review, conducted on March 12 and 17, 2008, and documented in the 100-H Area Orphan Sites Evaluation Report.

The drains considered include:

FD10 - a 0.46 meter (18 in) Drywell with a 45.5 meter (149.3 in) long, 0.1 (4 in) diameter cast iron (CI) pipe to the french drain. The pipeline ran from the 183-H Post Filter Building to the french drain. The site received drainage from the battery, electrical, pump house and chlorine room. The inverse elevation at the french drain is 124.4 meters (408.11 ft). The location is estimated. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (P-1221, P-4302, P-4305) (See orphan site photo # 03122008-957).

FD11 - a 0.9 meter (36 in) french drain with a 17.9 meter (58.7 ft) long, 0.1 m (4 in) diameter pipeline from 183-H (post filter) to the french drain. The site received drainage from the battery, electrical, pump house and chlorine room. The inverse elevation at the french drain is 124.4 m (408.11 ft). The location is estimated. (P-1221, P4302, P-4305) No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-958).

FD13 - a 8.0 meter (26.2 ft) long cast iron, 0.08 meter (3 in) diameter pipeline that ran from the 1717-H machine/welding shop typical heaters to a 0.76 m (30 in) french drain (remediated with waste site 100-H-4). No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil (P-1436) (See orphan site photo # 03122008-967).

FD15 - a 0.76 meter (30 in) french drain with a 7.8 m (25.6 ft) long, 0.08 (3 in) diameter cast iron (CI) pipeline that ran from 1717-H (east side) Electrical Shop and Mechanical Equipment room heaters to the french drain (P-1436). No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-968).

The locations for each of the French Drains are listed below. Washington State Plane coordinates are provided for each french drain. The associated drawings were rectified to Washington State Plane coordinates to obtain the coordinates listed below.

FD10 - E577782.08, N152761.73 (No french drain exists)
FD11 - E577778.37, N152752.41 (The location is estimated.)
FD13 - E578009.56, N152598.17 (see sitecode 100-H-4; The location is estimated.)
FD15 - E578009.69, N152570.62 (The location is estimated)

The french drains (and drywells) are related to 183-H and 1717-H and waste site 100-H-4.
Process Description: The process description was inferred from the construction drawings and the function of the associated building.

Waste Type: Asbestos (non-friable)

Waste Description: The waste is the french drain, piping to the french drain, and potentially contaminated soil.

Closure Info: French drain FD 10 and FD 15 test pit locations were excavated up to 0.6 meters (2 ft) below ground surface, attempting to locate the french drains. At FD 15 excavation, a utility encased in concrete was observed approximately 2 feet below ground surface, under asphalt, trending west-east direction. No french drains were observe. Additional scraping was performed to widen the bottom of the 0.6 meter (2 ft) test pit to a 6.1-meter (20 ft) diameter test pit. No french drains or any drain components were found at these locations. Based on the test pit observations and the nature of the soils (i.e., lack of rubble/debris, original asphalted location), it was determined that french drains were not constructed at these locations. The test pit excavation at FD 11 was not performed due to safety concerns of above ground interferences. A pump and treat water and power line is located next to this test pit location, making it impossible to safely excavate without impacting the power line and the associated water lines. Because both the FD 10 and FD 11 french drain locations were inferred from the construction drawing therefore estimating coordinates and the FD 10 was not found during the test pit excavation, it was determined that FD 11 is also unlikely to be present at its suggested location.

Fragments of drain piping, associated with the FD 13 french drain were remediated and disposed during the 100-H-4, 1717-H Hot Shop, French Drain, and Contaminated Storage Unit waste site excavation. The 100-H-4 waste site was reclassified as Interim Closed Out in June 2011.

The SubSite is Part Of:

Code: 100-H-49
Names: 100-H-49; Potentially Contaminated French Drains

Code: 100-H-50
Names: 100-H-50; 100-H Steam Condensate French Drains
Classification: Accepted
Reclassification: Interim No Action (6/16/2011)
Start Date: End Date:
Type: French Drain
Status: Inactive
Description: The site was evaluated and determined to require No Action. It consists of fourteen discrete locations, underlying soil and their associated below grade piping components for steam condensate French Drains. The French drains were discovered during the Orphan Site Evaluation (OSE) historical review. Each of the facilities that the French drains are associated with, were identified and processes or functions of the buildings summarized in the list below. Details of inlet pipe sizes, depths and French drain size and construction details and depths are provided when available in the descriptions below. When exact locations were not available from construction drawings the location was estimated by placing the location 4.6 meters (15 feet) away from building. In these cases the inlet piping is in a well defined location. See detailed spatial analysis map for French Drain locations.

Orphan sites field investigations were conducted on March 12th and 17th of 2008. Photographs of the present site conditions were obtained.

FD1. The site is a 1.22 meter (48 in) reinforced concrete pipe French drain with a 0.1 meter (4 in) clay tile 6.1 meters (20 ft) long at a 1% slope (1 in of slope per linear foot of pipe) from 1.1
m (42 in) raw water line. The site is associated with the 182-H Reservoir (north end) (P-4737 Sheet 1, P-4737 Sheet 2). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD2. The site is a 0.9 meter (36 in) French drain with a 0.1 meter (4 in) diameter cast iron (CI) pipeline from the 182-H Reservoir (south side) heater systems to the French drain (P-1368, P-1370). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD3. The site is a 0.46 meter (18 in) dry well with a 2.54 cm (1 in) steam condensate pipeline from the 190-H Building (north side) (H-1-14575, H-1-14580, H-1-14581). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD4. The site is a 0.46 meter (18 in) dry well with a 0.05 meter (2 in) steam condensate pipeline from the 190-H Building (east side) (H-1-14575, H-1-14580, H-1-14581). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD5. The site is a 0.61 meter (24 in) dry well, 1.4 meters (4.6 ft) deep with a 2.54 cm (1 in) steam condensate pipeline from 190-H Building to the dry well (H-1-14575, H-1-14580, H-1-14581). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD6. The site is a 0.61 meter (24 in) dry well with a steam condensate pipeline from the 1703-H Office Building (west side) to the dry well (P-9340). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD7. The site is a 0.61 m (24 in) French drain with a ventilation drainage pipeline from the 1703-H Office Building (east side) to the French drain (P-9340). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD8. The site is a 0.9 meter (36 in) French drain from the 184-H building (north side) that utilized steam radiator unit heaters with 1.9 cm (0.75 in) condensate blow off traps and drip legs which discharged to French drains with 0.1 m (4 in) diameter vitrified clay type (VCT) inlet piping to the French drain (P-1417).

FD9. The site is a 0.9 meter (36 in) French drain with a 0.1 meter (4 in) diameter VCT pipeline from a return riser and steam supply riser from the 184-H Boiler House (east side) to the French drain (P-1417). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD10. The site is a 0.9 meter (36 in) French drain with a 0.1 meter (4 in) diameter VCT condensate pipeline from the 184-H Boiler House (west side) to the French drain. (P-1417) No documents or records were obtained during historical research to indicate a final disposition for the site.

FD11. The site is a 0.61 meter (24 in) French drain with a 0.1 meter (4 in) diameter VCT pipeline from a return riser and steam supply riser from 184-H Boiler House (south side) to the French drain. (P-1417) No documents or records were obtained during historical research to indicate a final disposition for the site.

FD12. The site is a 1 m (36 in) French drain with a 9.4 meters (31 ft) long, 2.54 cm (1 in) line connecting from the 1901-H Water Tower trap discharge to the French drain (P-1426). There is an additional pipeline to the French drain that is a 8.8 meters (29 ft) long, 3.81 cm (1.5 in) line connecting from the 1901-H Water Tower ejector discharge to the French drain (P-1426). The
pipelines are soft water trap discharge lines (P-1416 and P-1426).

FD13. The site is a 0.9 meter (36 in) French drain with a 0.1 meter (4 in) vitrified clay (VC) pipeline to the French drain (P-1237). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD14. The site is a 0.61 meter (24 in) French drain filled with soil/gravel. The drain was discovered in the field during the orphan site evaluation. The French drain does not appear on any construction drawings. The proximity of French drain FD5 to FD14 suggests that they might one in the same. The French drain is believed to receive steam condensate from the 190-H Annex. This drain was later discovered to be the same as (duplicate) FD5.

**Location:**

Selected as built construction drawings were rectified into the Geographic Information System (GIS) for each of the French drains and associated piping locations. The coordinates are provided in Washington State Plane coordinates. The coordinates are listed in the same sequence as the elements in the site description.

**Process Description:**

The process descriptions were ascertained from construction drawings and are provided with construction drawing numbers. A spatial analysis was conducted for each of the French drains and dry well and all have been identified as receiving steam condensate. Steam was typically used at all facilities for heating purposes. The 184-H Power House boiler facility supplied high pressure steam to all buildings through an above grade pipeline system. The boiler facility utilized clean filtered water from the 183-H filter building. The steam supply was used in a non-contact radial heating system. As a non-contact system the steam remained uncontaminated. The steam transport process utilized a high pressure supply line and a low pressure return or discharge line. It was necessary to bleed both the supply and return lines to prevent condensate build up. The condensate was typical blow off from the above grade piping system into a below grade covered French Drain as illustrated on construction drawings as a safety precaution. French drains' diameters and construction material varied depending on steam piping size, service capacity or pounds per hour, and expected flow rate received.

**Waste Type:** Misc. Trash and Debris

**Waste Description:**

The waste is the French drain and associated piping.

**Closure Info:**

Confirmatory sampling activities were performed from October 5 to 11, 2010. One French drain from each of the building locations within the 100-H-50 waste site was selected for sampling, for a total of five French drain test pits. The French drains were selected based on confidence in the location, as determined by surface visibility and/or details from the historical building.
drawings. The five french drains that were selected for sampling are 2, 5, 6, 11, and 13. Active
pump and treat lines were observed at the french drain 2 location during confirmatory sampling,
and no excavation or sampling was conducted at the location because of the resulting surface
interference. At the location for French Drain 13, an area approximately 3 by 3 meters (12 by
12 ft) was excavated. Based on the absence of debris and rubble observed in the excavated area,
it was determined that there is no french drain at the location, and the excavation was
backfilled. The remaining site french drain locations were excavated and sampled. The sample
results indicated No Action was required.

Names: 100-H-51:1; 1703-H Sanitary Sewer Segment
Type: Process Sewer
Status: Inactive
Description: The subsite consists of a 15.2 centimeter (6 inch) diameter vitrified clay pipe (VCP) sanitary sewer segment. The line connects the 1703-H building with the 100-H-28, 100-H Water Treatment Facilities Underground Pipelines. The subsite also includes a short section of a 10.16 cm (4 in) soil pipe where the 15.2 cm (6 in) VCP connects to the 1703-H building.

The 1703-H building was constructed in 1949 and contained offices for area administrative and technical personnel. The building was demolished in 1974 leaving the footings and foundations after demolition of the building were buried and leveled (UNI-7231974). The 100-H-28:5 waste site has been identified by WCH for remediation, see WCH CCN #141052.

Location: The pipeline segment is located on the west side of 1703-H building and runs north, terminating at a manhole where it joins the 100-H-28:5 Sanitary Sewer pipeline.

Waste Type: Ash
Waste Description: The waste has been described as contaminated soil. The COPCs include: arsenic, barium, cadmium, chromium, hexavalent chromium, lead, selenium, silver, mercury, semivolatile organic compounds (SVOCs), polychlorinated biphenyls (PCBs), and chlorinated pesticides.

The SubSite is Part Of:

Process Sewer
Inactive

Names: 100-H-51:2; 117-H Seal Pit Crib Feedline
Type: Process Sewer
Status: Inactive
Description: The subsite consists of a 10 cm (4 in) diameter cement asbestos feed line that ran from the 117-H Air Filter Building to waste site 116-H-9, 117-H Crib, 117-H Seal Pit Crib.

The 117-H Air Filter Building and crib were constructed in 1960. The building was closed under a determination of residual contamination levels (ARCL) (UNI-3001). The 117-H building was demolished in 1984. A distribution header lies approximately 1.5 m (5 feet) below grade and is covered by a polyethylene barrier.

The pipeline was identified as part of the 116-H-9 waste site initially and later reassigned to the 100-H-51 waste site on 2/19/2009. This was done to facilitate closure of 116-H-9 while

**Location:** The pipeline segment is located between the 117-H Air Filter Building and the 117-H Seal Pit Crib.

**Waste Type:** Oil

**Waste Description:** The waste is remaining pipelines and any potentially contaminated soil. COPCs include: carbon-14, cesium-137, cobalt-60, europium-152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, tritium, radium-226, thorium-228, thorium-232, uranium-238, cadmium, chromium (total), hexavalent chromium, mercury, lead, selenium, silver, and PCBs.

**Type:** Process Sewer

**Status:** Inactive

**Description:** The subsite consists of two parallel pipelines, a 5.1 cm (2 in) steel brine discharge line and a 7.6 cm (3 in) steel filtered water line that ran from the 184-H Power House Building to the 184-H Salt Dissolving Pit and Brine Pump House.

Documentation established that the Power House was demolished in 1997. The 184-H Salt Dissolving Pit and Brine Pump House (100-H-16) were probably demolished in place as were similar brine pits at 184-B and 184-D.

**Location:** The pipelines were located between the 184-H Power House Building and the 184-H Salt Dissolving Pit and Brine Pump House.

**Process Description:** Filtered water was piped from the 184-H Power House to the 184-H Salt Dissolving Pit and Brine Pump House where sodium chloride was added and the brine was pumped back to the 184-H Power House for further use.

**Waste Type:** Sanitary Sewage

**Waste Description:** The waste is the remaining pipelines and any potentially contaminated soil.

**The SubSite is Part Of:**

**Code:** 100-H-51:4

**Names:** 100-H-51:4; 100-H Main Gate Storm Drain

**Type:** Process Sewer

**Status:** Inactive

**Description:** The subsite has been evaluated and determined to require No Action. It consists of a 15.2 cm (6
in) diameter vitrified clay pipeline (VCP) storm drain that ran north from the 1701-H, 1702-H and 1709-H Buildings to 100-H-27, 100-H Area Patrol Headquarters Storm Runoff Ditch. The pipeline includes two 10.2 cm (4 in) lateral sections of VCP feed pipe from 1702-H and 1709-H buildings to the 15.2 cm (6 in) pipeline.

Location: The subsite was located between the 1701-H Building and the 100-H-27 storm runoff ditch. Additionally, the pipeline ran parallel and approximately 11 m (36 ft) north of the former location of the 1607-H3 septic system.

Related Sites/Structures: 100-H-51:4 is associated with the 100-H-27 storm water ditch.

Waste Type: Misc. Trash and Debris
Waste Description: The waste will include the pipelines and any potential contaminated soil.

Closure Info: 100-H-51:4 was located adjacent to the 1607-H3 post-excavation boundary. Confirmatory samples for 100-H-51:4 were collected from the inside of the pipe at Test Pit 5. The pipeline was found 3 feet below ground surface. It was encased in concrete. Test Pit 5 was the only location not impacted by the 1607-H3 excavation. Field surveys found no radiological contamination or volatile organic compounds.

A reclassification to No Action for the 100-H-51:4 subsite is supported based on site history, process knowledge, field observations, and comparison of residual contaminant concentrations against RAGs.

The SubSite is Part Of:
Code: 100-H-51
Names: 100-H-51; Potentially Contaminated Pipeline Segments

</table>

Type: Product Piping
Status: Inactive

Description: The confirmatory sampling results support a reclassification to No Action. The pipeline is a steel pipe that ran from the Columbia River to the sanitary water system just south of the 1713-H building.

Location: The pipeline is located at the Columbia River shoreline and continues south ending 50 meters (164 ft) beyond the 128-H-1 Burn Pit.

Process Description: There is no process history associated with this subsite.

Waste Type: Construction Debris
Waste Description: The waste will include the pipelines and any potential contaminated soil.

Closure Info: The intent of sampling was to determine the size, type, and use of the 100-H-51:5 and 100-H-53 pipelines and to determine the nature and estimate the extent of potential contamination in and under the 100-H-51:5 and 100-H-53 pipelines. Soil was collected from beneath the 100-H-51:5 and 100-H-53 pipelines to determine if a leak associated with the pipelines may have resulted in contamination that would pose a risk to human health and the environment.
Confirmatory sampling of the 100-H-51:5/100-H-53 waste sites occurred on November 2010. The exposed portion of the 100-H-53 pipeline was breached with a drill. No material was found inside the pipeline to sample. According to the logbook, the pipe at this location was 3/8-inches thick and had a 10 inch diameter. The soil sample taken from below the pipe was composed of brown silt. A duplicate sample was taken from this location. At the 100-H-51:5 subsite, there was no material to sample inside the exposed end of the pipe. A sample of the brown-tan silt was taken from below the pipe.

The SubSite is Part Of:
Code: 100-H-51

Description: The 100-H-51:6 waste site is a section of 25-cm (10-in) pipe that starts approximately 70-m (231-ft) south of the 100-H-51:5 waste site and ends near the 1713-H Building. This particular section of carbon steel pipe is thought to have connected to the southern side of a temporary wooden water tank and ended near the 1713-H Building. This pipeline and water tank is suspected to be part of an extensive temporary water system for construction of the 100-H Area in 1948 (HW-24800-2). This section of pipe (that is currently named 100-H-51:6) used to be part of 100-H-51:5 and 100-H-53 waste site until confirmatory sample results exceeded direct exposure cleanup levels and was forced to be removed, treated, and disposed (RTD).

Location: The pipeline is located west of the 1713-H building.

Description: The site has been remediated and Interim Closed Out with 100-H-48. It consisted of a drain field and associated piping that supported the 184-HA boiler annex. In the center of the drain field (oriented east/west) were four, 20 centimeter (8 inch) diameter perforated concrete pipe laterals.

Location: The drain field was located on the west side of the 184-HA Building. It was approx. 20.8 meters (68.6 feet) east of the 190-HA building. Global Positioning System (GPS) coordinates for the drain field are E577820 N152595. These are the coordinates of where the 5.1 centimeter (2 inch) sanitary drain (SD) effluent pipe line connects into the east side of the drain field.
Related Sites/Structures: The septic system is associated with the 184-HA building and 100-H-48.

Process Description: The 184-HA Boiler House Building and associated equipment was constructed in approximately 1965 to replace the 184-H boiler house. The 184-HA building was removed and it's associated footings and foundations were demolished and backfilled in 1974. The site was leveled. The boiler provided steam to the administration and Central Shops buildings, which consisted of 1703H, 1704H, 1716H, 1717H, 1719H, 1722H, 1760H, and 1761H. Blow-down effluent from the boiler, drained via the 10.2 centimeter (4 inch) condensate line, that connected to the east end of the drain field, to the 20 centimeter (8 inch) perforated concrete main line.

Waste Type: Water
Waste Description: The drain field received effluent from two water softeners, the boiler deaerator and condensate from the boiler.

Closure Info: Geophysical surveys were done in 2007. Confirmatory sampling was done from within Test Trenches in November 2009.

Remediation of the combined 100-H-48 and 100-H-52 waste sites was performed from July 25, 2013 through July 29, 2013 to a depth of approximately 4.6 meters (15 ft). A combined volume of approximately 1,576 bank cubic meters (BCM) (2,061 bank cubic yards [BCY]) of contaminated soil and debris was excavated and stockpiled for disposal at the Environmental Restoration Disposal Facility (ERDF). Debris waste included piping associated with the former underground fuel tanks and piping associated with the 100-H-52 drain field. Other concrete and steel debris was encountered at the former underground tank location. During remediation, field screening for VOCs was conducted and no elevated readings were detected. All waste material was stockpiled, prior to shipment and disposal at ERDF. All waste material from the 100-H-48 and 100-H-52 waste sites have yet to be loaded out to ERDF. The waste staging pile area will be sampled and closed out with a separate waste site at a later date.

Code: 100-H-53
Names: 100-H-53; Carbon Steel Pipe in River Bank
Type: Process Sewer
Status: Inactive
Classification: Accepted
Reclassification: Interim No Action (4/12/2012)
Start Date:
End Date:

Description: The confirmatory sampling results support a reclassification of this site to No Action. The waste site is a 25 centimeter (10 in) diameter and 1.8 meters (6 ft) long (exposed portion) carbon steel pipe that runs northeast toward the river shore. A WCH Orphan Sites Field Evaluation was conducted in this area in August of 2007. Geophysics (GI # 0590309) was conducted in October 2007, and results indicate that the visible segment of the 25 centimeter (10 in) diameter pipe is not part of an intact system and does not extend below grade beyond the 1.8 meters (6 ft) currently visible.

Location: This waste site is located approximately 28 meters north-northeast of the southeast end of rejected WIDS site 600-258 (Pre-Hanford debris) and it is located near the shoreline.

Related Sites/Structures: Pipe is NE of 600-151, Dumping Areas 50 yards and 200 yards Downstream of River Mile 14. Co-located near 600-258.

Process Description: The process associated with this pipe is unknown. The pipeline may have been related to pre-Hanford activities, since there is this type of debris associated with 600-258. Site 600-258 is located on top of the bank and the pipe is located towards the south end of 600-258. See site 600-258.
Waste Type: Asbestos (non-friable)

Waste Description: The waste is the pipeline and any potentially contaminated soil underlying the pipe. Since the pipeline can not be related to any particular human activity, the contaminants of potential concern are unknown.

Closure Info: The intent of sampling was to determine the size, type, and use of the 100-H-51:5 and 100-H-53 pipelines and to determine the nature and estimate the extent of potential contamination in and under the 100-H-51:5 and 100-H-53 pipelines. Soil was collected from beneath the 100-H-51:5 and 100-H-53 pipelines to determine if a leak associated with the pipelines may have resulted in contamination that would pose a risk to human health and the environment. Confirmatory sampling of the 100-H-51:5/100-H-53 waste sites occurred on November 2010. The exposed portion of the 100-H-53 pipeline was breached with a drill. No material was found inside the pipeline to sample. According to the logbook, the pipe at this location was 3/8-inches thick and had a 10 inch diameter. The soil sample taken from below the pipe was composed of brown silt. A duplicate sample was taken from this location. At the 100-H-51:5 subsite, there was no material to sample inside the exposed end of the pipe. A sample of the brown-tan silt was taken from below the pipe.

Reclassification:

100-H-57; Water Tower Foundations at 100H Foundation

Inactive

Description: The waste site has been evaluated and determined to require No Action. The site consists of the underground piping, valves, sumps and other structures at the base of the two elevated water towers adjacent to the 105-H Reactor. The valve pits at both of the 105-H water towers were completely removed during the demolition and decontamination activities.

Location: The towers were located on either side of the 105-H Reactor.

Process Description: Water was provided as a means to remove heat from the pile. A network of interconnecting pipelines, by-pass lines, and standby pumping facilities were provided to insure that water service to the pile was maintained even when a part of the system was inoperable (TNX-PG-4). The principal purpose of the two elevated storage tanks at the 105-H Reactor was to provide standby storage of cooling water in the event that the service to the pile was interrupted. The 105-H Reactor had two 300,000 gallon capacity, ellipsoidal steel-plate tanks (187-H1 and 187-H2), elevated 120 feet above the ground level (HW-24800-2). Sodium silicate was supplied to the tanks for corrosion prevention (H-1-13254).

The construction drawings for the 187-H1 and 187-H2 tanks (P-1257 and P-2031) show a french drain receiving condensate through a 3.8 centimeter (1.5 in) pipeline. The drawings also suggest that the sump in the bottom of the valve pit was emptied into this french drain. The drawings show that the french drains were installed a minimum of 4.6 meters (15 ft) on the north side of the tanks. Multiple pipelines were located on the north side of the reactor that ran in an east-west direction just north of each water tower. The pipelines would have interfered with placement of any french drains 4.6 meters (15 ft) north of the towers footer piers. It is likely that the french drains were located elsewhere. The only identified french drain within a 4.6 meters (15 ft) perimeter of the east water tower (187-H2) footings is the 100-H-8 French Drain B waste site. Based on historical information, this french drain was determined to have received steam condensate from overhead steam lines, but it is possible that it could be associated with the valve pit for the east tower. Confirmatory sampling of the 100-H-8 french drain was performed in November 2008, with soil samples collected from beneath the french drain. Hexavalent chromium was undetected in all samples. Confirmatory sampling results...
showed the 100-H-8 site achieved remedial action objectives specified in the Remaining Sites ROD (EPA 1999). The site was reclassified to No Action in December 2009. There are no french drains identified in the area near the former 187-H1 west water tower.

Closure Info: A field walkdown at the 100-H-57 waste site was performed on November 6, 2012. Two Test Pits were excavated at the locations of each of the foundations on June 21, 2013. The test pits were excavated to a depth of 4 meters (13 ft). Two samples were collected from each test pit. The samples were taken from the backhoe bucket. No anomalies were identified. No radiological activity was detected. The confirmatory sampling results support a reclassification of the 100-H-57 waste site to Interim No Action.

<tr>
<td>Waste Description:</td>
<td>The site received diversion effluent from the 107-H Retention Basin during reactor outages due to fuel element ruptures and water and sludge from 107-H during deactivation of the unit.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Remedial action at the 116-H-1 site began on June 29, 1999. Excavation of the site involved removing the overburden materials and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. On June 8, 2000, the excavation was completed. The elevation of the bottom of the excavation was at 123.4 meters (405 feet) upon completion. The excavation was approximately 12,735 square meters (137,077 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 82,706 metric tons (91,168 tons) of material from the site were disposed of at ERDF. Cleanup verification sampling for the deep and shallow zones was done on June 15, 2000, and July 25, 2000, respectively. The final verification samples were submitted to offsite laboratories for analysis using approved U.S. Environmental Protection Agency analytical methods, as required per the SAP (DOE/RL-96-22).</td>
</tr>
</tbody>
</table>

Code: 116-H-2 Classification: Accepted
### Name: 116-H-2; 1608-H Crib & Trench; 1608-H Liquid Waste Disposal Trench

**Reclassification:** Interim Closed Out (3/1/2001)

**Type:** Trench  
**Status:** Inactive  
**Start Date:** 1/1/1953  
**End Date:** 1/1/1965

**Description:** The site has been remediated and Interim Closed Out. It included a trench that was fed by a 15 centimeter (6-inch) vitrified clay pipe that originated at the 1608-H Pump House.

**Location:** The site was located 76 meters (250 feet) south of the 105-H Reactor Building.

**Related Sites/Structures:** The trench is associated with the 105-H Reactor Building and 1608-H Pump House. In 1953, the 116-H-2 trench overflowed and flooded a triangular area bounded by railroad tracks, known as the 100-H-17 Overflow. The 100-H-30 Sanitary Sewer trench was also contaminated with effluent that overflowed from 116-H-2.

**Process Description:** From 1953 to 1965, the site received effluent from the 105-H Ball 3X project. Water was pumped from the 105-H Reactor Building to the trench via the 1608 Pump House.

**Waste Type:** Misc. Trash and Debris  
**Waste Description:** The site received coolant water from the 105-H Reactor Building during the Ball 3X system upgrade program. The site was used during other upgrade programs and when maintenance was necessary on the effluent system.

**Closure Info:** This area is located in an area that, prior to World War II and formation of the Hanford Site, was occupied by fruit tree orchards.

Remedial action at the 100-H-17 sites group (100-H-17, 100-H-30, 100-H-2 and 116-H-2) began on February 2, 2000. The sites were grouped together for remediation because of location and similar contaminants. Excavation of the area involved removing the overburden materials, miscellaneous debris, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. On February 10, 2000, the excavation was completed.

No evidence of buried waste was found during the excavation of the 100-H-2 site.

At the completion of the remedial action, the total excavation was approximately 6,240 square meters (67,170 square feet) in area with a maximum depth of approximately 2.6 meters (8.5 feet). Approximately 19,920 metric tons (21,960 tons) of material from the site were disposed of at the ERDF.

---

### Name: 116-H-3; Perf Decontamination Drain; 105-H Dummy Decontamination French Drain

**Reclassification:** Interim Closed Out (4/3/2001)

**Type:** French Drain  
**Status:** Inactive  
**Start Date:** 1/1/1950  
**End Date:** 1/1/1965

**Description:** This site has been remediated and closed out. The site was a french drain made of vitreous tile conduit. The upper surface of the french drain extended a few inches above the ground and had a metal cover. This waste site included 65 meters (215 feet) of pipeline.

**Location:** The site was located southeast of the 105-H Building.
The 116-H-3 French Drain received spent nitric acid and rinse water from the decontamination of fuel element spacers, reactor process tube caps, and other reactor hardware between 1950 and 1965.

The site was related to the 105-H Reactor Building.

**Process Description:**

The 116-H-3 French Drain received spent nitric acid and rinse water from the decontamination of fuel element spacers, reactor process tube caps, and other reactor hardware between 1950 and 1965.

**Waste Type:**

Equipment

**Waste Description:**

The site received spent acid and rinse water from the 105-H Dummy Decontamination Facility, which decontaminated fuel element spacers and other reactor hardware.

**Closure Info:**

Remedial action at the 116-H-3 site began on February 17, 2000. Excavation of the site involved removing the overburden materials, the french drain, 65 meters of pipeline leading from the reactor building to the french drain, and the underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF.

On June 26, 2000, the excavation was completed. The elevation of the bottom of the excavation was at 123.5 meters (405 feet) upon completion. The excavation was approximately 855 square meters (9,203 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 2,707 metric tons (2,985 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

**Code:** 116-H-4

**Classification:** Accepted

**Names:** 116-H-4; 105-H Pluto Crib

**Reclassification:** None

**Type:** Crib

**Start Date:** 1/1/1950

**End Date:** 1/1/1952

**Description:** The site is currently a flat, cobble covered field located inside the 105-H security fence. The crib location is not marked.

**Location:** The crib was located near the southwest corner of the 105-H Building and adjacent to the 132-H-3 Effluent Pumping Station.

**Related Sites/Structures:** The site was related to the 105-H Reactor.

**Waste Type:** Steam Condensate

**Waste Description:** The site received effluent from tubes containing ruptured fuel elements. A 1953 document reports that approximately 270 curies of fission products were released to the crib as a result of the rupturing of ten slugs and the presence of 1,000 kilograms (2,200 pounds) of sodium dichromate.

**Code:** 116-H-5

**Classification:** Accepted

**Names:** 116-H-5; 116-H-5 Outfall Structure; 1904-H Outfall Structure

**Reclassification:** Interim Closed Out (5/3/2012)

**Type:** Outfall

**Start Date:** 1/1/1949

**End Date:** 1/1/1965

**Status:** Inactive

**Description:** This site has been remediated and Interim Closed Out. It included the open-topped, compartmentalized, reinforced concrete outfall structure. A 183 centimeter (72 inch) concrete
process sewer line from the 1906-H Pump House, and two 152 centimeter (60 inch) diameter steel retention basin pipelines entered the eastern face. Two, 152 centimeter (60 inch) concrete pipelines exited the western face and extended to the river.

**Location:** The site was located on the Columbia River shoreline north of 107-H Retention Basin.

**Related Sites/Structures:**

The outfall is associated with 116-H-7 Retention Basin, 184-H Power House, 100-H-34 (River Effluent Pipelines), the 100-H-36 spillway, the 100-H-21 process effluent lines, the 100-H-34 river effluent pipelines, and the 1906-H Pump House and associated pipelines.

**Process Description:**

The outfall was a reinforced concrete weir box that directed the water through either the river discharge pipelines (100-H-34) or through the spillway (flume) (100-H-36). The spillway was a concrete flume used when the river pipelines were blocked, damaged or undergoing maintenance. Process sewer wastes, and reactor cooling water collected and temporarily stored in the 107-H retention basin, were pumped to the river via the 116-H-5 outfall structure and associated 100-H-34 river effluent pipelines.

**Waste Type:** Asbestos (friable)

**Waste Description:**

The site received effluent water through two lines from the 107-H Retention Basin. A third line from the 100 H Area process sewer also discharged to it. Contaminants of potential concern include Co-60, Cs-137, Eu-152, -154, -155, Ni-63, Pu-238, -239/240, Am-241, C-14, H-3, Tc-99, Sr-90, U-234, -235, -238, Cr+6, Cr (total), Pb, and Hg.

**Closure Info:**

Remedial action at the 116-H-5 waste site began on November 17, 2008, and continued through April 9, 2009, to a depth of approximately 7 meters (23 ft) on the eastern side of the excavation and 13 meters (43 ft) on the western side of the excavation. The excavation resulted in approximately 2,510 bank cubic meters (BCM) (3,283 bank cubic yards [BCY]) of contaminated soil and debris being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 15,696 BCM (20,529 BCY) of overburden material was stockpiled southwest of the excavation for use as clean backfill. Columnar basalt riprap boulders, cemented together and used as a retaining wall, were also excavated from the site and will be used as backfill. Most of the soil was direct loaded from the excavation. However, small staging pile areas were used for pipe, concrete, and fence material, which were later loaded out and disposed at the ERDF.

Several pipelines that discharged to or from the 116-H-5, 1904-H Outfall Structure remain at the site. A 183-cm (72-in.) reinforced concrete pipe (part of the 100-H-42, 1906-H Drainage Lift Station waste site that transferred effluent from the 1906-H Building to the 116-H-5 outfall) remains near the base of the western sidewall of the 116-H-5 excavation. The 100-H-36 spillway and the 100-H-34, 100-H River Effluent Pipelines that discharged effluent from the outfall structure to the river also remain.

**Code:** 116-H-7

**Classification:** Accepted

**Names:** 116-H-7; 107-H; 107-H Retention Basin

**Reclassification:** Interim Closed Out (7/24/2001)

**Type:** Retention Basin

**Start Date:** 1/1/1949

**End Date:** 1/1/1965

**Status:** Inactive

**Description:** This site has been remediated and closed out. The basin was a concrete-lined rectangular structure. Prior to the remedial action, the basin had been partially demolished and backfilled to a depth of approximately 1.2 meters (4 feet) above the floor, and sloped to the top of the walls.

**Location:** The site is located northeast of 105-H.

---

Hanford Site Waste Management Units Report
February 2015

487
Release Description: The unit and its effluent line developed leaks during the years of operation. The rate of leakage has been estimated to be as high as 19,000 to 38,000 liters per minute (5,000 to 10,000 gallons per minute). The extent of contamination from these releases was within the area encompassed by the unit.

Related Sites/Structures: Sludge and waste removed from this unit during repair work in the spring of 1953 were buried in a trench east of the unit (WIDS Site Code 100-H-5). The trench was originally covered to grade with 1.5 meters (5 feet) of soil. In May 1965, the location was excavated to a depth of approximately 1.8 meters (6 feet) to obtain fill material for this unit. There was no indication of remaining radioactivity, and consequently the trench was released from radiological controls.

Waste Type: Oil

Waste Description: This site received cooling water effluent from the 105-H Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Seventy percent of the total radionuclide inventory is contained within the soil adjacent to the unit. Approximately 10 curies have leached into the concrete floor and walls.

Closure Info: Remedial action at the 116-H-7 site began on March 17, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Due to leakage from the retention basin and its associated pipelines, numerous plumes were excavated along with the waste site. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. On July 17, 2000, the excavation of the waste site and associated plumes was completed.

Site excavation and waste disposal are complete, and the exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 23,660 square meters (254,700 square feet) in area with a depth of approximately 4.8 meters (15.7 feet). Approximately 218,130 metric tons (240,440 tons) of material from the site were disposed of at the ERDF.

Code: 116-H-9

Classification: Accepted

Reclassification: Interim Closed Out (12/22/2010)

Names: 116-H-9; 117-H Crib; 117-H Seal Pit Crib

Type: Crib

Start Date: 1/1/1960

End Date: 1/1/1965

Description: The site has been remediated and Interim Closed Out. It was a gravel filled crib. A distribution header was approximately 1.5 meters (5 feet) below grade and covered by a polyethylene barrier. The polyethylene barrier was covered by 1.2 meters (4 feet) of clean fill material. A large vent pipe marked the site and was placed off center of the crib structure. The site included a 10-centimeter (4-inch) cement asbestos feed pipeline that runs from the demolished 117-H Air Filter Building to the crib. The pipeline was approximately 80 meters (263 feet) long. Based on the results of the applicable Remaining Sites Verification Package (RSVP) document, authorization was given to remove the Soil Contamination Area and Underground Radioactive Material Area postings from this waste site.

Location: The site was located approximately 150 meters (492 ft) southwest of the 105-H Building (118-H-6).

Related Sites/Structures: The site was associated with the demolished 117-H Air Filter Building.

Process Description: During its period of operation from 1960 to 1965, the 116-H-9 Crib is reported to have received approximately 300,000 liters (79,200 gal) of low-level radioactive effluent that drained from the
117-H Filter Building confinement system seal pits.

**Waste Type:** Misc. Trash and Debris  
**Waste Description:** The site received drainage from confinement system 117-H Building Seal Pits.

**Closure Info:** Remedial action began on October 28, 2008, and continued through February 3, 2009, to a depth of approximately 4.6 meters (15 ft). Material was direct loaded for disposal, so no staging piles were created. The lateral extent of the excavation was determined based on the September 2008 geophysical survey that clearly defined a distinct boundary. No stained soil or radiological or chemical contamination was identified. Approximately 2,430 bank cubic meters (3,180 bank cubic yards) of soil and debris was removed for disposal at the Environmental Restoration Disposal Facility (ERDF).

Verification sampling was performed in July 2009, to collect data to determine if the site met remedial action goals. The results of the verification sampling showed that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River.

---

**Code:** 126-H-2  
**Classification:** Accepted  
**Names:** 126-H-2; 183-H Clearwells/Disposal Pit  
**Reclassification:** Interim Closed Out (10/18/2012)  
**Type:** Dumping Area  
**Start Date:** 1/1/1975  
**End Date:**  
**Status:** Inactive  
**Description:** The waste site has been remediated and Interim Closed Out. The clearwells were part of the 183-H Water Treatment Facility and consisted of two reinforced concrete basins (east and west), separated by a pump house. During reactor operations, the clearwells held clean, uncontaminated water. The east clearwell basin was later used for disposal of demolition debris, inert waste, and drums that were found to contain oil. The west clearwell basin was not used for waste disposal. A portion of the backfilled clearwells had been posted with Soil Contamination signs.

**Location:** The site is located approximately 220 meters (721.8 feet) north of the 105-H Reactor Building and just south of the demolished 183-H Solar Evaporation Basins.

**Related Sites/Structures:** The clearwells were associated with the 183-H Water Treatment Facility. A number of the drawings that are referenced are related to the 183-H Water Treatment Facility and have been included to provide context information.

**Process Description:** The 183-H clearwells were part of the 183-H water treatment facility. They consisted of two reinforced concrete basins (east and west) measuring 229 meters (750 ft) long and 41 meters (135 ft) wide with a 38-million-L (10-million-gal) capacity. The treatment facility began operation in 1949 to store Columbia River water being processed for reactor coolant. During reactor operations, the clearwells held clean, uncontaminated water. The east and west clearwells were separated by a pump room that had been previously demolished. The below-grade portion had been filled with pump room rubble, fly ash, and backfill material.

After the 105-H Reactor shut down, in 1965, part of the roof on the east clearwell was demolished to allow inert demolition waste to be placed into the clearwell cavity. Historical information indicates the east clearwell was used for disposal of nonhazardous, nonradioactive debris such as concrete, wood, pipe, insulation, transite, composition roof materials, rebar, and asphalt from 1974 through 1997. Uncertainty regarding the radiological decontamination of
rubble disposed in the clearwell from the 183-H Solar Evaporation Basins resulted in a portion of the east clearwell being posted as a radiological Soil Contamination Area and a Radiological Controlled Area. The west clearwell had not been used for waste disposal and remained intact until decommissioning in 2010.

Rubblized material remaining from the demolition of the 183-H Solar Evaporation Basins (116-H-6) was added to the clearwell, in the belief that all requirements for radiological release had been met. The concrete was scabbled to remove the outer layer of surface contamination (approximately 6 millimeters [0.25 inches]). This material was disposed of as radioactive material. The remainder of the concrete and debris was sent to the clearwell on October 23, 1995.

The site consisted of two below grade, reinforced concrete basins, having a capacity of approximately 3.8E+07 liters (1E+07 gallons). Each clearwell had a reinforced concrete roof, supported by 132 concrete columns. The roof was located at grade level and still remains over the west clearwell. The clearwells were separated in the center by a pump room. The pump room was reinforced concrete and largely below grade. The above ground portion of the pump room has been demolished, and the below ground portion has been filled with pump room rubble and backfill material. The east clearwell basin contains demolition debris and other nonradioactive nonhazardous solid waste. The west clearwell remains intact.

Waste Type: Misc. Trash and Debris

Waste Description: The unit now contains nonhazardous and nonradioactive demolition and inert waste from demolished facilities. This waste includes rubble from such facilities as 190-H, 151-H, 1701-D and the 183-H Solar Evaporation Basins. The following materials were taken to the 183-H Clearwell:

- On (date unknown), 0.78 cubic meters (27.7 cubic feet) of transite from the 1717H;
- On 11/10/1986, 125.4 cubic meters (164 cubic yards) of insulators from the Hanford power line cleanup;
- On (date unknown), 0.89 cubic meters (31.5 cubic feet) of transite from the 190H Annex;
- On 9/25/1987, 44.3 cubic meters (58 cubic yards) of non-excessible building equipment from the 1713H Storage Facility;
- On 3/3/1987, (volume unknown) of galvanized posts and concrete from the perimeter fence;
- On 11/17/1987, 45.9 cubic meters (60 cubic yards) of decommissioned utility fixtures and cross arms;
- On 1/14/1988, 72.6 cubic meters (95 cubic yards) of decommissioned utility guy wires, rebar, and gravel;
- On 1/15/1988, 22.9 cubic meters (30 cubic yards) of decommissioned utility guy wires and concrete;
- On 10/10/1988, 880 used wooden pallets (1.07 by 1.07 meters [3.5 by 3.5 feet]) from the 183-H Basin;
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #1 for 8/30/1990); (radiological release record included);
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #2 for 8/30/1990); (radiological release record included);
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #3 for 8/30/1990); (radiological release record included);
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #4 for 8/30/1990); (radiological release record included);
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #5 for 8/30/1990); (radiological release record included);
insulation (5%), pipe (5%) from 1701-D; (record #5 for 8/30/1990); (radiological release record included);
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #6 for 8/30/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #1 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #2 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #3 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #4 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (90%), rebar (5%), pipe/conduit (5%) from 1701-D; (record #5 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (90%), rebar (5%), pipe/conduit (5%) from 1701-D; (record #6 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (90%), rebar (5%), pipe/conduit (5%) from 1701-D; (record #7 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (90%), rebar (5%), pipe/conduit (5%) from 1701-D; (record #8 for 8/31/1990); (radiological release record included);
- On 9/7/1990, 9.6 cubic meters (12.5 cubic yards) of roofing asphalt (80%), pipe metal (5%), toilet wood (5%), windows (10%) from 2719-W;
- On 4/26/1991, 245 pallets, 2 cable spools, 53.6 meters (176 feet) of 2 by 6 (9.23 cubic meters [326 cubic feet]) of wood from 100-H;
- On 9/11/1993, 332.6 cubic meters (435 cubic yards) of wood (85%), metal (5%), concrete (10%) from 1722-D and 1713-D; (radiological release record included);
- On 9/2/1994, 30.6 cubic meters (40 cubic yards) of roofing material, including tar and gravel (asphalt), fiberboard, metal flashing and wood debris from 105-D roof replacement; (radiological release statement included);
including superstructure, walls, catwalks, pillars, rebar from 100-H/183-H Solar Basins; (See second waste record);
- On 12/14/1995, 11.5 cubic meters (15 cubic yards) of wood (50%), plastic (40%), metal (10%) from 100-N, N Reactor Deactivation;
- On 10/11/1995, 38.2 cubic meters (50 cubic yards) of wood (99%), soil/metal (1%) from 100-D/190-D demolition;
- On 10/11/1995, 7.6 cubic meters (10 cubic yards) of asphalt/concrete from 100-N waterline upgrade;
- On 10/23/1995, 0.8 cubic meters (1.0 cubic yard) of scrap electrical wire from 100-N potable waterline upgrade;
- On 11/10/1995, 122.3 cubic meters (160 cubic yards) of metal (75%), concrete (10%), wood (10%), conduit (5%) from 100-N, Buildings 1100 and 1101;
- On 2/20/1996, 22.9 cubic meters (30 cubic yards) of asphalt (80%), dirt (20%) from 100-N/Field Deactivation;
- On 3/4/1996, 0.4 cubic meters (0.5 cubic yards) of plastic (100%) from 100-HR-3 Pump and Treat;
- On 5/9/1996, 12.2 cubic meters (16 cubic yards) of iron (5%), tar-rock (95%) from 100-H;
- On 5/11/1996, 12.2 cubic meters (16 cubic yards) of tar (40%), iron (30%), wood (20%), tin (10%) from 100-H;
- On 5/12/1996, 12.2 cubic meters (16 cubic yards) of galvanized metal (60%), wood (40%) from 100-H; (truck #1);
- On 5/12/1996, 12.2 cubic meters (16 cubic yards) of galvanized metal (40%), wood (60%) from 100-H; (truck #2);
- On 5/17/1996, 12.2 cubic meters (16 cubic yards) of tar (95%), iron (5%) from 100-H;
- On 5/18/1996, 12.2 cubic meters (16 cubic yards) of tar (100%) from 100-H; (truck #1);
- On 5/18/1996, 12.2 cubic meters (16 cubic yards) of tar (85%), steel (15%) from 100-H; (truck #2);
- On 5/18/1996, 12.2 cubic meters (16 cubic yards) of tar (100%) from 100-H; (truck #2);
- On 5/19/1996, 12.2 cubic meters (16 cubic yards) of tar-rock (95%), iron (5%) from 100-H;
- On 8/18/1996, 24.5 cubic meters (32 cubic yards) of concrete (80%), iron (20%) from 100-DR;
- On 8/19/1996, 24.5 cubic meters (32 cubic yards) of concrete (80%), iron (20%) from 100-DR;
- On 2/12/1997, 84.1 cubic meters (110 cubic yards) of asphalt (95%), rock (4%), metal (1%) from 100-H/183-H;
- On 4/11/1997, 34.4 cubic meters (45 cubic yards) of old asphalt from 200 West Area, 200-ZP-1 Phase III;
- On 7/16/1997, 15.3 cubic meters (20 cubic yards) of fiberglass insulation from the exterior of the 1715-N Diesel Tanks;
- On 7/15/1997, 22.9 cubic meters (30 cubic yards) of fiberglass insulation from demolition from 163-N roofing;
- On 7/18/1997, 11.5 cubic meters (15 cubic yards) of fiberglass insulation from the exterior of the 1715-N Diesel Tanks;
- On 7/18/1997, 1.5 cubic meters (2 cubic yards) of hatch lid, metal on wood construction from 163-N Roof;
- On 8/7/1997, 7.6 cubic meters (10 cubic yards) of broken asphalt pieces from pipeline road crossings from 100-HR-3 Project;
- On 8/26/1997, 160.6 cubic meters (210 cubic yards) of concrete (80%), rebar (20%) from 100-N/105-NC;
- On 9/25/1997, 107.0 cubic meters (140 cubic yards) of concrete, rebar, metal roofing and miscellaneous steel from 100-N/1734-N;
- On 10/11/1997, 11.5 cubic meters (15 cubic yards) of concrete (90%), wood (10%) from 2614 E2, W2, W4, W5.

**Waste Type:** Misc. Trash and Debris
Waste Description: The suspected contaminated waste is concrete and debris from the demolition of the 183-H Solar Evaporation Basins (116-H-6). The area is posted as a soil contamination area. After removal of the surface of the concrete, prior to demolition, all surfaces were surveyed with field instrumentation. The survey results for all surfaces were less than 1,000 disintegrations per minute per 100 square centimeters (15.5 square inches) smearable (loose) contamination and less than 5,000 disintegrations per minute per 100 square centimeters (15.5 square inches) total contamination. On October 23, 1995, 2,666.5 cubic meters (3,487.6 cubic yards) of concrete (90%), iron (10%), including superstructure, walls, catwalks, pillars, rebar from 100-H/183-H Solar Basins were disposed of in the 183-H Clearwell.

Closure Info: Remedial action at the 126-H-2 east clearwell basin was performed from August 5, 2009 through January 28, 2010. The west basin had not been used for debris disposal and remained intact until it was demolished in 2012. The remedial activity consisted of removing debris from the east basin, down to the concrete floor. Approximately 29,593 metric tons (32,621 U.S. tons) of material was removed for disposal at the Environmental Restoration Disposal Facility. Coal ash was removed from the pump room area during July through September 2010.

A number of waste items were encountered and removed during remediation, including fire extinguishers, aerosol cans, glass bottles, cylinders, and metal drums. Many of the drums were located in the western portion of the east clearwell and found to contain oil. Some drums were breached during remediation, releasing contents into the soil inside the clearwell structure. Samples of soil, oil, and other waste material were collected as necessary to support waste characterization and disposal.

Radiological surveys performed during remediation did not identify any radiological contamination. However, technicium-99 was identified in samples of concrete debris located near the surface of the clearwell. This concrete is believed to have been disposed from demolition of the adjacent 183-H solar basins.

Code: 132-H-1
Names: 132-H-1; 116-H Reactor Exhaust Stack Burial Site
Type: Burial Ground
Status: Inactive
Start Date: 1/1/1945
End Date: 1/1/1965
Classification: Accepted
Reclassification: Interim Closed Out (6/26/2007)

Description: The site consists of an excavated trench that contains the demolition rubble of the Reactor Exhaust stack and foundation. The stack was originally part of the 105-H Reactor Gas and Exhaust Air system. The waste site has been evaluated and reclassified to Interim Closed Out.

Location: The stack was located on the south side (southwest corner) of the 118-H-6 (105-H Reactor Building). The stack burial trench was excavated in a south-by-southwesterly direction from the base of the stack, between the 132-H-2 (117-H Filter Building) and the 132-H-3 (1608-H Lift Station Building).

Related Sites/Structures: The stack was part of the 118-H-6 (105-H Reactor Gas and Exhaust Air system) and the 132-H-2 (117-H Filter Building).

Process Description: Before demolition the 116-H exhaust stack was part of the reactor building ventilation system, which was designed to provide clean air to the various work sites within the 105-H reactor building. The clean air entered the noncontaminated portions of the reactor building and then moved through zones with increasing levels of contamination before its discharge into the atmosphere. After the 1960 installation of the 117-H Filter Building, the air passed through HEPA (high-efficiency particulate air) filters and halogen (activated charcoal) filters prior to its atmospheric release. Following completion of the confinement project in 1960, the air was
diverted from the 118-H-6 (105-H Reactor) site via underground reinforced concrete ducts to
the 132-H-2 (117-H Filter Building). After flowing through the filters, the air went through
below-grade and above-grade concrete ducts and into the exhaust stack. Prior to demolition
the stack was 61 meters (200 feet) tall and had a diameter of 5.1 meters (16.58 feet) at its base.
The stack was toppled into a 60.96 meter (200 feet) long by 9.14 meter (30 feet) wide by 5.49
meters (18 feet) deep trench.

Waste Type: Misc. Trash and Debris
Waste Description: Air moving from the least contaminated zones through increasingly contaminated zones was
discharged to the stack unfiltered. At the time of demolition low-level smearable alpha
contamination was present measuring up to 30 disintegrations/minute per 100 square
centimeters (190 disintegrations/minute per 100 square inches). Smearable beta contamination
ranged from 100 to 5,000 disintegrations/minute per 100 square centimeters (650 to 32,000
disintegrations/minute per 100 square inches).

Closure Info: The 116-H exhaust stack was demolished in 1983. The 116-H exhaust stack was demolished
using explosives and the concrete rubble was buried under at least 1 meter (3.3 ft) of clean fill.
The stack base was removed to a minimum of 0.9 meter (3 ft) below grade before it was buried
in situ. The monolithic concrete base attached to the 116-H exhaust stack extends into the deep
zone, however, the concrete base was for structural support and did not come into contact with
contaminated exhaust. Therefore, no deep zone evaluation is necessary for this site. After
demolition activities were completed, the 116-H site was graded to conform with the
surrounding terrain. A portion of the vertical 15-centimeter (6-inch) condensate drain pipe
remained embedded in the center of the buried stack base. No deep zone evaluation was
necessary because the embedded condensate drain did not extend into the deep zone. The pipe
was a free draining condensate line that fed into the 1608-H effluent pumping station. The
potential contamination remaining within the drain was considered to pose little risk to human
health and the environment, such that further sampling activities were not required. Residual
contamination that could remain in the floor drain pipe would be analogous to residual
contamination in the buried 132-D-4 (105-D Reactor Exhaust Stack) and 132-F-4:2 (105-F
Reactor Exhaust Stack) embedded stack condensate drain lines. Although the condensate drain
lines were not sampled, these sites were reclassified as "Interim Closed Out" and "No Action,"
respectively.

Concrete core samples were collected from the 116-H exhaust stack for the purpose of
establishing an isotopic inventory of radionuclides and depth of radionuclide penetration into
the stack interior surface. Core samples were drilled from the outside surface of the stack
inward. A total of five core samples were obtained from the 4.6 meter (15 ft), 5.8 meter (19 ft),
9 meter (30 ft), 17 meter (56 ft), and 24 meter (80 ft) elevations. The depth of contaminant
penetration in the concrete was then determined by removing three successive layers from each
core. The core layer from the interior of the stack had the highest radiological readings with
levels of radiation greater than 200 counts per minute per probe size (2.5 sq. centimeters).
Results of the core samples showed that the contamination was confined to a 0.01 inch (0.4 in)
surface layer of the concrete wall of the inner surface of the stack. The 1983 sampling results
were used to support the waste site reclassification. Using the maximum radiological activities
from the pre-demolition characterizatin data to represent residual contamination levels over
the entire mass of concrete of the former stack, RESidual RADioactivity (RESRAD) modeling
was performed in 2006 to support the previous decision to demolish and bury the stack in place.

The RESRAD modeling was performed only for the contaminated rubble which was buried in
the shallow zone. An evaluation of the concrete foundation that extended greater than 4.5
meters (15 feet) was not required because the foundation was not contaminated. The condensate
drain embedded in the stack foundation was located in the shallow zone. The RESRAD
modeling accounted for radioactive decay from 1983 (year of sampling) to 2006 and predicted
that the site achieved the dose limits and risk objectives for rural-residential land use,
groundwater protection, and river protection.

The horizontal condensate drain line running from the stack base to the 1608-H effluent pumping station was removed during previous remedial actions associated with the 100-H-21 Reactor Effluent Pipelines. Based on excavation boundaries of the demolition activities required to place the 105-H Reactor into interim safe storage, the remaining portion of the horizontal condensate drain line external to the 105-H Reactor Safe Storage Enclosure has been removed. The drain line and underlying soils were not sampled; however, it was believed that contamination related to the drain line, as well as to the embedded drain remaining in the stack, was bounded by the waste profile for the 100-H-21 Reactor Effluent Pipelines.

</table>
sodium fluoride, oxalic acid, and citric acid.

**Closure Info:** The original demolition activities began in May 1987 with the excavation of the periphery around the 1608-H Building to a depth of approximately 5 meters (16.4 ft). All pipes entering the structure were isolated and plugged to prevent the potential for water draining into the facility after demolition. This piping was later removed and Interim Closed Out in 2001 as part of the 100-H-21 remediation. Prior to building demolition, holes were punched in the bottom of each sump floor in order to facilitate drainage.

Remediation of the 132-H-3 waste site was performed from September 27, 2010, through July 13, 2011. Contaminated soil and concrete debris associated with the demolished 1608-H facility was removed and stockpiled for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 34,465 metric tons (15,260 bulk cubic meters) of material was removed for disposal at the ERDF. The excavation proceeded to the planned excavation depth at approximately 116.5 meters (382 ft) above mean sea level (amsl) to support complete removal of the previously demolished pumping station structure. This excavation depth was reached in January 2011. However, stained soil was observed in the north sidewall of the deepest portion of the excavation. Field measurements and in-process soil samples indicated that residual radiological contamination exceeding cleanup criteria for protection of groundwater and the Columbia River was present in this stained soil. Therefore, additional excavation was performed in February 2011 to remove the stained soil on the north wall, to the extent allowed by the safety limits due to the steep slopes of the excavation and the need to prevent undermining the concrete structures northwest of the site. A second round of in-process samples was collected on March 10, 2011, to support a decision if additional excavation was needed. The results of this sampling indicated the presence of residual total chromium, technetium-99, and nickel-63 at concentrations exceeding groundwater and river protection criteria. The staining was believed to be associated with the location where the inlet pipes entered the pumping station (approximate elevation of 122 meters [400 ft] amsl). These pipes may have contained residual liquids that were released to the soil at the time of decommissioning the facility and may have been the source of radiological contamination observed in the north sidewall of the excavation. A decision was made to perform additional stained soil removal on the north excavation wall to the base of the excavation. In-process soil samples were collected on June 6, 2011, on the east, west, and south walls of the excavation to verify that no additional soil removal was required in these areas. The stained soil removal on the north/northwest wall of the excavation was completed in June 2011. An additional round of in-process samples were collected on July 5, 2011, from the north sidewall of the excavation to evaluate whether the stained soil was adequately removed. The results of this sampling indicated that contaminated soil removal was complete. Following remediation, verification sampling of the excavation was conducted on February 15, 2012.

Two pipelines, originally grouped with the 100-H-56 Miscellaneous Pipelines Waste Site (identified as lines 7 and 9), were removed during the excavation and sampling of the 132-H-3 waste site. #7 was a 15.2 cm (6in) vitrified clay sanitary sewer pipe. #9 was a 3.8 cm (1.5 in) steel sanitary water pipe.

**Classification:** Accepted  
**Reclassification:** Interim Closed Out (2/5/2001)

Hanford Site Waste Management Units Report  
February 2015  
496
is no longer marked or posted in the field. The unit included a septic tank, tile field, and associated piping (about 140 meters (460 feet) from the tank to the intersection with the Water Treatment Plant pipelines).

**Location:** The septic system was located north of the 105-H Reactor Building, north of the 182-H Reservoir and northeast of the 183-H (116-H-6) Solar Basins.

**Related Sites/Structures:** The site received sanitary waste from the 182-H, 183-H, 190-H, and other 100 H Area office and maintenance buildings.

**Waste Type:** Water

**Waste Description:** This unit received unknown amounts of sanitary sewage from 182-H, 183-H, 190-H, and all office and maintenance service buildings with "1700" designations. Based on measured sludge levels, the volume was estimated to be 28,500 liters (7,500 gallons).

**Closure Info:** The site has been remediated and was closed out on February 5, 2001.

Remedial action at the 1607-H2 site began on October 21, 1999. Excavation involved removing the overburden materials, the structure (septic tank, drain field, and piping), and underlying contaminated soil. Approximately 140 meters (460 ft) of the 8 inch diameter sewage influent pipe was removed during excavation. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. On November 11, 1999, the excavation was completed. At the completion of the remedial action, the total excavation was approximately 5,054 square meters (54,405 square feet) in area with a maximum depth of approximately 5.6 meters (18.4 feet) for the septic tank/piping excavation and 1.5 meters (4.9 feet) for the drain field excavation. Approximately 12,207 metric tons (13,456 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

On May 5, 2000, a test pit was excavated at the bottom of the 1607-H2 drain field excavation. The purpose of the test pit was to characterize soil lead and mercury concentrations at depth for development of a site-specific model The test pit was excavated to 4.6 meters (15 ft) below the bottom of the drain field excavation. Samples were collected from the test pit at intervals of 1 meter and analyzed for arsenic, total chromium, mercury, and lead. Test pit samples were not analyzed for radionuclides because the cleanup verification samples collected from the walls and floor of the site excavation indicated that remaining site soil radionuclide concentrations are at or below background.

Results of the sampling, laboratory analyses, and data evaluations for the 1607-H2 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

**Code:** 1607-H3

**Names:** 1607-H3; 1607-H3 Sanitary Sewer System; 1607-H3 Septic Tank; 1607-H3 Septic Tank and Associated Drain Field; 124-H-3

**Type:** Septic Tank

**Status:** Inactive

**Start Date:** 1/1/1948

**End Date:** 1/1/1968

**Description:** The waste site was a septic tank and drain field. The tank is constructed of concrete and measures 5.6 by 2.1 by 4.0 meters (18.5 by 7 by 13 feet) deep. The tank had a 100 person capacity with an average detention period of 24 hours.
The drain field was constructed of 10-centimeter (4-inch) vitrified pipe. It measured 15 by 30 meters (50 by 100 feet). It was oriented in-line with, and approximately 24 meters (80 feet) from the septic tank. A row of eight vent pipes were visible, running perpendicular to the entrance road.

**Location:** The 1607-H3 septic tank and drain field were located along H Avenue northeast of the 1701-H Badge House.

**Process Description:** The 1607-H3 septic system received sanitary sewage from the 1701-H Badge House, the 1709-H Fire Station, and the 1720-H Security Patrol Change Room. In addition to the sanitary sewage, liquids from the 1701-H Badge House darkroom (used for film badge processing) were disposed to the 1607-H3 septic system.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** This unit received unknown amounts of sanitary sewage from the 1701-H Badge House (security checkpoint), the 1720-H Security Patrol Change Room, offices, and the 1709-H Fire Station. The sewage per capita is 130 liters (35 gallons) plus 20% for sludge.

**Closure Info:** All of the facilities associated with the septic system have been removed to grade. Remedial action at the 1607-H3 waste site was performed between October 13 and November 10, 2009, and encompassed the removal of the below-grade septic tank and the drainage field pipelines. The site was excavated to depths ranging from approximately 1.6 meters (5.3 feet) at the drain field to 4 meters (13 feet) at the septic tank location, resulting in approximately 3,763 bank cubic meters (BCM) (4,922 bank cubic yards [BCY]) of soil and piping/debris being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). In addition, approximately 235 meters (771 feet) of vitrified clay pipe were removed. The soil was sorted within the excavation and direct loaded for disposal at ERDF. Approximately 1,729 BCM (2,261 BCY) of overburden soil was removed from above the drain field piping and stockpiled for evaluation for use as clean backfill.

The debris removed from the 1607-H3 waste site was consistent with that of a sewage system and in agreement with the pre-excavation geophysical survey findings. Some six and eight inch diameter piping was excavated that had soldered joints. These pipe segments were segregated for macro-encapsulation as a lead contaminate prior to disposal at ERDF. Small portions of lateral pipelines associated with the 100-H-51:4, 100-H Main Gate Storm Drain waste site were removed during the 1607-H3 waste site remediation.
Rev. 24

Waste Type: Barrels/Drums/Buckets/Cans
Waste Description: This unit received an unknown amount of sanitary sewage from the 181-H River Pumphouse. The sewage per capita is 130 liters (35 gallons) plus 20% for sludge.
Closure Info: Remedial excavation at the 1607-H4 site began on November 5, 1999 and completed July 24, 2000. The structure and contaminated underlying soil was removed. The elevation of the bottom of the excavation was at 120.4 meters (394.9 feet) upon completion. The excavation was approximately 161 square meters (1,732 square feet) in area with a maximum depth of approximately 3.6 meters (11.8 feet). Approximately 2,078 metric tons (2,286 tons) of material from the site were disposed at the ERDF.
100-HR-2

Code: 100-H-2
Names: 100-H-2; Buried Thimble Site; Thimble Pit
Type: Burial Ground
Status: Inactive

Description: This site has been remediated and Interim Closed Out. No evidence of buried waste was discovered during the excavation.

Location: The site was located south of the 105-H Reactor Building, in between and near the convergence of 2 north to south-running railroad spurs. This area is located in an area that, prior to World War II and formation of the Hanford Site, was occupied by fruit tree orchards.

Process Description: 100-H Reactor operated from October 1949 to April 1965. Reactor burial sites contain two types of radioactive waste: neutron activated steel and aluminum material containing cobalt-60 and surface contaminated waste contaminated primarily with zinc-65.

Waste Type: Oil

Closure Info: This area is located in an area that, prior to World War II and formation of the Hanford Site, was occupied by fruit tree orchards.

Remedial action at the 100-H-17 sites group (100-H-17, 100-H-30, 100-H-2 and 116-H-2) began on February 2, 2000. The sites were grouped together for remediation because of location and similar contaminants. Excavation of the area involved removing the overburden materials, miscellaneous debris, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF. On February 10, 2000, the excavation was completed.

No evidence of buried waste was found during the excavation of the 100-H-2 site.

At the completion of the remedial action, the total excavation was approximately 6,240 square meters (67,170 square feet) in area with a maximum depth of approximately 2.6 meters (8.5 feet). Approximately 19,920 metric tons (21,960 tons) of material from the site were disposed of at the ERDF.

100-H-37

Code: 100-H-37
Names: 100-H-37; 100-H Mud Dauber Contamination Area
Type: Contamination Migration
Status: Inactive

Description: 100-H-37 has been remediated and Interim Closed Out. The waste site consisted of multiple radiologically contaminated areas caused by mud dauber wasps that created nests from contaminated mud. The contaminated nests were discovered during remediation of the 105-H Fuel Storage Basin (118-H-6:4). While removing and processing dirt and sediment from the lower 38 cm (15 in) of the FSB, elevated airborne radioactivity levels that exceeded posting criteria were noted. One of the corrective actions was to maintain at least 5.1 centimeters (2 in)
of water on the basin floor. The mud daubers utilized the large source of contaminated mud in the 105-H Fuel Storage Basin (FSB) to construct their tube nests. The insects transported the contaminated mud from the FSB to multiple areas surrounding the reactor. The majority of the areas contained more than one nest, some were greater than ten nests. Forty three areas of contaminated nests were located. The postings were removed after the areas were remediated.

**Location:** The nests were estimated to be scattered across approximately 10.1 hectares (25 acres) throughout 100-H Area.

**Release Description:** On December 11, 2002, while removing and processing dirt and sediment from the floor of the 105-H Fuel Storage Basin (FSB) (118-H-6:4), elevated airborne radioactivity levels were generated and later observed on the air sample filter that was removed from the air sampler located on excavation equipment. A preliminary analysis of the filter indicated radioactivity greater than the threshold for posting an Airborne Radioactivity Area (ARA). The FSB was already posted as a Radiation Area/Contaminated Area (RA/CA) at the time of the work. It was then posted as an Airborne Radioactivity Area (ARA) and no one else entered the area.

Work in the 105-H FSB was to proceed using a manned track-hoe excavator to remove basin fill from the lower 38 cm (15 in) between the basin floor stem walls. A contamination survey of the excavator bucket showed removable contamination levels that were higher than expected for both alpha and beta-gamma contamination. Based on the elevated bucket contamination levels, the entire FSB was re-posted as a High Contamination Area (HCA). Analysis at the Radiological Counting Facility (RCF) indicated the presence of americium and plutonium. Based on the analysis, the FSB was posted and controlled as an Airborne Radioactivity Area (ARA). The probable source of the airborne radioactivity was the contamination entrained in the cement dust released from the basin floor and stem walls during the excavation process.

The 105-H FSB (118-H-6:4) was approximately 6.1 meters (20 ft) deep. The fill consisted of approximately 5.2 meters (17 ft) of clean fill over a 76.2 cm (30 in) layer of sludge, debris and potential fuel fragments. Some dust became airborne during the scraping of the basin floor and stem walls, and airborne radiological posting criteria were exceeded. Consequently, one of the corrective actions was to maintain at least 5.1 centimeters (2 in.) of water on the basin floor to reduce airborne dirt and sediment, which created mud. The mud dauber wasps transported mud from the FSB floor to other areas surrounding the 105-H Reactor Building using the mud for construction of their tube nests. The nests were radiologically contaminated.

**Related Sites/Structures:** The 100-H-37 contamination migration is associated with the 105-H Fuel Storage Basin (118-H-6:4). Some contaminated nests were deferred to 100-H-41 and 100-H-58. Other mud dauber sites in 100-H Area were remediated along with these sites, 126-H-2, 116-H-5, 118-H-6:4, 118-H-3, 118-H-5, and 118-H-1.

**Waste Type:** Process Effluent

**Waste Description:** The waste is contaminated mud dauber nests and other materials depending on the where the nest(s) were placed, including electrical utility poles, manholes, and other structures. The mud dauber contamination limits: removable - beta-gamma 1000 dpm/100cm2; alpha 20 dpm/100cm2. Total - beta-gamma 5000 dpm/100cm2; alpha 100 dpm/100cm2. The contaminants of potential concern include beta-gamma emitting isotopes C-14, Ni-63, H-3, Co-60, Sr-90, Cs-137, Eu-152, Eu-154. The alpha emitting isotopes would be Pu-239/240, and Am-241. RCF samples 11261,11262, 11263, 11259, 11260 were used to determine the radioactive isotopes for the site.

**Closure Info:** A mud dauber characterization strategy was developed and approved by DOE and Ecology to guide remediation activities and provide closure documentation for the 100-H-37 waste site. The waste site consisted of seven discrete nest areas east of the 105-H Reactor. A Remaining Sites Verification Package (RSVP) document was not prepared for the 100-H-37 waste site, because the applicable components were better addressed using attachments to the waste site.
reclassification form. No separate calculations or comparison to screening levels for the 100-H-37 waste site were done. The 100-H-37 waste site was included in the Explanation of Significant Differences for the 100 Area Remaining Sites Interim Remedial Action Record of Decision, for remediation, treatment, and disposal.

In July 7, 2009, Ecology concurred that the data collected for this study indicated that radiological field instruments are reliable to ensure RAGs are achieved. Remedial action began with the excavation of individual nests with a backhoe, due to the difficulty in hand digging and the sloughing of excavation material. Areas containing numerous and individual nests were removed. The number of nests in an area and the straw covered re-vegetated areas were considered in decisions to excavate individual nests or scrape an entire area. Forty small, dispersed excavations and three large areas of contamination were excavated. The three large areas were scraped to ensure remediation of locations containing many nests and to protect the field radiological instrumentation that could be damaged by taking readings in areas with dense rabbit brush and other vegetation. After excavation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed on these three large areas. Handheld radiological surveys verified that the forty smaller excavations were no longer contaminated. Several of the areas which appeared on the original, overall 100-H-37 site location map were remediated along with other waste sites at the 100-H Area, including 126-H-2, 116-H-5, 118-H-6:4, 118-H-3, 118-H-5, and 118-H-1. Several of the mud dauber areas were located on active power lines that serviced facilities in the 100-H Area. The power poles are located along H Avenue, Herron Avenue, and from the west of the 105-H Reactor Building to the warehouse. These locations have been deferred to the 100-H-58 waste site. Also, during confirmatory sampling activities at waste site 100-H-41, the radiological contamination inside a pipe was confirmed to be the result of contaminated mud dauber nests located on the pipe of concern. The nest was addressed with 100-H-41.

Excavations took place between July 14 and August 21, 2008. Two additional mud dauber areas were excavated in December 2009. This second event only took one day to complete. A total of 19,153 BCM were removed and disposed at ERDF.

The contaminated areas were remediated by removing radiologically contaminated materials to ensure remedial action goals (RAGs) were achieved. No RSVP was prepared. The reclassification was made with supporting documentation attached to reclassification form 2010-007.

<td></td>
</tr>
</tbody>
</table>
Test pit 1 (TP1) was excavated to a depth of 3 meters (10 ft) below ground surface (bgs) where native soil was encountered. A sample (J1RP26) was collected from the backhoe bucket of material brought up from the bottom of the excavation, and the excavation was then backfilled.

Test trench 1 (TT1) was excavated to a depth of 2.4 meters (8 ft) where native soil was encountered. A sample (J1RP27) was collected from the backhoe bucket of material brought up from the bottom of the excavation at the approximate midpoint of TT1, and the excavation was then backfilled.

Test trench 2 (TT2) was excavated to a depth of 3 meters (10 ft) where native soil was encountered. Two samples and a duplicate were collected from the backhoe bucket of material brought up from the bottom of the excavation; a sample (J1RP29) was collected at the east end of TT2 excavation, and a sample (J1RP28) and a duplicate (J1RP30) were collected at the west end of TT2 excavation. The excavation was then backfilled.

No elevated radiological or elevated VOC readings were noted in the field. No suspected asbestos-containing material or other anomalous material was observed during confirmatory sampling. Herbicides and pesticides were identified in the sample design, but sample material for these two analyses were not collected. Fortunately, sufficient excess sample material was available in the laboratory from other analyses to perform the overlooked analyses.

Confirmatory sampling results, in conjunction with field instrumentation screening results, indicated that the residual concentrations of contaminants of potential concern (COPC) at this site met the Remedial Action Goals for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the confirmatory investigation results support a reclassification of the 100-H-38 waste site to No Action.

<tr>
<td>Related Sites/Structures:</td>
<td>The site was associated with 1700-H buildings, including 1709-H, 1716-H, 1717-H and 1720-H (DC-0227).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The 100-H area was constructed between March 1948 and October 1949. The disposal of solid wastes during construction was documented in the Design and Construction History, Project C-165-A, Pile Area &quot;H&quot; (HW-24800-2). The report indicated that a burning pit (128-H-1) was &quot;established at the northwest corner of the area for disposing of the trash and rubbish plus the usual odds and ends of waste construction material&quot;. The construction of 100-H area also included the creation of a solid waste burial ground (118-H-1). The burial ground was used for the disposal of solid dry wastes (HW-27337). Other burial grounds were created during the facility operations for the purpose of disposing reactor hardware. Documentation of solid waste disposal during the reactor operations (1949 through 1965) was limited to the facility's radioactive wastes. The disposition of nonradioactive solid waste is not otherwise documented</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
but presumed to have disposed of at the 118-H-1 and 128-H-1 waste sites, with one notable exception.

**Waste Type:** Chemicals

**Waste Description:** Contaminants of potential concern may include lead, ICP metals, TPH, PAH, PCBs. This site may contain maintenance shop waste, e.g. paint cans and auto repair waste (Denton, L interview 1990).

**Closure Info:** Confirmatory sampling activities at the site were performed from October 27 to 29, 2009. The eight locations with indications of geophysical anomalies were excavated to investigate for potential buried maintenance shop debris. Test Pit excavations unearthed small pieces of metallic surface debris and transite siding, native soil and small volumes of debris at shallow depths. At test pit 7, material within the excavation was consistent with the burial of a demolished building.

---

**Code:** 100-H-58

**Classification:** Accepted

**Names:** 100-H-58; Mud Dauber Nests On Active Powerlines In 100H Area

**Type:** Contamination Migration

**Status:** Active

**Description:** The site consists of contaminated mud dauber (wasps) nests in the 100-H Area. Multiple mud dauber nests were discovered on power lines and power poles. The nests could not be remediated because the lines are in use.

**Location:** The nests were identified along H Avenue, Herron Avenue, and from the west of the 105-H Reactor Building to the warehouse.

**Related Sites/Structures:** Other mud dauber contamination sites were 100-H-37 and 100-H-41.

**Process Description:** During cleanup of the 105-H Fuel Storage Basin (FSB), dirt and sediment were removed from the lower 38 cm (15 in.) of the basin, which was 6.1 m (20 ft) below ground surface. Some dust became airborne during the scraping of the basin floor and stem walls, and airborne radiological posting criteria were exceeded. Consequently, one of the corrective actions was to maintain at least 5.1 cm (2 in.) of water on the basin floor to reduce airborne dirt and sediment, which created mud. The mud dauber wasps transported mud from the FSB floor to other sediment and debris areas surrounding the 105-H Reactor Building using the mud for construction of their tube nests. These mud dauber areas became the 100-H-37 waste site. However, during remediation of 100-H-37, multiple mud dauber nests were discovered on power lines that could not be remediated because the lines were in use. These lines are along H Avenue, Herron Avenue, and from the west of the 105-H Reactor Building to the warehouse. The nests are primarily within crevices in the wooden poles, and 35 nests have been counted. It is possible that more nests could be present, as characterization did not occur at heights above 7 ft. A mud dauber characterization strategy was developed and approved by the U.S. Department of Energy and Washington State Department of Ecology (Ecology) to guide remediation activities and provide closure documentation for the 100-H-37 waste site. The strategy included an initial characterization approach to verify the accuracy of radiological field instruments to be used in the place of soil sampling for verification and closeout purposes. On July 7, 2009, Ecology concurred that the data collected for this study indicated that radiological field instruments are reliable to ensure RAGs are achieved for the mud dauber waste site.

---

**Code:** 118-H-1

**Classification:** Accepted
**Names:** 118-H-1; 100-H Burial Ground No. 1; 100-H-1  
**Reclassification:** Interim Closed Out (10/12/2011)

**Type:** Burial Ground  
**Start Date:** 1/1/1949

**Status:** Inactive  
**End Date:** 1/1/1965

**Description:** The waste site has been remediated. During remediation, the burial ground was divided into two subsites - 118-H-1:1; 100-H Burial Ground Trenches and Sorting Cells and 118-H-1:2; Anomaly Staging Area and Fuel Bunker.

The waste site was a mixed solid waste burial ground. The overall site runs east and west. There are numerous trenches of various dimensions, generally running north and south. The boundaries are permanently marked with concrete posts numbered H-65-1 through H-65-23.

**Location:** The site is located about 396 m (1,300 ft) southwest of the 105-H Building.

**Release Description:** On October 4, 1960, a controlled fire was set at the north end of the burial site to reduce the volume of contaminated material. Control over the fire was lost when two large explosions and several small explosions occurred from underlying drums containing residual combustible materials.

**Process Description:** This is the primary solid waste burial ground for the 100-H Area. The wastes disposed of in it include process tubing, contaminated lead bricks, dummy fuel elements, and miscellaneous hardware.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The site received activated components and miscellaneous solid wastes (surface contaminated). Typical examples of activated components are aluminum dummies and process tubing, steel gun barrels and step plugs, thermocouple wires and balls from the 3X safety system. Portions of several horizontal control rods were buried in slit trenches near the southwest corner of the site. Typical examples of surface contaminated materials are hand tools, rags and sweeping compound, light bulbs, sheets of plastic and paper. This type of material was usually sealed in cardboard boxes and placed in separate trenches from the activated components.

**This Site has the Following SubSites:**

<table>

</tbody>
</table>

**Code:** 118-H-1:1  
**Classification:** Accepted

**Names:** 118-H-1:1; 100-H-1 Burial Ground trenches  
**Reclassification:** Interim Closed Out (7/29/2011)

**Type:** Burial Ground  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The 118-H-1:1 subsite has been remediated. It consisted of the original burial ground (trenches A-F) and sorting cells (1-3). In general, all trenches and sorting cells were angled from north to south. Based on the results of the applicable cleanup verification package (CVP or RSVP) documents, authorization was given to remove the Soil Contamination Area and Underground Radioactive Material Area postings from this waste site.

**Location:** The site was located about 396 meters (1,300 ft) southwest of the 105-H Building.

**Process Description:** The trenches (A-F) were the primary solid waste burial ground for the 100-H Area. Mixed solid waste such as lead bricks, process tubing, oil drums, and miscellaneous reactor hardware were
disposed in the trenches between 1949 and 1965. The trenches were backfilled to grade with 6 feet of soil cover. The sorting cells were created during remediation of the burial ground in 2008 and were used to determine the presence of suspect spent nuclear fuel and anomalies.

The burial ground trenches received activated components and miscellaneous solid wastes (surface contaminated). Typical examples of activated components are aluminum dummies and process tubing, steel gun barrels and step plugs, thermocouple wires and balls from the 3X safety system. Portions of several horizontal control rods were buried in slit trenches near the southwest corner of the site. Typical examples of surface contaminated materials are hand tools, rags and sweeping compound, light bulbs, sheets of plastic and paper. This type of material was usually sealed in cardboard boxes and placed in separate trenches from the activated components.

**Closure Info:** Remedial action began on July 22, 2008, and continued through June 29, 2009. Six trenches (A, B, C, D, E, and F) were excavated with approximately 8,160 bank cubic meters (BCM) (10,673 bank cubic yards [BCY]) of overburden soil stockpiled for use as clean fill. Approximately 34,496 BCM (45,119 BCY) of soil and debris were removed for disposal at ERDF. No spent nuclear fuel or thimbles were discovered at the site. Field observations during excavation indicated the presence of concrete, piping, lead bricks, perforated tubes, and control rods among the types of debris removed from the burial ground excavation. There were not any patterns of waste found from one trench to another; there was a random assortment of waste throughout the burial ground. Burial Ground anomalies included a breached pipe with a white solid inside, a forklift battery, suspect hydraulic oil, a damaged drum containing liquid, gray waxy material, oil stained soil, and a deteriorated drum.

**The SubSite is Part Of:**

**Code:** 118-H-1

**Names:** 118-H-1; 100-H Burial Ground No. 1; 100-H-1

**Type:** Burial Ground

**Status:** Inactive

**Description:** The 118-H-1:2 subsite consisted of one anomaly staging area, one anomaly characterization area and a suspect pent nuclear fuel bunker area. The areas were delineated using yellow and magenta rope with radiological postings.

On February 18, 2011, the suspect spent nuclear fuel bunker (SSNF) waste was transported from the 118-H-1:2 bunker staging area to the 100-D, 118-D-3:2 south bunker area. The fuel was later sent to the 100-K fuel storage basins.

All anomalous items found in the 118-H-1:1 Burial Ground were staged in the 118-H-1:2 anomaly staging areas. The anomalies stored there included concrete, piping, lead bricks, process tubing, reactor control rods, oil drums, and miscellaneous reactor hardware. The fuel bunker was constructed to store pieces of reactor fuel prior to characterization and dismantling. The staging area has been remediated.

118-H-1:1 anomalies include a breached pipe with a white solid inside, a forklift battery, suspect hydraulic oil, a damaged drum containing liquid, grey waxy material, oil stained soil, and a deteriorated drum. No spent nuclear fuel was discovered at the 118-H-1:1 Burial Ground.

**Location:** The fuel bunker was located approximately 400 meters southwest of the 105-H Reactor
Building and north of the 118-H-1:1 Trench E. The two anomaly staging areas were just west of 118-H-1:1 (one was north of Trench F and one was south).

**Process Description:**
The subsite area received anomalous material removed during the remediation of the 118-H-1 burial trenches. The material was inspected and sampled in this area prior to disposal.

**Closure Info:**
On February 18, 2011, the suspect spent nuclear fuel bunker (SSNF) waste was transported from the 118-H-1:2 bunker area to the 100-D, 118-D-3:2 south bunker area. The fuel was shipped from there (100-D Area) to the 100-K Fuel Storage Basins on April 27 and May 3, 2011.

Following the removal of the fuel and the concrete bunkers, and the characterization and processing of staged anomalies, a 0.3 meter (1 ft) scrape of the staging area, characterization area and SSNF bunker area was conducted. The soil was scraped from these areas to ensure that any potential contamination that may exist as a result of the anomaly characterization and processing has been removed. Approximately 272 bank cubic meters (BCM) (356 bank cubic yards [BCY]) of soil was direct loaded for disposal at the ERDF. An additional 80 BCM (105 BCY) was removed on June 8, 2011 to remove residual contamination identified after verification sampling was conducted.

**The SubSite is Part Of:**

- **Code:** 118-H-1
- **Names:** 118-H-1; 100-H Burial Ground No. 1; 100-H-1

**Code:** 118-H-2  
**Classification:** Accepted

**Names:** 118-H-2; H-1 Loop Burial Ground; P-13 Test Loop; 100-H Burial Ground No. 2  
**Reclassification:** Interim Closed Out (11/15/2010)

**Type:** Burial Ground  
**Start Date:** 1/1/1955

**Status:** Inactive  
**End Date:** 1/1/1965

**Description:** The site has been remediated. It was oriented east to west and contained two, in-line concrete vaults. Both vaults were covered to grade with approximately 3.7 meters (12 feet) of soil. The site boundaries were permanently marked with concrete posts numbered H-65-24 through H-65-29. Based on the results of the applicable cleanup verification package (CVP or RSVP) documents, authorization was given to remove the Soil Contamination Area and Underground Radioactive Material Area postings from this waste site.

**Location:** The site was located approximately 457 meters (1,500 feet) west of the 105-H Reactor Building.

**Process Description:** The burial ground operated between 1955 and 1965 to receive an irradiated test loop and contaminated piping from the 105-H Reactor. After the 105-H Reactor was shut down in 1965, the concrete vaults were filled and covered to grade with approximately 3.7 meters (12 ft) of soil.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The east vault received one stainless steel double tube removed from the reactor in 1955 after several years of irradiation. Within the same area there are also solutions which were used to clean the tube, and miscellaneous capsule components. The west vault was constructed in 1958 and used during deactivation of the 105-H Reactor Building for disposal of a small amount of contaminated pipe.

**Closure Info:** Remedial action began on April 20, 2009, and continued through June 3, 2009, with the removal of 4,366 bank cubic meters (BCM) (5,711 bank cubic yards [BCY]) of soil and debris. An initial Global Positioning Environmental Radiological Survey (GPERS) identified elevated
residual radioactivity in the eastern end of the excavated area within the waste site. Additional soil was excavated from that area on June 16, 2009, and a second radiological survey was conducted to verify that the contamination was removed.

Waste encountered during excavation consisted of concrete rubble produced from demolition of the two concrete vaults and some metal piping of varying sizes. One pipe had a 20 R/hr radiological contact dose rate, which distinguished it from the other metal debris. All metal and piping was size-reduced as necessary and disposed at ERDF along with contaminated soil. No spent nuclear fuel or other anomalous material (e.g., containers or stained soils) or indications of previous spills or releases were discovered at the waste site.

<td>Description:</td>
<td>This site has been remediated and Interim Closed Out. The site was an uneven polygon with sides measuring approximately 30 by 114 by 95 by 122 meters (100 by 375 by 313 by 400 feet). It ran in a northeast to southwest direction and was permanently marked with concrete posts numbered H-81-1 through H-81-13. The trenches had been covered to grade with 1.8 meters (6 feet) of soil. Based on the results of the applicable cleanup verification package (CVP) document, authorization was given to remove the Soil Contamination Area and Underground Radioactive Material Area postings from this waste site.</td>
<td></td>
</tr>
</tbody>
</table>

Location: The site was located southeast of the 105-H Building.

Process Description: The burial ground received components and hardware from reactor modification programs. The site operated from 1953 to 1957 to receive approximately 3,000 cubic meters (3,924 cubic yards) of reactor components and hardware, including contaminated 41 cm (16 inch) diameter pipes that were used as chutes that received the reactor vertical safety rod thimbles and other components removed from reactor modification programs. Originally, two northern trenches were used mostly for the disposal waste into the chute pipes. A third trench, south of the original two trenches, was developed later as a disposal site for large reactor components and hardware.

Waste Type: Equipment

Waste Description: The site contains sections of contaminated 41-centimeter (16-inch) diameter pipe used as chutes for removal of thimbles from the 105-H Building during outages, reactor hardware, and components from reactor modification programs. The COCs identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan and are: cobalt-60, cesium-137, europium-152, europium-154, strontium-90, uranium-233/234, and uranium-238.

Closure Info: Remedial action at the 118-H-3, Construction Burial Ground waste site began on March 4, 2009. The excavation of the waste site continued through April 22, 2009, to a depth of approximately 4.6 to 5.5 meters (15 to 18 ft), resulting in a total 6,384 bank cubic meters (BCM) (8,350 bank cubic yards [BCY]) of debris and soil removed for disposal at the ERDF. All material removed from within the trenches was taken to sorting cells for surveying and unloading. Large metal and reactor hardware components excavated from trench A were stockpiled in a waste staging area on the east side of the trench. These metal sections were staged for size reduction prior to shipment for disposal. After size reduction was completed on May 18, 2009, the metal debris and an additional 0.3 meter (1 ft) layer of underlying soil
(approximately 60 BCM [75 BCY]) within the waste staging area footprint was removed.

The debris from the 118-H-3, Construction Burial Ground consisted mostly of metal components and very large pieces of reactor hardware (pipes, elbows, etc.). Trench C also contained aluminum tubing. No areas of stained soil or anomalous soil material were identified during the excavation. The waste removed from the trenches was consistent with the types of material expected to be present in this burial ground site.

On March 17, 2009, a suspected flammable gas cylinder, believed to be propane, was discovered. This cylinder was approximately 1.2 meters (4 ft) tall and 51 cm (20 in.) in diameter. It was located in the southeastern part of trench A, at Washington State Plane coordinates N152204.8/E 577837.2. No leakage or soil discolored was observed. The cylinder appeared rusted with blue/gray oxidation on the outlet female valve and the circular valve handle. On May 19, 2009, the cylinder was inspected and found to be empty. Following inspection, the cylinder was reduced in size and shipped to ERDF. No other anomalous material was discovered during the excavation.

<td></td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Remedial action began on November 4, 2008, and continued through April 14, 2009 to an approximate depth of 4.5 m (14.8 ft), resulting in approximately 1,600 bank cubic meters (BCM) (2,100 bank cubic yards [BCY]) of soil and debris that were removed for disposal at ERDF. Additional material was removed on May 4, 2010, because verification sample results indicated residual contamination exceeding direct exposure RAGs was present at two statistical sample locations. A total of approximately 48 BCM (63 BCY) were removed from the SZ-9 and SZ-10 sample locations and disposed at ERDF. For verification sampling, the site was divided into two decision units: the burial ground excavation and the waste staging area footprints. Both statistical sampling design and focused sampling was utilized. Two potentially lead filled cylinders and one carbon steel canister with two metal tubes extending from it were removed from the excavation and staged. It was determined that cylinder was empty and the canister was lead lined, but empty.</td>

</tbody>
</table>
**Code:** 118-H-5  
**Classification:** Accepted  

**Names:** 118-H-5; 105-H Thimble Pit  
**Reclassification:** Interim Closed Out (1/5/2010)  

**Type:** Burial Ground  
**Start Date:** 1/1/1953  
**End Date:** 1/1/1960  
**Status:** Inactive  

**Description:** The 118-H-5, 105-H Thimble Pit has been remediated and Interim Closed Out. It was a mixed solid waste burial ground that operated in 1953 to receive a single experimental thimble assembly. It was reopened in 1960 to receive contaminated soil from the original 105-H Pluto Crib Site (116-H-4 waste site). The 105-H Pluto Crib received contaminated cooling water from reactor process tubes containing ruptured fuel elements. Based on the results contained in the cleanup verification package (CVP-2009-00009) document, authorization was given to remove the Soil Contamination Area and Underground Radioactive Material Area postings from this waste site.

**Location:** The site was located south of the 105-H Building, within the 105-H exclusion area fence.

**Related Sites/Structures:** The site is associated with 100-H-39.

**Process Description:** This site received a single experimental thimble assembly in 1953 and contaminated soil from the 105-H Pluto Crib in 1960.

**Waste Type:** Water  
**Waste Description:** The site contains a thimble assembly from the B Experimental Hole, 105-H X-level, buried in 1953. In 1960, the 105 Pluto Crib (116-H-4) was excavated due to the construction of the 105-H Confinement System and placed in this site.

**Closure Info:** Remedial action at the 118-H-5, 105-H Thimble Pit waste site began on September 11, 2008 to excavate and expose the single thimble and any other waste buried at the site. Remedial action at the site involved removing contaminated soil and a single thimble for disposal to ERDF. The excavated material was maintained within the waste site footprint; therefore, no staging piles were generated outside of the remediation footprint. After the thimble was located, all material was returned to the excavation until load out began on November 10, 2008. The excavation of the waste site continued through November 12, 2008 to a depth of approximately 3.5 meters (11.5 ft), resulting in approximately 400 bank cubic meters (BCM) (523 bank cubic yards [BCY]) of contaminated soil and debris removed for disposal to the ERDF.

---

**Code:** 128-H-1  
**Classification:** Accepted  

**Names:** 128-H-1; 100-H Burning Pit; 100-H Burning Pit No. 1  
**Reclassification:** Interim Closed Out (5/8/2012)  

**Type:** Burn Pit  
**Start Date:** 1/1/1949  
**End Date:** 1/1/1965  
**Status:** Inactive  

**Description:** The waste site has been remediated and Interim Closed Out. It was in a large natural depression that appeared to have been a borrow area. It contained scattered surface debris including wood, glass, metal, wire, cable, and clay pipe. There were also fragments of charred material, scattered concrete and metal. The majority of the surface debris was found between a berm and the eastern edge of the site. Some debris appeared to be solvent, spray paint cans, transite and large pieces of metal on wooden pallets. During remediation, a steel pipeline was found running north to south through the burn pit. It was determined to be part of the 100-H-51:5 pipelines. In 2009, the 100-H-56 water line was also found within the burn pit.

**Location:** The 128-H-1 waste site was located in a large natural depression approximately 15 meters (50
ft) east of the west perimeter road and north of the 126-H-1 ash pit.

Process Description: The site was used for the disposal of nonradioactive, combustible materials, such as paint waste, office waste, and chemical solvents. The 128-H-1, 100-H Burning Pit was an inactive, nonradioactive hazardous solid waste site that operated from 1949 through 1965. It was the primary burn pit for the 100-H Area and was located in a large natural depression. The site was reportedly used for the disposal of nonradioactive combustible materials such as paint waste, office waste, and chemical solvents. Waste oil containing polychlorinated biphenyls (PCBs) may have been disposed here. Old signs were posted at the site that read "Warning, Do Not Deposit Salvable Material".

Waste Type: Barrels/Drums/Buckets/Cans
Waste Description: The site was used for the disposal of nonradioactive, combustible materials, such as paint waste, office waste, and chemical solvents. The burning of solvents and experimental burns have been reported, by a past 100-H Area employee, to have taken place along the east side of the site.

Closure Info: Remediation of the 128-H-1 waste site was performed from June 23, 2009, through May 25, 2011. Approximately 16,310 bank cubic meters (21,333 bank cubic yards) of debris (e.g., wood, concrete, glass, ash, and batteries) plus contaminated soil was removed, stockpiled onsite, and later disposed at the Environmental Restoration Disposal Facility. Following remediation, verification sampling was conducted in June 2010. Results showed that six sample locations within the burn pit excavation area and one sample in the soil stockpile area exceeded cleanup criteria for various contaminants. As a result, from April 11 through May 26, 2011, additional remedial excavation was performed to remove contaminated soils in the burn pit excavation and stockpile sample locations. On May 26, 2011, additional samples were collected from the entire burn pit excavation and the new waste staging pile area using a new sample design. On June 16, 2011, a sample was also taken from the original failed location of the stockpile area. These results indicated that, following the additional remediation, residual contaminant concentrations met the remedial action objectives (RAOs) and remedial action goals (RAGs) for the 128-H-1 waste site.

Previous to the Manhattan Project, several orchards existed on the Hanford Site in the 100 Area. Prior to performing remediation, 0.3 meters (1 ft) of topsoil was scraped from this area and staged for post-remediation reuse. It was subsequently determined that surface soil scraped from this area contained arsenic and lead due to historic pesticide use because the waste staging area footprint was located in a historic orchard area. As agreed to by the Tri-Parties (Tri-Party Agreement Change Notice TPA CN 401 [DOE-RL 2010]), lead and arsenic contamination that resulted from pesticide use before the Manhattan Project are excluded as COPCs and will be discussed in a future Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) document.

Excavation of the burn pit area began in early July 2009 and proceeded to a maximum depth of approximately 7 meters (23 ft). Prior to remediation, a test pit was excavated in the burn pit area to a depth of 2.5 meters (8 ft). Batteries, glass, concrete, wood, ash associated with burning, and a blue-green material were found in the burn area.

Names: 128-H-2; 100-H Burning Ground #2
Type: Burn Pit
Status: Inactive
Classification: Accepted
Reclassification: Interim No Action (1/25/2010)
Start Date: 1/1/1965
End Date: 1/1/1965
Description: The site has been evaluated and determined to require No Action. It consisted of a depression and appeared as a graded rocky area with minimal soil. It was originally thought to be a burning
During a March 2000 visit, no evidence of burning was found. Although surface debris, including wood, metal cables, cans, lighting fixtures, concrete and a battery had been reported as being present and scattered throughout the site, no surface debris was found during the March 2002 site walk down.

Location: The site is located southwest of the 118-H-1 Burial Ground, west of the southwest corner of the 100-H Area perimeter road. The location of this site was verified by employees who said they had used it.

Waste Type: Equipment
Waste Description: The site received combustible materials such as vegetation, office waste, paint waste, and chemical solvents.

Closure Info: Historical photographs show that this site was in the southeast corner of what appears to be an orchard. A cultural resource inspection, performed in 2007, concluded that the trench associated with the 128-H-3 waste site was part of a pre-Hanford Site farm irrigation system and not a burn pit. Confirmatory sampling performed within the waste site mapped boundaries surrounding the cobble field and not within the trench, per agreement with the Washington State Department of Ecology (Ecology) and the U.S. Department of Energy, Richland Operations Office (RL). The site has limited access, deterring its selection as a burn pit site. No debris or waste consistent with burning pits has been found at the site.

A geophysical survey of 128-H-2 was done in August 2004. A geophysical survey of 128-H-3 was done in March 2007. No anomalies were found at 128-H-2. Wire debris was found at 128-H-3 that is similar to wire used in wooden irrigation piping. No anomalies characteristic of buried debris were identified.

Four test pits and one test trench were dug at 128-H-2 and five test pits were excavated at 128-H-3 to evaluate the subsurface soil for evidence of burning activities. Confirmatory sampling from the test pits was conducted on October 27, 2008. Lead was detected at a concentration (94.1 mg/kg) above both the groundwater (10.2 mg/kg) and river protection (10.1 mg/kg) lookup values.

Beyond a few pieces of surface trash consisting of a piece of heavy wire and the lid from a metal can, no debris or evidence of burning was found in the test pits.

---

**Code:** 128-H-3  
**Classification:** Accepted  
**Reclassification:** Interim No Action (1/25/2010)  
**Type:** Burn Pit  
**Start Date:**  
**End Date:**  
**Status:** Inactive  
**Description:** This site has been evaluated and determined to require No Action. It is a pit that resembles a trench. Dark colored rock is present but was determined by a geologist not to be the result of burning. The pit was almost completely filled with tumbleweeds.  
**Location:** The site is located west of 118-H-1 and north of 128-H-2. The pit is located on a rise above a cobble field.  
**Waste Type:** Barrels/Drums/Buckets/Cans  
**Waste Description:**  
**Closure Info:** Historical photographs show that this site was in the southeast corner of what appears to be an orchard.
A cultural resource inspection, performed in 2007, concluded that the trench associated with the 128-H-3 waste site was part of a pre-Hanford Site farm irrigation system and not a burn pit. Confirmatory sampling performed within the waste site mapped boundaries surrounding the cobble field and not within the trench, per agreement with the Washington State Department of Ecology (Ecology) and the U.S. Department of Energy, Richland Operations Office (RL). The site has limited access, deterring its selection as a burn pit site. No debris or waste consistent with burning pits has been found at the site.

A geophysical survey of 128-H-2 was done in August 2004. A geophysical survey of 128-H-3 was done in March 2007. No anomalies were found at 128-H-2. Wire debris was found at 128-H-3 that is similar to wire used in wooden irrigation piping. No anomalies characteristic of buried debris were identified.

Four test pits and one test trench were dug at 128-H-2 and five test pits were excavated at 128-H-3 to evaluate the subsurface soil for evidence of burning activities. Confirmatory sampling from the test pits was conducted on October 27, 2008. Lead was detected at a concentration (94.1 mg/kg) above both the groundwater (10.2 mg/kg) and river protection (10.1 mg/kg) lookup values.

Beyond a few pieces of surface trash consisting of a piece of heavy wire and the lid from a metal can, no debris or evidence of burning was found in the test pits.

---

**132-H-2**

**Classification:** Accepted

**Reclassification:** Interim Closed Out (8/1/2006)

**Start Date:** 1/1/1961

**End Date:** 1/1/1965

**Description:** The site has been remediated and interim closed. The structure had been demolished in-situ in 1984. The site now resembles a gravel parking lot.

**Location:** The site was located southwest of the 118-H-6 (105-H Reactor Building).

**Related Sites/Structures:** The building filtered exhaust air from 118-H-6 (105-H Reactor Building) to the 132-H-1 (116-H Reactor Exhaust Stack).

**Process Description:** The site consisted of a building that housed the filters for the 118-H-6 (105-H Reactor). The building received exhaust fan discharge through an inlet duct from 118-H-6 and discharged the filtered air through a discharge duct and out the 132-H-1 (116-H Stack). The building was a reinforced concrete structure, 10.7 meters (35 feet) high and 90% below grade. The maximum thickness of the walls and floors was 0.6 meter (2 feet), with the majority being 38 centimeters (15 inches) thick. The ducts were made of reinforced concrete with a maximum wall thickness of 46 centimeters (18 inches). The inlet duct was 23.2 meters (76 feet) long and the exhaust duct was 30.8 meters (101 feet) long.

**Waste Type:** Batteries

**Waste Description:** Total radionuclide inventory in the 117-H Building was estimated to be 0.41 millicuries. The radionuclides comprising this figure are tritium, carbon-14, cobalt-60, cesium-137, strontium-90, europium-154, europium-152, and plutonium-239/240. Of these radionuclides, strontium-90 is the most restrictive in the Allowable Residual Contamination Level (ARCL) calculations.

**Closure Info:** Demolition and site grading were completed in October 1984 using conventional heavy equipment, including a crane with a wrecking ball, earth-moving bulldozer, and trucks. Prior to demolition, the building roof covers and selected metal floor gratings were surveyed and found to be free of contamination. They were then removed and the 117-H Building floors were
perforated to allow for drainage. The ground above the ducts was excavated, then the exposed duct roofs were demolished. The ducts and the 117-H Building were filled to grade level with the demolished concrete and clean fill from nearby sources on the Hanford Site. A portion of the demolition rubble was left in place and covered with at least 1 meter (3.3 ft) of clean fill. The rubble from the seal pits was buried under at least 5 meters (16 ft) of clean fill. The site leveled and graded to blend with the surrounding terrain. As part of decommissioning activities, extensive radiological surveying and sampling activities were performed to characterize residual radiological contamination on the accessible internal surface areas of the 117-H Filter Building. Characterization results indicated that residual contamination was confined to the 1 millimeter (0.04 inch) vinyl paint layer. An evaluation of the concrete beneath the paint showed that the contamination did not penetrate the paint or absorb into the concrete.

The residual contamination occurred within a thin surface layer of paint on the interior surfaces of the building. It was determined that it is unlikely any contamination would be detected in the deep zone rubble resulting from demolition of the building. Additional excavation of the waste site to collect more information (i.e., samples) was not likely to result in a change to the Interim Closed Out decision for the 132-H-2 site.

The contaminated material was transported to the 200 Area for disposal.

The site was released for unrestricted use based on the ARCL Calculations for Decommissioning the 117-H Filter Building. The allowable residual contamination level (ARCL) calculation indicated that the demolished facility would contribute less than 1 millirem/year dose to a hypothetical, maximally-exposed site resident if the site was released for unrestricted use after the demolition and burial in situ of the facility. Consequently, demolition and site grading were performed in 1984 using conventional heavy equipment. The rubble was buried under at least 1 meter (3.3 feet) of clean fill, and the site was graded to blend with the natural terrain.

Using the maximum radiological activities from the pre-demolition characterization data to represent residual contamination levels over 100% of the paint and concrete surface of the former building, RESidual RADioactivity (RESRAD) modeling was performed in 2006 to support the previous decision to demolish and bury the building in place. The RESRAD modeling accounts for radioactive decay from 1984 (year of sampling) to 2006 and predicts that the site achieves the dose limits and risk objectives for rural residential land use with institutional controls, groundwater protection, and river protection.

**Classification:** Accepted

**Reclassification:** Interim Closed Out (9/1/2011)

**Start Date:** 1/1/1948

**End Date:**

**Description:** This waste site has been remediated. The 1607-H1 septic tank system was a nonhazardous, nonradioactive liquid waste site that began operation in 1948, and received sanitary sewage from the 105-H Reactor Building and the 151-H Primary Substation. The sanitary wastes from these buildings were conveyed to the 1607-H1 septic tank system via buried vitrified clay pipes (VCPs). These pipes are planned for remediation as the 100-H-28/4, 1607-H1 Sanitary Sewers waste site. The 1607-H1 drain field measured 17.1 by 15.2 m (56 by 50 ft) and was oriented on a northeast-southwest line from the tank. The at-grade portion of the septic tank was a concrete pad with two manhole covers and a third manhole cover located adjacent to the tank, which was clearly visible at the site in a photograph taken on September 30, 2009. In 1985, the 1607-H1
septic system was reactivated to be used by service trailers supporting deactivation and decommissioning (D&D) project personnel. At that time, the tank was discovered to have been backfilled with fly ash. The ash was vacuumed out of the septic tank and disposed to the ground surface prior to the successful reactivation of the septic system. No other records were located documenting the backfilling of the septic tank. During an interview with a former employee it was stated that it was common practice for showers and sinks in the 100-H Area change rooms to be used for personnel decontamination, and these drains lead to the sanitary sewers not the process sewers. In January 2007, the 1607-H1 waste site was assigned for remove, treat, and dispose in the interoffice memorandum "1607-H1 Remaining Site for Remedial Action". The septic tank has a 50-person capacity, is constructed of concrete and measures 4.6 by 1.7 by 4.4 meter (15 by 5.5 by 14.5 feet).

Location: The 1607-H1 waste site was located southwest of the 105-H Reactor Building and the 151-H Primary Substation, near the 118-H-2 Burial Ground, in the 100-HR-2 Operable Unit.

Related Sites/Structures: The septic system is associated with the 105-H Reactor and the 151-H substation.

Waste Type: Demolition and Inert Waste
Waste Description: The waste included carbon steel pipes and drainage tiles/pipe from the area of the septic tank inlet, from the drain field, and concrete/brick from the septic tank and adjacent manhole structure, including all soils excavated from below the drain field piping.

Waste Type: Demolition and Inert Waste
Waste Description: This unit received sanitary sewage from 151-H and 105-H Buildings. The flow rate to this unit was estimated to be 503 liters/day (140 gallons/day).

Closure Info: Remedial action at the 1607-H1 waste site was performed between September 24 and November 2, 2009, and included the removal of the below-grade septic tank and the manhole cover surface features. Excavation continued until all debris and contamination associated with the septic tank, drain field pipes, and connecting pipeline structure had been removed. The site was excavated to a depth of approximately 3.2 m (10.5 ft), removing the drain and tile field pipes at approximately 2.5 m (8.2 ft) below surface grade, and to a depth of approximately 4 m (13 ft) at the septic tank and adjacent manhole structure. A total of approximately 1,166 bank cubic meters (BCM) (1,525 bank cubic yards [BCY]) of soil and debris were removed and directly loaded for disposal at the Environmental Restoration Disposal Facility, including all soils excavated from below the drain field piping. This debris included carbon steel pipes and drainage tiles/pipe from the area of the septic tank inlet and the drain field, and concrete/brick from the septic tank and adjacent manhole structure.

An additional 528 BCM (691 BCY) of soil was removed from outside of the septic tank and overlying the drain field to form the overburden pile for the 1607-H1 waste site. The 1607-H1 remediation design identified the separation of overburden soil from the 1607-H1 drain field into two separate soil stockpiles. This overburden soil was intended to be used as backfill after it had been sampled, analyzed, and determined to meet cleanup criteria.
**Description:** The site has been remediated and Interim Closed Out. It was the debris remaining from a military installation that was located northwest of the 100H Area. A paved road entered the site from the southwest.

The 600-151 waste site consisted of scattered debris from U.S. Army Base Camp 130 (BC-130), a military camp covering approximately 162,000 square meters (40 acres) near the Columbia River, which was occupied from approximately 1950 to 1954. Debris found throughout the area in 1996 included a partially buried washtub, tin cans, a stove pipe, empty fuel and solvent cans painted "army green", broken concrete and transite, an old stove, wire fencing material, and a large pile of steel fence posts (screw in type for barbed wire fencing). There was evidence of ground disturbance at the site including three pits. A vertical culvert was observed at grade level extending into the ground. The culvert interior was obscured due to the presence of tumbleweeds. Several areas of stressed vegetation were also observed in the area.

The 600-151 waste site is located within this historic-archaeological site and contains the remnants of a farmstead (and orchards) intentionally demolished by Hanford-related activities. In 2009, prior to field remediation, were some domestic military debris, several pits (some with wood lining), and shallow trenches, related to communication lines, were documented.

**Location:** The site was located northwest of 105-H Reactor and begins 0.3 kilometers (0.2 miles) downstream of river mile post 14. The site has dirt and paved roads which form its boundary. A paved road enters the site from the southwest.

**Waste Type:** Equipment
**Waste Description:**

**Waste Type:** Equipment
**Waste Description:**

**Waste Type:** Equipment
**Waste Description:**

**Waste Type:** Equipment
**Waste Description:**

**Closure Info:** Prior to use by the Hanford Site Manhattan Project, the 600-151 waste site location was part of an historic agricultural site occupying some 202,000 square meters (50 acres) consisting of five tracts of land used circa 1938 to 1943. During the growing season, orchards were sprayed with lead arsenate from the time the trees bloomed until they were harvested. During remediation, a pattern of circular shaped, stained soil areas was noted beyond the areas identified for remediation in the remedial design. Field personnel suspected that these areas might be associated with historic agricultural pesticide applications and were not from Hanford waste disposal activities. In-process soil samples, collected to support waste characterization, identified high concentrations of arsenic (up to 229 mg/kg) and lead (up to 1,750 mg/kg) suspected to be associated with historic agriculture lead arsenate pesticide use.

Remediation of the 600-151 waste site consisted of mechanical excavation of concentrated debris and manually removing scattered debris from the ground surface as identified in the remediation design drawings. Areas of stained soil and stressed vegetation were scraped and
removed to a minimum depth of 0.31 meters (1 ft). In addition, two water valves and a water box associated with the former septic system (the 600-152 waste site) were also removed.

**Description:** The waste site has been remediated. It consisted of an underground septic tank and several surface features, including three in-line concrete covers and two manholes, which allowed access to the septic tank. Underground piping connected the surface features and the septic tank.

**Location:** The site is located northwest of 105-H Reactor and begins 0.2 miles downstream of river mile post 14. The site has dirt and paved roads which form a boundary surrounding the site. A paved road enters the site from the southwest.

**Process Description:** The site was constructed to support a military base camp that was created as part of Camp Hanford, which supported the established air defense systems at the camp. Base Camp 130 was located in the vicinity of the 600-151 dumping areas waste site and was abandoned by 1954. In October 2001, liquid in the septic tank was sampled. Results from the sample, described as rainwater, showed elevated gross beta results. No other radionuclides were detected in the analyses. Based on this result, the site was posted with Underground Radioactive Material signs.

**Waste Type:** Chemicals

**Waste Description:** The tanks remain in place and may contain remnants of septage. The contents are labeled radioactive here because sampling showed gross beta at 72 pCi/liter (see field work discussion for comparisons with Hanford Site background). The site was posted with Underground Radioactive Material signs.

**Closure Info:** In October 2001, liquid in the septic tank was sampled. Results from the sample, described as rainwater, showed elevated gross beta results (72pCi/l). No other radionuclides were detected in the analyses. Based on this result, the site was posted with Underground Radioactive Material signs. Prior to remediation in 2008, a visual inspection of the septic tank interior was conducted. No liquid was observed in the tank at that time. The fate of the liquid that was seen in 2001 is unknown, but it is possible that the liquid had evaporated.

Remedial action at the 600-152 waste site was performed between October 13 and November 10, 2008, and encompassed the removal of the below-grade septic tank, the surface features (three concrete covers and two manholes), and associated soils. The concrete piping that linked the septic tank to these surface features was also removed. A section of cast iron pipe containing seals made of lead was removed from the waste site. The lead-containing material was containerized after removal from the excavation. The site was excavated up to 5 meters (16 ft) below grade, resulting in the removal of approximately 287 BCM (375 BCY) of material for disposal at the Environmental Restoration Disposal Facility, including approximately 140 meters (460 ft) of pipe. Approximately 1,584 BCM (2,070 BCY) of soil (overburden) was removed and stockpiled for evaluation as clean backfill.

There is no process history to suggest that radiological contamination was present in the 600-152 septic tank. The in-process sample results from the tank contents (J17R76) did not detect radiological contamination; however, an elevated gross beta result from a water sample collected within the tank was reported in 2001. The beta emitter that is of most concern associated with this detection is strontium-90; therefore, strontium-90 was added as a COPC.
Site contamination extended slightly into the deep zone soils, however, the remediation footprint was evaluated against the more restrictive shallow zone criteria. The sample results demonstrated that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 ft]) and contaminant levels remaining in the soil were protective of groundwater and the Columbia River. Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep-zone are not required.

</tbody>
</table>
**Process Description:** The Riverland Rail Yard Maintenance Facility (Building 6718) steam cleaned and decontaminated railroad cars of grease and radioactive contamination in two pits prior to service and maintenance activities. The decontamination removed grease and oil from the undercarriage, wheels, axles and brakes. Diesel locomotives had their engine compartment, radiators and fans cleaned. Low levels of radioactive contamination was removed. Radioactively contaminated pads, gloves and other wastes were sent to the 200 Area for disposal. Periodically, the pit floor and walls were cleaned with a broom soaked in diesel fuel, then rinsed with water. Decontamination solutions drained into floor drains which then drained to an open ditch on the north side. The facility operated from 1943 until 1956. The facility was decontaminated in 1963 and the facility structures were sold to the public.

**Waste Type:** Steam Condensate

**Waste Description:** The site was used as a steam cleaning and low-level decontamination station for locomotive engines and cars used at Hanford.

**Closure Info:** In 1992 and 1993, the Riverland Expedited Response Action characterized and cleaned up the site. About 260 cubic meters (340 cubic yards) of concrete and fill material was removed from the wash pits and recycled through a concrete recycling plant. In the 100-B/C Area, and 330 cubic meters (430 cubic yards) of diesel contaminated soil were sent off site for bioremediation. Radiological surveys did not identify any levels above background. Small quantities of man-made radionuclides were observed in pre-remediation sampling. (A maximum of 19.6 pico curie per gram of cesium-137.) However, based on the levels observed the operable unit was considered nonradioactive. The cleanup level for diesel fuel residue was 200 parts per million (ppm); the confirmatory sample results showed less than 2 ppm remaining. The confirmatory samples also showed all man-made radionuclides were below 1 picocurie per gram.

About 330 cubic meters (430 cubic yards) of diesel contaminated soil and vitrified clay drain pipe fragments were removed. The diesel contaminated soil was bioremediated by "land farming" in the 100-C Area, and declared completed in 1996. The pits were backfilled with clean material from onsite. No further action was required for this site following the ERA and subsequent ROD. On July 8, 1998 the site was deleted from the NPL.

**Code:** 600-102  
**Classification:** Accepted  
**Names:** 600-102; 600 AMBS; 600 Area Army Munitions Burial Site  
**Reclassification:** Deleted From NPL (7/8/1998)  
**Type:** Burial Ground  
**Start Date:** 1/1/1971  
**End Date:** 1/1/1976  
**Status:** Inactive  
**Description:** The site has been remediated and Deleted from the National Priority List. It consisted of a shallow excavation area that contained a buried wooden crate. The crate contained emergency supplies of explosives and munitions used for military exercises during the 1970's (Smith & Stanley, 1993). The excavated area was approximately 0.61 meters (2 feet) wide by 0.91 meters (3 feet) long. The explosives were removed in 1986. The excavation was backfilled in 1993.

**Location:** The site is located northwest of 200 West area, approximately 100 meters west of Gate 12, near the McGee Ranch.

**Waste Type:** Steam Condensate

**Waste Description:** The unit received military explosives as follows: 6 gun blast simulators, Model 110, dated October 1953; 78 boxes (packed 5 to a box) of fuse igniters; Model M60, Lot KYC-1, dated May 1960; one trip flare, Model M49; one can containing 50 nonelectrical blasting caps, marked "ARMY"; 43 electrical blasting caps; ~500 ft of time fuse; ~200 ft of detonating cord;
and remnants of one grenade or artillery simulator.

**Closure Info:** On May 22, 1986, the box and its contents were removed and transported to the Yakima Firing Range for destruction. The crate contained six gun blast simulators, seventy eight fuse ignitors, one can of non-electric blasting caps, 43 electrical blasting caps, 500 ft of time fuse, 200 ft of detonating cord and the remnants of one grenade. The excavation was 0.61 meters (2 ft) by 0.91 meters (3 ft). The excavation was backfilled.

**Code:** 600-274  
**Names:** 600-274; Riverland; 2,4-D Can Site at McGee Ranch  
**Type:** Dumping Area  
**Status:** Inactive  
**Classification:** Accepted  
**Reclassification:** Deleted From NPL (7/8/1998)  
**Start Date:** 1/1/1994  
**End Date:**  

**Description:** The 2,4-D can site is surrounded by old-growth sagebrush with a cheatgrass understory. As it is near the far western border of the Hanford Site, there are no Hanford facilities nearby. Eleven 5-gallon cans were found here, nine of which were buried upright and adjacent to each other, with only their tops showing. Two other cans were on top of the ground nearby. The cans were removed and the soil sampled in 1994 as part of the closeout of the 100-IU-1 Operable Unit. In addition, while the original site was being located with the GPS coordinates in 2001, three other 5-gallon cans were found due north of the site about 100 meters (100 yards), also in sagebrush. This site was also GPS'd and flagged with white tape. All cans have been removed.

**Location:** The site is about 300 meters (300 yards) north of Highway 24, and 3.2 kilometers (2 miles) west of the Yakima Barricade.

**Related Sites/Structures:** It is not apparent who placed the cans at this site, or if they were associated with Hanford operations or a nearby farm.

**Process Description:** The material in the eleven cans removed in 1994 was 2,4-D, an herbicide. The three cans discovered in 2001 were empty and unmarked.

**Waste Type:** Chemicals

**Waste Description:** The site was 11 old herbicide cans (2,4-D) that had some soil and liquid (in one can) remaining.

**Closure Info:** The original eleven cans were removed in 1994. One container was laying on the surface, intact, no legible markings. A second container lying on the surface had mostly rusted away. Nine other containers were buried in two adjacent rows. The containers had open bung holes. One container had liquid inside. The other containers had varying amounts of soil inside.

Two composite samples were taken from the soil within the cans and one liquid (with one duplicate) sample. The liquid samples used up all the remaining liquid in the drum. After the cans were dug out of the hole, samples of the remaining soil immediately below the cans, and at 1, 2 and 3 foot depths were taken in three locations.

One of the samplers who was present in 1994, was interviewed in 2001. He said that, based on standard operating procedure, any soil from within the cans would have been placed in the 55-gallon drums, especially if there was an odor of herbicide (as the logbook reports). He also said that the excavation would not have been filled back in, but kept open pending receipt of the sampling results. If the results had indicated a problem, they could have gone back to excavate further and re-sample. Since the reports concluded there was no problem with the levels remaining at the site, they would not have gone back to the site. He believes the site may still be
visible as a depression.

The three remaining drums, located about 100 meters north of the original eleven drums, were removed and disposed of in December 2002. Site personnel determined that these drums were empty and not a RCRA concern. Due to the remote location of the site, it is considered a "Category 1" radioactive area which allows for landfill disposal.

Hanford Site Waste Management Units Report
February 2015 523
Waste Description: Nitric and hydrofluoric acids were discharged to the nearby Pickling Acid cribs. Sampling indicated slightly elevated levels of chrome and chloride when compared to background samples. Generally, the acid was neutralized prior to disposal, but may not have been completely neutralized prior to disposal.

Closure Info: This site was assumed to be associated with the Pickling Acid Cribs (sitecode 600-106). The Pickling Acid Cribs were characterized in 1992. Samples were also collected at three locations in the surface basin in 1992. A field walkdown done in April 2003 revealed no debris or anomalies. It was determined that no additional samples would be required.

Code: 600-98  Classification: Accepted
Names: 600-98; East White Bluffs City Landfills; East White Bluffs Dump and East White Bluffs Dump #2; East White Bluffs Landfill; EWBCL  Reclassification: Interim No Action (8/17/2004)
Type: Sanitary Landfill  Start Date: 1/1/1943
Status: Inactive  End Date: 1/1/1943

Description: The site has been evaluated and determined to require No Action. It consisted of two, pre Hanford dumping areas. A small amount of scattered surface debris (cans, glass and wood) was visible at dump #1. Dump area #2 was an area of gravel ridges and surface scars.

Location: The dump areas are north of 100-F Area. The East White Bluffs Dump was located approximately 150 meters (492 feet) north of the White Bluffs Ferry Landing. The East White Bluffs Dump #2 was located approximately 275 meters (902 feet) west of the White Bluffs Ferry Landing and north of Federal Avenue.

Process Description: The East White Bluffs Dump reportedly operated from 1850 to 1943. The East White Bluffs Dump #2 operated from 1900 to 1943.

Waste Type: Steam Condensate
Waste Description: Both sites were used to dispose of industrial and domestic wastes common to the time that it was being used. Surface debris found around the East White Bluffs Dump included cans, glass and wood. Surface debris found the East White Bluffs Dump #2 included wood, metallic, domestic (pots, bowls, and glassware), and industrial debris (cables and plywood sheets). The sites contain no known radioactive constituents.

Closure Info: A site walkdown was done in June 2004. Scattered surface debris, including glass, cans bricks, wood, wire and nails, was noted. There was no evidence of burning, asbestos or stained soil.

The evaluation of site history reviews, field observations, and geophysical surveys, provided the basis for reclassification of the site to no action.

The 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL-96-22, Rev. 4, Draft B) identified contaminants of potential concern (COPCs) for dumping areas. The SAP categorically assumed COPCs associated with disposal of hazardous debris. However, further evaluation of the debris observed at the site during the confirmatory sampling walkdown, indicated the debris to be non-hazardous and disposed of prior to Hanford Operations. Therefore, no further evaluation or confirmatory sampling was necessary for this site.

Code: 600-99  Classification: Accepted
Names: 600-99; J. A. Jones #2; JA Jones 2; JA JONES2  Reclassification: Interim No Action (9/12/2003)
Type: Burial Ground  Start Date: 1/1/1948
Status: Inactive  End Date: 1/1/1955
Description: The site has been evaluated and determined to require No Action. It was a previously exhumed, construction debris burial ground.
Location: The site was located northwest of the White Bluffs Townsite, north of H Avenue and east of Route 2.
Waste Type: Steam Condensate
Waste Description: This site contained minor construction equipment used by the J. A. Jones Construction Company, including wood scraps, concrete, and some metallic waste. However, the excavation records indicate that the site contents were removed to the 200 Areas Burial Grounds in 1971 because of radioactive contamination in the landfill.
Closure Info: Historical information indicated the waste site was exhumed in 1971, the contents moved to a 200 Area burial ground and the area was backfilled. A site walkdown was done in April 2003. No debris or anomalies were noted, but a geophysical survey was done to verify no subsurface debris was present. Based on the site history, site walkdown, and GPR evaluation, test pits were dug at the locations of three identified subsurface anomalies on May 20, 2003. These three anomalies were just outside the previously identified boundaries of 600-99, but close enough to be of concern as possible debris left behind from the previous excavation and removal project. Any debris encountered was to be evaluated by the sampler and certified waste shipper and samples taken to support waste designation. Test pits 1 and 3 found no anomalies. Test pit 2 found a concrete foundation, but no debris. The test pits were backfilled the same day they were dug. The results of the field activities demonstrate that there are no materials remaining at the 600-99 site that would exceed the RAGS.

---

Code: 600-100  Classification: Accepted
Names: 600-100; 600-119; WBL; White Bluffs City Dump; White Bluffs City Landfill; White Bluffs Landfill  Reclassification: Interim Closed Out (1/18/2011)
Type: Sanitary Landfill  Start Date:
Status: Inactive  End Date: 1/1/1943
Description: The waste site has been remediated and Interim Closed Out. It was believed to be an unlined excavation that received White Bluffs City industrial, commercial, domestic and farm wastes. It has been determined that the waste site was more likely used for opportunistic dumping rather than as a large scale landfill, and that this debris was buried during Hanford-era operations.
Location: The site was located west of Route 2 North and south of Federal Avenue. It is east of the White Bluffs Pickling Acid Cribs (600-106), approximately 540 meters (1,772 feet) south of the intersection of Route 2 North and Federal Avenue.
Waste Type: Steam Condensate
Waste Description: The site was used for normal commercial and domestic wastes at the time. It contains no known radioactive constituents. Per BHI-00049, the site was used for disposal of industrial, commercial, and domestic wastes, cans, bottles, and farm debris.
Closure Info: For consideration of potentially sensitive archaeological materials at the site, six test trenches were excavated in December 2009. The trench material was brought up in 0.3 meter (1 ft) lifts and sifted by field personnel. The results of the archaeological investigation indicated there was no buried debris or anomalous material. No material from the test trenches was disposed at ERDF and no samples were collected from the test trenches.
Remediation occurred from January 4 to 18, 2010. Because the previous archeological investigation determined buried debris was not present at this site, it was excavated to a depth of only 15 cm (6 in.), to remove surface debris. One 208-L (55-gal) stainless steel container was found while blading the road during remediation. It was unbreached, but partially crushed. Waste characterization and in-process soil samples were collected and analyzed. The surface debris and barrel were disposed at ERDF.

<tr>
<td>Waste Description:</td>
<td>The waste was solvents, waste oils, and flammable wastes. The site may have been used to dispose of other solid wastes. The site appears to have been backfilled with coal ash.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>Remediation of 600-120 and 600-297 occurred from January 7 to March 15, 2010. On January 7, 2010, several concrete structures associated with the 600-297 Imhoff Tank were encountered during initial remediation. A 10 centimeter (4 inch) diameter vitrified clay pipe was found protruding from each of the concrete structures. During demolition of the concrete structures, a 114 liter (30 gallon) tank was encountered on January 11, 2010. The tank resembled an old boiler and contained a small amount of black, non-oily, non-viscous liquid. A sample (J19WT1) was taken of this liquid on April 14, 2010. The concrete structure was fully removed. The bottom of the structure was at approximately 8 meters (28 feet) below ground surface. The materials that were excavated as a part of this remediation included coal ash and a concrete structure determined to be from the co-located 600-297 White Bluffs Imhoff Tank waste site. Groundwater was encountered at this location after the 600-297 waste site tank was removed. 600-120 Area 1 was a large depression that appeared to be an abandoned burn pit, backfilled with coal ash. Remedial action at the 600-120 waste site was performed from January to March 2010. Two test trenches were excavated for confirmatory sampling in Area 1. Evidence of vitrified clay pipe, rubber, burned wood, and coal were found. Confirmatory samples collected from the coal ash and native soil locations in Area 1 found that direct exposure remedial action.</td>
</tr>
</tbody>
</table>
goals (RAGs) were exceeded for benzo(a)pyrene, benzo(b)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene, indicating that site remediation was required. Barium, copper, and selenium were also present in concentrations exceeding soil cleanup criteria for groundwater or river protection.

600-120 Area 2 was determined to need no remediation.

600-120 Area 3 was identified during the geophysical survey as a depression northeast of Area 1 where buried debris was suspected to be present. One test trench was excavated in Area 3 for confirmatory sampling. Concrete walls, debris, coal ash, apparent rust, and oil stained soil were all observed in this test trench. Confirmatory samples of stained soils showed lead and silver concentrations in excess of direct exposure cleanup RAGs. Herbicides, pesticides, and polychlorinated biphenyls (PCBs) were also present in concentrations exceeding soil cleanup criteria for groundwater or river protection.

Following remediation, verification sampling was conducted in September 2010. The results indicated that the waste removal action achieved compliance with the remedial action objectives (RAOs) and RAGs for the 600-120 and 600-297 waste sites. The results of the verification sampling are used to make reclassification decisions for the 600-120 and 600-297 waste sites in accordance with the TPA-MP-14 procedure. The verification sampling results support a reclassification of this site to Interim Closed Out.

<tr>
<td>Closure Info: Remediation occurred from January 11 to 18, 2010. The excavation extended to a depth of approximately 1 meter (3 ft) bgs. The vadose zone beneath the excavation was approximately 8.3 meters (27.2 ft) thick. Approximately 1 meter (3 ft) of material was scraped from the surface and disposed at the Environmental Restoration Disposal Facility. Several paint cans containing various colors of paint, tar roofing, wood ad vitrified clay piping were encountered during remedial activities.</td>
<td></td>
</tr>
</tbody>
</table>

| Code: 600-125 | Classification: Accepted |
Names: 600-125; Waste Disposal Trenches; White Bluffs
Waste Disposal Trench 1

Type: Trench

Status: Inactive

Description: The waste site has been remediated and Interim Closed Out. The site was sandy depression with wood, ceramic and metal debris on the surface.

Location: The site was located west of Route 2 North and south of Federal Avenue. It is approximately 1020 meters (3347 feet) south of the intersection of Route 2 North and Federal Avenue. The site was on the west side of a powerline road.

Waste Type: Stormwater Runoff

Waste Description: The waste includes metal shavings, steel piping, plumbing fixtures, paint cans and automotive parts; as well as other metallic and wooden debris. In the same area there are several piles of used railroad ties, broken vitrified clay pipe, concrete pipe, 30.5-centimeter (12-inch) diameter, 6.1-meter (20-foot) long spiral welded pipe, plumbing fixtures, and degraded asbestos insulation.

Closure Info: The sandy depression contained metal shavings, steel pipe, plumbing fixtures, paint cans, railroad ties, vitrified clay pipe, asbestos insulation and wood debris.

Remediation occurred from February 11 to 17, 2010. The excavated area measured approximately 35 meters (115 ft) across in an irregular shape, and was 0.8 meters (2 ft) deep. The vadose beneath the excavation is approximately 10.6 meters (34.8 ft) thick. The waste material, which included several 12 meter (40 ft) of 12 inch diameter pipes, was staged in an area located southeast of the excavated area prior to being sent to the Environmental Restoration Disposal Facility.

Code: 600-127

Names: 600-127; Fuel Storage Area; White Bluffs
Loading Docks and Fuel Storage Area

Type: Storage

Status: Inactive

Description: The site has been remediated and Interim Closed Out. It was two loading docks and a rectangular area surrounded by a low soil berm that measured 0.5 meters (1.6 feet) high. The ground within the berm was covered by a layer of coal ash. The two loading docks, located adjacent to suspect fuel storage areas, were described as the north loading dock and a south loading dock. Each loading dock was approximately 20 meters (66 feet) long by 12 meters (39 feet) wide. A five foot diameter chemical spill area was located west of the north loading dock.

Inside the berm there were several wooden beams, the tops of which are flush with the ground surface. Wood shims were placed in a manner that suggested they once supported large, round horizontal fuel storage tanks. It appeared that four or five large tanks had been located at the site. Other small debris piles were located nearby that consisted of broken vitrified clay piping, plumbing fixtures, and concrete piping. On the north side, just outside the berm, was a smaller fuel tank site.

Location: The site is located west of Route 2 North and south of Federal Avenue. It is approximately 1,100 meters (3609 feet) southeast of the intersection of Route 2 north and Federal Avenue. The north loading dock is visible from Route 2 North.
**Release Description:** Removal of small areas of the ash ground cover reveals soil discoloration and evidence of petroleum product contamination. The soil around the fuel tank site on the north side of the berm is also discolored and appears to be contaminated with a petroleum product, probably gasoline. Adjacent to and on the south side of the berm there appears to have bulk dumping of heavy oils or other petroleum products. The soil contamination in this area extends to the south from the berm for about 4 meters (13 feet). Just west of the north loading dock is a 1.5-meter (4.9-foot) chemical spill spot that appears to consist of a petroleum product.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The waste is petroleum product contaminated soil.

During remedial activities as documented in RSVP-2004-064, it was observed that the inside of the berm contained coal ash and several wooden beams and shims thought to have once supported large tanks associated with fuel storage. To the west of the north loading dock was a chemical spill spot approximately 1.5 m (5 ft) in diameter, which appeared to consist of a petroleum product (BHI 1995). In addition to these areas, several small debris piles were located in the vicinity, and contained broken vitrified clay piping, plumbing fixtures, and concrete piping. Bulk dumping of petroleum products appeared to have occurred at the waste site.

**Closure Info:**

Eight test pits and trenches were excavated based on locations identified during a geophysical survey and site walkdown. Five of the test pits (pits 1, 2, 3, 5 and 7) showed no signs of hazardous debris or discolored soil, so no samples were collected. Confirmatory sampling at three locations (pits 4, 6 and 8) had elevated levels of barium, cadmium, copper, lead, zinc, polycyclic aromatic hydrocarbons (PAH), total petroleum hydrocarbons (TPH), and 4,4-DDE and required remediation.

Remedial action at the 600-127 waste site began on January 19, 2010, and was completed on June 7, 2010. The main excavation which encompassed two of the test pit areas was excavated to groundwater (approximately 8.5 meters [28 ft] below ground surface [bgs]) while chasing a plume of diesel or petroleum-product. The north loading dock and adjacent chemical spill spot was excavated to approximately 1 meter (3 ft) bgs, with an adjacent area being scraped to 15 centimeters (6 in.) bgs. Soil and debris were staged in two stages piles prior to disposal at the Environmental Restoration Disposal Facility (ERDF).

Initially, stained soil was observed and removed to approximately 4 meters (12 ft) below ground surface (bgs). A thin layer of black material, approximately 2.5 cm (1 in.) thick, was also observed during this initial excavation, and did not appear to be coal ash. Because stained soil was still present after the initial 4 meters (12 ft) depth, the excavation was extended to 5 meters (18 ft). Throughout this initial remediation, a strong odor, described as diesel or petroleum products was observed. However, the organic vapor monitors in the field did not detect any readings above background. On February 3, 2010, a soil sample, J19JX7, was collected from the base of the excavation on the southeast end at Washington State Plane (WSP) coordinates N147098/E578703. This was the deepest portion of the excavation, and the sample was comprised of random aliquots of stained, odorous soil at approximately 5 meters (18 ft) bgs. The excavator then removed an additional 1.5 meters (5 ft) of soil from this same location, and sample J19JX8 was collected from random aliquots of odorous soil at approximately 7 meters (23 ft) bgs. Finally, an additional 1.5 meters (5 ft) was excavated from this location.

Groundwater was encountered at approximately 8.5 meters (28 ft) bgs, and approximately 0.6 meters (2 ft) of groundwater filled the hole. An oily sheen could be observed on top of the water. Sample J19JX9 was collected from the soil just above groundwater. The diesel or petroleum-product smell was still present in the excavation when the sample was collected. A diesel or petroleum-product odor was also noted at the northwest end of the excavation, at coordinates N147119/E578681. The depth of the excavation at this end was approximately 5
meters (18 ft) bgs. Approximately 1.5 meters (5 ft) of additional material was excavated to collect sample J19Y0 at a depth of 7 meters (23 ft). This 1.5 meter (5 ft) deep test pit was backfilled after sample collection. Because of the odor encountered at the 600-127 waste site, the footprint of the excavation design was extended to a depth of 8.5 meters (28 ft) bgs. A final in-process sample, J19Y10, was collected from stained soil in the sidewall on June 7, 2010.

| Code: 600-128 | Classification: Accepted |
| Names: 600-128; Oil and Oil Filter Dump Site; White Bluffs Oil and Oil Filter Dump Site | Reclassification: Interim Closed Out (9/16/2003) |
| Type: Dumping Area | Start Date: |
| Status: Inactive | End Date: |
| Description: The site has been remediated and Interim Closed Out. The site had been an oil dump area that included several canister-type oil filters. Surface debris was removed in the spring of 2003. | |
| Location: The site was located west of Route 2 North and south of Federal Avenue. It was approximately 730 meters (2395 feet) south of the intersection of Route 2 North and Federal Avenue. | |
| Related Sites/Structures: The site was associated with the White Bluffs Automotive Repair Shop, site code 600-139. | |
| Process Description: Several Hanford site construction shops and warehouse facilities were located in this area. | |
| Waste Type: Chemicals | |
| Waste Description: The waste is oil contaminated soil, oil cans and filters. There are also several small areas with broken glass, cans, and other metal debris. | |
| Closure Info: A remedial action activity was implemented to remove contaminated soil and associated debris identified during the April 2003 site walkdown. The debris was removed to a depth of 25 centimeters (10 inches). Sampled were collected to support waste designation. The material was collected and packaged in accordance with waste management plans, and removed from the site for subsequent disposal at the Environmental Restoration Disposal Facility or other approved facilities. | |

| Code: 600-129 | Classification: Accepted |
| Names: 600-129; Pre-MED White Bluffs Community Dump Site (Oil Can Site); White Bluffs Pre-MED Community Dump Site 1 | Reclassification: Interim Closed Out (3/2/2005) |
| Type: Dumping Area | Start Date: |
| Status: Inactive | End Date: |
| Description: The site has been remediated and Interim Closed Out. It was a non-radioactive dumping area. It was a large depression containing cans, bottles, oil cans, wire, rope, dry and wet cell batteries and discarded automobile parts. | |
| Location: The site was located west of Route 2 North, south of Federal Avenue, on the east side of a north/south dirt road. It was approximately 1.7 kilometers (1.1 miles) south-southeast of the intersection of Route 2 North and Federal Avenue. | |
| Related Sites/Structures: The site was co-located with 600-191. | |
Waste Type: Chemicals

Waste Description: The main part of the site is littered with cans, bottles, oil cans, glass, wire, rope, toys, and automotive bodies and parts. On the southern edge industrial wastes include insulators, fuse boxes, conduit, and six 208-liter (55-gallon) drums, one of which is labeled "Carbon Tet". Because of the large number of oil cans, it is believed that the site was used by both Manhattan Engineering District (MED) and White Bluffs residents for the disposal of domestic type waste (Carpenter, 1994). Three glass vials containing an unknown white powder were found on a site walkdown in 1999. Dry cell batteries were also observed on April 22, 1999.

Closure Info: The site was 305 meters (1,001 feet) long by 80 meters (262 feet) wide with an irregular shape. The total area was 23,768 square meters (77,979 square feet). The site was an area littered with miscellaneous trash and debris. It appeared that it was used by both Manhattan Engineering District and White Bluffs residents for the disposal of domestic waste materials. The debris was concentrated in a swath along the west side of a dirt road. Areas devoid of vegetation were also observed; most were natural (e.g., clay, insects) and occurred due to a physical disturbance that does not recover for lack of moisture. This site was not originally identified as a remaining site, but was included in the removal action due to similarity in debris items and its location in the vicinity of the 600-129 site.

In May and June 2004, a site walkdown was conducted of the two sites and revealed debris and no evidence of burning. The site walkdown conducted in July 2004 included an EPA representative, who identified hazardous material to be removed. During the walkdown, it was also confirmed that a site-specific sampling plan would not be required. On July 28, 2004, a walkdown was conducted to identify, locate, and flag areas of hazardous material (mainly dry cell batteries) requiring removal. The flagged items were removed in October 2004 by an Environmental Restoration Contractor (ERC) subcontractor. The waste included dry and wet cell batteries, battery cases, asbestos-containing material, and paint materials.

The suspect hazardous debris was collected, characterized, and packaged in accordance with the waste management plan, and removed from the site for subsequent disposal at the Environmental Restoration Disposal Facility (ERDF) or other approved facility. The residual soil and debris remaining at the sites meets the remedial action goals and objectives.

600-191 is located adjacent to 600-129 and contained similar debris. It was agreed that 600-191 would be cleaned up as a proximity site to 600-129.

Interim Closure was based on site walkdowns and the removal and disposal of hazardous material.

**Waste Type:** Chemicals  
**Waste Description:** The waste was miscellaneous trash and debris, including concrete, transite, asphalt shingles, glass, and metallic debris. Transite contains asbestos, which was a hazardous substance. Asbestos was a CERCLA hazardous substance that may require action to mitigate a potential environmental impact. Asbestos wastes are excluded from the Dangerous Waste Regulations (WAC 173-303-071).  
**Closure Info:** On April 2003, a field walkdown, was done to gather information to finalize the sampling requirements. During the walkdown, areas of debris and anomalies were marked with flags. A remedial action was implemented to remove contaminated soil and debris from the site. The material was removed to a maximum depth of 1.7 meters (5.5 feet) and sampled to support waste designation. The material was packaged and disposed in ERDF.

<tr>
<td>Waste Type</td>
<td></td>
<td>Chemicals</td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td></td>
<td>If this site was actually the Construction Contractor Shop Landfill and not a borrow pit, the wastes that may have been disposed there could include oils, solvents, and cleaning agents (for example, carbon tetrachloride), typical of shop wastes. There may also be radioactive wastes, if this was not a mis-identified site (also see site 600-99). Carpenter (1995) identified two locations along the northwest boundary of the site with spots of oil (1.5-meter [4.9-foot] diameter for both spots). The waste that was visible in 1999 was surface debris, common to the entire 100-IU-2 Operable Unit, such as rusted metal cans, concrete rubble, a few pieces of transite, and wire. Two small piles of aluminum shavings are at the site, one on the floor of the pit and one at ground level, near the first pile. A small mound of dirt on the southwest corner, at the surrounding surface elevation, has partially buried pieces of yellow bricks and thick metal. A field walkdown done in April 2003 determined the site was a gravel borrow area and not a landfill.</td>
<td></td>
</tr>
<tr>
<td>Closure Info</td>
<td></td>
<td>After an April 2003 field walkdown, a remedial action activity was implemented to remove identified waste material and debris from the site for subsequent disposal at the Environmental Restoration Disposal Facility (ERDF). Waste included building rubble, wall board, asphalt shingles, oil cans and transite.</td>

**Code:** 600-139                      **Classification:** Accepted
### Automotive Repair Shop and Associated Waste Sites

**Names:** 600-139; Automotive Repair Shop; White Bluffs

**Type:** Dumping Area

**Status:** Inactive

**Description:** The site has been remediated and Interim Closed Out. The site was an area thought to be associated with an automotive repair shop. Surface debris included numerous battery caps, engine gaskets, dumped waste oils, and fragments of tail light lenses. The surface debris was removed in May 2003.

**Location:** The site was located west of Route 2 North and north of Federal Avenue. It was approximately 700 meters (2297 feet) southwest of the intersection of Route 2 North and Federal Avenue.

**Waste Type:** Sanitary Sewage

**Waste Description:** The waste included battery caps, engine gaskets, fragments of tail light lenses, and dumped waste oils.

**Closure Info:** In April 2003, a field walkdown was conducted to finalize contaminants of potential concern, identify sample locations, and identify sample types for development of a sampling design. Debris and anomalies were marked with flags. The debris included transite, metal cans, gasket material, wood, rubber and piping. A remedial action activity was implemented to remove the identified waste material and debris from the site for disposal at the Environmental Restoration Disposal Facility. The material was removed to a maximum depth of 0.41 meters (1.3 feet).

The maximum detected results and a composite sample of underlying soil at the location, suspected of having the greatest potential for residual contamination, were used to support site reclassification.

---

### White Bluffs Paint Disposal Area

**Names:** 600-176; White Bluffs Paint Disposal Area

**Type:** Dumping Area

**Status:** Inactive

**Description:** The site has been remediated and Interim Closed Out. It was a dumping area where excess paint materials were disposed of by pouring them on the ground. The ground had dried paint chips on the surface. The paint spills and chips were scattered over a large area. 600-176 was co-located with the 600-295 White Bluffs Paint Shop.

**Location:** The site was located approximately 570 meters (1870 feet) west of the intersection of Commercial Avenue and Federal Avenue within the warehouse storage area.

**Waste Type:** Process Effluent

**Waste Description:** Paint chips are on the surface of the ground.

**Closure Info:** Confirmatory sampling was done in April and May 2003. Remedial activities took place from December 7, 2009 to February 10, 2010. Visible, surface paint was placed into 208-L (55-gal) drums prior to excavation. Due to the presence of paint in
the subsurface soil, the excavation continued to a depth of approximately 1.5 meters (5 ft). The remedial design for the 600-176 waste site overlapped the 600-295 waste site. Therefore, remediation of the 600-176 waste site resulted in the concurrent remediation of the 600-295 Paint Shop waste site. Data from the 600-176 remediation supported the reclassification of 600-295.

On December 17, 2009, an empty 10-inch diameter vitrified clay pipe (VCP) was encountered during excavation and followed to the northeastern corner of the excavation, where it ended in a possible concrete septic tank that was approximately 1.5 meters (5 ft) long with unknown depth and width. This VCP was believed to be part of the sewer lines associated with the 600-295 paint shop as shown in drawing H-11-3909 (Atkinson-Jones 1948). The VCP was removed with the material excavated during the 600-176 remediation. This septic system and tank have been identified as part of the 600-301 waste site.

Odorous green soil was encountered and removed at a depth of an additional 1 meter (3 ft) below the base of the excavation, until the associated solvent odor was no longer present. Although the material had a strong solvent-type odor, nothing was detected with the photo ionization detector (0.0 ppm readings) and soil samples did not reveal the chemical responsible for the odor. Additionally, coal ash was encountered on the southern side of the excavation that was as much as 46 cm (18 in.) thick in some areas and thinned out across the extent of the excavation. This material was removed and included in the stockpile to the southeast of the excavation. Wood debris was also encountered and stockpiled. The final excavation depth was 1.5 meters (5 ft) bgs.

---

**Code:** 600-181  
**Classification:** Accepted

**Names:** 600-181; White Bluffs Oil Dump  
**Reclassification:** Interim Closed Out (9/12/2003)

**Type:** Dumping Area  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site has been remediated and Interim Closed Out. The site was an oil dumping area. The surface resembled asphalt in appearance as a result of the large quantities of oil that had been dumped at this location.

**Location:** The site was located west of Route 2 North and south of Federal Avenue. It was approximately 740 meters (2,428 feet) southeast of the intersection of Route 2 North and Federal Avenue. The site was on the west side of an old powerline access road.

**Waste Type:** Chemicals

**Waste Description:** The waste was oil contaminated soil. The top of the soil had formed into an asphalt-like surface.

**Closure Info:** In April 2003, a field walkdown was conducted to finalize contaminants of potential concern, identify sample locations, and identify sample types for development of a sampling design. Locations needing waste removal and areas for sample collection were marked. A remedial action activity was implemented to remove hydro-carbon contaminated soil and debris from the site for disposal at the Environmental Restoration Disposal Facility (ERDF). The excavation depth was 1 meter (3 feet). The maximum detected results for a composite sample of underlying soil at the location suspected of having the greatest potential for residual contamination were used to support site reclassification.

---

Hanford Site Waste Management Units Report  
February 2015  
534
Names: 600-182; White Bluffs Asbestos Pipe Lagging and Excess Piping

Reclassification: Interim Closed Out (1/4/2011)

Type: Dumping Area

Status: Inactive

Start Date: 

End Date: 

Description: The waste site has been remediated and Interim Closed Out. It was an area that included excess piping materials and some highly degraded piping insulation that appeared to be asbestos or a similar material. Several 6.1-meter (20-foot) sections of 30.5-centimeter (12-inch) spiral welded steel pipe were nearby. Other small debris piles were located very near that consisted of broken vitrified clay piping, plumbing fixtures, and concrete piping.

Location: The site was located west of Route 2 North and south of Federal Avenue. It is approximately 1050 meters (3445 feet) south of the intersection of Route 2 North and Federal Avenue and west of a power line road.

Waste Type: Oil

Waste Description: The waste is piping insulation material that appears to be made of asbestos or a similar material.

Closure Info: Remedial action was performed on February 10, 2010. All excess piping material, debris and potential ACM was removed. An overburden pile was created from the topsoil at the main excavation area. In addition to this excavation, two small areas were scraped where asbestos pipe lagging and vitrified clay pipe were found. A waste staging pile area was created to the side of these scraped areas. All scraped areas were excavated to approximately 8 centimeters (3 in.) below ground surface. The vadose zone beneath the excavation is approximately 5.1 meters (16.7 ft) thick.

The largest excavation had an area of approximately 1,000 square meters (10,700 sq ft). The scraped area with asbestos lagging was less than 100 square meters (1,000 sq ft). The scraped area with VCP was approximately 11 square meters (118 sq ft). The waste staging pile area was approximately 4 square meters (43 sq ft). The overburden pile is approximately 90 square meters (970 sq ft).

Code: 600-188

Classification: Accepted

Names: 600-188; White Bluffs Waste Disposal Trench 2

Reclassification: Interim Closed Out (3/16/2011)

Type: Trench

Status: Inactive

Start Date: 

End Date: 

Description: The site has been remediated and Interim Closed Out. It was an open trench containing industrial waste that filled about one-third of the site. There was evidence of chemical or oil dumping and burning along the east side of the trench. The White Bluffs Technical Baseline Report (BHI-00448) states discolored soils and empty 208-liter (55-gallon) drums that are bulging were present. The drum contents appeared to have been burned with the drums.

Location: The site is located west of Route 2 North and south of Federal Avenue. It is approximately 1000 meters (3,281 feet) southeast of the intersection of Route 2 North and Federal Avenue. The site is on the east side, and adjacent to, a powerline road.

Waste Type: Chemicals

Waste Description: The waste consists of industrial wastes of wooden and metallic debris. There has been chemical or oil dumping and burning. There are also empty 208-liter (55-gallon) drums.
Closure Info: The 600-188 waste site was remediated on February 10 and 11, 2010. Debris and soil to a depth no more than 1 meters (3 ft) below the existing borrow pit surface were removed from the waste site. The excavation was 2.5 meters (8 ft) below grade at the deepest area. Material removed from the perimeter around the excavation was placed into an overburden pile to be used as backfill material. Waste material was placed in a staging pile area, which was then loaded out to the Environmental Restoration Disposal Facility.

On March 3, 2010, three in-process soil samples (J1I9L34, J1I9L35, and J1I9L36), one duplicate sample (J19L37), and one equipment blank (J19L38) were collected to evaluate the adequacy of remediation. The footprint of the excavation was divided into three sample areas, and a sample was collected from multiple aliquots of soil across the top of each area (Appendix A). No contaminant concentrations of in-process soil samples exceeded direct exposure RAGs. Concentrations of several metals exceeded soil cleanup levels for protection of groundwater and/or the Columbia River but no organic chemicals exceeded soil RAGs.

<tr>
<td>Description:</td>
<td>The site has been remediated and Interim Closed-Out. It was a non-radiological dumping area.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
It was devoid of vegetation and contained miscellaneous trash and debris.

**Location:** The site was located west of Route 2 North and south of Federal Avenue. It was approximately 1.3 kilometers (0.8 miles) southeast of the intersection of Route 2 North and Federal Avenue. This site was north of 600-129, White Bluffs Pre-MED Community Dump Site 1, on the west side of a north/south dirt road.

**Related Sites/Structures:** The site was co-located with 600-129.

**Waste Type:** Process Effluent

**Waste Description:** The waste is miscellaneous trash and debris, including oil cans, cans, glass, domestic debris, car parts, and a few full 19-liter (5-gallon) cans of grease. During the April 1999 visit, the cans of grease described in the Technical Baseline Report could not be found. However, in addition to the debris already mentioned above, antifreeze containers and dry cell batteries were observed.

**Closure Info:** The site was 305 meters (1,001 feet) long by 80 meters (262 feet) wide with an irregular shape. The total area was 23,768 square meters (77,979 square feet). The site was an area littered with miscellaneous trash and debris. It appeared that it was used by both Manhattan Engineering District and White Bluffs residents for the disposal of domestic waste materials. The debris was concentrated in a swath along the west side of a dirt road. Areas devoid of vegetation were also observed; most were natural (e.g., clay, insects) and occurred due to a physical disturbance that does not recover for lack of moisture. This site was not originally identified as a remaining site, but was included in the removal action due to similarity in debris items and its location in the vicinity of the 600-129 site.

In May and June 2004, a site walkdown was conducted of the two sites and revealed debris and no evidence of burning. The site walkdown conducted in July 2004 included an EPA representative, who identified hazardous material to be removed. During the walkdown, it was also confirmed that a site-specific sampling plan would not be required. On July 28, 2004, a walkdown was conducted to identify, locate, and flag areas of hazardous material (mainly dry cell batteries) requiring removal. The flagged items were removed in October 2004 by an Environmental Restoration Contractor (ERC) subcontractor. The waste included dry and wet cell batteries, battery cases, asbestos-containing material, and paint materials.

The suspect hazardous debris was collected, characterized, and packaged in accordance with the waste management plan, and removed from the site for subsequent disposal at the Environmental Restoration Disposal Facility (ERDF) or other approved facility. The residual soil and debris remaining at the sites meets the remedial action goals and objectives.

600-191 is located adjacent to 600-129 and contained similar debris. It was agreed that 600-191 would be cleaned up as a proximity site to 600-129.

Interim Closure was based on site walkdowns and the removal and disposal of hazardous material.

| Code          | 600-201          | **Classification:** Accepted
|---------------|------------------|--------------------------
| Names:        | 600-201; White Bluffs Paint and Solid Waste Disposal Site | **Reclassification:** Interim No Action (9/12/2003)

| Status:       | Inactive         | **End Date:**
| Description:  | The site has been evaluated to confirm that it does not require remediation. The site has been

*Hanford Site Waste Management Units Report*

February 2015
reclassified to "No Action". Red paint appeared to have been dumped on the surface. Debris included glass, metal parts, metal shavings and canvas.

Location: The site was located east of Route 2 North and north of Federal Avenue. It was approximately 925 meters (3,035 feet) northwest of the intersection of Route 2 North and Federal Avenue and just south of 600-132, White Bluffs Construction Contractor Shop Landfill.

Waste Type: Soil
Waste Description: The waste was red paint and other debris including, glass, metal shavings, metal parts, and army-green canvas material.

Closure Info: In May 2003, a test pit was dug at an area of anomaly found with GPR. The test pit revealed a flattened steel bucket and some decaying wood. Field screening was done on all debris removed from the pit to determine if a sample needed to be collected. No hazardous material was found. No samples were collected from the pit. The debris was put back into the excavation. The test pit was backfilled the same day it was dug. A single sample of hardened paint was collected.

Code: 600-279
Classification: Accepted
Names: 600-279; Vegetation Free Area Between White Bluffs and 100F
Reclassification: Interim Closed Out (4/17/2014)
Type: Dumping Area
Start Date: 
End Date: 
Status: Inactive
Description: The site has been remediated and Interim Closed Out. It consisted of a large area of no vegetation covered with ash and bits of burned debris.

Location: The area was located northwest of the 105-F facility. It is on the west side of the 100 F Area western perimeter road, near the northwest corner of the 100-F Area. The coordinates for this waste site are N148089.2 E579584.2.

Process Description: The site was likely related to an old orchard. It is suspected that the site was the remains of a burned storage shed. The yellow material had a sulfur odor. Lead-arsenic and lime sulfur were used in orchards to control mold on fruit. The burned metal pieces could be pieces of farm equipment.

Closure Info: In-process sampling at the 600-279 waste site (for the purpose of waste management) consisted of two composite samples: J1RWK4 collected August 19, 2013, and J1T3J3 collected on October 8, 2013. A portion of the site was observed to be covered with ash, burned debris (pieces of brick, metal, and wood), and yellow stained soil with a sulfur odor in both waste management sampling events. All contaminated soil, ash, and debris was subsequently removed during the waste site remedial actions.

Remediation of the 600-279 waste site was performed over an area of 1,158 square meters (12,465 ft²) from September 30 through October 22, 2013. The 600-279 waste site is situated on a sloped area of land that inclines toward the southeast. Therefore, the maximum excavation depth is approximately 6.1 meters (20 ft) from the west side of the waste site and 3.7 to 4.6 meters (12 to 15 ft) from the east side. All material (stained and affected soil; surface debris such as wood, metal, and bricks) was directly loaded from the excavation into Environmental Restoration Disposal Facility (ERDF) containers for disposal at ERDF. The approximate volume of material removed from the 600-279 waste site was 765 bank cubic meters (1,001 bank cubic yards). No anomalous materials were encountered during the excavation. There are no overburden piles or waste staging pile areas associated with the 600-279 waste site.

<tr>
<td>Closure Info:</td>
<td>A ground penetrating radar (GPR) scan was done in 2007. The scan identified several anomalies that appeared to be part of the service station infrastructure. Confirmatory sampling from two test trenches was done in October 2010. A steel pipeline was identified. While removing the pipeline, a small amount of brown liquid discharged from the pipe. Three more pipelines were uncovered and one was observed to be leaking a small amount of oil. A concrete trench was uncovered that appeared to be a pit for servicing vehicles. No underground tank (UST) was found.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Remediation of the 600-293, White Bluffs Service Station #1 was performed on March 25 and June 24, 2013. Approximately 432 bank cubic meters (BCM) (659 bank cubic yards [BCY]) of materials were excavated and direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). The floor of the 600-293 waste site excavation varies from approximately 2.4 to 3 meters (8 to 10 ft) below ground surface. During the 600-293 waste site remedial activities, no UST was found. A number of pipeline segments associated with the service station were excavated from the 600-293 waste site for disposal at ERDF. Various forms of waste and debris were observed during remediation, including the concrete slab that covered most of the waste site and approximately 0.6 meters (2 ft) of bedding sand below the slab where more pipelines were observed and excavated. One sample location exceeded the remediation goals for PCB’s. An additional 30 BCM (39 BCY) of contaminated soil was excavated direct located for disposal at ERDF.

<td>Description:</td>
<td>The site has been remediated and Interim Closed Out. It was the location of a service station with the potential for an underground storage tank (s), associated piping and underlying soils. The service station building was demolished and buried in place in 1975. No underground storage tank was found during remediation.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Location:** The site is located in the White Bluffs area west of the railroad tracks, north of Federal Avenue and near the southeast corner of the equipment lot.

**Process Description:** The service station dispensed fuel for automotive use. The service station contained two gasoline pumps and two buried tanks with a total capacity of 4,000 gallons and one diesel fuel pump and a 1,000 gallon buried tank. It had a lube rack and a steam cleaning pad.

**Waste Type:** Chemicals

**Waste Description:** The waste includes petroleum product contaminated soil, underground storage tanks and associated piping. Contaminants of potential concern may include petroleum products (TPH, PAH) and possibly ICP metals.

**Closure Info:** Confirmatory sampling was conducted on October 20, 2010. Suspected asbestos-containing materials were observed on the ground surface. Characterization sampling involved excavation of two test pits, one test trench and collection of two focused samples and two surface asbestos samples. During excavation of Test Pit 1, two 5 centimeter (2 in.) diameter stainless steel pipelines were uncovered approximately 1 meter (3 ft) bgs. The pipelines were found to be empty. A sample (J1C2C7) of soil underlying the pipelines was collected for analysis at approximately 1.2 meters (4 ft) bgs. No debris, stains or pipelines were uncovered during the excavation of test pit 2. Excavation was extended to 4 meters (13 ft) bgs, although native soil was observed at 1.8 meters (6 ft) bgs. During the excavation of the Test Trench, a 6.1 meter (20 ft) piece of 1.2 meter (4 ft) diameter corrugated pipe was uncovered 1 meter (3 ft) bgs. A 7.6 centimeter (3 inch) diameter steel pipeline was observed protruding from the east side of the corrugated pipe. It was determined the corrugated pipe was a potential drain.

Remediation of the 600-294 south area was performed from March 28 through April 1, 2013. Approximately 63 bank cubic meters (BCM) (82 bank cubic yards [BCY]) of excavated materials were removed for direct disposal at the Environmental Restoration Disposal Facility (ERDF). The final depth of the south area excavation was approximately 1.8 meters (6 ft) bgs. Remediation of the northern area of waste site 600-294 was performed from June 19 through July 16, 2013. Approximately 99 BCM (129 BCY) of excavated materials, including two 1.2 meter (4 ft) diameter sections of corrugated piping, were removed and loaded for direct disposal at ERDF. The final depth of the northern excavated area was 3 meters (10 ft) bgs. Yellow soil staining was observed during excavation of the northern area. An in-process sample (J1RNY4) was collected from the yellow stained soils and analyzed for metals and hexavalent chromium. The data results showed that metals and hexavalent chromium concentrations were below the remedial action goals (RAGs). An estimated total volume of 162 BCM (211 BCY) of contaminated soil and materials was excavated from the 600-294 waste site and disposed of at ERDF.

<tr>
<td>Description:</td>
<td>The site has been remediated and Interim Closed Out. It consisted of surface and underlying soils associated with the former Paint Shop that was used to support the White Bluffs Central Shops. The footprint of the building was easily recognizable due to a lack of vegetation. It was co-located with the 600-176 Paint Disposal Area waste site. The two waste sites were remediated at the same time.</td>
</tr>
<tr>
<td>Location:</td>
<td>The site is located northwest of Federal Avenue and southeast of Route 2N. The paint shop was located north of Federal Avenue and east of Gasoline Alley. This site is located approximately</td>
</tr>
</tbody>
</table>
17 meters (56 feet) northeast of 600-176 (White Bluffs Paint Disposal Area).

**Related Sites/Structures:**
The paint shop is associated with the 600-176 dump site.

**Process Description:**
Paint shop supported the White Bluffs shops operations.

**Waste Type:**
Process Effluent

**Waste Description:**
Contaminants of potential concern would include VOA, semi-VOA, ICP metals with mercury in the soil.

**Closure Info:**
The 600-176, White Bluffs Paint Disposal Area underwent remediation in November 2010. The remedial design for the 600-176 waste site completely overlapped the 600-295 Paint Shop waste site. Therefore, remediation of the 600-176 waste site resulted in the concurrent remediation of the 600-295, White Bluffs Paint Shop waste site. The location of 600-295 waste site was within the excavation boundary of the 600-176 waste site. Verification sample EXC-10 was collected from within the 600-295 boundary.

---

**Code:** 600-296  
**Classification:** Accepted  
**Reclassification:** Interim No Action (4/26/2011)

**Names:** 600-296; White Bluffs Fire Department Septic System

**Type:** Sanitary Sewer  
**Status:** Inactive

**Description:** The waste site has been evaluated and determined to require No Action. It consisted of the septic system for the White Bluffs Fire Department. It is a 1 by 1.5 meter (3.3 by 5 feet) sump with lid, a soil filled 1.5 by 2 meter (5 by 6.5 feet) concrete below grade box, a potential septic drain field with associated piping and the underlying soil. A 15 centimeter (6 inch) drain line extends from the fire house to the septic tank and onto a drain field. These features are all suspected of being the components of the former Hanford Works Fire Station septic system at White Bluffs.

**Location:** The site is located near the intersection of White Bluffs road and Route 2N. The fire house was located at the corner of Federal Avenue and First Street. The septic system is located northeast of the fire station.

**Process Description:** The site is a septic system that was used to support the White Bluffs Fire Station.

**Waste Type:** Process Effluent

**Waste Description:** The site includes the septic tank, drain field, associated piping and surrounding soils.

**Closure Info:** Confirmatory sampling indicated that environmental contamination was not present at this waste site. The analytical results indicate that the residual concentrations of COPCs at this site meet the RAGs and corresponding remedial action objectives for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the verification sampling results support a reclassification of the 600-296 waste site to No Action.

---

**Code:** 600-297  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (3/16/2011)

**Names:** 600-297; White Bluffs Imhoff Tank

**Code:** 541

---

*Hanford Site Waste Management Units Report*  
February 2015
Type: Settling Tank
Status: Inactive

Description: This waste site has been remediated and Interim Closed Out. It consisted of an Imhoff tank (separations tank) and its underlying soils. 600-297 (White Bluffs Imhoff Tank) and 600-120 (White Bluffs Spare Parts Burn Pit) were remediated at the same time.

Location: The site was located southwest of Route 2 North and south of Federal Avenue, under a set of BPA lines. The Imhoff Tank was located south of Federal Avenue, west of the Chicago Milwaukee Railroad and approximately 47 meters (154 feet) east of waste site 600-120.

Related Sites/Structures: The tank is associated with the White Bluffs facility complex and Pickling Acid crib (sitecode 600-106). 600-297 was remediated with the White Bluffs Spare Parts Burn Pit (sitecode 600-120).

Process Description: The 600-297, White Bluffs Imhoff Tank was thought to have consisted of a septic tank associated with the White Bluffs sanitary sewer system. However, during remediation of this waste site, it was determined that the structure was actually an old boiler, and was likely not associated with the sanitary sewer system. Further investigation found it facilitated separation of solids from the influent going to the 600-106 Pickling Acid Cribs (as shown on H-11-3709), located approximately 170 meters (558 feet) southwest of the tank. 600-106 was used to dispose of spent pickling acid that was utilized to pickle galvanized piping. Generally, the hydrofluoric and nitric acid used for pickling was neutralized prior to disposal, but may not have been completely neutralized prior to disposal. The 600-106 Pickling Acid Cribs waste site was Closed-Out in 1996. However no information concerning the Imhoff tank was discussed in the 600-106 report.

Waste Type: Process Effluent
Waste Description: Contaminants associated with the effluent to the tank from the White Bluffs facility complex have not been evaluated, so they are presently unknown.

Closure Info: Remediation of 600-120 and 600-297 occurred from January 7 to March 15, 2010.

On January 7, 2010, several concrete structures associated with the 600-297 Imhoff Tank were encountered during initial remediation. A 10 centimeter (4 inch) diameter vitrified clay pipe was found protruding from each of the concrete structures. During demolition of the concrete structures, a 114 liter (30 gallon) tank was encountered on January 11, 2010. The tank resembled an old boiler and contained a small amount of black, non-oily, non-viscous liquid. A sample (J19WT1) was taken of this liquid on April 14, 2010. The concrete structure was fully removed. The bottom of the structure was at approximately 8 meters (28 feet) below ground surface. The materials that were excavated as a part of this remediation included coal ash and a concrete structure determined to be from the co-located 600-297 White Bluffs Imhoff Tank waste site. Groundwater was encountered at this location after the 600-297 waste site tank was removed.

600-120 Area 1 was a large depression that appeared to be an abandoned burn pit, backfilled with coal ash. Remedial action at the 600-120 waste site was performed from January to March 2010. Two test trenches were excavated for confirmatory sampling in Area 1. Evidence of vitrified clay pipe, rubber, burned wood, and coal were found. Confirmatory samples collected from the coal ash and native soil locations in Area 1 found that direct exposure remedial action goals (RAGs) were exceeded for benzo(a)pyrene, benzo(b)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene, indicating that site remediation was required. Barium, copper, and selenium were also present in concentrations exceeding soil cleanup criteria for groundwater or river protection.

600-120 Area 2 was determined to need no remediation.
600-120 Area 3 was identified during the geophysical survey as a depression northeast of Area 1 where buried debris was suspected to be present. One test trench was excavated in Area 3 for confirmatory sampling. Concrete walls, debris, coal ash, apparent rust, and oil stained soil were all observed in this test trench. Confirmatory samples of stained soils showed lead and silver concentrations in excess of direct exposure cleanup RAGs. Herbicides, pesticides, and polychlorinated biphenyls (PCBs) were also present in concentrations exceeding soil cleanup criteria for groundwater or river protection.

Following remediation, verification sampling was conducted in September 2010. The results indicated that the waste removal action achieved compliance with the remedial action objectives (RAOs) and RAGs for the 600-120 and 600-297 waste sites. The results of the verification sampling are used to make reclassification decisions for the 600-120 and 600-297 waste sites in accordance with the TPA-MP-14 procedure. The verification sampling results support a reclassification of this site to Interim Closed Out.

<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>Surface debris and material that stained the soil was released to ground during the construction, operating, and decontamination and decommissioning (D &amp; D) activities within the 100-IU-2 Operable Unit (OU).</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The field walkdown was completed using 30 meter by 30 meter grids covering the operable unit. A global positioning system (GPS) was used to navigate each grid and to record the location of field observations. A digital camera was used to photograph each observation as recorded in a field logbook with the GPS record number. The GPS files with coordinates and attributes were downloaded daily to a GIS database for plotting on a map and for maintaining the coordinates and observations electronically. The digital camera files were downloaded daily to a dated folder on a share drive for coordination of photos with GPS data and the field logbook entries. The field walkdown of the Operable Unit did not include known waste sites or posted areas. The field walkdown was limited to observations. No sampling was conducted. Areas potentially containing CERCLA hazardous substances are found scattered throughout the operable unit at the documented coordinates. Observations of potential physical hazards, cultural artifacts, and nonhazardous, non-dangerous solid waste were recorded in logbook EL-1617.

Closure Info: The 600-298, 600-299 and 600-300 parent sites and their subsites have been remediated and Interim Closed Out in a single document and three Reclassification form (2013-040, 2013-041, 2013-042).

The debris was left during deactivation, decontamination, decommissioning, and demolition (D4) activities at the White Bluffs Central Shops Area. 600-298 included eight subsites of
surface debris and stained soil, 600-299 included six subsites and 600-300 included twelve subsites. The total material removed from all the areas was 2300 bank cubic meters. It was all disposed at ERDF.

Characterization soil samples were collected in March and April 2011. GPR scans were done over a time span from June 2011 through January 2013. The remediation activities removed soil and debris between January 31, 2012 through March 5, 2013. At 600-298, most areas were remediated to a depth of 0.9 meters (3 ft). 600-298:5 was excavated to a depth of 2.4 meters (8 ft). The depth of excavation at all the 600-299 and 600-300 areas was 0.3 meters (1 ft).

The remediation activities removed soil and debris between January 31, 2012 through March 5, 2013. At 600-298, most areas were remediated to a depth of 0.9 meters (3 ft). 600-298:5 was excavated to a depth of 2.4 meters (8 ft). The depth of excavation at all the 600-299 and 600-300 areas was 0.3 meters (1 ft).

The SubSite is Part Of:
Code: 600-298
Names: 600-298; Surface Debris and Stained Soil in 100-IU-2

The SubSite is Part Of:
Code: 600-299
Names: 600-299; Surface Debris and Batteries

The SubSite is Part Of:
Code: 600-300
Names: 600-300; Surface Debris and Batteries

Description: The parent site and the subsites have been remediated and Interim Closed Out in a single document and Reclassification form (2013-040). The subsite consisted of a wooden floor like structure of approximately 1 by 2 meters (3 by 6 ft) with remnants of a thin stained layer of material. The site lacks vegetation.

Location: The site was located approximately 811 meters (0.5 miles) east of Federal Avenue and 877 meters (0.5 miles) north of Route 2 North in the former White Bluffs Community area. Area 8 is at E578932.55, N148079.35.

Closure Info: The 600-298, 600-299 and 600-300 parent sites and their subsites have been remediated and Interim Closed Out in a single document and three Reclassification form (2013-040, 2013-041, 2013-042).

The debris was left during deactivation, decontamination, decommissioning, and demolition (D4) activities at the White Bluffs Central Shops Area. 600-298 included eight subsites of surface debris and stained soil, 600-299 included six subsites and 600-300 included twelve subsites. The total material removed from all the areas was 2300 bank cubic meters. It was all disposed at ERDF.

Characterization soil samples were collected in March and April 2011. GPR scans were done over a time span from June 2011 through January 2013. The remediation activities removed soil and debris between January 31, 2012 through March 5, 2013. At 600-298, most areas were remediated to a depth of 0.9 meters (3 ft). 600-298:5 was excavated to a depth of 2.4 meters (8 ft). The depth of excavation at all the 600-299 and 600-300 areas was 0.3 meters (1 ft).

Description: The parent site and the subsites have been remediated and Interim Closed Out in a single document and Reclassification form (2013-040). The subsite consisted of a wooden floor like structure of approximately 1 by 2 meters (3 by 6 ft) with remnants of a thin stained layer of material. The site lacks vegetation.

Location: The site was located approximately 811 meters (0.5 miles) east of Federal Avenue and 877 meters (0.5 miles) north of Route 2 North in the former White Bluffs Community area. Area 8 is at E578932.55, N148079.35.

Closure Info: The 600-298, 600-299 and 600-300 parent sites and their subsites have been remediated and Interim Closed Out in a single document and three Reclassification form (2013-040, 2013-041, 2013-042).

The debris was left during deactivation, decontamination, decommissioning, and demolition (D4) activities at the White Bluffs Central Shops Area. 600-298 included eight subsites of surface debris and stained soil, 600-299 included six subsites and 600-300 included twelve subsites. The total material removed from all the areas was 2300 bank cubic meters. It was all disposed at ERDF.
document and Reclassification form (2013-041). The site consisted of six areas of scattered surface debris and batteries found during site walkdowns in 2007. The waste site was originally divided into five subsites. A sixth area was found later and became subsite 6.

Location: The walkdown area was located southwest of Route 2 North and south of Federal Avenue, adjacent to a powerline road.

Process Description: The debris and batteries are believed to have been discarded during the demolition of the White Bluffs Central Shop Area. Subsite 2 was in an old orchard area. From November 2006 to February 2007 a field walk-down of the 100-IU-2 Operable Unit was conducted as a final closure screening activity. The surface debris, which was identified as potentially containing CERCLA hazardous substances, was precisely located and recorded using Global Positioning Satellite (GPS) technology, digital photography, and field logbook EL-1617. The field walk-down was completed in 30 meter by 30 meter grids that covered the Operable Unit. A handheld global positioning system (GPS) was used to navigate each grid and to record the location of field observations. A digital camera was used to photograph each observation as recorded in a field logbook with the GPS record number. The GPS files with coordinates and attributes were downloaded daily to a database for plotting on a map and for maintaining the coordinates and observations electronically. The field walk-down of 100-IU-2 did not include known waste sites or posted areas. The field walk-down was limited to observations. No sampling was conducted. Potential CERCLA hazardous substances was found scattered throughout the Operable Unit at the coordinates provided. Observations of potential physical hazards, cultural artifacts, and nonhazardous, non-dangerous solid waste were also recorded.

Waste Type: Water

Waste Description: A dry cell battery is typically composed of zinc, ammonium chloride, zinc chloride, carbon and manganese (IV) oxide (http://en.wikipedia.org/wiki/Dry_cell). A wet cell battery may include lead and sulfuric acid as contaminants of potential concern.

Closure Info: The 600-298, 600-299 and 600-300 parent sites and their subsites have been remediated and Interim Closed Out in a single document and three Reclassification form (2013-040, 2013-041, 2013-042).

The debris was left during deactivation, decontamination, decommissioning, and demolition (D4) activities at the White Bluffs Central Shops Area. 600-298 included eight subsites of surface debris and stained soil, 600-299 included six subsites and 600-300 included twelve subsites. The total material removed from all the areas was 2300 bank cubic meters. It was all disposed at ERDF.

Classification: Accepted
Names: 600-299:1; Surface Debris and Batteries Area 1
Reclassification: Interim Closed Out (11/21/2013)
Type: Unplanned Release
Status: Inactive

**Description:**
The parent site and the subsites have been remediated and Interim Closed Out in a single document and Reclassification form (2013-041). The subsite consisted of scattered remnants of batteries that are located throughout the area. Most have been removed with the exception of what appear to be thousands of wet cell battery caps. Yellow staining of the soil is found in some places.

**Location:**
The site was located approximately 724 meters (0.4 miles) west of Federal Avenue and 599 meters (0.4 miles) south of Route 2 North in the former White Bluffs Community area. Location 1 is at E577373.69, N148034.57.

**Closure Info:**
The 600-298, 600-299 and 600-300 parent sites and their subsites have been remediated and Interim Closed Out in a single document and three Reclassification form (2013-040, 2013-041, 2013-042).

The debris was left during deactivation, decontamination, decommissioning, and demolition (D4) activities at the White Bluffs Central Shops Area. 600-298 included eight subsites of surface debris and stained soil, 600-299 included six subsites and 600-300 included twelve subsites. **Description:** The parent site and the subsites have been remediated and Interim Closed Out in a single document and Reclassification form (2013-042). The site consisted of twelve areas containing miscellaneous scattered debris. The site was divided into twelve subsites.

**Location:** The walkdown area was near the previous White Bluffs community.

**Process Description:** Various sizes and forms of CERCLA surface debris were created during the construction, operating, and decontamination and decommissioning (D&D) activities within the 100-IU-2 Operable Unit (OU). From November 2006 to February 2007 a field walk-down of the OU was conducted as a final closure screening activity. Surface debris, which was identified as potentially containing CERCLA hazardous substances, was precisely located and recorded using a hand-held Global Positioning Satellite (GPS) unit, digital photography, and documented in field logbook EL-1617. The field walk-down was completed in 30 meter by 30 meter grids that covered the Operable Unit. A hand-held global positioning unit (GPS) was used to navigate each grid and record the location of field observations. A digital camera was used to photograph each observation as recorded in a field logbook with the GPS record number. The GPS files with coordinates and attributes were downloaded daily for post-processing and data correction and for maintaining the coordinates and observations electronically. The digital camera files were downloaded daily to a dated folder on a share drive for coordination of photos with GPS data and the field logbook entries into EL-1617.

**Closure Info:**

The 600-298, 600-299 and 600-300 parent sites and their subsites have been remediated and Interim Closed Out in a single document and three Reclassification form (2013-040, 2013-041, 2013-042).

The debris was left during deactivation, decontamination, decommissioning, and demolition (D4) activities at the White Bluffs Central Shops Area. 600-298 included eight subsites of surface debris and stained soil, 600-299 included six subsites and 600-300 included twelve subsites. The total material removed from all the areas was 2300 bank cubic meters. It was all disposed at ERDF.

Characterization soil samples were collected in March and April 2011. GPR scans were done over a time span from June 2011 through January 2013. The remediation activities removed soil and debris between January 31, 2012 through March 5, 2013. At 600-298, most areas were remediated to a depth of 0.9 meters (3 ft). 600-298:5 was excavated to a depth of 2.4 meters (8 ft). The depth of excavation at all the 600-299 and 600-300 areas was 0.3 meters (1 ft).

Status: Inactive

Description:
The parent site and the subsites have been remediated and Interim Closed Out in a single document and Reclassification form (2013-042). The subsite consisted of a 2 by 2 meter (6.6 by 6.6 ft) area with dried, bright yellow paint chips.

Location:
The site was located approximately 61 meters (200 ft) west of Federal Avenue and 858 meters (0.5 miles) south of Route 2 North in the former White Bluffs Community area. Location 2 is at coordinates E577567.28, N147603.22.

Closure Info:
The 600-298, 600-299 and 600-300 parent sites and their subsites have been remediated and Interim Closed Out in a single document and three Reclassification form (2013-040, 2013-041, 2013-042).

The debris was left during deactivation, decontamination, decommissioning, and demolition (D4) activities at the White Bluffs Central Shops Area. 600-298 included eight subsites of surface debris and stained soil, 600-299 included six subsites and 600-300 included twelve subsites. The total material removed from all the areas was 2300 bank cubic meters. It was all disposed at ERDF.

Characterization soil samples were collected in March and April 2011. GPR scans were done over a time span from June 2011 through January 2013. The remediation activities removed soil and debris between January 31, 2012 through March 5, 2013. At 600-298, most areas were remediated to a depth of 0.9 meters (3 ft). 600-298:5 was excavated to a depth of 2.4 meters (8 ft). The depth of excavation at all the 600-299 and 600-300 areas was 0.3 meters (1 ft).

Description: The parent site and the subsites have been remediated and Interim Closed Out in a single document and Reclassification form (2013-042). The subsite consisted of an enclosed, 19 liter (5 gal) container. It appeared to be mostly empty but field personnel were not sure. This container may have been used for desiccant or other dry materials.

Location: The site was located approximately 792 meters (0.5 miles) east of Federal Avenue and 260 meters (853 feet) south of Route 2 North in the former White Bluffs Community area. Location 4 is at E578306.11, N147516.74.

Closure Info: The 600-298, 600-299 and 600-300 parent sites and their subsites have been remediated and Interim Closed Out in a single document and three Reclassification form (2013-040, 2013-041, 2013-042).

The debris was left during deactivation, decontamination, decommissioning, and demolition (D4) activities at the White Bluffs Central Shops Area. 600-298 included eight subsites of surface debris and stained soil, 600-299 included six subsites and 600-300 included twelve subsites. Hanford Site Waste Management Units Report
February 2015
Names: 600-300:5; Miscellaneous Surface Debris Area 5  
Reclassification: Interim Closed Out (11/21/2013)

Type: Unplanned Release  
Status: Inactive  
Start Date:  
End Date:  

Description: The parent site and the subsites have been remediated and Interim Closed Out in a single document and Reclassification form (2013-042). The subsite consisted of various containers ranging in size from 2 to 9 liters (0.5 to 5 gallons). Some are empty while others are partially full of suspect petroleum product. There are approximately ten containers in a 3 by 3 meter (10 by 10 ft) area.

Location: The site was located approximately 1 kilometer (0.6 miles) west of Route 2 North and 1.4 kilometers (0.9 miles) north of Route 1 in the former White Bluffs Community area. Location 5 was at E578472.68, N146629.03.

Closure Info: The 600-298, 600-299 and 600-300 parent sites and their subsites have been remediated and Interim Closed Out in a single document and three Reclassification form (2013-040, 2013-041, 2013-042).

The debris was left during deactivation, decontamination, decommissioning, and demolition (D4) activities at the White Bluffs Central Shops Area. 600-298 included eight subsites of surface debris and stained soil, 600-299 included six subsites and 600-300 included twelve subsites. Description: The parent site and the subsites have been remediated and Interim Closed Out in a single document and Reclassification form (2013-042). The subsite consisted of concentrated area rusted metal including metal turnings, wood and one dry cell battery. There was no vegetation in about a 1 meter (3 ft) diameter area.

Location: The site was located just outside the 100-F Area approximately 914 meters (0.6 miles) east of Federal Avenue and 2.1 kilometers (1.3 miles) north of Route 2 North. Location 12 is at E579583.47, N148621.43.

Closure Info: The 600-298, 600-299 and 600-300 parent sites and their subsites have been remediated and Interim Closed Out in a single document and three Reclassification form (2013-040, 2013-041, 2013-042).

The debris was left during deactivation, decontamination, decommissioning, and demolition (D4) activities at the White Bluffs Central Shops Area. 600-298 included eight subsites of surface debris and stained soil, 600-299 included six subsites and 600-300 included twelve subsites. The total material removed from all the areas was 2300 bank cubic meters. It was all disposed at ERDF.
Characterization soil samples were collected in March and April 2011. GPR scans were done over a time span from June 2011 through January 2013. At 600-298, most areas were remediated to a depth of 0.9 meters (3 ft). 600-298:5 was excavated to a depth of 2.4 meters (8 ft). The depth of excavation at all the 600-299 and 600-300 areas was 0.3 meters (1 ft).

**The SubSite is Part Of:**

- **Code:** 600-300
- **Names:** 600-300; Miscellaneous Surface Debris Sites

**Code:** 600-301  
**Classification:** Accepted

**Names:** 600-301; White Bluffs Sanitary Sewer Pipelines  
**Reclassification:** Interim Closed Out (1/16/2014)

**Type:** Sanitary Sewer  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The waste site has been remediated and Interim Closed Out. It consisted of the sewer pipelines in the White Bluffs area. It included five components consisting of the historical sewer system and underlying soils documented on construction drawing H-11-3709 and four suspected, related features discovered during the Orphan Site Evaluation (OSE) field investigation.

The first related feature was at coordinates E578241/N148296. It consisted of two square holes about 0.5 meters (1.5 feet) deep with 2 clay pipes protruding upward, but still below grade level. The holes were approximately 1 by 1 meter (3 by 3 feet) square and 2 meters (6 feet) apart. It is not known whether this feature is associated with a pre-Hanford farmstead or is a potentially a component of the sanitary sewer system of White Bluffs.

The second related feature was at coordinates E578309.8/N147971.6. It consisted of a 1 meter (3 foot) diameter manhole that is concrete lined with a carbon steel lid. A fifteen centimeter (6 inch) diameter horizontal orientated below grade pipe exited the west side of the manhole. The manhole was located near Washington and Second Avenue, southwest of an unknown facility. It is suspected to be a sanitary sewer cleanout.

The third related feature consisted of a 1 by 1 meter (3 by 3 feet) concrete foundation and potential below grade structure at coordinates E577540.06/N147742.44. The fourth related feature was a concrete manhole. It was 1.5 meter (61 inches) in diameter, 14 centimeter (5 inch) wall thickness, 23 centimeter (9 inches) deep, and partially filled with dirt. It is at coordinates E577894.91/N147786.64.

**Location:** The sewer system was located throughout the White Bluffs area.

**Related Sites/Structures:** Eleven facilities are shown on H-11-3709, that connect to the sanitary sewer system from the south side of town. See Sitecode 600-176.

**Process Description:** The sanitary sewer system is a network of pipelines connect to multiple facilities all discharging to a Imhoff Tank prior to being released to the filter and leaching bed, as shown in White Bluffs drawing plot plan H-11-3709. Septic system transfer piping connecting to the septic tank. Little is known about the sanitary sewer service piping. The pipeline size, depth and construction material are all unknown.

**Closure Info:** Confirmatory samples were collected from four test pits, placed at the locations of the four features related to the 600-301 waste site. Elevated levels of arsenic and nitrate at test pits 1 and 2, as well as elevated concentrations of cadmium and TPH at test pit 7 (main site excavation) were identified in the confirmatory data. Between April 22 and June 20, 2013, approximately 963 bank cubic meters (1,260 bank cubic yards) of rock, gravel, and pipe were removed from
the areas associated with test pits 1, 2, and a segment of pipeline associated with test pit 7. These materials were disposed at the Environmental Restoration Disposal Facility (ERDF). The maximum depth of the excavation is approximately 2.1 meters (7.0 ft) below ground surface. All material removed from the waste site was direct loaded for disposal at ERDF, and no soil staging pile areas or overburden areas were utilized.

### Code: 600-302
### Names: 600-302; French Drain with Vent Pipe
### Type: French Drain
### Status: Inactive
### Classification: Accepted
### Description: This wastes site was evaluated and determined to require No Action site. Letter: MSA-1400080 (1/27/2014) Contract Deliverable CD1033 Annual Class V Underground Injection Control (UIC) Wells Update for calendar year 2013 states the estimated backfill date of this drain is 10/1/2010. The site consisted of a french drain, and underlying soil, with a vent pipe located approximately 2 meters (6 feet) northeast. The drain is about 1 meter (3 feet) in diameter, both have covers.

### Location: The site is located approximately 361 meters NNE of the intersection of Route 2 North and Sand Bar Road.

### Closure Info: Results of confirmatory sampling performed in October 2010 concluded that remediation was not necessary.

During confirmatory sampling, it was observed that the french drain extended to approximately 1 meter (3 ft) below ground surface. The vent pipe was a 1 inch (3 ft) diameter section of pipe that was attached to nothing. The linear features identified on the geophysical survey were determined to be 1 in. diameter, 0.5 in. diameter, and 6 in. diameter stainless steel sewer and vent lines leading directly to the french drain. Material for sampling was not present in these pipelines.

No radiological activity or volatile organic compounds (VOCs) were detected during confirmatory sampling. Additionally, no anomalous or stained soil was observed. Confirmatory sampling indicated that environmental contamination was not present at this waste site. Based on confirmatory sampling, remedial action was determined to be unnecessary.

### Code: 600-303
### Names: 600-303; Vertical Pipes
### Type: Unplanned Release
### Status: Inactive
### Classification: Accepted
### Description: The waste site has been remediated and Interim Closed Out. It consisted of a 3 by 3 meter (9.8 by 9.8 foot) area with 4 vertical pipes, 2.5 to 3.8 centimeter (1 to 1 1/2 inch) in diameter, extending up from the ground.

### Location: The site was approximately 361 meters (1185 feet) north/northeast of the intersection of Route 2 North and Sand Bar Road. The feature is located approximately 4 meters from the SE corner of the footprint of the former office building at E577419.03, N148906.44.

### Process Description: The purpose of these pipes is unknown.
Closure Info: In October 2010, confirmatory samples were taken at the 600-303 waste site. The project team conducted site visits at various times from June 2011 to January 2013. The objective of the visits was to perform geophysical surveys and determine the extent (if any) of buried debris associated with the waste sites.

Remediation of the 600-303 waste site occurred on February 11, 2012, and February 12, 2012. The soil within this waste site was excavated to a depth of approximately 1.8 meters (6 ft) below ground surface (bgs) and resulted in the removal of 35 bank cubic meters (BCM) (46 bank cubic yards [BCY]) of soil and debris, which were disposed at the Environmental Restoration Disposal Facility (ERDF). The remediation of the 600-321 waste site subsites occurred between June 28, 2011, and March 19, 2013. The soil within the subsites was excavated to a depth of approximately 1.2 meters (4 ft) bgs and resulted in the removal of 235 BCM (307 BCY) of soil and debris, which were disposed at ERDF.

The waste site dimensions were revised during the remedial investigation. The final extent of the excavations at these waste sites removed all subsurface staining and debris present.

Closure Info: Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012.
The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

This Site has the Following SubSites:

Description: The waste site has been remediated and Interim Closed Out. The subsite consisted of a roll of roofing product that was considered potential asbestos containing material (ACM).

Location: The site was located approximately 365 meters (0.2 miles) west of Federal Avenue and 442 meters (0.3 miles) south of Route 2 North in the former White Bluffs Community area.

Closure Info: Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.
For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

*Hanford Site Waste Management Units Report*

February 2015
Description: The waste site has been remediated and Interim Closed Out. The subsite consisted of fabric-like material that was potential asbestos containing material (ACM).

Location: The site was located approximately 1.2 km (0.75 miles) east of Federal Avenue and 759 meters (0.5 miles) south of Route 2 North in the former White Bluffs Community area.

Closure Info: Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on
August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The waste site has been remediated and Interim Closed Out. The subsite consisted of a 2 by 2 meter (6 by 6 ft) area with potential asbestos containing material (ACM) insulation that might also have been fiberglass.

**Location:** The site was located approximately 944 m (0.6 miles) east of Federal Avenue and 395 meters (0.25 miles) south of Route 2 North in the former White Bluffs Community area.

**Closure Info:** Remediation of the combined 100-IU-2/6 debris and burn area waste sites occurred between August 10, 2011 and May 29, 2012. The activity resulted in a total of approximately 523 bank cubic meters (BCM) (682 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within
this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

A post-excavation global positioning survey (GPS) walk-around for the excavated waste sites was performed following excavation. Excavated material from all subsites and waste sites was direct loaded for disposal to ERDF, and no soil staging pile area or overburden areas were utilized.

The SubSite is Part Of:
Code: 600-305
Names: 600-305; Suspect Asbestos Containing Material Sites

disposed at the Environmental Restoration Disposal Facility (ERDF).

Based on observations during the field walkdowns to support remedial action, it was determined that the 600-305, 600-308, 600-309, 600-310, 600-311, 600-312, 600-313, 600-314, 600-317, 600-319, and 600-324 waste sites required remediation. The 600-314 subsites required removal of only telecommunication equipment on the ground surface with no excavation.

Remediation of the 600-305:1 and 600-305:2 subsites occurred on April 4, 2012. The soil within these subsites was excavated to a depth of approximately 0.3 meters (1 ft) below ground surface (bgs). No excavation occurred at the 600-305:3 waste site since surface removal of a pipe was the only scope. The remediation of the 600-305:4 subsite occurred on May 14, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs. The remediation of the 600-305:5 subsite occurred on May 15, 2012. The soil within this subsite was excavated to a depth of approximately 0.3 meters (1 ft) bgs.

The remediation of the 600-308 waste site occurred on May 29, 2012. The soil within this waste site was excavated to a depth of approximately 0.6 meters (2 ft) bgs.

The remediation of the 600-309 waste site occurred on May 23 and 24, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-310 waste site occurred on May 22 and 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-311 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-312 waste site occurred on May 14, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

The remediation of the 600-313 waste site occurred on May 16, 2012. The soil within this waste site was excavated to a depth of approximately 1 meter (3 ft) bgs.

For the five 600-314 subsites, only component item removal was required, since only telecommunications components were lying on the surface with no stained or additional anomalous material. Component removal at the 600-314 subsites occurred on May 1, 4, and 14, 2012. All the components were disposed of at ERDF.

The remediation of the 600-317 waste site occurred on May 21 and 22, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-319:1 subsite occurred on May 23, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:2 subsite occurred on May 4, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs. The remediation of the 600-319:3 subsite occurred on August 10, 2011. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

The remediation of the 600-324 waste site occurred between April 26 and 30, 2012. The soil within this waste site was excavated to a depth of approximately 1 meters (3 ft) bgs.

Closure Info: Geophysical surveys were conducted to detect subsurface anomalies. Remediation of the 600-306 waste site occurred on April 3 and 4, 2012, and resulted in approximately 73.5 bank cubic meters (96.1 bank cubic yards) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility (ERDF). Remediation of the 600-307 waste site occurred on April 3, 2012, and resulted in approximately 87.6 bank cubic meters (114.6 bank cubic yards) of soil and debris being removed and disposed at the ERDF. The 600-325:1 and 600-325:2 waste subsites were remediated between July 5 and 13, 2011, and resulted in approximately 176.0 bank cubic meters (230.2 bank cubic yards) of soil and debris being removed and disposed at the ERDF. No overburden soil was stockpiled to be used as backfill.
