</thead>
<tbody>
<tr>
<td>This pipeline discharged effluent from 2723-W (old laundry/mask cleaning), 2724-W Laundry and the 284-W Powerhouse. Additional pipelines from the 282-W water reservoir, 283-W filter plant and the 277-W fabrication shop also connect to the main pipeline. Portions of this pipeline are associated with the 2724-W building foundation (WIDS sitecode 200-W-64). This pipeline is also associated with 200-W-221-PL (Laundry Waste Crib Pipeline).</td>
<td>The pipeline transported radioactive contaminated laundry and mask cleaning effluent to the 216-U-14 Ditch along with non-radioactive effluent from the powerhouse and shops. The waste originated from the 2723-W (Old Laundry) and 2724-W (New Laundry). 2724-W waste was rerouted to 216-W-LWC (laundry crib) in 1981. After 1984, water from the other buildings continued to use this pipeline, but the waste was collected in the Powerhouse Pond that was built on top of the head end of the 216-U-14 Ditch. Soiled protective work clothing (coveralls, gloves, hoods, canvas boots and rubber shoe covers) were sent to the laundry facility from all the Hanford work areas. Two thirds of the laundry received was radioactively contaminated. One third consisted of non contaminated blue coveralls and towels. The non-contaminated laundry was washed separately from the contaminated laundry. The masks were radiologically decontaminated at 2706-T prior to being washed and sanitized at the 2723-W mask cleaning station. Therefore, the radiological contamination in the 2723-W floor drains and pipeline should be minimal. By 1981, when the effluent was rerouted to 216-W-LWC, approximately three million pounds of laundry was processed per year in 600 pound capacity washing machines and 400 pound capacity dryers. The combined average of 26,250,000 liters (691,000 gallons) of waste water was being discharged from the 2723-W and 2724-W facilities in 1981. It should be noted that portions of the existing pipeline were used to reroute effluent to the 216-W-LWC (see sitecode 200-W-221-PL).</td>
</tr>
</tbody>
</table>
Waste Type: Misc. Trash and Debris

Waste Description: Detergents and radioactive contamination from laundry worn in radiation areas are included in the laundry effluent discharge. A 1945 letter indicates the detergent used at the original laundry facility was named Igepal CA. 3% acetic acid was added to remove beta contamination and 3% citric acid was added to remove alpha contamination. Non-radioactive effluent from the 277-W fabrication shop, the powerhouse and the 283-W filter building.

Code: 200-W-147-PL-A  Classification: Accepted
Type: Radioactive Process Sewer  Start Date:
Status: Inactive  End Date:

Description: The waste site has been evaluated under a removal action and reclassified to Interim Closed Out. Due to the restructuring of Operable Units, as described in the Agreement for Central Plateau Cleanup, the original site (200-W-147-PL) has been split into separate WIDS sites. It was an underground 20 centimeter (8 inch) diameter vitrified clay pipe, extending from the 207-SL retention basin to the 216-S-19 pond. 200-W-147-PL-A is the portion of pipeline that extends south of the manhole, south of 200 West Area in the Outer Area, terminating at the 216-S-19 pond. Subsites were created for the portions of pipeline to the north and to the south of the remediation haul road. Both subsite sections were remediared.

Location: This portion of the pipeline was located in the 600 Area, south of 200 West Area and the 222-S facility. It extends from the manhole located in the Outer Area boundary to the 216-S-19 Pond.

Related Sites/Structures: This portion of pipeline is associated with the 222-S laboratory waste, the 216-S-19 pond and 200-W-147-PL-B portion of the pipeline that remains in the 200 West Inner Area. It is also associated with subsites 200-W-147-PL-A:1 and 200-W-147-PL-A:2.

Process Description: The pipeline carried waste from the 222-S and 202-S facilities to the 216-S-19 Pond via the 207-SL Retention Basin. In 1984, the 216-S-19 Pond was replaced with the 216-S-26 crib. The pipeline to the crib was connected to the 216-S-19 Pond pipeline at manhole #3 (see 200-W-148-PL). The portion of the pipeline from 207-SL to Manhole #3 continued to be used to feed the 216-S-26 crib until 1995. The portion of pipeline southward from Manhole #3 to the 216-S-19 Pond was abandoned in 1984.

Closure Info: The removal action at the 200-W-147-PL-A waste site was conducted from November 2010 through June 2011. The activities included the removal of overburden soil, and the pipeline itself, followed by collection of soil samples from locations within the excavation trench, as prescribed in the SAP (DOE/RL-2009-60). During RTD activities, a portion of the 200-W-147-PL-A pipeline beneath an access road to sites 216-S-19 and 216-S-26, could not be excavated without compromising the integrity of the access road. As a result, the pipeline was split into two subsites in WIDS: 200-W-147-PL-A:1 and 200-W-147-PL-A:2. Both segments were eventually properly remediared. Direct visual inspection of the site surface was performed, using available site information as a guide for visual cues such as staining, discoloration, absence of vegetation, presence of debris, and other anomalies. Radiological field screening was performed at the surface of the waste site to provide an indication of the presence of radiological COPCs.

The removal of the 200-W-147-PL-A:1 and 200-W-147-PL-A:2 subsites of the pipeline, and adjacent soils, was completed using radiological field screening and visual indicators to determine the extent of excavation. Where radiological dose rates greater than background were found, excavation continued in the area. The vertical extent of excavation ranged from 3 to 4.6
m (10 to 15 ft) below ground surface. The lateral extent of excavation at the waste site was
determined utilizing visual and radiological indicators.

The waste site was backfilled in July 2011.

Hanford Site Waste Management Units Report
February 2015
Closure Info: The removal action at the 216-S-26 and 200-W-148-PL waste sites was conducted from March 2011 through August 2011 and included the removal of overburden soil, and the pipe itself, followed by collection of samples from locations within the excavation. Implementation of the selected Remove, Treat, Dispose (RTD) alternative was performed. Soil and piping were removed from the two waste sites. Direct visual inspection of the site surface was performed as a guide for visual cues such as staining, discoloration, absence of vegetation, presence of debris, and other anomalies. Radiological field screening was performed at the excavation surface of the waste site to provide an indication of the extent of radiological contaminants. Soil was removed to a depth of approximately 4.6 meters (15 ft) below ground surface. Characterization sampling was performed at depths of 4.6, 4.9, 5.5, and 6.1 meters (15, 16, 18, and 20 ft) and the analytical results evaluated to demonstrate achievement of Removal Action Objectives. Backfill of the 216-S-26 and 200-W-148-PL waste sites was completed on August 30, 2011.

Reclassification:
216-W-LWC; 216-W-LWC Crib; Laundry Waste Crib; 216-W-1; 216-W-LC

Inactive

Names:
216-W-LWC; 216-W-LWC Crib; Laundry Waste Crib; 216-W-1; 216-W-LC

Type: Crib

Start Date: 1/1/1981

End Date: 1/1/1994

Classification: Accepted

Recategorization: None

Location: The site is located east of Beloit Ave., south of 20th Street.

Related Sites/Structures: The crib received effluent from the 2724-W, 2724-WA, 2724-WB Laundry facilities, MO-412 Mask Cleaning facility and the 2723-W Old Laundry. The pipeline from the laundry facility to the Laundry Waste Crib is sitecode 200-W-221-PL.

Description: The site is constructed of two cribs, surrounded by a single Underground Material posted area. The Laundry Waste Crib began receiving effluent in 1981 from the Laundry Complex which included the 2724-W, 2724-WA, 2724-WB, MO-406 and 2723-W (Old Laundry). In 1984 mask washing was moved from 2723-W to MO-412, which was placed adjacent to the 2724-W Laundry Complex and became the Mask Cleaning and Maintenance Facility.

Soiled protective work clothing (coveralls, gloves, hoods, canvas boots and rubber shoe covers) were sent to the laundry facility from all the Hanford work areas. Two thirds of the laundry received was radioactively contaminated. One third consisted of blue (non contaminated) coveralls and towels. The non-contaminated laundry was washed separately from the contaminated laundry. By 1981, approximately three million pounds of laundry was processed per year in 600 pound capacity washing machines and 400 pound capacity dryers. An average of 2,615,435 liters (691,000 gallons) of waste water was discharged to the new crib each month.

Waste Type: Not Specified

Waste Description: The site received all the process wastewater (averaging 2,615,435 liters per month) from the contaminated laundry facility (2724-W/WA) and mask cleaning station (MO-412). The waste
included radioactive residue from the contaminated laundry and detergents. Bleach and flame retardant chemicals were added to some of the wash and rinse cycles. From 1981 to 1983, some waste oils, from a nearby fabrication shop, entered the waste stream through manhole B. The site became inactive in January 1994 when operations were initiated at an offsite contracted laundry facility. TPA M-17-34 required elimination of all discharge to the Crib by January 1995.

Code: 2607-W1  Classification: Accepted
Names: 2607-W1  Reclassification: None
Type: Septic Tank  Start Date: 1/1/1944
Status: Active  End Date:
Description: The 2607-W1 Septic Tank is constructed of reinforced concrete and receives sanitary wastewater and sewage. There is a drain field associated with the system. This system was reconstructed in 1994.

Location: This unit lies southeast and across Bridgeport Avenue from the associated drain field, and northeast of the 2713-WB Building.

Process Description: The 2607-W1 Septic Tank and associated drain field are designed to accept sanitary sewer effluent from connected facilities. In 1999, PFP waste was diverted to 2607-W1 when 2607-Z1 shut down. The additional volume was more than 2607-W1 could handle. A new septic system, 2607-W16, was built in 2001 to receive the PFP waste.

Code: 2607-WL  Classification: Accepted
Names: 2607-WL; 2607-WL Septic System  Reclassification: None
Type: Septic Tank  Start Date: 1/1/1962
Status: Inactive  End Date: 1/1/1999
Description: The 2607-WL Septic System is constructed of reinforced concrete. The septic system includes a trench-type drainfield. The septic tank and drainfield are surrounded by a chain barricade with a sign stating "Septic Tank" posted.

Location: This unit lies north of the 272-WA Building and west of the 2401-W Building.

Related Sites/Structures: The 2607-WL Septic Tank is associated with a drain field and the 272-WA Building. Site 200-W-34 was a duplicate of this site, and has been classified as Not Accepted because it is a duplicate entry. Site 2607-WWA may also be a duplicate of this site.

Process Description: The 2607-WL Septic Tank was designed to accept and treat sanitary sewer effluent from the associated facility, and discharge the effluent to the 2607-WL Drain Field. This drain field in turn, discharges the effluent into the ground.

Code: 600 OCL  Classification: Accepted
Names: 600 OCL; Original CLF; 600 Area Original Central Landfill  Reclassification: None

Hanford Site Waste Management Units Report
February 2015
**Type:** Sanitary Landfill  
**Start Date:** 1/1/1973

**Status:** Inactive  
**End Date:** 1/1/1973

**Description:** This site is a backfilled trench that is posted "Underground Radioactive Material".

**Location:** This site is located 2.4 kilometers (1.5 miles) southeast of Army Loop Road and 30.5 meters (100 feet) north of Highway 4 South.

**Process Description:** The site received miscellaneous trash and debris from the Hanford Site.

**Waste Type:** Soil

**Waste Description:** This site contains general office wastes, some glass, electrical wastes, and minimal metal wastes. Radioactive contamination was found at this site in 1988 during investigative (test pit) activities.

---

**Code:** 600-36  
**Classification:** Accepted

**Names:** 600-36; Ethel Railroad Siding (Burn Pit)  
**Reclassification:** Interim Closed Out (5/20/2011)

**Type:** Burn Pit  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The waste site has been evaluated under a removal action and Interim Closed Out. The site had been an area of scattered debris and some evidence of burning, adjacent to the Ethel railroad siding. Metal and wood debris were observed during the pre-remediation visual inspection performed in August 2009. The previously documented batteries and burn pit were also observed. Visual indicators of the burn pit included a circular area approximately 9.1 meters (30 ft) in diameter. Several discrete areas of surface discoloration and devegetation were observed in the eastern portion of the waste site. Historical information suggests the discolored areas may have been caused by a release of oil into the ground surface. Tar like deposits not previously identified were also encountered towards the western portion of the waste site.

**Location:** The site is approximately 1 mile (1.6 kilometers) northeast of the 200 West Area. It is located northwest of the 251 Electrical Substation, north of Route 11A.

**Waste Type:** Process Effluent

**Waste Description:** There is evidence of oil spills.

**Waste Type:** Process Effluent

**Waste Description:** The waste at the unit appears to be from burning activities. The current form of all waste material is solid. No evidence exists (historical or present) that chemical or radiological processes involving sustained releases of materials are associated with this waste site.

**Closure Info:** The removal action at the 600-36 waste site was conducted between September 2009 and September 2010 and included the collection of focused and random samples from locations within the waste site. Radiological field screening was performed at the surface of the waste site to provide an indication of the presence of radiological COPCs. No radiological readings were greater than the measured background and no radiological contamination was found. The selected alternative for the 600-36 waste site was Confirmatory Sampling/No Further Action (CS/NFA). The results of the initial sampling indicated COPC concentrations greater than the RALs in the six sampled areas. The removal action activities progressed to implementation of the RTD alternative for those areas. As a result of analytical results exceeding the Remedial...
Action Limits, excavation of soil was done in zones of potential contamination (ZPCs) 2 (battery area) and 4 (burn pit), and focused sample (FS) locations FS 1, FS 2, FS 3 (stained and devegetated areas) and FS 5 (tar deposits). Excavation of soil at FS 4, which was considered analogous to FS 1, FS 2, and FS 3 based on visual indicators.

<tr>
<td>Description</td>
<td>The waste site has been evaluated under a removal action and Interim Closed Out following sampling of the dry wells per SAP DOE/RL-2009-60. Analytical results were less than RALs, thus no action was required. The dry wells and above ground tanks at waste site 600-37 were left in place. The dry wells were not backfilled. They are listed on the UIC Master List as UU221. The waste site consists of four steel tanks and dry wells. The tanks had been resting on railroad ties approximately 1.2 meters (4 feet) above ground. A range fire burned through the area in June 2000. The southern-most tank was untouched by the fire and the tank supports remain intact. The wooden support structures under the other three tanks were burned and the tanks are now sitting on the ground. The dry wells are double encased with pipe used to center the inner casing within the outer casing. Three of the dry wells have a inside diameter of 38 centimeters (15 inches) and are approximately 4.9 meters (16 feet) deep. The fourth dry well has a much larger diameter, differs from the others with an outside diameter of 2.18 meters (7 ft). It contains an internal substructure in the form of a separate pipe oriented the same as the outer casing. The upper ends of the outer and inner structures terminate at the outer French drain cover. The dry wells were unaffected by the fire in June 2000. There is a dirt road that runs through the unit that appears to be surfaced with used oil.</td>
</tr>
<tr>
<td>Location</td>
<td>The site is located southeast of 200 West at the southern boundary of the Environmental Restoration Disposal Facility (ERDF) land easement.</td>
</tr>
<tr>
<td>Process</td>
<td>The four steel tanks appear to be of military origin. The configuration of the wells and tanks appear appropriate for an infiltration test. Raw water was assumed to have been disposed of in the wells, however sample testing should be conducted in the unit.</td>

<tr>
<td>Waste</td>
<td>Raw water was assumed to have been disposed of in the dry wells, however sample testing is needed to confirm this theory.</td>
</tr>
<tr>
<td>Closure Info</td>
<td>The 600-37 waste site was reclassified as interim closed out following sampling of the dry wells per SAP DOE/RL-2009-60. Analytical results were less than Removal Action Limits, thus no action was required. The dry wells and above ground tanks at waste site 600-37 were left in place and the dry wells not backfilled. Soil sampling was conducted between May 18 and 26, 2010. Soil samples were collected from bottom surfaces inside each of the four french drains. The french drains were approximately at 4.9 meters (16 ft) deep. The soil media was a fine soil type collected from beneath the gravel layer in each French drain. One sample was collected from French drain 1, one sample was collected from French drain 2, and one sample was collected from French drain 4. Two samples were collected from the large diameter French drain, known as French drain 3. One sample was taken from the inside the drain structure and one from the annular space between the inner and outer structure.</td>
</tr>
</tbody>
</table>
No radiological postings were present at the waste site. Of the radiological surveys performed during removal action activities, all radiological dose readings were at or below the measured background and no radiological contamination was found.

</table>
| Closure Info:| Waste Site 600-38 was investigated between December 2009 and March 2010 through field observations and sampling to determine the nature and extent of contaminants of potential concern (COPCs) present in the waste site soils as part of the selected removal action alternative of CS/NFA prescribed in the Action Memorandum. This investigation was performed in accordance with DOE/RL-2009-60, Sampling and Analysis Plan for Selected 200-MG-1 Operable Unit Waste Sites and DOE/RL-2009-53, Removal Action Work Plan for 11 Waste Sites in the 200-MG-1 Operable Unit (RAWP). Through the investigation summarized in this report, it was found that analytical results from confirmatory sampling demonstrated that soil conditions at the waste site did not meet removal action levels (RALs). Therefore, in accordance with the methodology prescribed in the Action Memorandum, the alternative was changed to removal, treatment, and disposal (RTD). The removal action at the 600-38 waste site was conducted between March and October 2010 and included the collection of focused and/or
random samples from locations within the waste site.

Direct visual inspection of the site surface was performed, using available site information as a guide for visual cues such as staining, discoloration, absence of vegetation and other anomalies. Observations made during the site walk down included areas of devegetation, areas of darkened soil, and scattered debris consisting of rusted 18.9 liter (5 gallon) containers, metal, wood pallets, and refuse. Based on these observations, 16 individual zones of potential concern (ZPCs) were established at the 600-38 waste site to facilitate an organized removal action approach. Radiological field screening was performed at the surface of the waste site to provide an indication of the presence of radiological COPCs. No radiological postings were present at the waste site. Of the radiological surveys performed during removal action activities, all radiological readings were at or below measured background, and no radiological contamination was found.

Backfill of the 600-38 Waste Site was completed on February 9, 2011.

---

**Code:** 600-40  
**Classification:** Accepted

**Names:** 600-40; West of West Lake Dumping Area  
**Reclassification:** Interim Closed Out (7/21/2011)

**Type:** Dumping Area  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** This waste site has been remediated. The site had been an old dumping area. The debris was mostly consolidated in one of two locations, either along the road or on the hillside. The waste site included concrete rubble, wood, roofing materials, and miscellaneous metal debris and containers. The area along the road was approximately 364 square meters (3918 square feet). The portion on the hillside was 123 square meters (1324 square feet) in area. The area listed in the dimensions field represents the total area of both dumping areas. Additionally, a few pieces of scattered debris was found on the hillside. The debris at 600-40 was removed and sent to ERDF.

**Location:** The site was located in the 600 Area, east of route 4 North and 105 meters (345 feet) west of West Lake. The debris was located on a dirt road at the T-intersection from 4 North to West Lake. Additional debris was found on the hillside that slopes down to West Lake.

**Process Description:** This area is a former waste dump site.

**Waste Type:** Sludge

**Waste Description:** The waste along the dirt road includes chunks and slabs of concrete, lumber, miscellaneous metal debris, rusted cans approximately 30.5 centimeters in diameter and 40.6 centimeters tall (12 inches in diameter and 16 inches tall), and what appears to be roofing (black, tarry sheets with gravel) materials. On the hillside are 2 small wooden structures approximately 1.8 meters by 1.8 meters by 1.2 meters (6 feet by 6 feet by 4 feet), a pile of wooden posts with each post approximately 20.3 centimeters in diameter and 1.8 meters long (8 inches in diameter and 6 feet long), other wood debris, what appears to be a wheelbarrow, and 2 large rusted metal cans approximately 20.3 centimeters by 20.3 centimeters by 35.6 centimeters tall (8 inches by 8 inches by 14 inches tall) and 30.5 centimeters in diameter by 35.6 centimeters tall (12 inches in diameter by 14 inches tall).

**Closure Info:** The waste site was comprised of two discrete debris dump sites. One was located adjacent to the gravel access road, at the T of the access road intersection, known as Zone of Potential Contamination (ZPC 1). The second area was located on the hillside that slopes down toward West Lake (known as ZPCs 2, 3a, and 3b). Initial sampling and analysis indicated that soil...
concentrations of COPCs were greater than the RALs, thus confirming the implementation of the RTD alternative. Activities involved in the RTD action including soil excavation and verification sampling to demonstrated that the remaining in situ COPC concentrations in soil are less than or equal to the established RALs, and that no additional removal action is required. No radiological dose readings were greater than the measured background, and no radiological contamination was found. Excavation at the four ZPCs commenced in March 2010. Soil removal occurred to a total depth of approximately 0.6 meters (2 ft) and was laterally bound by the areas of wood debris and areas void of surface vegetation. Additionally, three test pits, each evaluated to a total depth of approximately 4.7 meters (15 ft) below ground surface, were dug east of ZPC 1 to verify that the extent of the 600-40 waste site was limited to the area of excavation. Backfill of the 600-40 waste site was completed on May 26, 2011.

</tbody>
</table>
Waste Description: Concrete building foundations, pads and walkways, pipe, sandbags and sheetmetal remain.

Closure Info: The removal action at the 600-49 waste site was conducted between May and June 2011. Activities included direct visual inspection of the site surface using available site information as a guide for visual cues such as staining, discoloration, absence of vegetation and other anomalies; the collection of random verification samples from locations within the shooting range backstop of the waste site and excavation of soil under the RTD alternative from shooting range backstop to eliminate a source of contamination from lead slugs remaining in the soil. Observations made during previous site evaluations indicated the presence of six concrete foundations and footings, walkways, four artillery emplacements marked by revetments, and some sheet metal and pipe. Radiological field screening performed at the surface of the waste site to provide an indication of the presence of radiological COPCs. No chemical or radiological processes involving sustained releases of material are associated with this site. No radiological contamination was found. The available 600-49 waste site historical information and process knowledge was sufficient to proceed directly to implementation of the RTD alternative without requiring additional field observations or sampling to determine the nature and extent of contaminants of potential concern (COPCs) present in the waste site soil. The shooting range backstop consisted of soil mounded elevated greater than the general surface grade of the area. The mound was removed. No depression was created in the ground surface RTD activities, so backfilling was not required.

Code: 600-51  Classification: Accepted
Names: 600-51; Chemical Dump; Pile of White Powder  Reclassification: Interim Closed Out (2/9/2011)
Type: Dumping Area  Start Date:
Status: Inactive  End Date:
Description: The waste site has been evaluated under a removal action and Interim Closed Out. The site is an elliptical area with little or no vegetation.
Location: This site is located west of Route 4 North, between Route 1 and Route 11A. It is between the 1901-Z Building and well 699-64-62, just west of the export water line.
Waste Type: Soil
Waste Description: A sample of this material was analyzed with the HAZCAT field analysis kit. The bulk of this material appears to be a sodium compound.
Closure Info: The waste site was first identified in 1994. Shortly after being discovered, a HAZCAT field sampling kit was used to determine to powder was a sodium substance. A site visit in October 1999 found the pile of material was no longer present. The 600-51 waste site was investigated again in October 2009 through field observations. The original alternative for 600-51 was anticipated to be Remove, Treat and Dispose (RTD). Historical photographs of the pile of white powder (when it was present on the site) defined conservative northern and southern boundaries of the piles footprint. The silty, sandy, and rocky soil matrix showed no signs of discoloration. Confirmatory sampling was done to determine the nature and extent of contaminants of potential concern (COPCs) present in the waste site soils. It was determined that site conditions met removal action levels (RALs) and removal action objectives (RAOs) without further removal action. In accordance with the methodology prescribed in the Action Memorandum, the alternative was changed from RTD to confirmatory sampling/no further action (CS/NFA).

Code: 600-65  Classification: Accepted
Dumping Area

inactive

Start Date: 
End Date: 

Description: This waste site has been reclassified to Interim Closed Out. In 1995, two crushed and flattened 55-gal drums, one oil filter housing (approximately 2 quarts [1.9 liters]), a metal cable, one large concrete block (0.5 cubic yards [0.4 cubic meters]), and indications of possible petroleum disposal were identified. In 2001, the items noted above could not be located, and the area is possibly being used for fill material. Further investigations were conducted between June 2010 and February 2011 through field observations and sampling to determine the nature and extent of contaminants of potential concern.

Location: The debris was located approximately 0.5 miles east of the 200 Area Fire Station. It is west of 200 East Area on the north side of Route 3, near Gravel Pit 30.

Related Sites/Structures: 607 Batch Plant Gravel Pit

Waste Type: Sanitary Sewage

Waste Description: Two crushed and flattened 55-gal drums, one oil filter housing, one large concrete block, and indications of possible petroleum disposal. In October 2001 these items could not be located at the site.

Closure Info: The removal action at the 600-65 waste site was conducted between June 2010 and February 2011. It included the collection of focused and random samples from locations both within the boundaries of the waste site and in surrounding areas. The original selected alternative for the subject waste site was Remove Treat and Dispose (RTD). This alternative was selected because, based on the types of debris present, concentrations of contaminants of potential concern (COPCs) had the potential to exceed the Removal Action Levels (RAL). Investigative sampling and analysis demonstrated that soil concentrations of contaminants were less than or equal to the Remedial Action Levels without the need for further action. As a result, in accordance with the Action Memorandum, the alternative was changed to Confirmatory Sampling/No Further Action (CS/NFA). Field activities included ground penetrating radar (GPR) scanning, radiological surveys and soil sampling. The GPR scan and metal detector survey performed at the last known location of the drums and oil filter identified one anomaly within the WIDS boundary of the 600-65 waste site approximately 1 meter (3 ft) below ground surface and a second anomaly within a mound of overburden. No radiological readings were greater than the measured background, and no radiological contamination were found. Analytical results from the investigative sampling evolution at the 600-65 waste site showed that concentrations of COPCs were less than or equal to RALs, thereby demonstrating compliance with the established RAOs. Sample results determined excavation was not required at the 600-65 waste site. These results also support reclassification to Interim Closed Out status.

Code: 600-66

Classification: Accepted

Names: 600-66; 607 Batch Plant Orphan Drums

Reclassification: None

Type: Dumping Area

Start Date: 
End Date: 

Status: Inactive

Description: The site consists of one rusted 55-gallon (208 L) drum laying on the ground surface on its side. No label or hazardous substance are evident.

Location: The drum is located north of Route 3, approximately 400 meters (1300 feet) east of the 607 Batch Plant.
Related Sites/Structures: The abandoned drum may be associated with the Batch Plant.

Waste Type: Sanitary Sewage
Waste Description: The waste consists of two rusted drums, contents unknown.

Description: The site consists of an area of charred ground, a piece of rusted sheet metal and small pieces of debris. In June 2004, the expansion of Gravel Pit 30 pushed soil over the northern portion of the 600-71 Burn Pit.

Location: The site is located west of route 4, north of route 3. Precisely, on the batch plant entrance road turn east on the first dirt road; follow road for about 350 meters (1150 ft); walk north about 70 feet (23 meters) to the site.

Related Sites/Structures: The 607 Batch Plant is adjacent to the Burn Pit.

Process Description: Although the Burn Pit is located adjacent to the Batch Plant, it does not seem to be associated with the Batch Plant operation.

Waste Type: Sanitary Sewage
Waste Description: Metal, wood, glass, and rubber debris. Charred remains of burned material. This material was still present during the 2002 site visit.

Description: The waste site has been evaluated under a removal action and Interim Closed Out. It consisted of demolition debris consisting of wood, pipe, barbed wire, metal fence posts, empty oil cans, empty paint cans, food cans, and sheet metal. The dumping area was irregularly shaped and was comprised of two distinct areas. The larger area measured 20 meters by 74 meters (67 feet by 243 feet). The smaller area was approximately 48 meters (157 ft) northeast of the larger portion, and was rectangular in shape, measuring approximately 1.5 meters (5 ft) by 1.8 meters (6 ft).

Location: This site was located just southwest of the intersection of Route 11 and Route 6. It is 0.4 miles south of Route 11 and just west of Army Loop Road. The site is in the east half of the northeast quarter of Section 34, Township 13 north, Range 25 east. The dumping area is located in the SW portion of the site.

Related Sites/Structures: This dumping area is related to the Anti-Aircraft site 600-216.
**Waste Type:** Process Effluent  
**Waste Description:** Empty oil cans, paint cans with dried paint.

**Waste Type:** Process Effluent  
**Waste Description:** Wood waste from former buildings, concrete footings, pipe, sheet metal, barbed wire, steel fence posts.

**Closure Info:** The dumping area was irregularly shaped and was comprised of two distinct areas. The larger area measured 20 meters by 74 meters (67 feet by 243 feet). The smaller area was approximately 48 meters (157 ft) northeast of the larger portion, and was rectangular in shape, measuring approximately 1.5 meters (5 ft) by 1.8 meters (6 ft). It consisted of demolition debris consisting of wood, pipe, barbed wire, metal fence posts, empty oil cans, empty paint cans, food cans, and sheet metal. The analytical results from initial sampling demonstrated that soil conditions at the waste site did not comply with established removal action levels (RALs). Therefore, the alternative was changed to removal, treatment, and disposal (RTD). The removal action at the 600-218 waste site was conducted between August 2009 and May 2011, and included the collection of statistically based random and focused samples from locations within the boundaries of the waste site. Nineteen random locations were selected. Locations R4, R9, R11 and R17 were sampled at depths of 4 feet and 8 feet. Soil excavation was required at location R3 and R14. Samples were collected from the excavated areas for remedial verification. Radiological surveys performed for the 600-218 waste site resulted in no radiological dose readings greater than the measured background, and no radiological contamination was found. Since RTD activities were limited in depth to less than 0.6 meters (2 ft) (i.e., surface debris removal at the waste site), backfill was not required at the 600-218 waste site.

**Code:** 600-220  
**Names:** 600-220; H-51 Anti-Aircraft Artillery Site Dumping Area  
**Type:** Dumping Area  
**Status:** Inactive  
**Description:** The waste site has been evaluated under a removal action and Interim Closed Out. It consisted of three dumping areas. One area was surrounded with T-posts. Observations made during the 2010 site evaluation included an area covered with a white, granular material, an area containing burned material and other debris, a small area containing what appeared to be a tar-like substance, an area of visible debris such as partially buried containers, and a mound containing a wide variety of debris such as heavily corroded metal cans and containers, glass, and batteries. In addition, two mounds were observed that might have been used as a firing range containment berm. The debris at 600-220 was determined to be culturally significant and was not removed.

**Location:** The site was on Army Loop Road, approximately 2 miles southwest of 200 West Area and extends to the southwest near SR 240. This site is located in the southeast quarter of Section 15, Township 12 North, Range 25 East.

**Related Sites/Structures:** This site is associated with 600-53, the site building foundations, and 6607-3, the site's septic system.

**Process Description:** The dumps are located in three general areas. The July 2000 fire burned off all flammable material, such as wood, that had remained at the site. The dump area with the T-posts around it...
contains metal, transite, fluorescent light bulbs, metal ducting, fiberglass insulation, an
unknown white granular substance, pipe, and wire. The second area is mostly wood, little
remains now. The third area is a relatively large area consisting of empty cans and empty food,
oil, paint and bleach bottles. Several wooden ammunition boxes and cardboard canisters were
observed before 2000, but are now gone. The area appears to have been scraped with a
bulldozer. Several waste materials are partially buried. The permanent structures included
barracks, latrines, mess halls, craft shops, pump houses, motor pools, and radar facilities. Each
site typically had a small arms range, water storage cistern, sanitary, and sewage disposal
facilities. Pathways, sidewalks, roadways, and parking lots connected the structures.

Waste Type: Chemicals
Waste Description: Transite siding

Waste Type: Chemicals
Waste Description: Wood, metal, transite, fiberglass, piping, glass, fluorescent light tubes, a white granular
substance, empty cans, buckets, and bottles, fence posts, barbed wire, and concrete.

Closure Info: The analytical results from confirmatory sampling demonstrated that soil conditions at the
waste site did not meet removal action levels (RALs). Therefore, the alternative was changed to
removal, treatment, and disposal (RTD). Radiological surveys performed during sampling
activities indicated no radiological readings greater than the measured background, and no
radiological contamination was found.

Seven Zones of Potential Concern (ZPC) and three biased locations were established during site
evaluation. Focused samples were collected from ZPCs 1 through 4 and biased samples at BS 1
through 3 based on historical and process knowledge and visual indicators from the surface,
which is generally defined as 0 to 0.3 m (0 to 1 ft) below ground surface. Random samples were
collected from ZPC 5 through 7 (using Visual Sample Plan (VSP) software as direct visual
indicators were absent for these ZPCs). Analytical results from the initial sampling evolution
indicated contaminants of potential concern (COPC) concentrations exceeded Removal Action
Levels in three areas; ZPC 1 (white granular material), ZPC 2 and BS 1 (debris areas) and BS 2
(battery area) thus initiating RTD in those areas. The areas comprising ZPC 1, ZPC 2, and BS 1
were excavated to a vertical depth of approximately 0.9 to 1.2 meters (3 to 4 ft) below ground
surface. In addition to the removal of the impacted soil from ZPC 1, ZPC 2, and BS 1,
miscellaneous scattered debris, along with approximately 0.9 to 1.2 meters (3 to 4 ft) of
underlying soil, was removed, thus enlarging the area of excavation beyond the three areas of
impact identified during initial and in process sampling.

Code: 600-222
Names: 600-222; H-60 Gun Site
Type: Military Compound
Status: Inactive
Description: The waste site has been evaluated under a removal action and Interim Closed Out. There was
very little evidence of the former military gun site. A few trees, walkways, roads and an old
"Underground Telephone - Contact Signal Officer before excavating" warning sign is present (a
second "underground telephone" sign burned in the July 2000 fire). After the July 2000 fire,
other material left at the site has become visible, including pieces of ceramic pipe, a dumpsite
with two oil filters, coat hangers, and a few small pieces of transite siding. South of the access
road are several small piles of decayed batteries or fuses.

Location: The H-60 Gun site was located approximately 1.2 miles west of 200 West Area and is just east

Hanford Site Waste Management Units Report
February 2015
Several artillery were installed around the 100 and 200 Areas to protect the chemical separation plants and reactors from attack by air. Typically, the artillery sites consisted of residential and office buildings, with gun emplacements situated within semi-circular revetments made of sandbags and wood planking, which were located separately from the residential and administrative facilities. Buildings at these sites were often prefabricated lumber, metal, and concrete block structures for residential and office use. The use of these gun sites ended in the mid to late 1950s, at which time the structures were removed or demolished.

Waste Type: Water
Waste Description: South of the main area and access road are several small piles of decayed batteries or fuses. In another pile are two oil filters, one whole and the other in parts.

Closure Info: As a result of the field investigation, it was found that analytical results from confirmatory sampling demonstrated that soil conditions at the waste site did not meet removal action levels (RALs). Therefore the remedy was changed to removal, treatment, and disposal (RTD). The removal action at the 600-222 Waste Site was conducted between April and December 2010, and included the collection of focused samples. The key activities pertinent to the removal action included collecting soil samples based on visual indicators, excavating soil in the zone of potential contamination (ZPC) 3, and areas identified by focused sample locations FS 1, FS 2, FS 2b, and FS 4 as a result of analytical results exceeding the RALs and removing debris and underlying soil at FS 3, as a result of visual indicators. Random and focused samples were collected from the excavated areas for verification purposes, laboratory analysis for COPCs, and evaluation of analytical results to demonstrate compliance with the RALs.

The key activities pertinent to the removal action at the 600-222 Waste Site included the collection of judgmental soil samples based on visual indicators, excavation of soil, under the Remove, Treat, Dispose (RTD) alternative, in the zone of potential contamination (ZPC) 3, and areas identified by focused sample locations FS 1, FS 2, FS 2b, and FS 4 as a result of analytical results exceeding the RALs and the removal of debris and underlying soil at FS 3 as a result of visual indicators. Observations made during a site walkdown in 1997 found little evidence remained of the former artillery site. Features observed included roadways, a few trees, and a sign marking an underground telephone line. Miscellaneous debris included various metal items, small batteries or fuses, ceramic piping, oil filters, and transite siding. Batteries, oil filters, and miscellaneous debris were physically located outside the previously established waste site boundary. However, since these items are included in the site historical site description, the observed debris was considered part of the 600-222 Waste Site, and was included within the scope of this removal action.

Excavation at the 600-222 Waste Site commenced on October 14, 2010. The extent of excavation at the areas impacted was initially determined from the sampling data, using visual indicators to guide excavation depth during RTD. The initial depth of excavation in the impacted areas was determined to be approximately 0.6 meters (2 ft) bgs. In process sampling and chemical field screening were conducted during RTD activities in the areas of excavation at the 600-222 Waste Site. Analytical results of the in-process sampling indicated concentrations of lead (FS 2 only) and total petroleum hydrocarbon (TPH) diesel (FS 1 only) were still present at concentrations greater than the RALs. As a result, in conjunction with the chemical field screening, the excavation depth was further refined to approximately 1.5 meters (5 ft) bgs at FS 1 and FS 2b, and 0.9 meters (3 ft) at FS 2. Although analytical results indicated COPC concentrations were less than the RALs at FS 3, debris in that area was removed during RTD activities, along with underlying soil to a depth of approximately 0.6 meters (2 ft). Backfill activities were completed on February 9, 2011. In accordance with the ecological compliance review conducted for the 600-222 Waste Site, this area does not meet the requirements of a Level III or Level IV designation as described in DOE/RL-96-32, Hanford Site Biological
Resources Management Plan; therefore, revegetation at the 600-222 Waste Site is not required.

<td>Closure Info:</td>
<td>The Remove, Treat, Dispose (RTD) alternative was selected for 600-226 as the preferred alternative as documented in the Action Memorandum. The RTD action included excavation of contaminated soil and other materials. Direct visual inspection of the surface of the 600-226 waste site was conducted, using available information as a guide for visual cues such as staining, discoloration, absence of vegetation, and other anomalies. The visual inspection incorporated observational indicators and historical information to identify areas of concern, which included several rusted metal containers of various capacities (18.9 liters [5 gallon], 3.78 liters [1 gallon], and 0.94 liters [0.25 gallon]) scattered over an area approximately 3.71 square meters (40 square feet) in size. Radiological field screening was conducted at the surface of the waste site to provide an indication of the presence of radiological contaminants. Surface geophysical surveying (using ground penetrating radar) was conducted to identify subsurface features. Chemical field screening performed during RTD activities was used to verify the extent of contamination or, in conjunction with visual indicators, to identify areas of potential contamination that would require RTD. During RTD activities, a section of metal bar stock was observed projecting above the ground surface near the 600-226 waste site. As a result of operational safety concerns, the metal bar stock was removed, which led to the discovery of</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
additional assorted metal debris. The unearthed metal was collected for disposal. Revegetation at the 600-226 waste site is not required, however, the 600-226 waste site has been reseeded.

The removal action at 600-226 was conducted between January and December 2010. Key activities were pertinent to the removal action at 600-226 included collecting investigative soil samples based on visual indicators, excavating impacted soil that, due to analytical results, exceeded the RALs, collecting bias samples from the area adjacent to the excavation to demonstrate that the extent of contamination has been mitigated by the excavation and is bounded by the verification samples and collecting random samples from excavated areas for verification purposes. Backfill and contouring was completed on March 3, 2011.

<td>Description:</td>
<td>The site has eight building foundations, four ammunition storage structures and a valve pit remaining. The foundations are: #1. Kitchen/mess hall foundation with four floor drains: 12.4 meters by 9.8 meters (40.5 feet by 32 feet) #2. Shower/toilet foundation with five floor drains and ten toilet drains: 6 meters by 16.5 meters (20 feet by 54 feet) #3. Concrete pad: 4 meters by 3.2 meters (13.5 feet by 10.5 feet) #4. Concrete pad: 15 meters by 7.3 meters (49.5 feet by 24 feet) #5. Concrete pad: 3.7 meters by 5.5 meters (12 feet by 18 feet) #6. Concrete pad: 1.8 meters by 2.4 meters (6 feet by 8 feet) #7. Concrete pad: 5.5 meters by 6.7 meters (18 feet by 22 feet) #8. Concrete pad: 3.7 meters by 6.4 meters (12 feet by 21 feet). The valve pit is a vertical steel culvert, 1.2 meters (4 feet) in diameter by 1.5 meters (5 feet) deep. The water main to the site is visible in the bottom of the pit, with a valve and pipes branching off toward to individual buildings. The four ammunition storage structures on top of the hill are constructed of rock, soil, sandbags, wood, metal and tar paper. The ammunition storage bunkers are approximately 23 meters (75 feet) in diameter. On the south side of the site is a concrete-transite pipe 35 centimeters (14 inches) high, and 10 centimeters (5 inches) in outside diameter. At the base of the pipe are pebbles averaging 4 centimeters (1.5 inches) in diameter. Neither the pipe nor the pebbles are stained. An area surrounding the pebbles is evidence of boards that have burned away, about 1.8 meters (72 inches) by 2 meters.</td>

Hanford Site Waste Management Units Report
February 2015
1206
Waste Description: Concrete foundations, pipe, wood and sandbags remain at the site.

Code: 600-228
Names: 600-228; H-40 Gun Site Dumping Area
Type: Dumping Area
Status: Inactive

Description: The waste site has been evaluated under a removal action and Interim Closed Out. The site included four dumping areas, located in pits in the southern portion of the H-40 area. The pit located west of the main site measured about 12 meters (40 feet) in diameter and contains sheetrock, metal, transite, glass and empty paint cans. Two small pits, located south of the main site, were each about 4 meters (15 feet) in diameter. One pit was empty and the other contains steel fence posts and barbed wire. The largest pit was to the south-southeast, and on the topographic slope facing to the south. It contained a large quantity of metal objects, as well as some transite and glass. The July 2000 fire burned much of the wood debris in this pit and the western pit.

Location: This site is located southeast of the 200 East Area, on the south side of Route 4 South. Trees viewed from Route 4 South aid in locating the site. The dumping areas are located to the southeast and west of the H-40 Gun Site.

Related Sites/Structures: This site is related to 600-227 (the building foundations), and 6607-1 (the septic tank).

Process Description: These pits received debris from several years of military operation of the anti-aircraft site. Typically, Camp Hanford's anti-aircraft artillery sites were each roughly 20 acres in size and contained any number of buildings (typically around 20), various utility distribution systems, roads, and sidewalks. Each site consisted of emplacements protected by revetments made of sandbags and wood planking, wooden structures, prefabricated metal buildings, and, later, permanent, concrete block structures. The prefabricated buildings had aluminum walls and roofs with wooden or concrete floors set on concrete pier blocks and were the most commonly constructed. The permanent structures included barracks, latrines, mess halls, craft shops, pump houses, motor pools, and radar facilities. Each site typically had a small arms range, water storage cistern, sanitary, and sewage disposal facilities. Pathways, sidewalks, roadways, and parking lots connected the structures.

Closure Info: The analytical results from confirmatory sampling demonstrated that soil conditions at the waste site did not meet removal action levels Removal Action Levels (RALs). Therefore, the alternative was changed to removal, treatment, and disposal (RTD). The removal action at the 600-228 waste site was conducted from February 2010 through July 2011 and included the collection of focused and random samples from locations within the waste site.

Direct visual inspection of the site surface was performed for visual cues such as staining, discoloration, absence of vegetation, presence of debris and other anomalies. Due to the presence of empty paint cans and material that appears to be dried paint, the site is listed as having had a potential for liquid release. Radiological surveys were performed. No radiological dose readings above background nor radiological contamination was found.

Each of the four pits were considered zones of potential contamination (ZPCs). Random, focused soil samples were collected during the initial sampling, based on historical and process knowledge of the waste site as a dumping area, and visual indicators from ZPC 1, ZPC 2, ZPC 3 and ZPC 4. Analytical results of samples collected from ZPC 2 and ZPC 3 did not indicate any contaminant concentrations greater than RALs. Areas of scattered debris observed at ZPCs...
2 and 3 were removed during the RTD activities at the 600-228 waste site. Initial samples collected from ZPC 1 and ZPC 4 indicated concentrations of antimony and lead were greater than the RALs, thus indicating RTD for those areas. The area comprising ZPC 1 was excavated to depths ranging from approximately 0.91 meters (3 ft) below original ground surface in the southeast corner to approximately 2.4 meters (8 ft) in the northwest corner. The area comprising ZPC 4 was excavated to a depth of approximately 0.61 meters (2 ft) below original ground surface.

<td>Description</td>
<td>The waste site has been evaluated under a removal action and Interim Closed Out. It was investigated and sampled in 2010. Sample results were below regulatory concerns, so no excavation was required. The radiological posting was removed in April 2010. The site includes a test crib and twenty one monitoring wells, that were grouted in 2007. The entire test site area is surrounded by metal fence posts. In 1999, no warning signs or postings are visible at the site. The ground surface is gently rolling. Northeast of the test crib is a depressed area approximately the same size as the crib. The soil is sandy and no discoloration is apparent. Vegetation at the site is composed primarily of grasses but includes a few small shrubs.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location</td>
<td>The site is located east of Route 4 North, southwest of West Lake.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description</td>
<td>A model test crib was built in 1959 for a field experiment for predicting crib capacity and crib waste retention. The field experiment was designed to check the validity of laboratory results and allow the scientists to observe the behavior of solutions put into the ground in a field setting. The location near West Lake was chosen because the depth to groundwater was only 3.7 meters (12 feet). In May 1959, 34,200 liters (9,000 gallons) of calcium nitrate solution spiked with strontium-85 was placed into the 0.36 square meter (4 square foot) crib. According to HW-61476, seven 5 centimeter (2 inch) diameter wells were placed around the crib to monitor the infiltration of the solution through the soil. HW-61476 refers to them as wells &quot;A&quot; through &quot;G.&quot; All the wells were drilled vertically except for well &quot;F&quot;, located 1.2 meters (4 feet) east of the crib. Well &quot;F&quot; was drilled at an angle that intersected the water table below the center of the crib. For the first week of the experiment, samples were collected from the wells every four hours. Nitrate was detected after 4256 liters (1120 gallons) of solution had been added to the crib. Well &quot;F&quot; detected strontium-85 after 16,900 liters (4450 gallons) of solution had been added to the crib. Well &quot;E&quot;, located (4 feet) northeast of the crib, detected strontium-85 after 21,660 liters (5700 gallons) of solution had been added to the crib. The total infiltration of strontium-85 had not reached completion by the time the experiment was terminated. HW-71573, written in 1962, describes the test crib being used again for a similar experiment. Fifteen additional monitoring wells were placed in the area. The infiltrate solution was also calcium nitrate spiked with Strontium-85.</td>

<tr>
<td>Waste Description</td>
<td>A concentrated solution of calcium nitrate and strontium-85 was prepared in the laboratory. 900 milliliters of the concentrated solution was added to a 55 gallon drum containing sanitary water. The resulting solution contained 600 parts per million of calcium and 0.00013</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
microcuries per milliliter. During the month of May, 1959, 34,200 liters (9000 gallons) of this solution was discharged to the ground through the wooden crib box. In 1961, another test was done at this site. A total of 61,560 liters (16,200 gallons) of water spiked with calcium nitrate and strontium-85 was injected into the crib.

Closure Info: The 600-262 Waste Site achieved the established Removal Action Objectives without implementation of the Remove, Treat, Dispose alternative. No excavation was done and no backfill and/or contouring activities were required at this waste site.

Sampling activities at the 600-262 waste site was conducted on February 2, 2010, and included the collection of focused samples from locations within the boundaries of the waste site. A total of six soil samples were collected from two locations. The upper layer of soil (surface depth of approximately 0.5 m [1.6 ft.]) found inside the test crib structure during site evaluation consisted of blown in sand. It was not involved in the experimentation, and was not targeted for sampling. Based on 1959 site historical documentation, an increase of radioactivity was found to be present at about 1 meter (3.3 ft.) below the bottom of the test crib. Therefore, the sampling depth at Sample Location 1 was set at 1.5 meters (5 ft.) below ground surface to target that area. Three samples were collected from Sample Location 1, at 0.5 m (1.6 ft.) below the original soil surface (the bottom of the crib), 1.5 m (5 ft.) below ground surface and at 2.4 m (8 ft.) below ground surface. Sample Location 2 was downgradient, approximately 2.9 meters (9.5 ft) from the test crib box in a northeast direction between capped Wells G and 8. Three samples were taken at this location at 0.3 meters (1 ft), 1.5 meters (5 ft.), and 2.4 meters (8 ft.) below ground surface.

<tr>
<td>Description:</td>
<td>The waste site has been evaluated under a removal action and Interim Closed Out. The original bunkers and guard house had been previously removed. The site was well defined by a perimeter fence. The access roads are visible bladed areas where the seven bunkers had been located. Rectangular mounds of soil, each approximately one meter (3 feet) high, where the igloo structures had been located, were removed.</td>
</tr>
<tr>
<td>Location:</td>
<td>The site was located approximately one mile west of the 200 West Area, south of Route 11A.</td>
</tr>
<tr>
<td>Process Description:</td>
<td>Drilling equipment for the Basalt Waste Isolation Project was also stored in the igloos. Later, radioactive material (plutonium scrap waste) was stored in the igloos.</td>
</tr>
<tr>
<td>Closure Info:</td>
<td>A successful completion of the removal action was conducted at the 600-275 waste site, also known as the former Igloo Army Ammo Storage Site. The alternative proposed in DOE/RL-2008-44, Engineering Evaluation/Cost Analysis for the 200-MG-1 Operable Unit Waste Sites (EE/CA) and selected in DOE/RL-2009-48, Action Memorandum for Non-Time Critical Removal Action for 11 Waste Sites in 200-MG-1 Operable Unit (Action Memorandum) was removal, treatment, and disposal (RTD). The 600-275 waste site was investigated in December 2009 through field observations and sampling to determine the nature and extent of contaminants of potential concern (COPCs) present in the waste site soils as part of the selected removal action alternative. In September 2010, the igloo foundations were removed from the</td>
</tr>
</tbody>
</table>
600-275 waste site; visual inspections of the foundations and underlying soil were conducted, and soil samples were collected between September 2010 and February 2011. Analytical results from initial sampling demonstrated that soil conditions at the waste site did not comply with established removal action levels (RALs).

The removal action at the 600-275 waste site was conducted between December 2009 and February 2011. Activities included the collection of judgmental and random samples from locations within the boundaries of the waste site, removal of seven concrete igloo foundations, and approximately 0.3 meters (1 foot) of underlying soil. Collection of judgmental and random samples was based on historical and process knowledge, and visual indicators. Excavation of soil under the RTD alternative was done in zones of potential contamination (ZPCs) 1 and 2, identified as igloos T-101 and T-104, respectively. Random samples were collected from the excavated areas at ZPC 1 (T-101) and ZPC-2 (T-104) for verification purposes, laboratory analysis for COPCs, and evaluation of analytical results to demonstrate achievement of RALs.

In August 2010, the cover soil was removed from the igloo foundations. Visual inspections and radiological surveys were performed on all seven foundations, which were observed to be intact with only superficial hairline cracks, no visual indicators (i.e., staining or discoloration) were observed, and radiological screening did not indicate evidence of contamination or dose rates greater than background. Concrete patches were observed at the T-104 igloo, indicating that the foundation may have been altered after its original construction, suggesting a potential event may have occurred. All seven foundations were subsequently removed along with approximately 0.15 meters (0.5 feet) of underlying gravel. No soil discoloration was observed beneath the seven igloo foundations.

Excavation of impacted soils at ZPC 1 commenced in January 2011.

---

**Code:** 600-281  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (9/21/2011)  
**Type:** Dumping Area  
**Status:** Inactive  
**Start Date:**  
**End Date:**

**Description:** The waste site has been evaluated under a removal action and Interim Closed Out. After the range fire in June 2000, additional areas of debris were visible. Five areas of concentrated debris were identified. The debris includes material suspected to be asbestos, charred wood, glass, metal pipes, gauges and green metal containers, 55 gallon drums and batteries.

**Location:** The waste site has been remediated. The areas of debris are located south of Army Loop Road, approximately 150 meters east of the H-42 Gun Site.

**Related Sites/Structures:** The debris is associated with sitecode 600-49 and 600-226.

**Waste Type:** Chemicals

**Waste Description:** Five areas of concentrated debris were identified. The debris includes material suspected to be asbestos, charred wood, glass, metal pipes, gauges and green metal containers. Three compressed gas cylinders were found adjacent to well 699-16-51.

**Closure Info:** Direct visual inspection of the site surface was performed for visual cues such as staining, discoloration, absence of vegetation, presence of debris and other anomalies. Radiological surveys were performed during sampling activities. No radiological readings greater than background, and no radiological contamination was found. The site was confirmed to be a
nonradiological site. Ten Zones of Potential Contamination (ZPC) were identified. Initial random samples were collected from each zone. The results of the initial, confirmatory sampling indicated contaminant concentrations greater than the Removal Action Levels (RAL) in five of the sampled areas (ZPC 1, ZPC 2, ZPC 5, ZPC 6 and ZPC 8), thus the Remove, Treat, Dispose (RTD) option was initiated in these areas. The removal action at the 600-281 waste site was conducted from March 2010 through July 2011 and included the collection of focused and random samples from locations within the waste site. The excavation depths ranged from 2 to 7 feet below ground surface. Two areas of transite debris were identified during site evaluation and were removed during RTD activities at the 600-281 waste site. Additional focused samples were collected from these areas. The excavated areas were contoured and backfilled in August 2011.

<td></td>
</tr>
</tbody>
</table>
| Closure Info: | Sampling results from the confirmatory sampling demonstrated that the waste site did not achieve compliance with the removal action levels (RALs). Based on the analytical results, the alternative was changed to removal, treatment, and disposal (RTD). The removal action at the 600-282 waste site was conducted from August 2010 through April 2011 and included the collection of focused and random soil samples. Based on the visual indicators and observations made during the site evaluation, eight Zones of Potential Contamination (ZPCs) were identified at the 600-282 waste site. Focused samples were collected from each ZPC, based on process knowledge and visual indicators for the initial sampling evolution. Visual indicators observed at ZPC 6 (which appeared to be a well with a rectangular wood frame) and ZPC 7 (an open drainage ditch) suggested a potential for contamination below the surface of the waste site in these areas. Therefore, in process sampling at a depth of approximately 1.2 meters (4 ft) below ground surface was conducted. The analytical results in those areas confirmed that they met the established RALs and did not require RTD. Zone 2 (ZPC2) exceeded Removal Action Levels (RAL), resulting in the implementation of the RTD alternative. Removal of impacted soils in that area commenced on March 30, 2011, with the lateral extent of excavation at the ZPC determined utilizing visual indicators. Samples were collected at depths of 2.4 and 3.4 meters (8 and 11 ft) below ground surface to refine the...
vertical extent of excavation to a total depth of approximately 2.4 meters (8 ft). In addition to excavation at ZPC 2, scattered debris from locations throughout the 600-282 waste site was removed, along with underlying soil to a depth of approximately 1 meter (0.3 ft) during RTD activities. Backfill of the 600-282 waste site was completed on May 26, 2011.

No radiological dose readings were greater than background was identified and no radiological contamination was found.

---

**Code:** 616-WS-1  
**Classification:** Accepted  
**Names:** 616-WS-1; 616 NRDWSF French Drain  
**Reclassification:** Closed Out (10/24/2001)  
**Type:** French Drain  
**Start Date:** 1/1/1986  
**End Date:** 1/1/2001  
**Status:** Inactive  
**Description:** This french drain was sampled and Closed Out in 2001. It is a perforated concrete pipe set vertically into the ground. The ground surface is flush with the top of the pipe. The pipe has a layer of gravel at its bottom and a concrete cover over its top. The lid is 10.2 centimeters (4 inches) thick and 1.2 meters (3 feet 10 inches) in diameter. Two railroad ties lie on opposite sides of the lid.  
**Location:** The site is located north of the northeast corner of the 616 Facility. The 616 Building is located on the north side of Route 3 between 200 East and 200 West Areas.  
**Related Sites/Structures:** The site is associated with the loading pads at the 616 Nonradioactive Dangerous Waste Storage Facility (616 NRDWSF).  
**Process Description:** This french drain was designed to receive liquid collected from the east and north loading pads of the 616 Facility. It serviced both the north and the east loading dock trenches. The loading and unloading areas are provided with a sloped, curbed and plugged drainage trench. All liquid accumulations, including precipitation were sampled. Liquids with chemical concentrations above Ecology guidelines for unconditional release to the environment were recovered, processed, and shipped as regulated waste. Liquids with chemical concentrations below the Ecology guidelines were released to the french drain.  
**Waste Type:** Process Effluent  
**Waste Description:** The unit received liquid from loading pad collection troughs. The water was sampled to ensure it met release criteria before being released to the drain.  
**Closure Info:** Because operating records did not demonstrate that early operations within the 616 facility met spill cleanup requirements, the building was considered potentially contaminated and underwent decontamination. Equipment used for waste handling was removed. The storage cell floors, sumps, trenches, and outdoor loading pads were cleaned using nonregulated detergents. The rinsates were collected, analyzed, designated and disposed of as nondangerous waste. Some minor residual staining/discoloration of coated surfaces remained after decontamination. This was allowed in the closure plan.  
Completion of closure plan requirements was certified by a Professional Engineer on 6/13/2001. The RCRA permit Closure Certification was transmitted to the Washington Department of Ecology on 9/5/2001. Ecology accepted the Closure Certification on 10/24/2001.  
Sampling of the french drain was required as part of the Closure Plan for the 616 facility. The gravel within the french drain was removed and stored pending sampling results. A single soil sample was taken from the center of the drain. The sample was analyzed for pH, volatile organic compounds, semi-volatile organic compounds, RCRA (Resource Conservation and Recovery Act) metals, PCBs (polychlorinated biphenyls), herbicides, pesticides, phosphorous...
pesticides, cyanide, total organic halides, anions, phenols, and chrome VI. The sample met closure standards for all constituents.

---

**Code:** CTFN 2703-E  
**Classification:** Accepted  
**Names:** CTFN 2703-E; 200-E Chemical Drain Field; Chemical Tile Field North of 2703-E  
**Reclassification:** None  
**Type:** Drain/Tile Field  
**Status:** Inactive  
**Description:** The waste site consists of a trench and seepage basin. As of 1994, this unit had no free standing liquids nor any sign of natural vegetative growth. The seepage basin is referred to as the 200-E Chemical Drain Field. It has not been backfilled or filled with any materials that would facilitate drainage.

**Location:** This unit lies west of the 2607-E1 septic system, north of the 2703-E Building and northwest of the intersection of Fourth Street and Baltimore Avenue, in the 200 East Area.

**Related Sites/Structures:** The CTFN of 2703-E is associated with the 272-E Building and the 2703-E Building. The pipeline associated with this tile field is sitecode 200-E-287-PL.

**Process Description:** The drain field was designed to receive non-hazardous liquid waste from the 272-E and 2703-E Buildings. Wastewater from the 272-E Building floor drain was discharged to a process sewer line which extends to the disposal site (see 200-E-287-PL). Wastewater from two floor sumps in the 2703-E Building was discharged to the same process sewer line and combined with the 272-E Building effluent before reaching the disposal site.

**Waste Type:** Oil  
**Waste Description:** The Chemical Tile Field North of 2703-E is currently inactive. The wastewater from the 272-E Building was hydrotesting wastewater which was not treated before being discharged to the floor drain. The wastewater discharged from the two sumps in the 2703-E Building included: floor wash, rinse water, cooling water, sinks, and steam condensate.

---

**Code:** OCSA  
**Classification:** Accepted  
**Names:** OCSA; Old Central Shop Area; Central Shop Area  
**Reclassification:** None  
**Type:** Foundation  
**Status:** Inactive  
**Start Date:** 1/1/1945

**Description:** The site consists of building foundations and scattered debris. The central shops had been surrounded by over 1.3 miles (2.1 kilometers) of fencing. The structures in the shop complex included offices, storage huts, boiler houses, warehouse and storage facilities as well as multiple shop facilities (automotive repair, sheet metal welding, paint, etc). There were also bulk fuel storage and a septic system. A site visit on 12/4/1997 observed pieces of lumber, corrugated metal, bricks, shingles, buckets, a barrel, office furniture, and wooden tables. There are two pits containing debris and nails.

**Location:** The site is located in the 600 Area approximately half way between 200 East and West areas, south of Route 11A and north of Route 4S.

**Process Description:** During Hanford construction the central shops were established as a staging area, repair shops, and specialized fabrications area. It was a central location for construction being conducted at 200 East, 200 West, 100-B, 100-D, and 100-F Areas. It included materials storage areas for
construction materials and fuel storage. All facilities in the central shops area were considered temporary construction facilities and were identified as TC-29 Buildings. The sanitary sewer system consisted of a gravity feed septic tank system open trench and open settling ponds.

There were three fuel storage areas: One was associated with a gas station, and had kerosene as well as diesel and gasoline in 3,000-gallon storage tanks (also "white" in a 2,000 gallon tank). The second was a fuel storage yard, with six 25,000 gallon tanks and two 12,000 gallon tanks; the drawings show this as both "Gasoline storage area" on one side and "Fuel Oil storage" on the other. The third is one 100,000-gallon storage tank that was connected to a Boiler, which was likely the heat source for the area buildings.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** The site contains miscellaneous demolition debris and several foundations can be seen. There is also evidence of burning.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** The site contained a sanitary sewer system consisting of a tank(s), open trench, and settling ponds.

---

**Code:** UPR-200-E-11

**Names:** UPR-200-E-11; Railroad Track Contamination Spread; UN-200-E-11

**Type:** Unplanned Release

**Start Date:** 1/1/1957

**Status:** Inactive

**Description:** This unplanned release is no longer marked or posted. Portions of the TC-4 Spur (a.k.a. UPR-200-E-88) and a section of track south of the 218-E-5 Burial Ground (UPR-200-E-95) have been covered with dirt and posted with Underground Radioactive Material signs.

**Location:** The unplanned release effected the railroad track extending from the PUREX tunnel to the 218-E-5 Burial Ground.

**Release Description:** In 1957, fission product contamination spots dripped along the railroad track extending from Plutonium Uranium Extraction (PUREX) to the 218-E-5 Burial Ground. Contaminated tracks sections included the track from the PUREX tunnel entrance to the west exclusion area fence, the spur into the 218-E-5 Burial Ground, and the "TC" spur. Specific release details are unknown.

**Related Sites/Structures:** The site is associated with UPR-200-E-11, UPR-200-E-88, UPR-200-E-95, 200-E-43 and 200-E-44.

**Process Description:** Some burial casks were shielded with water that was removed before placing the material into the burial ground. Sometimes railcars were washed down to remove loose contamination before transporting the load to the solid waste burial ground.

**Waste Type:** Steam Condensate

**Waste Description:** The release consisted of fission products dripping from a railroad car transporting material from PUREX to the burial ground.

Type: Contamination Migration  
Status: Inactive

Description: Periodic radiological surveys conducted between 1958 and 1998 (and beyond) have identified radiological contamination outside the boundaries of the engineered crib and trench structures. Each survey effort redefined the soil contamination boundaries. The size and shape of the posted area varied with each survey. Radiological surveys (1996-1998) identified contamination extending south from Route 4 South to Army Loop Road and extending east to the Central Landfill area. A soil remediation project began in 2009 and continued through 2011. For remediation purposes, the BC Controlled Area was re-defined and divided into two subsites; the Northern Area, that includes cleanup areas A and B, and the Southern Area that includes cleanup area C.

Location: The site is located south of 200 East Area, adjacent to the BC Cribs and Trenches.

Release Description: The source of the large contaminated area known as the BC Controlled Area has been determined to be due to the BC Cribs and trenches. The cribs and trenches received large amounts of liquid radioactive process waste from the Uranium Recovery project (1952 to 1956). In 1958, radioactive rabbit and coyote feces were found scattered over the ground surface. A radiation survey (#DS 01266 - May 7, 1958) states the maximum reading on rate on the crib vent was 200 millirad per hour with 40,000 counts per minute smearable contamination. The overground transfer line in 1958 was reading 250 millirem per hour at a distance of 5.1 centimeters (2 inches). The ground under the overground line was reading 10,000 counts per minute. Rabbit droppings found in 1958 were contaminated to levels from 2,000 counts per minute to 100,000 counts per minute. In one area, 80% of the rabbit droppings were contaminated from 5,000 to 100,000 counts per minute. It was determined that a badger or some other animal had burrowed into the 216-B-28 Trench and exposed a radioactive salt layer. Over time, rabbits ingested the contaminated salts and defecated over approximately 10 square kilometers (4 square miles) of undisturbed sagebrush covered land. The burrow was filled with asphalt in 1964. The asphalted area was visible and documented on a 1981 radiation survey (#T81-0930, July 1, 1981). In 1973, Battelle Northwest Laboratories collected data regarding the distribution and contamination levels of animal droppings in the BC Crib and Trench area. Their study attempted to correlate the data to animal behavior patterns, soil characteristics, vegetation, prevailing winds and other environmental influences. From a designated center point, field personnel walked a total of 29 radii. Radiological and biological data was collected at intervals equaling 20 human steps. (approximately 16 meter [52 feet] intervals). Most of the contamination was found south, southeast and southwest of the BC Cribs. The data collected to determine the contamination distribution was recorded in the report (BNWL-1794), but no conclusions were made. A series of radiological surveys done in 1978 showed the contamination had moved onto the roadways in the area. Contamination levels ranged from 300 counts per minute to greater than 100,000 counts per minute. A 1981 radiation survey identified nine highly contaminated areas. Several areas of highly contaminated soil were noted as well as contaminated tumbleweeds, tumbleweed roots and tumbleweed fragments. General contamination levels ranged from 200 to 100,000 counts per minute and areas of 50 to 150 millirem per hour. Other possible sources of contamination include the US Ecology disposal facility and PUREX operations. In October 1960 a significant contamination spread occurred at PUREX. A sketch attached to Radiation Occurrence Report 60-3 shows a large contamination spread from the 241-A-151 Diversion Box spread across Route 4S. The 241-A-151 Diversion Box is located on the south side of the PUREX plant (202-A). Sparsely spaced particles (less than 5 per 9.3 square meters [100 square feet]) are shown in the BC Crib and Trench Area (see UPR-200-E-26). In 1969, the BC Trenches were graded and covered with sand and gravel. In 1973, a Battelle Northwest Laboratory study attempted to define the distribution of the contaminated rabbit feces. A 1981 radiological survey identified a large amount of surface contamination, contaminated tumbleweeds and contaminated...
Waste Type: Ordnance

Waste Description: The contamination spread consists of radioactive feces (and urine) from coyotes and rabbits. Strontium-90 (81 curies) and cesium-137 (14 curies) are the major contaminants in the feces. Specks of contamination found in the soil may be wind blown particulates from filling the open trenches with waste (1952-1958) and major contamination events in 200 East Area. In 1999, the cryptogamic layer and underlying soils were analyzed for a selected number of radionuclides based on the contaminant of concern list. Analysis included plutonium-239, americium-241, cesium-37 and strontium-90.

<td>Description: The northern portion of the UPR-200-E-83 waste site includes the soil remediation areas known as Zone A and Zone B. Zone A is approximately 140 acres of densely contaminated soil, south of the BC trenches. Zone B is the remaining (approximately 3600 acres) of spotty contaminated soil. During 2009 through 2011, a remediation activity removed approximately 140 acres of contaminated soil from Zones A and B. Zone A and isolated area within Zone B were downposted in August 2011 (per DOE/RL-2011-101). A low level, high resolution aerial survey was conducted of the site in September 2009, resulting in approximately 1566 acres of Zone B being downposted over time, through September 2010.</td>

Type: Unplanned Release
Status: Inactive

Description: The site is posted as an Underground Radioactive Material area.

Location: The site is located in the old burning ground, east of the 221-U Building, adjacent to the corner of Beloit and 16th Street.

Release Description: Contamination was discovered in the spring of 1950 in the Old Burning Ground, located east of the U-Plant Facility. An area of approximately 13.9 square meters (150 square feet) was observed to be contaminated, with a maximum dose rate of 45 rads/hour at 5 centimeters (2 inches). The area was covered with 3 meters (10 feet) of clean dirt.

Related Sites/Structures: This site is associated with 200-W-71.

Waste Type: Storage Tank
Waste Description: Fission products were discovered at the site with approximately 1 curie and a maximum dose rate of 45 rads/hour at the surface.

Code: UPR-200-W-58
Names: UPR-200-W-58; Railroad Track Contamination; UN-200-W-58

Type: Unplanned Release
Status: Inactive

Description: The Unplanned Release is not separately marked or posted from other postings on the railroad track.

Location: In 1965 this release caused spotty contamination to spread along the railroad track from the T-Plant railroad cut to the 200 West Burial Ground.

Release Description: On April 26, 1965, a beta-gamma contamination spread occurred during the process of transporting 221-T Plant canyon cell blocks from the 221-T canyon and burying them in the
200 West Burial Ground. Two small spots approximately 15 centimeters (6 inches) in diameter with reading of 5 rads/hour were found on one end of the deck of flat car #19382. Railroad bed surfaces in the 221-T cut were found to have spotty contamination to a maximum of 100,000 counts per minute. The undercarriage of the locomotive used was contaminated generally to 20,000 counts per minute. A rigger and a train crew brakeman received contamination on their shoes and socks. The contamination spread from the underside of an improperly prepared cell block to the deck of the flat car. Further spread occurred when the radiation monitor failed to capture the train following detection of loss of radiological control in the 221-T cut.

Waste Type: Process Effluent
Waste Description: The release consisted of beta/gamma contamination with levels ranging from 100,000 counts/minute to a maximum of 5 rads/hour.

<td></td>
</tr>
<tr>
<td>Location: The 200 West Burning Pit is located south of the 216-W-LWC Crib and east of Beloit Ave. It is located within the 200 West Ash Disposal Basin.</td>
<td></td>
</tr>
<tr>
<td>Release Description: On January 22, 1973, a quarterly routine survey of the 200 West Area Burning Pit revealed several spots of beta-gamma contamination measuring 5,000 to 50,000 counts per minute along the bumper rails at the edge of the combustible trench. Additional surveys disclosed other contamination measuring from 20,000 counts per minute to 30 millirads/hour in the trench proper and a one-gallon bucket contaminated in excess of 100,000 counts per minute (250 millirads/hour). Samples of the contamination were obtained for laboratory analysis. A dump area on the south side of the combustible trench, about 3.7 by 6.7 meters (12 by 22 feet), was found to contain alpha contamination with readings ranging from 5,000 to 200,000 disintegrations per minute. The cause of the contamination was the unauthorized disposal of contaminated material in a non contaminated burning trench.</td>
<td></td>

</table>
| Description:                 | The 600-284-PL underground transfer line extends from the 241-UX-154 diversion box, adjacent to U Plant in 200 West Area, to the 241-ER-151 Diversion Box in 200 East Area. The Unplanned Release waste site includes the contaminated soil and vegetation located on the surface of the cross site transfer line and surrounding the 241-ER-151 Diversion Box. The surface of the underground line has been stabilized and is currently posted with "Underground Radioactive Materials" signs. There is also a large mound of soil, located south of the 241-EW-151 Vent Station, that is associated with the original transfer line surface stabilization activities. The soil mound is posted with Underground Radioactive Material signs. |}

#### Location: The site extends from the 241-ER-151 Diversion Box in 200 East Area and to the 241-UX-154 Diversion Box in 200 West Area. The majority of the transfer line is located in the 600 Area, between 200 East and West Areas, south of Route 3. The pipeline is approximately 2.3 miles long.

#### Release Description: The surface of the buried waste transfer line became contaminated through biological transport of radioactive materials that leaked in the pipeline encasement and windblown particulates from the vent station. In March 1988, while conducting a radiological survey of the 241-EW-151 Vent Station (located approximately mid way between 200 East and 200 West Areas on the transfer line) contamination was identified approximately 100 meters (300 feet) outside the established radiation zone boundaries of the vent station above the transfer line. The Mobile Surface Contamination Monitor (MSCM) tractor was used to survey the entire surface of the
The original cross site transfer line was originally constructed in 1952 to support the Uranium Metal Recovery operations. Various process and tank farm waste has been transported between 200 East and 200 West areas through this concrete encased, underground pipeline. The original cross site transfer line (sitecode 600-284-PL) consists of six stainless steel pipelines (V360, V361, V362, V363, V364, V366) inside a concrete encasement. The encasement type is known as 6-59, indicating there are six lines inside a 59 inch wide encasement. The concrete encased stainless steel pipelines are buried at depths that range from 1.5 to 4.5 meters (5 to 15 feet). There are 58 encasement test risers (swab risers) spaced regularly along the pipeline that provided access to the encasement void space. The old original cross site line was replaced with a new pipeline in 1995 (see 600-269).

Related Sites/Structures:
- UPR-600-20 is associated with the 600-284-PL pipeline, the 241-ER-151 Diversion Box (east end of the pipeline), the 241-EW-151 Vent Station (along middle of pipeline), and the 241-UX-154 Diversion Box (west end of the pipeline). Also see 600-296, Replacement Cross Site Transfer Pipeline.

Process Description: The original cross site transfer line was originally constructed in 1952 to support the Uranium Metal Recovery operations. Various process and tank farm waste has been transported between 200 East and 200 West areas through this concrete encased, underground pipeline. The original cross site transfer line (sitecode 600-284-PL) consists of six stainless steel pipelines (V360, V361, V362, V363, V364, V366) inside a concrete encasement. The encasement type is known as 6-59, indicating there are six lines inside a 59 inch wide encasement. The concrete encased stainless steel pipelines are buried at depths that range from 1.5 to 4.5 meters (5 to 15 feet). There are 58 encasement test risers (swab risers) spaced regularly along the pipeline that provided access to the encasement void space. The old original cross site line was replaced with a new pipeline in 1995 (see 600-269).

Waste Type: Storage Tank
Waste Description: The surface of the buried waste transfer line became contaminated through biological transport of radioactive materials that leaked in the pipeline encasement and windblown particulates from the vent station. The contaminated soil contained cesium-137, plutonium-239/240, strontium-90, and uranium from tank farm waste transferred between 200 East Area and 200 West Area through the underground line.

Code: UPR-600-21
Classification: Accepted
Reclassification: Interim Closed Out (2/25/2011)
Names: UPR-600-21; Contamination Found Northeast of 200 East Area; UN-216-E-31
Type: Unplanned Release
Start Date: 1/1/1985
End Date: 1/1/1991
Status: Inactive
Description: The remediation evaluation for this waste site was completed and the waste site reclassified to Interim Closed Out in 2011. The site had been a large radiologically posted area located northeast of 200 East Area. The area is no longer marked or posted. The site was originally posted with Radiological Controlled Area warning signs. In 1990, the Health Physics group changed the posting to Surface Contamination. In 1991, all radiological postings were removed.
Location: Radiological contamination was originally identified in an area located east and northeast of the 200 East Area fence, south of Route 11A.
Release Description: The release was a result of contaminated tumble weeds that migrated and decomposed in the area and possibly specks from the PUREX stack or a nearby burial ground.
Closure Info: In July and August 2009, the 200-E-110 and UPR-600-21 waste sites were investigated through observation, field screening and radiological surveys for the purpose of determining if radiological contaminants were present above the removal action levels (RALs). The survey results analysis confirmed that soil contaminant concentrations are at or below the RALs and that no further action is required. Both 200-E-110 and UPR-600-21 waste sites achieved compliance with the removal action levels (RALs) and thus met the removal action objectives.
(RAOs). These results support reclassification to Interim Closed Out status.

<td>The tile field is associated with the 216-Z-1&amp;2 Cribs, the 216-Z-3 Crib, 241-Z-361 settling Tank and associated underground transfer lines. The replacement (2 inch) stainless steel lines are documented in sitecode 200-W-174-PL.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The site received waste from the Z Plant 234-5Z, 236-Z and 242-Z facility operations. The tile field was originally constructed to receive liquid waste overflow from the 216-Z-1 and the 216-Z-2 Cribs. Later the cribs were bypassed and the waste was routed directly into the tile field. The 216-Z-1A Tile Field initially was taken out of service in March 1959 after low concentrations of plutonium were detected in 1958 in the soil at the bottom of a well 46 meters (150 ft) deep, and 15 meters (50 ft) above the water table, near the 216-Z-3 Crib (Well 299-W18-57). The 216-Z-1A Tile Field had been receiving overflow from the 216-Z-3 Crib during...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
this time, and was taken out of service when the 216-Z-3 Crib was replaced. In 1964, the 216-Z-1A Tile Field was reactivated to receive plutonium reclamation operation waste liquids directly through the pipelines from the Plutonium Reclamation Facility, bypassing the 216-Z-1&2 and 216-Z-3 Cribs. Two groundwater wells (Wells 299-W18-6 and 299-W18-7) were drilled on the west and east sides of the tile field, respectively, to monitor the groundwater. From 1964 to 1969, the 216-Z-1A Tile Field was operated as a specific retention facility. The tile field was taken out of service in 1969 when it had received the prescribed liquid waste volume.

Hanford Site Waste Management Units Report
February 2015

1223
operations.

Location: The trench is located south of Nineteenth Street and east of the 234-5Z Building.

Release Description: On November 16, 2010, the 299-W15-47 extraction well head failed, causing more than 95 liters (25 gallons) of groundwater to spill onto the ground. The ground water contained minor amounts of carbon tetrachloride, nitrates, technetium-99, chromium and tritium. The pump and treat process was halted and the area was assessed. The well is located northeast of 216-Z-9 crib.

Related Sites/Structures: The site is associated with the Z Plant RECUPLEX process, the steel waste transfer lines, and the soil mining facility (216Z9A). A stormwater pond occurred near this crib in the 1960's. See sitecode 200-W-124. The pipeline that fed this crib is sitecode 200-W-206-PL.

Process Description: 216-Z-9 is an enclosed trench that received solvent and aqueous wastes from the Z Plant RECUPLEX process. The 216-Z-9 trench was the only waste site used for solvent disposal during the RECUPLEX operation. Solvents used in the process included carbon tetrachloride, dibutyl phosphate and dibutyl butyl phosphonate (DBBP). In 1976 and 1977 the trench floor was mined for plutonium using remotely operated equipment. Three above grade structures (216-Z-9A, 216-Z-9B and 216-Z-9C) were constructed to support the crib soil mining operations. 216-Z-9A received the excavated crib sediments into a glove box via a conveyor system. The sediments were packaged into 10 liter cans, assayed and removed from the glove box. The cans were placed into overpack drums for storage and transportation. 216-Z-9B contained the observation area (with a leaded glass window into the crib interior) and controls for conducting the remote sediment removal. 216-Z-9C contained the mechanical components of the sediment removal equipment. This structure was sealed at the interface of the cribs concrete slab roof. Removal equipment was suspended from two openings in the crib roof, allowing access to the crib from both the north and the south areas of the crib.

---

Code: 216-Z-12  Classification: Accepted
Names: 216-Z-12; 241-Z-12 Crib  Reclassification: None
Type: Crib  Start Date: 1/1/1959
Status: Inactive  End Date: 1/1/1973
Description: The site is an inactive, below-grade waste management unit. The site consists of a deep rectangular excavation with a vitrified, perforated, clay pipe running the length of the crib. A second six inch diameter steel pipe (bypass pipeline) was installed in 1968 and runs the length of the crib to the west of the original pipe. The bottom 1.5 meters (5 feet) of the excavation was backfilled with gravel and covered with a polyethylene barrier. The remaining excavation was backfilled to grade. It is marked and posted with Underground Radioactive Material signs.

Location: This unit is located southwest of the 234-5Z Building, outside the security fence.

Related Sites/Structures: Structures associated with this crib include 10 monitoring wells, diversion boxes No.1 and No.2 (200-W-58 and 200-W-59), transfer lines, and monitoring instrumentation. The pipeline that fed the crib is 200-W-208-PL.

Process Description: The crib received Plutonium Finishing Plant liquid process waste and laboratory waste from the 234-5Z Building, via the 241-Z-361 Settling Tank.

---

Code: 216-Z-18  Classification: Accepted
Names: 216-Z-18; 216-Z-18 Crib  Reclassification: None
Type: Crib  Start Date: 1/1/1969

Inactive

**Status:**

The 216-Z-18 Crib is a below grade inactive management unit. The crib consists of five parallel, north-south running trenches bisected by a steel distribution pipe. Near the center of each trench two perforated, fiberglass reinforced epoxy pipes exit each side of the distribution line. The distribution and trench piping lie on a 0.3-meter (1-foot) thick bed of gravel. The pipes were buried under an additional 0.3 meters (1 foot) of gravel, a membrane, and sand cover. The trenches were then backfilled to grade. The site is marked and posted with Underground Radioactive Material signs.

**Location:**

This unit is southwest of the 216-Z-1A Tile Field and south of the 234-5Z Building.

**Related Sites/Structures:**

The crib is associated with 216-Z-1A, 241-Z-361 and UPR-200-W-103. The pipeline to the crib is 200-W-174-PL.

**Process Description:**

216-Z-18 crib replaced the 216-Z-1A tile field. The unit received wastes via the 241-Z-361 Settling Tank. The crib disposed of solvent and acidic aqueous waste from the Plutonium Reclamation Facility in the 236-Z Building and waste from the 242-Z Waste Treatment and Americium Recovery Facility.

**Code:** 241-Z-361

**Classification:** Accepted

**Reclassification:** None

**Names:** 241-Z-361; 241-Z-361 Settling Tank; IMUST; Inactive Miscellaneous Underground Storage Tank

**Type:** Settling Tank

**Start Date:** 1/1/1949

**End Date:** 1/1/1976

**Description:**

The unit is an underground reinforced concrete structure with a 0.95 centimeter (3/8 inch) steel liner. The tank has inside dimensions of 7.9 by 4.0 meters (26 by 13 feet) with 0.3 meter (1 foot) thick walls. The bottom slopes, resulting in a internal height variation between 5.2 and 5.5 meters (17 and 18 feet). The top is 0.6 meters (2 feet) below grade. A 15 centimeter (6 inch) stainless steel inlet pipe from the 241-Z Tank Pit (WIDS SiteCode 241-Z) enters the tank from the north. A single 20 centimeter (8 inch) stainless steel pipe exits the tanks from the south. There are two manhole covers and frames and several risers visible above grade.

**Location:**

The tank is located south of the 236-Z building and was inside the Z Plant security fence.

**Related Sites/Structures:**

**Process Description:**

The tank served as a settling tank for liquid waste from the 234-5Z, 242-Z and 236-Z buildings. The waste streams were routed through the 241-Z sump tanks for neutralization and then to the 241-Z-361 tank to settle out any solids. After passing through the settling tank, the waste was routed to 216-Z-1, 216-Z-2, 216-Z-3, 216-Z-1A, 216-Z-12 and 216-Z-18.

### Description:
The crib is marked and posted with Underground Radioactive Material (URM) signs. Both the 216-A-7 and 216-A-1 cribs are inside the same posted URM area.

### Location:
The site is located inside of the 200 East Area perimeter fence, east of 241-A Tank Farm and east of Canton Avenue.

### Related Sites/Structures:
The site is associated with PUREX, the 241-A-152 Diversion Box and the 241-A-302B catch tank. The pipeline associated with this crib is Sitecode 200-E-182-PL.

### Process Description:
The crib began receiving catch tank and sump waste from the 241-A-152 Diversion Box in January 1956. The effluent pipeline between the 241-A-152 Diversion Box sump and the crib was blanked off in July 1959. The sump waste was rerouted to the catch tank. From July 1959 through November 1966, the crib received TBP-Soltrol from PUREX and pump pit/catch tank drainage from the 241-A-152 Diversion Box. A 15 centimeter (6 inch) perforated vitrified clay pipe is placed horizontally 3.0 meters (10 feet) below grade. A 3.0 meters (10 feet) length of 15 centimeter (6 inch) perforated vitrified clay pipe is perpendicular to the first pipe, forming a cross pattern. It is 4.9 meters (16 feet) deep and is filled with approximately 2.1 meters (7 feet) of coarse rock with a volume of 99 cubic meters (3,500 cubic feet). The site has been backfilled. The side slope from the surface to 3.0 meters (10 feet) is 1:1 and from 3.0 meters (10 feet) to the bottom, 2:1.

### Waste Type:
Demolition and Inert Waste

### Waste Description:
From January 1956 through July 1959, the site received the catch tank overflow waste, the sump waste, and the pump pit drainage from the 241-A-152 Diversion Box. From July 1959 to November 1966, the site received the catch tank overflow waste and the pump pit drainage from the 241-A-152 Diversion Box. In November 1966, the site received the tri-butyl phosphate soltrol organic inventory from the 202-A Building. The waste is low in salt and is neutral to basic.

### Description:
The crib and overflow area are surrounded by chain and concrete AC-540 markers. They are posted with Underground Radioactive Material signs. Crib overflow was accomplished through a 40.6 centimeter (16 inch) diameter pipe exiting to the north at the east end of the crib (see H-2-56157). The pipe emptied into a narrow ditch that flowed northward. A small overflow pond was excavated at the northeast end of the ditch to receive the excess waste water from the crib. A 61 centimeter (24 inch) diameter, schedule 20, perforated distribution pipe is located 2.1 meters (7 feet) below grade along the length of the crib. The site contains approximately 5830 cubic meters (206,000 cubic feet) of gravel fill. The crib excavation side slope is 1:2. Four test risers extended above grade. A 20 centimeter (8 inch) diameter vent riser extended from the distribution pipe had been located at the west end of the crib. The vent...
riser was removed in 1995. Two layers of sisalkraft paper separate the gravel fill from the backfill. The 216-A-508 control structure is located west of the crib (See drawing H-2-56157).

Location: The crib is located east of the 200 East Area perimeter fence, east of the 241-A Tank Farm.

Process Description: The crib was originally constructed in 1955 to receive condensate and cooling water discharge from the 241-A and 241-AX tank farms. In May 1958, it was determined that the crib had reached its radionuclide capacity. The effluent was routed to the 216-A-24 crib via the 216-A-508 control structure. The cooling water was routed to the 216-A-25 pond. However, the 216-A-8 crib was intermittently reactivated over the years (from 1966 until 1983) to receive additional tank farm condensate effluent.

Waste Type: Chemicals

Waste Description: From 11/55 to 12/57, the site received condensate from the waste storage tanks in the 241-A and -AX farms. From 12/57 to 5/58, the site received the above effluents and cooling water from the contact condenser in the 241-A-431 Building. The site was inactive except for the following periods: 1/66-4/76, received condensate from 241-A and -AX farms; 1/78-4/78, received 241-A, -AX, & -AY farm condensate; 10/83, received 241-AY and -AZ farm condensate; 3/84, same as 10/83. In early 1985, flow was again diverted from the crib to double-shell tanks. Document RPP-7494 reports a total discharge of 1.18E+09 liters differing slightly from the WIDS total. Condensate has not been discharged to the crib since early 1985. The distribution box was filled with concrete in 1995 to permanently isolate the crib.
unknown amount of effluent to flow to the 216-A-24 Crib. The 216-A-24 Crib had been classified as inactive since January 1966. The fact that the open valve allowed effluent to flow to the 216-A-24 Crib for thirteen years warranted the situation to be classified as an Occurrence. The 216-A-508 Diverter Box was permanently isolated with concrete in 1995.

**Related Sites/Structures:** The crib is associated with the 216-A-524 Diversion Box (control structure), located at the west end of the 216-A-24 Crib. The crib is also associated with the 216-A-508 Diversion Box (control structure), located west of the nearby 216-A-8 Crib. The pipeline between the two control structures is sitecode 200-E-165-PL. The Control Structures controlled whether the effluent flow was diverted to the 216-A-8 or the 216-A-24 Crib. This site is also associated with the PUREX process, the 241-A tank farms and UPR-200-E-56.

**Process Description:** The crib was built to receive condensate waste from the 241-A, 241-AX, 241-AY and 241-AZ tank farms. The installation of surface condensers greatly reduced the volume of liquid being discharged to the cribs.

**Waste Type:** Equipment

**Waste Description:** The site received condensed vapors from the waste storage tanks in the 241-A and 241-AX Tank Farms via the 241-E-411 and 241-E-412 Contact Condensers from 1958 through the early 1960's and until 1966, via the 241-A-401 and A-417 Tank. This crib was constructed to receive the condensate after the 216-A-8 Crib reached its radionuclide capacity. The waste is low in salt, neutral to basic and has a record of organic content. The crib was believed to have been valved out in January 1966. However, it was found to still be receiving liquid in 1979 (Occurrence Report #79-113). The valve has since been closed. Because of this inadvertent use, the radionuclide exact inventory and waste volume are unknown for 1967 through 1979. Document RPP-7494 reports a total discharge of 7.94E+08 liters differing slightly from the WIDS total.

**Code:** 216-A-31  **Classification:** Accepted

**Names:** 216-A-31; 216-A-31 Crib

**Type:** Crib

**Status:** Inactive

**Start Date:** 7/1/1964  **End Date:** 11/1/1966

**Description:** The crib is located inside a large Underground Radioactive Material area that has a WIDS sitecode of 200-E-103. The crib is marked with cement posts on four corners.

**Location:** The site is located approximately 152 meters (500 feet) south of the 202-A Building.

**Release Description:** Although no contamination was released, a dose rate incident report was written in August 1961. The report indicates that the 216-A-31 Crib tie-in was made on August 25, 1961. No final inspection of the welds was done at this time. On August 27, 1961, an attempt was made to jet solvent from the F-13 tank to the new crib. Some material was transferred, but it appeared that the line was plugged. The transfer effort resulted in radioactive material being trapped in an uncovered crib line. On August 28, 1961, two employees entered the crib excavation to inspect the welds. They were in the crib excavation for approximately 5 minutes. Later the inspectors were told that an attempt had been made over the week-end to use the new crib. Radiological surveys were made to clarify what the dose rate conditions were in the crib excavation. On August 29, 1961, the exposed crib line was reading a maximum of 500 R/hr. This condition resulted in an exposure of 2 R/hr for the two weld inspectors.

**Related Sites/Structures:** The crib is associated with 202-A (L cell) and the 241-A-151 Diversion Box. The pipelines associated with this crib are sitecodes 200-E-183-PL and 200-E-186-PL.

**Process Description:** The crib received effluent from 202-A "L-Cell" via the 241-A-151 Diversion Box. L-Cell was the location of the final plutonium concentration step in the PUREX process. The site was
deactivated in 1966 by blanking the L Cell nozzles to the 241-A-151 Diversion Box, which routed effluents to the unit. The unit consists of a 21 by 3.1 by 7.3 meters (70 by 10 by 24 feet) deep excavation that includes a 7.6-centimeter (3-inch) schedule 10 stainless steel perforated distribution pipe placed horizontally 6.4 meters (21 feet) below grade. The excavation has 1.8 meters (6 feet) of gravel fill and has been backfilled. The side slope is 1:1.5.

Waste Type: Process Effluent

Waste Description: The site received organic waste from 202-A Building (L Cell - Pu concentration waste). The waste was low in salt and is neutral to basic. Most documents state that 10,000 liters (3000 gallons) of organics were discharged to the unit since startup. However, ARH-231 states that a total of 30,545 liters (8070 gallons) were discharged to the crib from the date it was put into service (January 1963).

Code: UPR-200-E-56
Type: Unplanned Release
Status: Inactive
Start Date: 1/1/1979

Description: The site is currently a surface stabilized area located north of the west end of the 216-A-24 Crib. It is posted and marked as an "Underground Radioactive Material" area.

Location: The site is located adjacent to the north side of the 216-A-24 Crib.

Release Description: On June 13, 1979, Radiation Monitoring was informed that moisture was noticed in the excavation east of the 200 East Area perimeter fence where fill dirt was being obtained for the construction of 241-AN Tank Farm. The construction contractor backfilling around the new tanks in 241-AN Tank Farm had mistakenly selected a borrow area adjacent to the 216-A-24 Crib instead of the designated area, which was further north. Radiological surveys revealed beta contamination up to 8,000 counts per minute in the moist excavation, on the earthmoving equipment, and in the newly hauled-in soil around the new 241-AN Tanks. The source of the contamination was determined to be moisture from the 216-A-24 Crib that had migrated laterally over the surface of a 10.2-centimeter (4-inch) crust of hardpan. The hardpan was approximately 4.6 meters (15 feet) below normal ground surface. The excavation was dug sloping from 1.5 to 6.1 meters (5 to 20 feet) deep, 131.1 meters (430 feet) long, and an average of 33.5 meters (110 feet) wide. The size of the excavation was approximately 0.4 hectare (1 acre).

Related Sites/Structures: The site is associated with the 216-A-24 and 216-A-8 Cribs. UPR-200-E-91, UPR-200-E-92 and UPR-200-E-93, UPR-200-E-100 were also scraped and placed into this excavation.

Waste Type: Steam Condensate

Waste Description: The contamination found in the moist excavation included beta/gamma readings up to 8,000 counts per minute. When the mistakenly excavated soil was returned to the excavation area from 241-AN Tank Farm, there was not sufficient volume to fill the hole. It was decided to place contaminated soil and vegetation from several areas along the perimeter and tank farm fences to help fill the void before covering with a layer of clean dirt. Additional contaminated soil from around the 244-A Lift Station was also disposed in this location in 1985.

</table>
Z Well; 299-W15-51

**Type:** Injection/Reverse Well  **Start Date:** 1/1/1945

**Status:** Inactive  **End Date:** 1/1/1945

**Description:** This site is a reverse well that protruded approximately 0.31 meters (1 foot) above grade. The protruding end is capped with a flange. The well casing is constructed of steel pipe. The site was interim stabilized in 1990.

**Location:** The reverse well is east of the 231-Z Building and west of the 216-Z-17 Crib.

**Related Sites/Structures:** Structures associated with this reverse well include a manometer, three inlet lines, the 231-Z-151 Sump, and three monitoring wells (299-W15-59, 299-W15-60 and 299-W15-61). The pipeline from 231-W-151 vault to 216-Z-10 is sitecode 200-W-204-PL. The pipeline to 216-Z-5 (200-W-202-PL) includes an overflow line connected to the 216-Z-10 pipeline.

**Process Description:** The 216-Z-10 Reverse Well received process and laboratory waste from the 231-Z Building via the 231-Z-151 Sump between February and June 1945.

---

**Code:** 241-Z-8  **Classification:** Accepted

**Names:** 241-Z-8; 241-Z-TK-8; IMUST; Inactive Miscellaneous Underground Storage Tank; Silica Slurry Tank; 216-Z-8

**Type:** Settling Tank  **Start Date:** 1/1/1955

**Status:** Inactive  **End Date:** 1/1/1962

**Description:** The tank is a horizontal cylindrical vessel located 1.8 meters (6 feet) below grade. The area above the tank is surrounded by a light weight chain barricade marked "Caution Underground Radioactive Material" and IMUST signs. Inside the barricade on the north end are two capped 10 centimeters (4 inches) steel vent pipes.

**Location:** This unit is located in 200 West Area, due east of the 234-5Z building. It is south of 19th Street and west of Camden Ave.

**Release Description:** In July 1959, records indicated that the tank was at its overflow capacity, which is 58,430 liters (15,435 gallons). The tank was deactivated in 1962, and no records were found that the tank had been pumped prior to that. Surveillance data from April 6, 1974, indicates a liquid content of 28,960 liters (7,650 gallons) and sludge content of 1,890 liters (500 gallons), for a total waste volume of 30,850 liters (8,150 gallons). This means that up to 27,580 liters (7,285 gallons) may have been lost between 1962 and 1974. This possible loss has not been accounted for and no records found explain the loss.

**Related Sites/Structures:** The 216-Z-8 french drain received overflow from this unit. The pipeline to the tank is sitecode 200-W-205-PL.

**Process Description:** The tank was used as a solids settling tank for back flushes of the Recuplex feed filters. Silica gel was used as a settling agent. The solids and silica gel were flushed to the 241-Z-8 tank with nitric acid. Overflow from the tank went to the 216-Z-8 French Drain, located approximately 11 meters (36 feet) east of the settling tank.
### 200-SW-1

| Code: 600 CL | Classification: Accepted |
| Names: 600 CL; 671 Facility; Central Landfill; Central Waste Landfill; CWL; Solid Waste Landfill; SWL; 600 Area Central Landfill | Reclassification: None |
| Type: Sanitary Landfill | Start Date: 1/1/1973 |
| Status: Inactive | End Date: 1/1/1996 |

**Description:** The landfill is approximately 15.4 hectares (38 acres) consisting of 39 unlined solid waste trenches and 5 unlined liquid disposal trenches. All trenches have been backfilled. The landfill had been enclosed by a 2.4 meter (8 foot) tall fence with lockable gates. Only the southern portion of the fence still remains, due to the 2000 range fire. The Nonradioactive Dangerous Waste Landfill (NRDWL) is located adjacent to the Phase I trenches, on the north end of the landfill.

**Location:** The landfill is located southeast of 200 East Area on Army Loop Road (south of Route 4S).

**Related Sites/Structures:** The Non-Radioactive Dangerous Waste Landfill (NRDWL) is located adjacent to the Central Landfill property. The two landfills are separated by a fence. NRDWL was isolated from the Central Landfill in 2001, when the NRDWL was completely enclosed by a chain-link fence with a separate lockable gate.

**Waste Type:** Water

**Waste Description:** Prior to 1982, detailed log books were not maintained. It is estimated that Phase I received approximately 179,000 cubic meters, (234,000 cubic yards) and Phase II received approximately 417,000 cubic meters (546,000 cubic yards) of solid waste. Forty percent of the solid waste is assumed to be office waste consisting mostly of paper products. Construction and demolition debris consists mostly of wood and wooden pallets. Asbestos waste accounts for approximately 10% (by volume) of the inventory. Trenches 36, 37, 38 and 40 contain asbestos. Miscellaneous wastes include empty containers, medical waste from the first-aid stations and inert materials. Large bulky items such as appliances and office furniture were also placed in the solid waste trenches. An estimated 3,800,000 to 5,700,000 liters (1,000,000 to 1,500,000 gallons) of sewage and 380,000 liters (100,000 gallons) of 1100 Area catch basin wastes were placed in the liquid trenches. Spot checks of items in the landfill found occasional low level radioactive material on SWP (special work permit) clothing. Remediation waste from the Sodium Dichromate Barrel Disposal Landfill (sitecode 600-105) included approximately 5000 crushed barrels that were transported to the Central Landfill in 1993.

| Code: 600 NRDWL | Classification: Accepted |
| Names: 600 NRDWL; Nonradioactive Dangerous Waste Landfill (Central Landfill); NRDW Landfill; NRDWL; 600 Area Nonradioactive Dangerous Waste Landfill | Reclassification: None |
| Type: Sanitary Landfill | Start Date: 1/1/1975 |
| Status: Inactive | End Date: 1/1/1988 |

**Description:** This Nonradiological Dangerous Waste Landfill (NRDWL) consists of nineteen unlined trenches. Several trenches received asbestos containing material. The nineteen trenches are located adjacent to the Phase I trenches, on the north end of the Central Waste Landfill (CWL) (WIDS sitecode 600 CL). The Phase I trenches and the Phase II (CWL) trenches are separated.
by a wire fence. Both the CWL trenches and the NRDWL trenches have been backfilled and covered with 1.8 to 3 meters (6 to 10 feet) of soil.

**Location:**
This site is located on Army Loop Road, southwest of the intersection with Route 4 South and southeast of the 200 East Area.

**Release Description:**
In February and March 2001, the average result of quadruplicate samples from downgradient wells 699-25-34A and 699-25-34B exceeded the critical mean value for specific conductance. A notification was reported to the DOE for transmittal to Ecology. The specific nonconductance is believed to be caused by nonhazardous constituents (sulfate, calcium, magnesium, and chloride) from the adjacent solid Waste Landfill.

**Related Sites/Structures:**
This site is adjacent to 600 CL, the Central Waste Landfill.

**Process Description:**
This site provided disposal of dangerous waste generated from process operations, research and development laboratories, maintenance activities, and transportation functions throughout the Hanford Site. The permitted chemical trenches ceased to operate in 1985. One asbestos trench was active until 1988.

**Waste Type:** Soil

**Waste Description:** One instance occurred where Trench 34 received approximately 5,300 liters (1,400 gallons) of septic tank sludge.

**Waste Type:** Soil

**Waste Description:** This waste consisted largely of office and lunchroom waste and construction/demolition debris. Trench 1N received this waste.

**Waste Type:** Soil

**Waste Description:** The bulk of the waste asbestos material came from building demolition or renovation activities. This material was disposed of in Trenches 2N, 20, 21, 22, 23, 25, 27, 29, and 30. The asbestos waste was generally not containerized before disposal. It is probably a mix of friable and non-friable material.

**Waste Type:** Soil

**Waste Description:** This waste consisted of small quantity laboratory chemicals, bulk organic waste, solvent waste, battery acid, paints, paint thinners, waste oils and empty containers. Some small containers of liquid wastes were included. Trenches 2N, 20, 21, 22, 23, 25, 27, 29 and 30 were used for disposal of asbestos waste from 1975 through 1988. Trenches 19N, 26, 28, 31, 33, and 34 were used for the above described chemicals.

**Location:** The site is located north of B Plant and southeast of 241-BX Tank Farm, adjacent to 218-E-2 Burial Ground.
Waste Type: Ash

The large area with multiple narrow trenches received industrial dry waste and small boxes. The north end of the long single trench contains railroad boxcars contaminated with uranyl nitrate hexahydrate (UNH).

---

Code: 218-E-5A

Classification: Accepted

Reclassification: None

Names: 218-E-5A; Equipment Burial Ground #5A; 200 East Industrial Waste No. 005A

Type: Burial Ground

Start Date: 1/1/1956

End Date: 1/1/1959

Description: The 1980 Burial Ground Characterization Report indicates the site to be a single, large excavation measuring 30.5 by 36.6 meters (100 by 120 feet).

Location: The site is located north of B-Plant and southeast of 241-BX Tank Farm, adjacent to the 218-E-5 Burial Ground. The site is co-located with Burial Grounds 218-E-2, 5 and 9.

Waste Type: Stormwater Runoff

Waste Description: The site received waste from PUREX L Cell, referred to as the 202-A Burial Package, in the form of 4 large boxes containing failed equipment and industrial wastes. One of the boxes was damaged during unloading. The contents were pushed into the trench. The D-2 Column from PUREX K Cell and a J-2 Pulse column were also buried in this site.

---

Code: 218-E-8

Classification: Accepted

Reclassification: None

Names: 218-E-8; 200 East Construction Burial Grounds

Type: Burial Ground

Start Date: 1/1/1958

End Date: 1/1/1959

Description: The site consists of an unknown number of trenches. The trenches are backfilled.

Location: The site is located north of the 218-E-12A, on the hillside adjacent to the 218-E-12B Burial Ground.

Waste Type: Water

Waste Description: The site received mixed fission product/transuranic (MFP/TRU) waste, including repair and construction wastes from 293-A and the PUREX new crane addition.

---

Code: 218-E-9

Classification: Accepted

Reclassification: None

Names: 218-E-9; Burial Vault (HISS); 200 East Regulated Equipment Storage Site No. 009

Type: Burial Ground

Start Date: 1/1/1953

End Date: 1/1/1958

Description: The site was used as an above-ground storage site, covering 62,000 square meters (74,000 square yards). The unit was never used as a burial ground.

Location: The site is located north of B Plant and east of the 218-E-2 Burial Ground.
Waste Type: Oil
Waste Description: This unit was a storage site for fission product equipment that became contaminated in the uranium recovery program at the tank farm.

| Code: 218-E-10 | Classification: Accepted |
| Names: 218-E-10; Equipment Burial Ground #10; 200 East Industrial Waste No. 10 | Reclassification: None |
| Type: Burial Ground | Start Date: 1/1/1960 |
| Status: Active | End Date: |

Description: The site consists of 18 trenches running north and south and 1 trench running east-west. Trench #1 is 7.3 meters (24 feet) deep with bottom dimensions of 400 meters (1,300 feet) long by 4.6 meters (15 feet) wide. Trenches #2 to #17 are 4.6 meters (15 feet) deep, 4.9 meters (16 feet) wide at the bottom, and vary in length from 245 meters (805 feet) to 350 meters (1,145 feet). The backfilled trench running east-west has bottom dimensions of 30 meters (100 feet) long by 4.6 meters (15 feet) wide.

Location: The site is located inside 200 East Area, northwest of B Plant and directly west of the 218-E-5A Burial Ground.

Release Description: On June 10, 1960, a partially covered burial box containing PUREX tube bundles caused an airborne contamination spread (UPR-200-E-23). UPR-200-E-24 documents the large plume of contamination discovered on June 12, 1960 that resulted from the burial box that collapsed it the 218-E-10 Burial Ground, identified several days after the box was buried. UPR-200-E-30 occurred on April 20, 1961. A wooden burial box, containing highly contaminated process jumpers and other equipment was pivoted on the railroad car and pulled down the unloading ramp. The box collapsed as it was being covered over with soil in the burial trench. Contamination (maximum 500 millirad/hour) was spread over a 400,000 square foot area within the burial ground. The majority of the contamination was confined to the burial ground.

Related Sites/Structures: The 218-E-10 Burial Ground is associated with the designated expansion area known as WIDS sitecode 200-E-20.

Process Description: The site has received failed equipment and mixed industrial wastes from PUREX, B-Plant and 100-N.

Waste Type: Stormwater Runoff
Waste Description: The site has received failed equipment and mixed industrial wastes from PUREX, B-Plant and 100-N. The trench, running east to west, contains 69 PUREX cover blocks and 4 PUREX centrifuge blocks. Other waste includes concrete and wooden burial boxes containing tube bundles, jumper vessels, pumps, columns and filters. The trenches contain low level radiological waste, low level mixed waste, and unsegregated, remote handled waste. Trenches 9 and 12 contain some mixed-waste. Trench 9 specifically contains asbestos, di-n-octyl phthalate, and lead as mixed wastes. As of August 1995, this burial ground had received 21,764 cubic meters of waste.
Description: The site contains 28 burial trenches that have been backfilled and surface stabilized. The site is marked with concrete AC-540 markers and posted "Underground Radioactive Material." The area of the burial ground is 10.5 hectares (26 acres).

Location: The site is located northwest of the 241-C Tank Farm and south of 218-E-12B Burial Ground.

Waste Type: Stormwater Runoff Waste Description: Trenches 1 through 3, 12 through 14, and 17 through 25 contain predominately dry waste packaged in cardboard boxes and plastic bags. Trenches 4 through 11, 15 through 16, and 26 through 28 contain predominantly acid-soaked material. Specific contents of Trench 28 are unlisted. A waste inventory logbook dated March 24, 1960 to February 16, 1961 documents burials of tank farm dip tubes, an impact wrench, contaminated cable, jumpers, animal carcasses from 108-F and an offsite shipment of depleted uranium.

Code: 218-E-12B Classification: Accepted Names: 218-E-12B; 218-E-12B Burial Ground; 200 East Dry Waste No. 12B
Reclassification: None Type: Burial Ground Start Date: 1/1/1967 Status: Inactive End Date: 3/8/1968

Description: The burial ground is marked and radiologically posted. The original burial ground was designed to have 29 trenches. The expansion to the north and west enlarged the burial ground to include the potential for a total of 138 trenches running north and south. Only 38 of the proposed trenches received waste. The unused, expansion area became WIDS sitecode 218-E-12B ANNEX. In 2014, the active, naval reactor core component of 218-E-12B (Trench 94) was separated into a new WIDS waste site (see 200-E-304).

Location: The burial ground is located inside 200 East Area, north of the 241-C Tank Farm and south of 12th Street.

Related Sites/Structures: This burial ground is associated with WIDS site 218-W-12B ANNEX and 200-E-304 (Trench 94).

Process Description: The burial ground received waste from 200 East Area facilities. It was designed to receive a variety of container types and a broad spectrum of waste types. Only thirty six trenches were filled completely and two trenches were partially filled (38 total). The first six trenches were 0.9 meters (3 feet) wide and 1.2 meters (4 feet) deep. The rest of the trenches were designed to be 4.8 meters (16 feet) deep. Two trenches contain retrievably stored TRU waste. A large portion of the property designated as 218-E-12B was never been used (see 218-E-12B ANNEX).

Waste Type: Storage Tank Waste Description: From 1987 to 1990, asbestos and copper were disposed in Trenches 38, 43, 48 and 53.

Waste Type: Storage Tank Waste Description: All trenches are orientated in a north-south direction. This burial ground was used primarily for low-level waste generated mostly from facilities located in the 200 East Area. A special burial of Mixed Fission Product (MFP) was placed in Trench 28. Two trenches (trenches 17 and 27) contain 55 gallon drums, 30 gallon drums, fiberboard boxes, metal boxes, HEPA filters and equipment suspected of containing TRU waste. Coordinates for these drums were documented to allow them to be retrieved. Some waste included plutonium contaminated process piping, pumps and other equipment. As of 1995, the site had received 78,740 cubic meters of waste. Thirty six trenches were filled, two were partially filled, Trenches 38, 43, 48 and 53 was used
for low-level mixed waste that included asbestos and copper. (Trench 94, used for the disposal of U.S. Navy vessel defueled reactor compartments, became WIDS sitecode 200-E-304)

radiation readings taken around the shoreline of the unit ranged from 2,000 to 15,000 counts/minute.

**Related Sites/Structures:**
The site is associated with the 216-T-4-1 Ditch and the 218-W-2A Burial Ground.

**Process Description:**
The pond received cooling water and steam condensate from 221-T and 224-T via the 207-T Retention Basin and the 216-T-4-1 Ditch. The pond became active in November 1944 with the startup of the 221-T Chemical Separation Plant. The waste water in the ditch flowed through a culvert that went under the 218-W-2A Burial Ground railroad spur and then ran into a shallow ditch cut to a natural surface depression in the desert floor.

**Waste Type:**
Process Effluent

**Waste Description:**
Until September 1951, the site received process cooling water from 221-T and 224-T Buildings via 207-T Retention Basin and steam condensate from 221-T Building. From September 1951 to July 1955, the site received same as above plus condenser cooling water and steam condensate from the 242-T Evaporator. From July 1955 to August 1956, same as November 1944 to September 1951. From August 1956 to June 1957, the site received steam condensate from 221-T Building. From June 1957 to July 1964, the site was on standby. From July 1964 to December 1965, the site received decontamination waste from 2706-T Building. From December 1965 to November 1970, same as above plus condenser cooling water from 242-T Building. After November 1970, the site received condenser cooling water from 242-T Building.

---

**Code:** 216-T-4B  **Classification:** Accepted

**Names:** 216-T-4B; 216-T-4 New Pond; 216-T-4-2 (P); 216-T-4-2 Pond

**Type:** Pond  **Start Date:** 1/1/1972

**Status:** Inactive  **End Date:** 1/1/1995

**Description:** The pond is no longer visible. The a portion of the pond is located within the area designated as the 218-W-3AE burial ground. It is not separately marked or posted from the burial ground postings.

**Location:** The pond was located east of old the pond 216-T-4A, north of 23rd Street. A portion of the 218-W-3AE Burial Ground was built over the dry pond location. The pond's size has been estimated as 1.5 acres.

**Related Sites/Structures:** The pond was associated with the 216-T-4-2 Ditch, 200-W-81 and the 218-W-3AE Burial Ground.

**Process Description:** The pond was a natural depression that received overflow run off from the 216-T-4-2 Ditch. The effluent was usually absorbed in the ditch, leaving the pond area dry.

**Waste Type:** Water

**Waste Description:** The site received steam condensate and condenser cooling water from the 242-T Evaporator and nonradioactive wastewater from 221-T air conditioning filter units and floor drains.

<tr>
<td>Process Description:</td>
<td>This site was the first burial site in the 200 West Area to receive large, contaminated equipment. The site contains approximately 10 burial areas. Some are typical trenches but several areas are described as burial holes. The exact locations of the burial holes are not known, but they are within the area designated as No. 3 on H-2-2516. A semi-circular railroad spur divided the area into north and south sections. The spur is no longer visible. Most of the equipment was buried in wooden boxes, which eventually rotted and settled, causing the surface to subside. Most of these sink holes were filled in 1975. Prior to stabilization, large 1.8-meter (6-foot) thick concrete cell blocks were stored above ground, south of the railroad tracks.</td>

<tr>
<td>Process Description:</td>
<td>The site is an industrial, solid waste burial site containing 19 trenches (numbered #1 to #11, and #20 to #27). Trenches #11 through #15 are considered a cell block burial area. They have a north-south orientation, located between Trenches #24 and #27. All trenches were dug with centerlines running northwest from the railroad tracks, except Trenches #1 to #3, which are shorter trenches, grouped in the extreme southwest corner of the site. Trench #16 is located east of Trench #24.</td>
<td></td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Construction Debris</td>
<td></td>
</tr>
<tr>
<td>Waste Description:</td>
<td>The unit contains mostly miscellaneous radioactive solid waste from facilities located in the 200 West area. The solid waste consists mainly of tanks, concrete blocks, facility wastes, and process equipment. Sixteen trenches are filled with dry industrial waste. Trench #27 contains contaminated soil scraped from the 216-T-4-1 Pond. Waste buried since November 1980 does not contain hazardous materials. It is possible that wastes disposed of prior to this date may contain hazardous wastes. Of the 25,100 cubic meters (887,000 cubic feet) of waste contained in the unit, only 340 cubic meters (12,000 cubic feet) were disposed of after November 1980. The waste disposed of before November 1980 is both low-level and byproduct, while the waste disposed of since that date is strictly low-level. A waste burial logbook dated January 1958 through November 1963 specifically documents the burial of REDOX centrifuges, jumpers, pumps, filters and miscellaneous cell equipment and wastes. Many of the shipments were contained in large wooden or concrete boxes. One specific inventory sheet states that on October 10, 1973 a large burial box (marked B-Plant 58526) was placed in Trench 21 and contained a PU glove box and miscellaneous scrap.</td>

Ground.

**Waste Type:** Soil

**Waste Description:** This site received miscellaneous unsegregated mixed transuranic (TRU) and non-TRU wastes. A logbook dated February 1959 through June 1961 documents the burial of 109 drums of uranium scrap (depleted) from California and Oregon, placed in Trench 17, a vehicle (ID - 491) buried at the east end of Trench 14 and 49 barrels of depleted uranium from Colorado and Oregon placed in Trench 14. Waste from 221-T, 291-T, 222-U, 234-5Z, 231-Z, 202-S, 308 building and lab waste is also noted.

**Code:** 218-W-3A

**Classification:** Accepted

**Reclassification:** None

**Names:** 218-W-3A; Dry Waste No. 003A

**Type:** Burial Ground

**Start Date:** 1/1/1970

**Status:** Active

**Location:** The site is located west of the 221-T Building and north of 218-W-3 Burial Ground.

**Related Sites/Structures:** 218-W-3A is associated with UPR-200-W-134.

**Code:** 218-W-3AE

**Classification:** Accepted

**Reclassification:** None

**Names:** 218-W-3AE; Dry Waste No. 3AE; Industrial Waste No. 3AE

**Type:** Burial Ground

**Start Date:** 3/31/1981

**Status:** Active

**Description:** The site was originally designed to consist of 24 trenches. To make the best use of available space, the site was redesigned to contain 12 trenches with deeper depths.

**Location:** This site is directly east and adjacent to the 218-W-3A Burial Ground in the 200 West Area.

**Related Sites/Structures:** The site is related to the 216-T-4B Pond.

**Waste Type:** Soil

**Waste Description:** Wastes disposed of to this site include: aluminum, asbestos, beryllium, bis(2-ethylhexyl)phthalate (DOP), calcium carbonate, cement, charcoal, clay, silicas, talc, copolymer of styrene, copper, di-n-octyl phthalate, graphite, hydrotreated heavy naphtha isopropyl alcohol, lead, mixed esters, phthalate, nylon, peroxydisulfuric acid, disodium salt, resin, sodium chloride, sodium nitrate, sodium phosphate dibasic, steel, tantalum, uranium, and yttrium oxide.

**Waste Type:** Soil
Waste Description: The site has been receiving miscellaneous wastes such as rags, paper, rubber gloves, disposable supplies, broken tools, etc. and industrial waste such as failed equipment, tanks, pumps, ovens, agitators, heaters, hoods, jumpers, and accessories. Trenches 2 and 3 have received remote-handled low-level waste. Trenches 5 and 10 are wide bottom stacking trenches. 218-W-3AE Trench 8 contains waste that has been encased in concrete monoliths. The monoliths are approximately 25 ft long by 10 ft wide and 13 feet tall. Most of the monoliths are placed together with only a cold joint separating them. Waste in the monoliths is typically category 3 waste and/or waste that requires stabilization because of mobile radionuclides. Trench 26 was designed for disposal of contaminated railroad cars and large tanks.

Reclassification: 218-W-4A; Dry Waste No. 04A

Burial Ground Inactive

Names: Type: Status:
218-W-4A; Dry Waste No. 04A Burial Ground Inactive

Start Date: End Date: 1/1/1961 1/1/1968

Description: The site is a burial ground that has been backfilled and stabilized. It is inside a chain link fence and is posted as Underground Radioactive Material. The unit contains 21 miscellaneous dry waste trenches and six vertical storage units (dry wells). The trenches are oriented in an east to west direction with Trench #1 on the southern end of the site and Trench #21 on the northern end. The six 4.6 meter (15-foot) deep dry wells were installed near the east end of Trench #16. The wells were made by welding together 210 liter (55-gallon) steel drums with the ends cut out. The units were buried vertically and used for remote disposal of small, highly radioactive items. The site may also contain two larger caissons located at the extreme east end of the burial ground, between Trenches #17 and #18 and between Trenches #18 and #19. A Hanford drawing (H-2-32487) describes them 12 gage, 66 centimeter (26 inch) diameter well casings that extend 14.6 meters (48 feet) below grade.

Location: The site is located southeast of the intersection of 23rd Street and Dayton Avenue.

Waste Type: Soil

Description: This site received miscellaneous dry, unsegregated mixed transuranic (TRU) and non-TRU waste. Specific trench contents are mentioned on Drawing H-2-32487 and in the Burial Ground logbook. These sources document the burial of approximately 500 drums of depleted uranium from offsite contractors, pumps and equipment, laboratory hoods from 234-5 Z, 231-Z, 222-U and REDOX, and plutonium contaminated 300 Area laboratory waste. On 5-7-65, ten concrete barrels of high level plutonium were placed in Trench 16. On February 2, 1966 a Special Burial of waste from 234-5Z was made in Trench 20. Drawing H-2-32487 indicates the east end of Trench 19 contains Recuplex waste. (additional information available in the WIDS library)

Reclassification: 218-W-4B; Dry Waste No. 04B

Burial Ground Active

Names: Type: Status: 218-W-4B; Dry Waste No. 04B Burial Ground Active

Start Date: End Date: 1/1/1967 1/1/1990

Description: The site contains 13 trenches and one row of 12 caissons. Trenches 7 and 11 contain retrievable TRU waste. The other trenches contain unsegregated TRU and non TRU radioactive waste. The row of caissons include 5 alpha caissons, 6 mixed fission product (MFP) caissons and one silo type caisson used for high activity N-Reactor waste. The alpha caissons and 2 of the MFP caissons are 2.7-meter (8.75-foot) diameter, 3-meter (10-foot) high
concrete containers with steel lifting lugs and a 91-centimeter (36-inch) diameter access chute. Two of the MFP caissons are constructed of corrugated steel instead of concrete. The silo type caisson is a 3-meter (10-foot) diameter, 9-meter (30-foot) tall container placed on a concrete foundation with a top concrete shielding slab. It has a 107-centimeter (42-inch) diameter access chute. All three caisson types are equipped with air filter systems.

Location: The site is northwest of the 234-5Z Building, directly west of 231-Z Building.

Waste Type: Not Specified

Waste Description: The site received miscellaneous radioactive solid waste from 100, 200 and 300 Areas as well as offsite shipments. Solid waste consists of rags, paper, cardboard, plastic, pumps, tanks, process equipment, and other miscellaneous high dose rate and TRU dry waste. The site contains 114,300 cubic feet of segregated (post-1970) TRU waste. Trenches 7 and 11 contain retrievable TRU waste. The other trenches contain unsegregated TRU and radioactive waste. There are twelve caissons that received remote handled high dose rate and TRU wastes. Five caissons were designated as alpha caissons, but only four were used. They were used from 1970 to 1979. Seven caissons were designated as beta/gamma caissons and were used from 1968 to 1979. The last shipment of waste was deposited into MFP caisson #6 in 1990. No additional waste is planned to be placed in the caissons. As of August 1995, the burial ground had received a total of 10,466 cubic meters of waste. (The WIDS Library has an original logbook for this burial ground)

Code: 218-W-4C
Classification: Accepted

Names: 218-W-4C; Dry Waste No. 004C
Reclassification: None

Type: Burial Ground
Start Date: 1/1/1978
End Date: 

Description: The burial ground is located on the east side of Dayton Ave. The trenches are marked with Radiation Area, Radioactive Material Area and Underground Radioactive Material Area signs.

Location: This burial ground is located southwest of the 234-5Z Building, east of Dayton Ave.

Related Sites/Structures: 218-W-4C burial Ground is associated with the unused portion known as WIDS sitecode 218-W-4C Annex.

Process Description: The burial ground and annex were designed to contain up to 65 trenches. The main burial ground was designed to include forty-eight trenches, orientated east to west. The burial ground annex was designed to include seventeen trenches, running north to south. The burial ground annex area has never been used. Only fifteen trenches in the main burial ground have been activated. The 218-W-4C activated trench numbers are NC, 1, 4, 7, 14, 19, 20, 23, 24, 28, 29, 33, 48, 53 and 58. The burial ground annex was never used.

Waste Type: Not Specified

Waste Description: Wastes disposed of to this site include: copper, bis(2-ethylhexyl)phthalate (DOP), lead, and nitrogen.

Waste Type: Not Specified

Waste Description: Trenches #1, 4, 7, 20, 24 and 29 contain retrievably stored, suspect TRU waste. Trench #19 contains one drum of CH-TRU that is mixed with LLW. Trench 19 is being evaluated for redefinition as a Low Level Waste trench. Trench #1 contains drums with plutonium-contaminated soil from the 216-Z-9 trench and noncombustible TRU waste. Trench #4 contains drums of assorted combustible TRU waste and one module of noncombustible TRU waste. The remaining trenches are proposed. Additional waste information is available in the
WIDS hardcopy file for 218-W-4C.

<tr>
<td>Description:</td>
<td>The waste site is a large solid waste burial ground, backfilled with soil and cobbles. It is marked with radiological postings. In 1979, a large area adjacent to the northwest corner of 200 West Area was annexed and designated the Central Waste Complex and 218-W-5 burial ground. The annexed area extended north from 16th Street to 27th Street and westward to coordinates E564176/N137630. Within the large annex, 84 acres were designated as Low Level Solid Waste Burial Grounds. 218-W-5 originally was designed to contain 18 low level solid waste trenches and 4 low level mixed waste trenches. Only ten low level solid waste trenches and two low level mixed waste trenches were used. In 2014, the active, mixed waste Trenches 31 and 34 were separated into a separate WIDS waste site (see 200-W-254).</td>

<tr>
<td>Related Sites/Structures:</td>
<td>The basin is associated with the 202-S facility, the 216-S-17 pond, UPR-200-W-13, UPR-200-W-15, UPR-200-W-95 and the 200-W-152-PL pipeline.</td>
</tr>
<tr>
<td>Process Description:</td>
<td>The basin received process cooling water and steam condensate from the 202-S facility before it was discharged to the 216-S-17 or 216-S-16 ponds. The basin was removed from service in 1954 following a 202-S coil leak that contaminated the basin above permissible limits. The basin was a 39.6 meter by 39.6 meter (130 foot by 130 foot) concrete structure with a volume of 3.23E+06 liters (8.53E+05 gallons). The walls are approximately 25 centimeters (10 inches) thick, and the floors are 20.3 centimeters (8 inches) thick. The system included approximately 610 meters (2,000 feet) of 61-centimeter (24-inch) diameter vitrified clay pipe used to convey the waste water into and out of the unit. There is an overflow tank located in the center of the north end, just inside the basin wall, composed of 0.48-centimeter (3/16-inch) steel walls, 1.7 meters (5.5 feet) high. The tank diameter was 6.1 meters (20 feet). There is also an outlet weir structure adjacent to the south wall, outside the basin.</td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Process Effluent</td>
</tr>
<tr>
<td>Waste Description:</td>
<td>The site received process cooling water and steam condensate from the 202-S Building. The water was then discharged to the 216-S-17 Pond or the 216-S-16 Pond. Coil leaks inside the 202-S facility often caused contaminated effluent to be discharged to the retention basin.</td>

</tr>
<tr>
<td>Description: The cribs are located within a common radiologically posted area. The surface is free of vegetation. The area is marked and posted with Underground Radioactive Material and Cave-in Potential signs. There is an additional, small posted Underground Radioactive Material area adjacent to the south side of the cribs and the 299-W22-11 well. The Dyncorp Integrated Soil, Vegetation and Animal Control group has stated that growing, contaminated weeds were found inside this area in September 2000. The contaminated weeds were removed and disposed of properly. The site consists of two open-bottomed crib boxes made of timbers. The cribs are connected in series where overflow from the crib box S1 flows into crib box S2 via an underground pipe. The boxes were set in a gravel lined trench and backfilled.</td>
</tr>
<tr>
<td>Location: The cribs are located east of the 241-SX Tank Farm, and southeast of the 241-S-151 Diversion</td>
</tr>
</tbody>
</table>
Rev. 24

DOE/RL-88-30

Box.

Release 
Description: In August 1955, process vapors and high dose rates were observed at the 207-S-11 Test Well (alias 299-W22-3), adjacent to the cribs. See UPR-200-W-36.

Related Sites/ Structures: The associated structure is the 241-S-151 Diversion Box, 200-W-137-PL pipeline and the 216-S-7 crib.

Process 
Description: This unit was used as a subsurface liquid distribution system that received cell drainage and process condensate from the REDOX facility. The waste had a pH of 2.1. The waste was discharged to the cribs in batches. Each batch was approximately 19,000 liters (4940 gallons). An average of 10 batches were discharged each day. When the crib was abandoned, it had received approximately 750,000 curies of mixed fission products. It was replaced by the 216-S-7 crib.

Waste Type: Storage Tank

Waste 
Description: The site received cell drainage from the D-1 Receiver Tank and process condensate from the D-2 Receiver Tank in the 202-S Building. The inorganics disposed of at the site were nitrate, aluminum nitrate, nitric acid, and sodium.

Description: The site is marked and posted with Underground Radioactive Materials signs. The site is constructed of two vertically buried metal culvert pipes.

Location: This unit is located to the east of the 216-U-10 Pond and northwest of the 216-S-21 Crib.

Related Sites/ Structures: The site is associated with the condensers on the 241-S-101 and 241-S-104 Tanks located inside the 241-S Tank Farm.

Process 
Description: The site is constructed of two rock-filled, 6.1 meter (20 foot) long metal culverts, connected in parallel. The site received liquid from the 241-S-101 and 241-S-104 tank condensers via an aboveground pipe. The site was deactivated by removing the aboveground piping.

Waste Type: Process Effluent

Waste 
Description: During August and September 1953, the site received condensate and cooling water from condensers on the 241-S-101 and 241-S-104 Tanks in the 241-S Tank Farm. After September 1953, the site received the cooling water but the condensate waste was routed to the 216-S-3 Crib. The chemical component of this waste was nitrate.

Description: The site consists of a gravel-filled crib and an overflow trench. The crib was constructed of two lengths of perforated, corrugated metal pipe that form a cross. The crib has been surface
stabilized. It is marked and posted with Underground Radioactive Material signs. The overflow trench is located south of the crib structure (see subsites).

**Location:** This unit is outside of the 200 West Area perimeter fence, southwest of 207-S Retention Basin and west of the 216-S-10 Ditch.

**Related Sites/Structures:** The site is associated with the 202-S Building, the 207-S Retention Basin, and 216-S-6. The pipelines to the 216-S-5 crib is discussed in sitecode 200-W-154-PL and 200-W-152-PL.

**Process Description:** This unit received subsurface liquid disposal for the 202-S Building process vessel cooling water and steam condensate via an underground clay pipeline. The crib was built to replace the 216-S-17 Pond.

**Waste Type:** Storage Tank

**Waste Description:** The site received process vessel cooling water and steam condensate from 202-S Building via the 207-S Retention Basin. The waste was acidic and contained nitrates.

<tr>
<td>Description: In 1956, the large cooling water discharge volumes made it necessary to cut a hole along the top edge of the crib to discharge overflow cooling water to a trench immediately southwest of the crib structure rather than allowing the crib to flood (see drawing H-6-466). The overflow of 50 to 100 gallons per minute represented approximately 5% of the total flow to the 216-S-5 crib. The emergency overflow continued throughout the summer of 1956. In September 1956, the REDOX A-2 dissolver and H-4 coils failed. The dose rates along the edge of the crib overflow area increased from 100 millirad per hour to 350 millirad per hour with some spots reading up to 17 rad per hour. The emergency crib overflow pond was used until the 216-S-16 Pond was completed in September 1957.</td>

</tbody>
</table>
| Process Description | The crib was built to replace the 216-S-1 & 2 cribs. It received REDOX cell drainage and process condensate waste. The unit consists of two wooden cribs measuring 4.9 meters (16.1 feet) square and 1.6 meters (5.2 feet). The crib boxes are set 15.3 meters (50 feet) apart, center to center, in one excavation. The cribs were set in gravel and covered with backfill. The two cribs are connected in parallel by a pipe, allowing the flow to be equally distributed to both...
cribs. Each crib box had two risers that extended to the surface.

Waste Type: Chemicals

Waste Description: From January 12, 1956 to April 12, 1959, the unit received REDOX cell drainage from the D-1 Receiver Tank, process condensate from the D-2 Receiver Tank, and condensate from the H-6 Condenser in 202-S Building. A buildup of beta activity in this crib prompted the rerouting of H-6 waste material. On April 12, 1959, jumper changes were completed that routed the H-6 liquid waste to the underground waste storage tanks. The crib continued to receive waste from D-1 and D-2 Vessels until July 1965. The chemicals disposed at the site included nitrate, aluminum nitrate, nitric acid, and sodium.

Code: 216-S-8
Names: 216-S-8; Cold Aqueous Crib; Cold Aqueous Grave; Cold Aqueous Trench; Unirradiated Uranium Waste Trench; 216-S-3
Type: Trench
Status: Inactive
Start Date: 1/1/1951
End Date: 1/1/1952
Description: The site consists of one trench that has been backfilled to grade. It was fed with aboveground piping. It is marked and posted with Underground Radioactive Material signs.
Location: This unit is located on the east side of the 241-SX Tank Farm and southwest of the 216-S-1 & 2 Cribs.
Related Sites/Structures: The associated structure is the 202-S Building.
Process Description: The site was a single use trench that received unirradiated uranium start-up waste from the 202-S Building.
Waste Type: Storage Tank
Waste Description: The site received unirradiated start-up waste from the 202-S Building. The Monthly Report for October 1951 stated approval had been given for the excavation of a trench to receive uranium test run waste. Waste concentrations were estimated to be 0.2 grams of uranium per liter. The estimated total volume was expected to be only 152,000 liters (40,000 gallons). HW-28471 states that the trench was used between October 1951 through January 1952. This document states that a total of 309,700 liters (81,500 gallons) containing 193 kilograms (430 pounds) of unirradiated uranium was discharged to this trench.

Code: 216-S-12
Names: 216-S-12; 291-S Stack Wash Sump; REDOX Stack Flush Trench; UPR-200-W-30
Type: Trench
Status: Inactive
Start Date: 1/1/1954
End Date: 1/1/1954
Description: This site consists of one, single-use liquid waste disposal trench. The site is surrounded with cement marker posts and chain, posted with "Underground Radioactive Material" signs. It labeled 216-S-12.
Location: The site is located northeast of the 202-S (REDOX) facility, north of the 291-S Stack.
Process Description: The site was used for liquid disposal of 291-S Stack flush water. It was fed with an overground pipeline. In July 1954, the REDOX stack was flushed and approximately 68,100 liters (18,000 gallons) of flush water that was drained into this trench.

Waste Type: Storage Tank

Waste Description: The site received 68,100 liters (18,000 gallons) of flush water from the 291-S (REDOX) Stack. The water contained ammonium nitrate (600 kilograms). The material contained an estimated five curies of beta particle emitters and two to three curies of gamma particle emitters that were predominantly ruthenium and zirconium-niobium. Potential contaminants of concern include cobalt-60, cesium-137, strontium-90, plutonium-239/240, and uranium-238.

Related Sites/Structures:
The site is associated with the 291-S Stack.

Process Description: This site consists of a backfilled trench that received hexone contaminated with trace amounts of unirradiated uranium from the initial test runs in the 202-S REDOX facility. The waste site was fed with an aboveground pipeline.

Waste Type: Equipment

Waste Description: The site received approximately 76,000 liters (20,000 gallons) of hexone (methyl isobutyl ketone) contaminated with trace amounts of unirradiated uranium used in the initial testing of the 202-S Building (REDOX). The site was retired when discharge of hexone to the unit was completed. The radionuclide content is unknown, but it is assumed to be low-level contamination. In 1971 core drillings were taken at this site. There was a strong odor of hexone from each of the sample cores and core holes. No radioactivity was found and the site was released from radiation zone status.

Related Sites/Structures:
The site is associated with the 202-S Building.
with light weight chain and Underground Radioactive Material signs.

Location: The site is located north of 13th Street, east of 241-S Tank Farms and southwest of 216-S-9 Crib.

Related Sites/Structures: The site is associated with UPR-200-W-114.

Process Description: This site was originally used as a steam cleaning pit for contaminated equipment. It was later used to consolidate contaminated soil from the surrounding area and backfilled to grade.

Waste Type: Storage Tank

Waste Description: The site was originally a vehicle decontamination pit. The pit was excavated in 1972. The contaminated material was taken to a 200 West Area burial ground. In 1995 and 1997, the open trench was used to consolidate nearby surface soil contamination. The contaminated soil was covered with 1.8 meters (6 feet) of clean dirt to bring the site up to grade. The area was posted as an "Underground Radioactive Material" area.

Code: 216-S-20
Names: 216-S-20; 216-SL-1&2 Crib; 216-SL-2
Type: Crib
Status: Inactive

Description: The site is posted with Underground Radioactive Material (URM) signs at each corner. Two areas above the crib structures, inside the URM, are marked with post and chain and Cave-In Potential signs. An abandoned waste unloading station is located approximately 7.6 meters (25 feet) south of the posted crib. The unloading station was posted with Contamination Area signs, but later backfilled and changed to Underground Radioactive Material Area.

Location: The unit is located southeast of the 202-S (REDOX) facility and east of the 222-S Laboratory building.

Related Sites/Structures: The site is associated with the 222-S Building, 219-S building, the 207-SL Retention Basin, and the "manhole" unloading station that received 300 Area Laboratory wastes via truck. The pipelines associated with 216-S-20 crib are discussed in sitecode 200-W-149-PL.

Process Description: The site received liquid waste from the 222-S Building and 300 Area laboratory waste via truck that was unloaded into the manhole. The manhole unloading structure is located approximately 7.6 meters (25 feet) south of the 216-S-20 radiologically posted area. The unit contains two 3.7 meter by 3.7 meter (12 foot by 12 foot) crib boxes that are 15 meters (50 feet) apart. The bottom of each wooden crib box is filled with 1.2 meters (4 feet) of gravel. Each wooden crib box has two risers extending from the top of the box to above ground. The crib boxes are connected in series with one box overflowing into another via a pipe. The cribs are backfilled to grade.

Waste Type: Storage Tank

Waste Description: From January 1952 to July 1953, the site received miscellaneous waste from lab hoods and decontamination sinks in the 222-S Building via the 219-S Retention Building. From July 1953 to September 1963, the site received the above effluent via the 207-SL Retention Basin, the 219-S Retention Building and 300 Area laboratory waste via truck, unloaded into the manhole. From September 1963 to January 1969, the site received miscellaneous waste from lab hoods and decontamination sinks in 222-S via the 219-S Retention Building. From January 1969 to November 1972, the crib was inactive due to surface subsidence on this unit. The 300 Area lab waste was rerouted to the 216-T-28 Crib.

**Description:** The crib is marked and posted with Underground Radioactive Material signs.

**Location:** The crib is located east of 202-S Building and northeast of 216-S-20 Crib.

**Process Description:** The site provided subsurface liquid disposal for the 293-S Building waste. The crib is a gravel structure with a side slope of 1:1.5. A pipe enters the unit below grade, branches out at right angles downwards to the bottom, and runs along the bottom for the length of the unit. The section of pipe along the crib bottom has open joints. The rest of structure is filled with backfill. (see sitecode 200-W-146 PL)

**Waste Type:** Storage Tank

**Waste Description:** The site received liquid waste from the acid recovery facility in the 293-S Building. The chemicals disposed at the site were nitrate and sodium.

**Description:** The crib is marked with concrete AC-540 markers and posted with Underground Radioactive Material signs.

**Location:** This unit is located northeast of the 241-SY Tank Farm and north of the 216-S-9 crib.

**Process Description:** This unit provided subsurface liquid disposal for the 202-S Building. The unit is a crib with a perforated pipe set in a gravel layer, running the length of the crib. At one end of the crib a filter and gage well riser connects to the pipe. The rest of the crib contains backfill.

**Waste Type:** Process Effluent

**Waste Description:** The site received REDOX process condensate from D-2 Receiver Tank in the 202-S Building. The waste is low in salt and is neutral to basic.

**Description:** The site is marked with AC-540 markers and posted with Underground Radioactive Material signs.
A distribution pipe is located 2.1 meters (7 feet) below grade. The site contains approximately 1160 cubic meters (41,000 cubic feet) of gravel. Three gage wells and vent systems made of 20 centimeter (8 inch) SCH 40 PVC with a 15 centimeter (6 inch) SCH 40 PVC perforated distribution pipe.

Location: The crib is located south of 13th Street and west of the 241-SX Tank Farm; outside the 200 West perimeter fence, south and east of 216-U-10 Pond.

Release Description: The Groundwater Monitoring Compliance Report for August 1986 states that well #299-W23-09: contaminant alpha had been exceeding the U-238 concentration limit since July 1985. An increasing trend is evident due to either remedial action involving 216-U-1 & 2 cribs or to the deactivated U Pond. However, concentrations of all uranium isotopes are below their respective concentration limits. Contaminant H-3 continues to show an increasing trend even though discharge to the unit from U-1 and U-2 pumping has stopped. Well #299-W23-10: contaminant alpha has exceeded the U-238 concentration limit since June 1985. Uranium isotopic analysis of the October sample indicates U-238 exceeds the concentration limit. This report led to a groundwater pump and treat activity. The treated water was discharged to the 216-S-25 crib.

Related Sites/Structures: The crib is associated with the 242-S Evaporator building. The pipeline associated with this crib is sitecode 200-W-161-PL.

Waste Type: Process Effluent

Waste Description: Until 11/80, the site received the 242-S Evaporator process steam condensate. Since 11/80, the 242-S Evaporator has been in standby mode. In 1985, this crib received the effluent from the 216-U-1 and 2 groundwater pump and treat effort. The 241-SX Sludge Cooler Steam Heater was shut off in 1992 due to leaking tubes. A new steam heater unit was installed in 1993 and scheduled to start up in 1995. It was to operate for five months (through winter and early spring) producing approximately 15 to 30 liters (4-8 gallons) of condensate per hour that would be discharged to the 216-S-25 crib.

Code: 207-SL
Names: 207-SL; 207-SL Retention Basin; 222-S Retention Basin; REDOX Lab Retention Basin
Type: Retention Basin
Status: Active
Start Date: 1/1/1952
End Date:

Description: The site consists of a large below ground basin that is divided into two 94,625 liter (25,000 gallon) holding basins. The below ground basins are constructed of reinforced concrete walls 30 to 41 centimeters (12 to 16 inches) thick, and the floor is 38 centimeters (15 inches) thick. The unit also consists of three above ground 75,700 liter (20,000 gallon) holding tanks, added in 1994 to support the TEFD system.

Location: The site is located east of the 222-S Laboratory Buildings and west of Beloit Avenue.

Related Sites/Structures: The basin is associated with the 216-S-19 Pond, the 216-S-26 crib and the TEDF system.

Process Description: The retention basin received low-level radioactive waste from the 222-S laboratory ventilation cooling water, laboratory hoods and sinks. Until 1984, the basin effluent was discharged to the 216-S-19 Pond. From 1984 to 1995 the effluent was discharged to the 216-S-26 crib. After
1995, non-radioactive, non-hazardous liquid effluents from the 222-S Laboratory, the 222-SA Laboratory, the 219-S Operating Gallery sump, and the package boiler unit, flow into the below ground basins for retention prior to transfer to the Treated Effluent Disposal Facility (TEDF). The effluents can be transferred to and from the below ground basins to the above ground holding tanks to provide additional extended storage before transfer.

**Waste Type:** Process Effluent

**Waste Description:** From 2/52 until 12/54, the site received low-level waste, including ventilation cooling water and miscellaneous wastes from laboratory hoods and sinks in the 222-S Laboratory. These were then discharged to the 216-S-19 Pond. From 12/54 to 10/55, the site was inactive (radioactivity levels of waste exceeded set limits). After 10/55, the site received nondangerous/nonradioactive waste. This unit discharged to the 216-S-19 Pond until 11/94, then was routed to the 216-S-26 Crib until 7/94, and since 7/94 discharges to the 200 Area TEDF.

**Code:** 216-SX-2  
**Classification:** Accepted  
**Names:** 216-SX-2; 216-SX-2 Crib  
**Reclassification:** None  
**Type:** Crib  
**Start Date:** 1/1/1952  
**End Date:** 1/1/1965  
**Description:** The crib is currently surrounded by light post and chain and posted with Underground Radioactive Material signs. It is labeled "216-SX-2" on three sides with old style black and white signs. It is a gravel filled crib topped with a subsurface layer of Sisalkraft paper.

**Location:** The crib is located on the east side of Cooper Ave. adjacent to the 241-SX tank Farm. It is approximately 7.6 meters (25 feet) south of the 241-SX-701 Compressor house and 23 meters (75 feet) west of the 241-SX Tank Farm fence.

**Related Sites/Structures:** The crib is associated with the 241-SX-701 Compressor House. The pipeline associated with this crib is sitecode 200-W-162-PL.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The crib received waste from the 241-SX-701 Compressor House.

**Code:** 207-T  
**Classification:** Accepted  
**Names:** 207-T; 207-T Retention Basin; T Plant Retention Basin  
**Reclassification:** None  
**Type:** Retention Basin  
**Start Date:** 1/1/1944  
**End Date:** 1/1/1995  
**Description:** The retention basin has been backfilled to grade. It is delineated with concrete AC-540 markers that define it as an Underground Radioactive Material area. There is a single WIDS sitecode sign that says 207-T.

**Location:** The site is located west of 221-T Building and north of 23rd Street.

**Release Description:** On September 12, 1985, 1900 liters (500 gallons) of aqueous 5% sodium hydroxide solution containing 100 kilograms (219 pounds) of sodium hydroxide was released from T Plant to the basins and subsequently to 214-T-4-2 Ditch. At the time of the release, pH was 12.5. No cleanup actions were undertaken. After 6 hours of dilution by continued condensate discharge,
the pH was 7.67.

Related Sites/Structures: The basin is associated with 221-T, 224-T, 216-T-12, 200-W-53 and 216-T-4-1 and 216-T-4-2 Ditches. The inlet pipelines associated with this basin are WIDS sitecodes 200-W-88-PL, 200-W-165-PL, 200-W-166-PL and 200-W-167-PL. The outlet pipeline that leads to the 216-T-4 ditch is WIDS sitecode 200-W-164-PL.

Process Description: The unit was a concrete structure, divided into two sections, with a 3,800,000 liters (1,000,000 gallon) capacity. The bottom dimensions for each basin are 106 by 106 feet (32.3 by 32.3 meters). The basin received cooling water effluent from 221-T and 224-T. The basin effluent was released to the 216-T-4-1 and 216-T-4-2 Ditches. There was an inlet structure on the east side and an outlet structure on the west side, adjacent to the outside walls of the basins. Two 40.6 centimeter (16 inch) diameter cast iron pipes connected to two 0.9 meter (3 foot) sumps, one for each basin. Approximately 1830 meter (6000 feet) of 61 centimeter (24 inch) diameter vitrified clay pipeline was used to convey waste water to and from the basin. H-2-3019 shows a black iron pipeline that exits the east side of the basin, traveling south, connecting to a pipeline that is associated with the 216-TY-201 flush tank.

Periodically the sludge that accumulated on the bottoms of the basins was cleaned out. The sludge was placed in holes located around the perimeter of the basin and covered with clean dirt. One of these holes is documented as 216-T-12. Additional holes were probably dug and filled with sludge, but not individually documented.

Waste Type: Process Effluent

Waste Description: The unit received potentially low-level radioactive waste from T Plant process cooling and ventilation steam condensate, which was discharged to the 216-T-4-1 and 214-T-4-2 Ditches. From 11/44 to the 1950's, the site received process cooling water from process equipment jackets in 221-T and 224-T buildings. From early 1950's to 1955, the site received the same, plus 242-T Evaporator cooling water. From 1955 to 1965, the site received the same minus 242-T Evaporator cooling water. From 1965 to late 1960's, the site received the same plus 242-T Evaporator cooling water. From late 1960's to 1973, the site received the same minus 242-T Evaporator cooling water. From 1973 to 1976, the site received the same plus 242-T Evaporator cooling water. After 1976, the site received intermittent flow from 221-T, 221-TA, and 224-T buildings. The effluent discharge was rerouted to the 200 Area TEDF in 1995. The unit was backfilled with dirt in 1996.

### Code: 216-T-12  
**Classification:** accepted

**Names:** 216-T-12; 207-T Sludge Grave; 207-T Sludge Pit; 216-T-11  
**Reclassification:** none

**Type:** Trench  
**Start Date:** 1/1/1954  
**End Date:** 1/1/1954

**Description:** There is no visible evidence of this waste site. The area around the 207-T Retention Basin, including the northeast corner where this pit was located, has been stabilized with clean backfill material and posted with Underground Radioactive Material signs. The sludge pit is not separately marked.

**Location:** This site is located at the northeast corner of the 207-T Retention Basin.

**Related Sites/Structures:** The associated structure is the 207-T Retention Basin.

**Process Description:** The site was a small trench that was dug November 1954 with a backhoe at the northeast corner of the 207-T Retention Basin. Sludge dredged from the 207-T Retention Basin was put into the trench and covered.
Waste Type: Process Effluent
Waste Description: The site received contaminated sludge from the 207-T Retention Basin. The waste is low in salt and is neutral to basic.

Code: 216-T-13
Names: 216-T-13; 269-W Decontamination Pit or Trench; 269-W Regulated Garage; 269-W Regulated Garage Decontamination Pit; 216-T-12
Type: Trench
Status: Inactive
Start Date: 1/1/1954
End Date: 1/1/1964
Description: The site consisted of a single open trench located west of the 269-W Regulated Garage. The garage has been demolished. Currently, there is a concrete ramp covered with 0.6 meters (2 feet) of gravel that is visible near the site of the garage. The trench is no longer marked or posted.
Location: This site is located on the north side of the 241-TY Farm, north of the tank farm perimeter fence. The site has been shown at two locations on different maps. Drawing H-2-1495 (originally made in 1952) shows the location of the trench adjacent to the 269-W garage and northwest of the 241-TY Tank Farm, while a later drawing (H-2-32526, 1967 Rev 3) shows the trench due north of the 241-TY Tank Farm. The mapped location in HGIS is due north of the Tank Farm as of December 2001.
Related Sites/Structures: The site was associated with activities at the 269-W Regulated Garage, but the garage was not physically connected to the vehicle decontamination trench.
Process Description: This site was used to clean contaminated vehicles. A Tip Rack was located in the bottom of the open trench. Vehicles were driven into the trench and onto the rack. The vehicles were then sprayed with water or steam to remove the contamination. The decontamination was often required prior to vehicles being serviced at the 269-W Garage.
Waste Type: Chemicals
Waste Description: The site received vehicle decontamination liquid waste. The inventory prior to the removal of 3.06 cubic meters (4 cubic yards) of soil was estimated through 1972 as follows. ARH-2757, part 3 states the volume was 0.98E+05 liters; <0.100E+00 grams - plutonium; 0.840E+02 curies - beta; 0.100E00 curies - strontium-90; 0.400E+02 curies - ruthenium-106; 0.100E+00 curies - cesium-137; > < 0.100E+00 curies - cobalt-60; <0.500E-01 kilograms - uranium. ARH-1608 states the volume was 0.026E+06 liters; <=0.100E+00 grams - plutonium; 60 curies - beta; 1.00E+00 curies - strontium-90; 40 curies - ruthenium-106; 1.00E+00 curies - cesium-137; > < 0.100E+00 curies - cobalt-60; <.1 pounds of uranium. Readings up to 1,500 counts per minute were measured in the excavated soil. Although no cleaning agents are listed, the possibility of hazardous chemical contamination.

Code: 216-T-20
Names: 216-T-20; 216-T-20 Crib; 216-TX-2; 241-TX-155 Contaminated Acid Grave
Type: Trench
Status: Inactive
Start Date: 11/1/1952
End Date: 11/1/1952
Description: The site has a small concrete block structure on the surface with a metal lid labeled Confined
Space and Potential Internal Contamination. There is a single concrete marker with an Underground Radioactive Material sign on it. The concrete block structure is surrounded with the same type of cobbles that surround the powerhouse pond.

Location: The unit is located east of Camden Avenue, adjacent to the north end of the 200 West Area Power House Pond.

Related Sites/Structures: The site is associated with the 241-TX-155 Diversion Box.

Process Description: The historical documentation describes the site as an excavation, similar to a pit. It was a single use pit dug specifically to receive contaminated acid from the 241-TX-155 Diversion Box. There is no mention of the concrete block access structure currently located at the site.

Waste Type: Process Effluent
Waste Description: The site received contaminated nitric acid from 241-TX-155 Diversion Box Catch Tank.

Code: 216-T-27
Names: 216-T-27; 216-TX-2 Cavern; 216-TX-2 Crib; 216-TY-2 Cavern; 216-TY-2 Crib
Type: Crib
Status: Inactive
Description: The 216-T-26, 216-T-27 and 216-T-28 cribs are enclosed within a common steel post and chain barricade that is posted "Underground Radioactive Material". The 216-TY-201 flush tank is located in the northeast corner of the area.
Location: This site is located inside 200 West Area, south of 23rd Street and east of Camden Ave.
Related Sites/Structures: The crib is associated with 221-T, 2706-T, 216-TY-201 Flush Tank, 200-W-188-PL and 200-W-82 Truck Unloading Station. The pipelines associated with this crib are 200-W-175-PL and 200-W-188-PL.
Process Description: The underground pipeline from the 241-TY Tank Farm to the 216-T-26 crib was isolated with a blank flange in 1956. An underground pipeline from the 241-T Tank Farm was used to transfer waste from T Plant (after it cascaded through tanks 241-T-110, 241-T-111 and 241-T-112) to the 216-T-27 and 216-T-28 cribs. The tanks contained steam condensate and process decontamination waste from T Plant along with 2607-T equipment decontamination waste. In 1964, 300 Area laboratory waste was shipped from the 340 facility by truck to the 200 West Area. The 300 Area waste was combined with the T-Plant waste that was discharged to cribs 216-T-27 and 216-T-28. Lundgren (1971) mentions a crib riser being used for the disposal of 300 Area waste (see sitecode 200-W-82).

A letter written by G.L. Ritter (1966) stated that the 300 Area waste and the T Plant waste had been diverted from the 216-T-28 Crib to the 216-T-27 Crib in November 1965 due to an increase in the groundwater contamination levels below the 216-T-28 Crib. Only a limited amount of 300 Area waste had been expected and the 216-T-27 Crib was estimated to be used for approximately 18 months. However, information was collected that indicated the 300 Area waste discharged to the 216-T-27 Crib did not react favorably with the soil at this crib location. It was recommended that this crib be deactivated earlier than expected (see ISO-636).

Waste Type: Process Effluent
**Waste Description:** The site received 300 Area lab waste containing nitrates, 221-T steam condensate and process decontamination waste and equipment decontamination waste from 2706-T. A page of typed, unsigned notes was found that documents the transport of "round the clock" trucking of waste from the PRTR rupture incident in September 1965. The notes indicate that the waste would be discharged into the 216-T-27 crib. A different page of notes, also unsigned, states that more than 100 truck loads of liquid waste from the PRTR incident was discharged into the 216-T-28 crib during September and October 1965. Since the same truck unloading station would have been used for either crib, it is difficult to be sure how much waste was discharged to the 216-T-27 and how much was discharged to the 216-T-28 crib.

**Description:** The 216-T-26, 216-T-27 and 216-T-28 cribs are enclosed within a common steel post and chain barricade that is posted "Underground Radioactive Material". The 216-TY-201 flush tank is located in the northeast corner of the area.

**Location:** This site is located inside 200 West Area, south of 23rd Street and east of Camden Ave.

**Related Sites/Structures:** The associated structures are the 221-T Building, 2706-T Building, 216-TY-201 Flush Tank and 200-W-82 Truck Unloading Station. The pipelines associated with this crib are 200-W-175-PL and 200-W-188-PL.

**Process Description:** The underground pipeline from the 241-TY Tank Farm to the 216-T-26 crib was isolated in 1956. The 216-T-27 and 216-T-28 Cribs were active from February 1960 to December 1966. An underground pipeline from the 241-T Tank Farm was used to transfer waste from T Plant (after it cascaded through tanks 241-T-110, 241-T-111 and 241-T-112) to the 216-T-27 and 216-T-28 cribs. The tanks contained steam condensate and process decontamination waste from T Plant along with 2607-T equipment decontamination waste. In 1964, 300 Area laboratory waste was shipped from the 340 facility by truck to the 200 West Area. The 300 Area waste was combined with the T-Plant waste that was discharged to cribs 216-T-27 and 216-T-28.

Lundgren (1971) mentions a crib riser being used for the disposal of 300 Area waste (see sitecode 200-W-82 Truck Unloading Station). In May 1966, waste from the 2706-T Building was rerouted to the 216-T-4 Ditch. In December 1966, the pipeline to the crib and the 300 Area waste disposal riser were isolated. The 300 Area laboratory waste was sent to the 216-T-34 Crib. The T Plant effluent was rerouted to the 216-T-36 Crib.

**Waste Type:** Steam Condensate

**Waste Description:** From February 1960 through February 1963, the crib received steam condensate and process decontamination waste via the 241-T-112 tank in the 241-T Tank Farm. In 1963, 2706-T equipment decontamination waste was added to the waste stream. In 1964, 300 Area laboratory waste was sent to this crib via tanker trucks from the 340 Waste Transfer Facility. A page of typed, unsigned notes dated October 26, 1965 indicated that 189 truck loads of liquid waste from 300 Area were discharged into the 216-T-28 crib between September 13, 1965 and October 25, 1965. The total volume during that time was 945,000 gallons. Most of the waste was from the PRTR rupture incident. The crib was deactivated in December 1966 when the prescribed radionuclide disposal limit was reached.

_Hanford Site Waste Management Units Report_

February 2015

1264
**Names:** 216-T-29; 216-T-29 French Drain; 291-T Sand Filter Sewer  
**Reclassification:** None  
**Type:** French Drain  
**Start Date:** 1/1/1949  
**Status:** Inactive  
**End Date:** 1/1/1964  
**Description:** The 291-T Sand Filter is located northeast of the 221-T building. The 216-T-29 French Drain is part of the sand filter construction. The sand filter is marked and posted as a Contamination Area. There is a vent riser protruding through the roof of the northwest corner of the sand filter. This is assumed to be the location of the drain.  
**Location:** The french drain is located adjacent to the north end of the 291-T Sand Filter and northeast of the 221-T Building.  
**Related Sites/Structures:** The associated structure is 200-W-45 (291-T Sand Filter).  
**Process Description:** This site received canyon air condensate from the 291-T Sand Filter. In the 1950's, silver reactor filters, made of fiberglass soaked in silver nitrate, were added to the stack ducts.

**Waste Type:** Steam Condensate  
**Waste Description:** The site waste was moisture condensed from canyon air and included 8000 kilograms of nitric acid. In the 1950's, silver reactor filters were added to the stack ducts. They were made of fiberglass soaked in silver nitrate. The filters reacted with the radioiodine to form silver iodide.

*Hanford Site Waste Management Units Report*  
February 2015  
1265
Radioactive Material signs. The site consists of a rectangular crib with perforated vitreous clay inlet pipe set into a gravel layer. A layer of plastic sheeting, clean sand, and backfill are above the pipe.

Location: This unit is located west of 221-T Canyon Building and southwest of 2706-T.

Related Sites/Structures: The site is associated with the 2706-T Decontamination Building. The pipeline associated with this crib is 200-W-173-PL.

Process Description: This site provided subsurface liquid disposal for the 2706-T Building. After the line plugged, the 2706-T waste was routed to the 216-T-28 crib, via the 241-T-112 tank.

Waste Type: Process Effluent

Waste Description: The site received equipment decontamination waste from the 2706-T Building. The waste is low in salt, neutral to basic, and contains sodium hydroxide. There total effluent discharged to the crib is questionable, due to the fact that the discharge line plugged shortly after the crib became active.

**Location:** The site consists of a single vitreous clay distribution pipe resting in a gravel layer that is in a rectangular trench. Backfill covers the pipe and gravel. The crib also has a gage well riser and a filter riser.

**Location:** The site is located southwest of the 241-T Tank Farm and south of the 216-T-7 Tile Field.

**Release Description:** The May 2000, the Dyncorp Integrated Site Vegetation and Animal Control (ISVAC) Priority List and the Contamination Zone map identified a long, narrow area of posted contamination adjacent to the east end of the 216-T-36 Crib (#12 on their list). The posted area appears to be located over the buried pipeline that fed the crib. (See WIDS 200-W-79-PL).

**Related Sites/Structures:** The associated structures are the 221-T, 221-U, 2706-T Buildings and the 241-T-151 Diversion Box. The pipelines associated with this crib is 200-W-79-PL and 200-W-130-PL.

**Process Description:** This site provided subsurface liquid disposal for steam condensate, equipment decontamination waste, and miscellaneous waste from the 221-T and 221-U Buildings. It also received decontamination waste from the 2706-T Building.

**Waste Type:** Process Effluent

**Waste Description:** The site received steam condensate, equipment decontamination waste, and miscellaneous waste from the 221-T, 221-U and the 2706-T buildings. Some waste contained sodium hydroxide.

Description: The 241-T-361 Tank is enclosed with light post and chain and concrete AC-540 markers. The underground tank is posted with Inactive Miscellaneous Underground Storage Tank and Underground Radioactive Material signs.

Location: The tank is located southwest of the 221-T Building and north of 23rd Street. It is adjacent to the 216-T-6 Cribs.

Related Sites/Structures: The settling tank is associated with the 216-T-3 Reverse Well, 216-T-6 Cribs and the 221-T and 224-T facilities. The pipeline from 224-T that fed the reverse well via the 241-T-361 tank is sitecode 200-W-226-PL.

Process Description: The 241-T-361 Settling Tank received radioactive contaminated liquid from the 221-T and 224-T Buildings. The tank discharged to the 216-T-3 Reverse Well during 1945 and 1946. When the reverse well was abandoned, the settling tank discharge was directed to the 216-T-6 Cribs. The 241-T-361 Settling Tank was deactivated in June 1951. Settling Tank 241-T-361 is cylindrical and is made of reinforced, pre-stressed concrete. The tank is located underground for shielding purposes.

Waste Type: Soil

Waste Description: The tank received waste from 221-T and 224-T. Sludge samples taken in 1976 contained 23 micrograms of plutonium, 12 microcuries per gram of strontium-90 and 67.6 microcuries per gram of cesium-137. The liquid supernate contained 3.71 microcuries per gallon of cesium-137 and 14.5 milligrams per gallon of plutonium.

</table>

Description: The unit is a plastic lined concrete basin divided into two equal halves, with a capacity of 3.785E+06 liters (1E+06 gallons). The basin structure is posted as a Contamination Area. The bottom dimensions for each basin are 32 by 32 meters (106 by 106 feet). The total overall dimensions at the top ledge 75 by 38 meters (246 by 123 feet), 2 meters deep (6.5 feet). There is an inlet structure on the east and an outlet structure on the west side, on the outside of the basins. Each basin has a 0.9 by 0.9-meter (3 by 3-foot) sump. There is also a sampler cabinet and a sample vault on the east side of the basins near the inlet structure. There are two unplanned release sites (UPR-200-W-111 and UPR-200-W-112) adjacent to the basin where sludge was removed and buried. These burial sites are located within 3.1 meters (10 feet) of the basin on the north side and on the south side, near the western corners. An unused sampler cabinet is located on the east side of the basin, as well as a sample vault that is a confined space.

Location: The site is located inside 200 West Area, west of 221-U Building, north of 16th Street, and east of the 241-U Tank Farm.

Release Description: Occurrence Report 86-46 states that on August 6, 1986, 2365 liters (625 gallons) of recovered nitric acid, containing 39 kilograms (86 pounds) of uranium was discharged though the chemical sewer to the 207-U retention Basin. Prior to the discovery of the release, the outlet valves on the retention basin were open to the 216-U-14 Ditch. The acid released to the ditch was greatly diluted with the 300 gallon per minute flow of cooling water from the 224-U facility being processed through the chemical sewer system. The Hanford Site Waste Management Units Report (1987) reported different release values. It states that approximately 3,000 liters (796 gallons) of 50% reprocessed nitric acid was released to the basin and subsequently to 216-U-14 Ditch. The total release to the environment consisted of approximately 102,000 kilograms (225,000 pounds) of corrosive solution (pH less than 2.0) and
45.4 kilograms (100 pounds) of uranium.

**Related Sites/Structures:**
There is an inlet structure on the east and an outlet structure on the west side, on the outside of the basins. Each basin has a 0.9 by 0.9-meter (3 by 3-foot) sump. There is also a sampler cabinet and a sample vault on the east side of the basins near the inlet structure. The chemical sewer pipeline that fed the basin is sitecode 200-W-192-PL. The outlet pipe to the 216-U-14 ditch is sitecode 200-W-222-PL.

**Process Description:**
Currently, the basin receives stormwater runoff from the 224-U Building and grounds. The outlet was plugged so that the basins would serve as an evaporation pond for the stormwater it receives. During the Uranium Trioxide (UO3) facility deactivation, the trench that runs between 224-UA and 224-U was tied into the 207-U retention basin pipeline to route the stormwater buildup from the contaminated zones on the backside of the facility to the 207-U Basins for solar evaporation. The basin outlets have been isolated with concrete. The stormwater accumulating in the basin is allowed to evaporate. The Hanford Operational Environmental Monitoring Program will continue to monitor the air and soil in the vicinity of the basins to meet requirements stated in the National Emissions Standards for Hazardous Air Pollutants (NESHAP) for monitoring of diffuse and fugitive sources. Originally, the basin received chemical sewer waste from the 221-U Building and cooling water from the 224-U Building. The water was held in the basin, sampled, and then discharged to the 216-U-10 Pond via the 216-U-14 Ditch.

**Waste Type:**
Not Specified

**Waste Description:**
Until 1972, the unit received steam condensate and cooling water from 224-U Building and chemical sewer waste from the 221-U Building. After 1972, the unit has received only cooling water from 224-U Building. The basin was temporarily replaced by 216-U-16 Crib (1984 through 1986) but was reactivated when 216-U-16 Crib was taken out of service. The effluent from the basin was discharged to the 216-U-10 Pond via the 216-U-14 Ditch until the basin outlet was plugged in 1994. Presently, the basin is receiving storm water run off from the 224-U building. The water is allowed to evaporate in the basin.

**Code:** 216-U-1&2  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 216-U-1&2; 216-U-2; 216-U-3; 216-UR #1&2 Crib; 361-WR (Crib 2); 216-U-1; 216-U-1 & 2

**Type:** Crib  
**Start Date:** 1/1/1951  
**End Date:** 1/1/1967

**Status:** Inactive

**Description:** The crib area has been surface stabilized with clean dirt. The wood timber cribs are co-located in a common Underground Radioactive Material area. Each crib is delineated with posts and chain with Cave-In Potential signs.

**Location:** The site is north of 16th Street, west of 221-U and east of the 207-U Retention Basin.

**Release Description:**
See UPR-200-W-19 and Unusual Occurrence 85-17.

**Related Sites/Structures:** The cribs are associated with the 241-U-361 Settling Tank, UPR-200-W-19, the 224-U Building and 221-U Building. The pipeline associated with this crib is 200-W-194-PL.

**Process Description:**
The cribs received overflow from the 241-U-361 Settling Tank. The tank received cell drainage from the 5-6 tank in 221-U and waste from the 224-U Building until the Uranium Recovery process operations shut down in 1957. From July 1957 through May 1967, the 216-U-1&2 Crib received waste from the 224-U Facility and equipment decontamination waste and reclamation waste from the 221-U canyon. The cribs are two wooden structures that operated in series.
From March 1952 to June 1957, the site received cell drainage from Tank 5-6 (221-U Building) and waste from the 224-U Building via the overflow from the 241-U-361 Settling Tank. From June 1957 to July 1957, the site received waste from the 224-U Building via the overflow from the 241-U-361 Settling Tank and contaminated solvent from the 276-U Settling Tank Solvent Storage area. The discharge of 221-U waste was discontinued during shutdown of production operations. From July 1957 to May 1967, the site received waste from the 224-U Building and equipment decontamination and reclamation wastes from Chemical Processing Division (CPD) Services Operations in the 221-U Building canyon. Crib 2 was deactivated in May 1967. The waste is low in salt and is neutral to basic.

**Code:** 216-U-3  
**Classification:** Accepted

**Names:** 216-U-3; 216-U-3 French Drain; 216-U-11  
**Reclassification:** None

**Type:** French Drain  
**Start Date:** 1/1/1954  
**End Date:** 1/1/1955

**Description:** This site consists of a french drain with light steel posts and chain with "Underground Radioactive Material" signs. The drain is a 3.6 meter (12 foot) deep, 1.8 meter (6 foot) diameter, rock-filled excavation with sloping sides and a 10 centimeter (4 inch) diameter vent riser.

**Location:** This site is located south of the 241-U Tank Farm on the south side of 16th Street.

**Related Sites/Structures:** The french drain is associated with the 241-U-104, 241-U-110 Tanks and the 200-W-169-PL pipeline.

**Process Description:** This site received condensate from the steam condensers on the 241-U-104 and 241-U-110 Tanks. Most reference documents mention this site receiving waste from 241-U-110, but drawing H-2-44004 also shows the 241-U-104 tank having a condenser that is attached to the same pipeline as the 241-U-110 tank.

**Waste Type:** Soil

**Waste Description:** This 216-U-3 crib received condensate from the steam condensers on the 241-U-104 and 241-U-110 tanks. The 241-U-104 and 241-U-110 tanks held REDOX boiling waste. The site waste contains nitrate. The closed loop cooling water for the condensers was discharged to the 216-U-14 ditch.

**Code:** 216-U-4  
**Classification:** Accepted

**Names:** 216-U-4; 216-U-4 Dry Well; 222-U Dry Well; 222-U-110 Dry Well; 216-U-2  
**Reclassification:** None

**Type:** Injection/Reverse Well  
**Start Date:** 1/1/1947  
**End Date:** 1/1/1955

**Status:** Inactive

**Description:** This site consists of a deactivated reverse well. The well consists of pipe sunk into the ground with the bottom 8 meters (25 feet) of pipe perforated. The end of the pipe is nearly closed by flattening. The site is marked with a small cement cover and a bronze medallion. It is posted as "Underground Radioactive Material".

**Location:** This site is located at the southwest corner of the 222-U Building.

**Related Sites/Structures:** The site is associated with the 221-U building and the 216-U-5 trench.

**Process Description:** This site was used as liquid disposal site for unirradiated uranium waste from the cold start-up run at 221-U.
Waste Type: Not Specified
Waste Description: In March 1952, the site received liquid, unirradiated uranium waste from the cold start-up run at 221-U. The waste included 200 kilograms of nitrate.

Code: 216-U-7
Names: 216-U-7; 221-U Counting Box French Drain; 221-U Vessel Vent Blower Pit French Drain
Type: French Drain
Status: Inactive
Start Date: 1/1/1952
End Date: 1/1/1957

Description: The french drain is within a larger area that has been stabilized and posted with Underground Radioactive Material signs. This drain is constructed of a concrete pipe set vertically into the ground. Gravel fills 1.1 meters (3.5 feet) of the pipe.

Location: This site is located on the southeast side of the 221-U Building near Section 6. It is northwest of the 241-UX-154 Diversion Box.

Related Sites/Structures: The site is associated with the 221-U Building, UPR-200-W-162 and UPR-200-W-138. The pipeline from the counting box to the french drain is sitecode 200-W-217-PL.

Process Description: This site received liquid wastes from a counting box floor drain during the metal recovery program at the 221-U Building.

Waste Type: Not Specified
Waste Description: The site received liquid wastes from a counting box floor drain during the metal recovery program. The site waste contains nitrate. Due to UPR-200-W-138, it is assumed that 13 kilograms (30 pounds) of uranium in uranyl nitrate hexahydrate (UNH) solution were also introduced to the soil through the 216-U-7 French Drain. However, the release associated with UPR-200-W-138 may be associated with a different french drain. The release information is vague. It is possible the event effected the 216-U-7 French Drain if sufficient liquid volume was released to the surface to flow southward and reach the 216-U-7 French Drain location.

Code: 216-U-8
Names: 216-U-8; 216-U-9; 216-WR-1,2,3 Cribs
Type: Crib
Status: Inactive
Start Date: 1/1/1952
End Date: 1/1/1960

Description: The site is marked and posted with Underground Radioactive Material signs. The site consists of three wood timber cribs set in series. Each crib is 4.9 by 4.9 by 3.0 meters deep (16 by 16 by 10 feet deep). The cribs were filled with 1.3-centimeter (0.5-inch) crushed stone to the tops of the wooden structures. There is roughly 2,070 cubic meters (73,000 cubic feet) of gravel fill in the cribs. The cribs were fed by a vitrified clay pipeline.

Location: The site is located west of Beloit Avenue and south of 16th Street.

Related Sites/Structures: The site is associated with 270-W, 216-U-12, 200-W-42, the 221-U and 224-U Buildings and the 291-U Stack.

Process Description: The cribs received acidic process condensate from the 221-U and 224-U buildings along with drainage from the 291-U stack via an underground vitrified clay pipeline.
Waste Type: Not Specified
Waste Description: The site received process condensate from 221-U and 224-U Buildings and the 291-U Stack drainage. The waste is acidic.

Code: 216-U-12
Names: 216-U-12; 216-U-12 Crib
Type: Crib
Status: Inactive

Description: The site is marked and posted with Underground Radioactive Material. The bottom of the crib was filled with approximately 264 cubic meters (9,320 cubic feet) of gravel. A perforated 30-centimeter (12-inch) vitrified clay pipe runs horizontally the length of the unit below grade.

Location: The crib is located south of 16th Street and west of Beloit Avenue. It is south of the 216-U-8 crib.

Related Sites/Structures: The crib is associated with 270-W, 216-U-8, the 224-U facility, 291-U stack and pipeline sites 200-W-42-PL and 200-W-151-PL.

Process Description: The 216-U-12 Crib was built in 1960 to replace the 216-U-8 Crib when it showed signs of cave-in potential. 216-U-12 was operational until 1988, when the pipeline was cut and capped. The 216-U-12 Crib was replaced by the 216-U-17 Crib.

Waste Type: Not Specified
Waste Description: From April 1960 to May 1967, the site received 291-U-1 Stack drainage, 241-WR Vault waste (aka 244-WR vault), and 224-U process condensate via the C-5 Tank. Contaminated water from the 241-WR Vault was discharged to the crib in October 1965 that included 3.14 kilograms (6.9 pounds) of thorium. From May 1967 to September 1972, the site received the above wastes (excluding the 241-WR Vault waste) and occasional waste via the C-7 Tank in the 224-U building. From September 1972 to November 1981, the site was taken out of service. From November 1981 to January 1987, the site received corrosive process condensate (corrosive: [D002] typical pH range is 0.5-1.5) from the 224-U building. The crib also received miscellaneous storm drain wastes from 224-U building. Between April 1960 and September 1972, 6.7 E5 kilograms of nitrate was released to the crib from the Uranium Tri-Oxide process.

Code: 216-U-13
Names: 216-U-13; 216-U-13 Crib; Vehicle Steam Cleaning Pit
Type: Trench
Status: Inactive

Description: This site consisted of two trenches of equal dimensions. The trenches were sloped so that vehicles could be driven down to the decontamination station at the bottom. The two trenches are no longer marked or posted. Some debris is visible in the area. The area is not level. Many deep gullies are located in the area west of the 241-U Tank Farm.

Location: This site was located west of the 241-U Tank Farm.

Process Description: The site received drainage from equipment steam cleaning and decontamination activities done inside the trenches. The pits were used mainly to decontaminate trucks and cranes bearing low levels of radioactive contamination. Several large pumps used in the Uranium Recovery
process were also cleaned here, but the residue was scraped and taken to the 200 West Burial Grounds.

Waste Type: Not Specified
Waste Description: The site used steam and water hoses to remove radioactive contaminants from vehicles, equipment and pumps from the Uranium Recovery operation. The site waste may include traces of detergent and nitric acid.

Code: 216-U-14  Classification: Accepted
Names: 216-U-14; 216-U-14 Ditch; Laundry Ditch  Reclassification: None
Type: Ditch  Start Date: 1/1/1944
Status: Inactive  End Date: 1/1/1995

Description: The entire ditch has been backfilled and surface stabilized. It is posted as Underground Radioactive Material.

Location: The ditch originated west of the 284-W Powerhouse, west of Bridgeport Avenue. It extended southward, terminating at the 216-U-10 Pond.

Release Description: Occurrence Report 86-46 states that on August 6, 1986, 2365 liters (625 gallons) of recovered nitric acid, containing 39 kilograms (86 pounds) of uranium was discharged through the chemical sewer to the 207-U retention Basin. Prior to the discovery of the release, the outlet valves on the retention basin were open to the 216-U-14 Ditch. The acid released to the ditch was greatly diluted with the 1140 liter (300 gallon) per minute flow of cooling water from the 224-U facility being processed through the chemical sewer system. The outlet valves from the retention basin were closed shortly after the discovery of the release and the remainder of the acid release was contained in the retention basin. The effluent in the retention basin was neutralized with 270 kilograms (600 pounds) of sodium carbonate. The Hanford Site Waste Management Units Report (1987) reported different release values. It stated approximately 3000 liters (796 gallons) of 50% reprocessed nitric acid was released to the unit. The total release to the environment consisted of approximately 101,250 kilograms (225,000) pounds of corrosive solution (pH less than 2.0) and 45.4 kilograms (100 pounds) of uranium.

Related Sites/Structures: The ditch is associated with the 284-W Powerhouse, 2723-W (old laundry facility), 2724-W (new laundry facility), 221-U, 224-U, 271-U the 242-S Evaporator building and the 241-U-110 tank. The 200 West Area Powerhouse Pond was constructed over the location of the head end of the 216-U-14 Ditch. The direct pipeline from 221-U is 200-W-84-PL. The pipeline from 2724-W is 200-W-102-PL. A pipeline from 241-U tank farm to the 216-U-14 ditch is sitecode 200-W-168-PL. The outlet pipe from 207-U is sitecode 200-W-222-PL. The effluent discharge pipe from 242-S Evaporator to the 216-U-14 ditch is sitecode 200-W-223-PL.

Process Description: The 216-U-14 ditch was excavated in 1944 and was the original effluent route to the 216-U-10 Pond. It received powerhouse waste water, laundry waste water (until 1981) via 200-W-102 Pipeline, and steam condensate and cooling water from 221-U, 224-U and the 242-S Evaporator. Near the head end of the ditch, a 0.6 meter (2 foot) diameter pipe allowed 284-W Powerhouse and laundry effluent to flow under 19th Street and connect to the main portion of the ditch. The ditch also had a 1.22 meter (4 foot) diameter culvert that allowed effluent to flow under 16th Street to the portion of the ditch located north of the 242-S Evaporator and also flowed under Cooper Ave. to terminate at 216-U-10 Pond.

Waste Type: Not Specified
Waste Description: From 7/44 to 9/44, the site received wastewater from the 284-W Powerhouse. From 9/44 to 1/50, the same plus waste from 2723-W (original laundry and mask cleaning station). From 1/50 to 3/52, received wastewater from 284-W and 2724-W Laundry Building (new laundry.
facility). From 3/52 to 5/54, the same plus chemical sewer waste from 221-U and cooling water from 224-U. From 5/54 to 8/55, the same plus cooling water from 241-U-110 condenser tank. From 8/55 to 11/73, the same plus 271-U cooling water. From 11/73 to 4/80, the same plus 242-S Evaporator condensate and cooling water. From 4/80 to 9/81, the same minus 242-S condensate, 2723-W and 2724-W waste. From 9/81 to 7/84, the same minus 221-U, 224-U, and 271-U waste. The 221-U and 224-U effluent entered the ditch after passing through the 207-U Retention Basin. The 216-U-16 crib was built in 1984 to accept 224-U effluent that had previously been discharged to the ditch. However, the 216-U-16 crib failed in 1985. Some 224-U effluent was diverted back to the 216-U-14 Ditch until November 1994, when the outlet pipe to the 207-U Retention Basin was permanently isolated and filled with concrete. The portion of the ditch, located west of Cooper Ave., received effluent from the 242-S Evaporator and remained active until April 1995. Discharge from the 242-S Evaporator was eliminated in 1995 ending all discharges to this unit.

### Code: 216-U-15
- **Classification:** Accepted
- **Reclassification:** None
- **Start Date:** 1/1/1957
- **End Date:** 1/1/1957
- **Type:** Trench
- **Status:** Inactive
- **Description:** The site is the result of a deliberate discharge of liquid waste into a hole in the ground. No surface markers exist to identify the exact location of this waste unit. Originally, the site was delimited by a wooden fence and posted with Underground Contamination signs. The perimeter fence and all identification markings of this site were removed in 1971.
- **Location:** The site was located west of the 271-U Building and north of 16th Street.
- **Related Sites/Structures:** The 216-U-15 Trench was associated with the 388-U Tank and the 276-U Solvent Storage Area.
- **Process Description:** Approximately 26,500 liters (7000 gallons) of material was discharged via an overground pipeline. The hole was backfilled and the piping was removed after the transfer was completed. HW-50584 indicates conflicting information. The May 1957 monthly report states that 79,494 liters (21,000 gallons) of organic solution (RAX) was originally scheduled to be transferred to the PUREX plant, but was buried because it was found to be incompatible with the PUREX process. The material was buried, with minor ground contamination occurring when the overground line used to transport the material from 276-U leaked. One 8 inch culvert was replaced and the contaminated ground was dug up and buried.
- **Waste Type:** Not Specified
- **Waste Description:** This site received 26,500 liters (7,000 gallons) of waste from the 388-U Tank in the 276-U Solvent Building. The waste consisted of interface crud, activated charcoal, and diatomaceous earth containing approximately 1 curie of fission products. HW-50584 indicates conflicting information. The May 1957 monthly report states that 79,494 liters (21,000 gallons) of organic solution (RAX) was originally scheduled to be transferred to the PUREX plant, but was buried because it was found to be incompatible with the PUREX process.

### Code: 216-U-16
- **Classification:** Accepted
- **Reclassification:** None
- **Start Date:** 1/1/1984
- **Type:** Crib
- **Names:** 216-U-16; UO3 Crib
Inactive Status: 1/1/1987 End Date: 1/1/1987

Description: The crib is identified with concrete AC-540 markers and is posted with Underground Radioactive Material signs.

Location: The crib is located south of 16th Street, between Beloit and Cooper Avenues, southwest of the 224-U Building.

Related Sites/Structures: The crib is associated with the 224-U and the 221-U facilities and the 216-U-14 ditch. The pipeline that feeds this crib is sitecode 200-W-170-PL.

Process Description: The crib was activated on July 20, 1984. The 216-U-16 crib was built to receive waste from the 224-U Uranium Oxide Processing Facility. The crib is constructed of two header pipes, 20 centimeters (8 inch) reducing to 15 centimeters (6 inch) that are located 0.9 meters (3 feet) above the crib bottom, running the length of the unit, one on each side. At each end of the pipe is a 15 centimeter (6 inch) vent pipe. Connecting the two header pipes were twenty-two 10 centimeter (4 inch) perforated pipes running the width of the unit, equally spaced, 0.9 meters (3 feet) above the bottom. Each header pipe has a 10 centimeter (4 inch) vent riser. An acid resistant distribution box is located at the crib inlet (northeast edge). A short pipeline connected the crib to the existing VCP Process Sewer line. In July 2000, the vent risers were sealed and cut off below grade. There are three gage wells, one near the north and south ends and one near the center. The bottom is filled with 1.5 meters (5 feet) of gravel. Covering the gravel is a reinforced polyethylene liner extending 2.4 meters (8 feet) up the sides of the excavation. The crib structure has been backfilled over to grade. A 15 centimeter (6 inch) subdrainage pipe runs the width of the unit at the west side.

Waste Type: Not Specified

Waste Description: The site received 224-U steam condensate, 224-U chemical sewer waste, 271-U compressor cooling water, 221-U chemical sewer waste, and 224-U process condensate.

---

Inactive Status: 1/1/1988 End Date: 1/1/1994

Description: The crib is marked and posted with Underground Radioactive Material signs.

Location: The crib is located south of 16th Street and east of Beloit Ave. inside the 200 West Area. It is southeast of the 221-U facility.

Related Sites/Structures: The crib is associated with the 224-U facility and the 200-W CSLA. The pipeline associated with the crib is sitecode 200-W-195-PL.

Process Description: The crib was built to replace the 216-U-12 cribs. The crib received effluent from the 224-U building process condensate from the conversion of urynal nitrate hexahydrate (UNH) to Uranium Tri-oxide (UO3) through the calcining operations. The process condensate was neutralized prior to discharge to the crib. Effluent flow was evenly distributed over the entire unit from the distribution line lying in an aggregate field with a PVC vapor barrier. The site footprint is 70 meters by 26 meters (230 feet by 86 feet). The stormwater runoff from the 224-U facility was rerouted to the 207-U basins.

Waste Type: Not Specified

Waste Description: The unit received 224-U process condensate. A neutralization system was placed into operation before startup of this crib to preclude the discharge of process condensate outside the range of...
2.0 to 12.5 pH.

<td>Description: The site was originally described as a pit that is approximately 15.3 meters (50 feet) by 31 meters (100 feet). The surface of the area has the appearance of drilling mud, and has the typical surface that is left from evaporated or percolated liquid. Vegetation is absent from the area. Two samples were collected in 1995. The results identified bentonitic clay and diatomaceous material.</td>
<td></td>
</tr>
<tr>
<td>Location: The site is located west of REDOX, outside the REDOX exclusion fence. It is north of 10th</td>

Hanford Site Waste Management Units Report
February 2015 1278
Street.

**Related Sites/Structures:** The site is associated with 200-W-17 and 200-W-18.

**Code:** 200-W-2
**Classification:** Accepted
**Names:** 200-W-2; REDOX Berms West
**Reclassification:** None
**Type:** Spoils Pile/Berm
**Start Date:**
**Status:** Inactive
**End Date:**
**Description:** The majority of the area is level, with evidence of soil disturbance over several acres. The site consists of two bermed areas. One berm is approximately 1.5 meters (5 feet) high by 9.2 meters (30 feet) wide. The other berm is approximately 3.1 meters (10 feet) high and 15.3 meters (50 feet) wide. The berms are not marked or posted.
**Location:** The site is located northwest of the 202-S Facility, outside the REDOX exclusion area fenceline.

**Code:** 200-W-6
**Classification:** Accepted
**Names:** 200-W-6; 200-W Painter Shop Paint Solvent Disposal Area
**Reclassification:** None
**Type:** Dumping Area
**Start Date:**
**Status:** Inactive
**End Date:**
**Description:** The site consists of contaminated soil. The soil was identified in 1993, while performing building modifications at the paint shop.
**Location:** The site is located inside 200 West Area, north of 19th Street and east of Bridgeport Ave. It is within the construction forces shop complex at the 2318W Annex (previously referred to at 15019 shop building).
**Release Description:** Soil within an excavation exhibited a strong solvent odor.
**Process Description:** The construction forces shop complex has been situated at this location for many years.

**Code:** 200-W-9
**Classification:** Accepted
**Names:** 200-W-9; Project W291 Excavation VCP Contamination
**Reclassification:** None
**Type:** Unplanned Release
**Start Date:** 1/1/1994
**Status:** Inactive
**End Date:**
**Description:** The site is currently a gravel area with two metal caissons. The area is not marked or posted. The tops of the caissons are labeled MH T-1 and MH T-2. While excavating for MH T-2 manhole for the new TEDF line from T-Plant to the 200 Area Treated Effluent Disposal Facility (project W291), contamination was discovered on an existing 25 cm (10 inch) vitrified clay pipe that was exposed during the excavation activity.
**Location:** The site is located in 200 West Area, near the southeast corner of 221-T. It is 42 meters (138 ft)
An old vitrified clay pipe was uncovered while excavating for MH T-2 manhole for the new waste line from T-Plant to the 200 Area Treated Effluent Disposal Facility (project W291). The pipeline was left in the excavation.

The 25 centimeter (10 inch) vitrified clay pipe (see 200-W-163-PL) carried chemical sewer effluent from 291-T, 222-T and 224-T to the 216-T-3 crib.

The old vitrified clay pipe is assumed to be a chemical sewer line associated with 221-T and 222-T (see 200-W-163-PL).

### Code: 200-W-11
- **Classification:** Accepted
- **Reclassification:** None

### Names: 200-W-11; Concrete Foundation South of 241-S; S-Farm Foundation and Dump Site

### Type: Dumping Area
- **Start Date:**
- **End Date:**

### Status: Inactive

### Description: A concrete foundation, small burn areas, bare areas and scattered debris are located south of 241-S Tank Farm.

### Location: The site is north of 10th Street and west of Camden Ave., south of the 241-S Tank Farm.

### Related Sites/Structures: The site is possibly associated with the construction of the 241-SX, 241-SY, 241-S Tank Farms.

### Code: 200-W-12
- **Classification:** Accepted
- **Reclassification:** None

### Names: 200-W-12; 201-W Soil Mound and Plastic Pipe

### Type: Dumping Area
- **Start Date:**
- **End Date:**

### Status: Inactive

### Description: The site consists of a soil mound with one 0.76-meter (2.5-foot) above-ground plastic pipe and one 20-centimeter (8-inch) above-ground plastic pipe topped with tees and elbows. There are also insulated electrical wires and an electrical heat controller.

### Location: The site is located northwest of 201-W and approximately 75 meters (246 feet) north of 13th Street and west of Albany Avenue.

### Related Sites/Structures: The site may be associated with other adjacent test sites. See 200-W-35 and 200-W-10.

### Process Description: During the 1970's, the Atlantic Richfield (ARCO) and Rockwell Research Departments used this area for testing equipment and processes to support the waste management operations. This area was selected for testing because it was adjacent to the REDOX facility (where the Research Department offices were located) and because the area did not contain any contaminated facilities or vadose contamination.

### Code: 200-W-14
- **Classification:** Accepted
- **Reclassification:** None

### Names: 200-W-14; 200 West Heavy Equipment Storage Area

### Hanford Site Waste Management Units Report
February 2015
**Type:** Unplanned Release  
**Start Date:** 1/1/1995  
**Status:** Inactive  

**Description:** The site appears as a bare area. Several large, discolored areas were previously documented in this area. During August through October 2014, the adjacent buildings and structures, known as the Engineering Projects and Construction camp, were demolished to slab on grade. This activity also removed the oil stained soil. It was disposed in ERDF. No verification samples were collected.

**Location:** The site is located northwest of the intersection of Bridgeport Ave. and 19th Street, in 200 West Area. It is near the 2713 WB Maintenance Shop. It was also adjacent to several craft shop buildings.

**Related Sites/Structures:** The site is associated with the building trades craft shops and support structures.

**Process Description:** The site was a heavy equipment (including cranes, forklifts, diesel generators, backhoes, vehicles) parking area with five or six large spots of petroleum contaminated soil. Contaminated soil was encountered down to a depth of 0.61 meters (2 feet) or more. During the 1995 site visit, the equipment continued to overflow and leak. No drip pans or containment were being used.

<td>200-W-21; 204-T Unloading Station; T-Plant Waste Railcar Unloading Facility; Unloading Station 1 and Unloading Station 2</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Type:** Pump Station  
**Start Date:** 1/1/1966  
**Status:** Inactive  
**End Date:** 1/1/1968  

**Description:** The unloading station consisted of two unloading platforms, Unloading Station 1 and Unloading Station 2. The platforms and piping from both stations were removed in 1996. The area has a short railroad siding extending from the main rail line into T-Plant. The concrete structure foundations remain and are posted with Underground Radioactive Material signs.

**Location:** The 204-T Unloading Station platform structures were located west of 221-T at the north end of the 216-T-34 crib.

**Related Sites/Structures:** The site is associated with the 216-T-34 crib, 216-T-35 crib and the 340 facility in 300 Area. The pipeline from Unloading Station 1 to the 216-T-34 crib is sitecode 200-W-196-PL. The pipeline from Unloading Station 2 to the 216-T-35 crib is sitecode 200-W-197-PL.

**Process Description:** The platform structures were used to unload 300 Area liquid laboratory waste sent in railroad tanker cars from the 340 Facility. The waste was pumped into the adjacent 216-T-34 and 216-T-35 Cribs.
There are also two small, posted URMA's located under the abandoned steam line, on the south end of this site.

Location: The site is located northwest of the 202-S Facility.

Process Description: The 203-S, and 205-S Facilities were constructed in the early 1950's to process and decontaminate the uranium nitrate hexahydrate (UNH) produced by Reduction Oxidation (REDOX) operations. The primary process unit consisted of a column filled with silica gel that removed traces of fission products from the UNH. The silica gel column (SG-1) was located in the underground 205-S Vault. The vault also contained a waste neutralization tank. Operations in the vault were accomplished remotely. The 205-S Facility was a two story, aboveground, chemical make-up building. It contained two chemical make-up tanks, a UNH sample room and extensive piping connected to the REDOX facility and the underground vault. The 203-S Facility was an aboveground UNH storage facility that consisted of two 19,000 liter (5,000 gallon) stainless steel tanks that were set in an open concrete basin. There was also a 204-S Tank Farm, that consisted of four 190,000 liter (50,000 gallon) above-ground tanks set in two open concrete basins. A UNH Unloading Facility was located at the adjacent railroad siding. An above-ground UNH pipeline connected the 203-S, 204-S, 205-S Area to the 224-U Facility. During the REDOX Plant operation, the UNH solution was pumped from REDOX to the 205-S silica gel column for purification. The purified UNH was stored in the 203 and 204 tanks and the routed to 224-U, via an above ground line, for final processing. The fission products left in the silica gel column were stripped out with nitric acid. The acid was neutralized and sent to cribs. UNH from the PUREX Plant were transported by truck to the unloading station and placed in the 204-S tanks. The PUREX solutions were then processed through the silica gel column. After REDOX shut down (1965), the 203-S and 205-S were placed on standby. The Unloading Station was converted to a railcar unloading station. The 204-S tanks continued to store material from the Unloading Station. Shipments included thorium nitrate from PUREX, 100-N Reactor decontamination solutions and 300 Area Laboratory wastes. The thorium nitrate was stored in tanks 204-S-1, 204-2 and 204-3. After an extended storage time, the thorium nitrate was shipped to Fernald, Ohio. The 203-1, 203-2 and 203-3 tanks were flushed. Tank 204-S-4 tank was used to hold the 100-N Reactor and 300 Area wastes. Tank 4 was connected to the 240-S-151 Diversion Box so that waste could be transferred to tank farms. Substantial dose rates were associated with these shipments. Several feet of sludge built up in the bottom of tank 4 and increased the dose rate problem. Increasing dose rate issues and contamination spreads lead to the construction of an enclosed unloading facility in 200 East Area (204-AR) that opened in 1981 and replaced this outdoor unloading station at REDOX.

Code: Classification: Accepted
Names: 200-W-42; 200-W-42-PL; U Plant Radioactive Process Sewer from 221-U to 216-U-8 & 216-U-12 Cribs
Reclassification: None
Type: Radioactive Process Sewer
Start Date: 1/1/1952
Status: Inactive
End Date: 1/1/1988
Description: A large portion of this pipeline was removed in 2006. The portion removed was from the neutralization tank (southward) to the 216-U-8 crib. The excavation (approximately 15 feet deep) was left open when remediation activities ceased in 2006. The open trench is marked with steel posts along the entire length. The angle of the side slopes were greater than the requirements for safe entry. The steepness of the slope resulted in surveillance, tumbleweed
removal and sampling activities being conducted remotely from the top of the trench. Blown in tumbleweeds and live, growing contaminated tumbleweeds in the open trench caused the area to be posted as a Contamination Area. In 2010, six to 36 inches of clean backfill material was added to the open excavation on the south side of 16th Street. The area was downposted to Underground Radioactive material Area. In 2012 six to 36 inches of clean backfill was added to the open excavation on the north side of 16th Street. This activity achieved a safe side slope and covered residual radiological contamination. The Contamination Area on the north side of 16th Street was downposted to an Underground Radioactive Material Area in July 2012. A portion of the pipeline from 221-U to the neutralization Pit still remains. The portion of the pipeline from 216-U-8 to 216-U-12 crib is also still intact.

Location: The waste site is an underground pipeline that extends from the 221-U Building to the 216-U-8 and 216-U-12 Cribs. It is located west of Beloit Avenue. A portion of the pipeline is north of 16th Street, but the majority of it is located south of 16th Street.

Release Description: Over the years, growing contamination over the pipeline absorbed radioactive contamination. The posted contaminated area over the pipeline south of 16th Street was given the number UPR-200-W-163.

Process Description: The underground vitrified clay pipeline transferred process condensate from the 221-U and 224-U Buildings and the 291-U Stack to the 216-U-8 and 216-U-12 Cribs. The waste was acidic. The pipeline was originally connected to the 216-U-8 Crib which became active in 1952. The 216-U-12 Crib was built in 1960 to replace the 216-U-8 Crib when it showed potential signs of cave-in. A WYE joint was made in the 216-U-8 Crib pipeline to reroute and extended the pipeline to the 216-U-12 Crib.

---

Code: 200-W-51
Names: 200-W-51; Septic Tank (Abandoned)
Type: Septic Tank
Status: Inactive
Description: The site is an abandoned septic tank that has been filled and covered. The septic tank was discovered during excavations (for exhauster upgrades) outside 241-SY Tank Farm. The tank is not marked or posted.
Location: The site is located north (and slightly east) of the 241-SY-101 tank, north of the 241-SY Tank Farm fence.

---

Code: 200-W-53
Names: 200-W-53; Contaminated Soil East of 207-T Retention Basin
Type: Unplanned Release
Status: Inactive
Description: This site was an area of surface soil contamination located east of the 207-T Retention Basins. It was identified in 1994, resulting in approximately 155,706 square feet of land being marked and posted as a Soil Contamination Area (SCA). The contaminated soil was scraped and placed inside the 207-T Retention Basin. The scraped area is currently posted as an Underground Radioactive Material Area (URM). A site visit in 2014 found the posting had not changed.
Location: The site is a large area of posted Underground Radioactive Material, located east of the 207-T Retention Basin. The source of the contamination was assumed to be the 241-T Tank Farm and the 207-T Retention Basin. A small Underground Radioactive Material area surrounding well 299-W11-28, on the west side of the retention basin, is considered to be part of 200-W-53 also.

Release Description: Specks of contamination spread from the operation of 241-T Tank Farm on the wind.

Related Sites/Structures: The site is associated with the 207-T basin.

---

Code: 200-W-54
Names: 200-W-54; Contamination Migration from 241-SX Tank Farm
Type: Contamination Migration
Status: Inactive
Description: This site is an expanding area of contamination migration. A major radiological zone reduction activity was done in October 2011. Three and one half acres were covered with gravel and downposted to Underground Radioactive Material Area. The original unplanned release was defined in 1997. It was a large, irregular shaped Soil Contamination Area (SCA) located on the east side of 241-S/SX Tank Farms. In 1997, it measured approximately 175 meters (575 feet) by 100 meters (330 feet). Another Global Positioning Survey was done in 1998. The posted Soil Contamination Area had been extended approximately 50 meters (165 feet) to the west (up to the tank farm fence) and approximately 200 meters (660 feet) in the north-south direction. A site visit in August 2000 found multiple additional radiologically chained and posted areas in this vicinity. There is also one separately posted Contamination Area located north of 241-SY Tank Farm, across a gravel road. In 2009, contaminated rabbit feces were found outside the posted areas. Some areas of rabbit feces and specks were delineated and posted as a Contamination Area. The posted area size and shape varies with additional radiological surveys.

Location: The site is located east and north of the 241-S, SX, SY Tank Farm fence. It extends eastward to the west edge of the 216-S-9 Crib. The posted area size and shape varies often, with additional radiological surveys.

Related Sites/Structures: The site is associated with activity in the 241-S, SX and SY Tank Farms.

---

Code: 200-W-55
Names: 200-W-55; Dumping Area North of 231-Z
Type: Dumping Area
Status: Inactive
Description: The site consists of scattered debris inside the north end of a large depression. The debris consists of concrete rubble, wood, cans, pipes and rusted sheet metal. The site is not marked or radiologically posted.

Location: The site is located approximately 240 meters (800 feet) north of the 231-Z building.

---

Code: 200-W-63
Classification: Accepted

Hanford Site Waste Management Units Report
February 2015
Names: 200-W-63; Contaminated Concrete Pad  
**Reclassification:** None

**Type:** Unplanned Release  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site was a "T" shaped concrete pad that had been posted with Surface Contamination Area signs. A site visit in September 1999 found the pad had been covered with gravel and reposted as Underground Radioactive Material.

**Location:** The pad is located approximately 180 meters (591 feet) northwest of 241-TY Tank Farm and 80 meters (262 feet) south of 23rd Street in 200 West Area.

**Process Description:** Employees who have worked in 200 West Area state the pad was used to store radiologically contaminated tanks in the late 1980's. The tanks were removed in 1991 and the pad was left posted as a Surface Contamination Area.

---

**Code:** 200-W-67  
**Classification:** Accepted

**Names:** 200-W-67; Contaminated Soil at the Corner of Cooper and 16th Street  
**Reclassification:** None

**Type:** Unplanned Release  
**Start Date:** 1/1/1998

**Status:** Inactive  
**End Date:**

**Description:** The site is currently posted as an Underground Radioactive Material area.

**Location:** The site is located inside 200 West Area, east of the 16th Street and Cooper Ave. intersection. It is adjacent to the 216-U-3 Crib.

**Release Description:** A radiological survey done by the 200 West Tank Farm Radiological Protection group in April 1998 identified contamination specks and a contaminated ant hill near the intersection of 16th Street and Cooper Ave. The maximum reading on the specks was 11 mr/hr. Another speck was found that read 6 mr/hr. Other contamination levels ranged from 500 counts per minute to 70,000 counts per minute. The ant hill read 3000 counts per minute. Some of the contamination was removed as it was found. The rest of the area was posted as a Contamination Area (CA) in April 1998. The source of the contamination has not been determined.

---

**Code:** 200-W-71  
**Classification:** Accepted

**Names:** 200-W-71; Undocumented Burn Pit; Undocumented Trench  
**Reclassification:** None

**Type:** Trench  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The open trench was visible on a 1948 aerial photograph of 200 West Area. The trench is also visible on photograph number 3757, taken in May 1956. Smoke is emitting from the trench, indicating it was used as a burn pit. The trench has been backfilled. The area where the trench had been located is not marked or posted. The area seems somewhat disturbed and is covered with cheatgrass and some rabbitbrush.

**Location:** The open trench was located southeast of the 221-U facility. It was south of 16th Street and east of Beloit Avenue.

**Related Sites/Structures:** The site is associated with the Construction Surface Laydown Area (sitecode 200-W CSLA).
It is not known exactly what the trench was used for. Hanford drawing H-2-1495 shows the trench and labeled it "Maintenance Disposal Ground". The 1948 aerial photograph shows an open trench and a spoil pile. Historical photographs from 1950 and 1956 show smoke emitting from the trench, indicating it was used as a burn pit. There are no designated burial grounds at this location. Later, the same area was used as a construction lay down area for the reconfiguration of U Plant for the uranium recovery process. When choosing the site for the 216-U-17 Crib, a meeting was held on July 2, 1987 with several knowledgeable long time employees. The subject of the existence of an old burial ground located adjacent to the 216-U-17 Crib site was discussed. The obvious surface debris was attributed to the surface lay down area that supported the U Plant re-construction activities. There was a general recollection among the older employees that natural uranium was once sent to a trench in this area. However, no radioactivity was ever detected during various core sampling done in the area over the years.

The site consists of four underground Radiological Logging System (RLS) equipment calibration silos. The silos are galvanized steel containers with metal lids bolted on top. The silos have somewhat different design constructions, for calibrating different types of equipment. One type consisted of a 25 centimeter (6 inch) capped well casing is inserted through the centers of the silos. There are two risers with bolted lids adjacent to the well casing. The silos are posted with Underground Radioactive Material signs.

Three calibration silos are located west of the 202-S building, south of the 276-S building and north of the 211-S tanks. One calibration silo is located west of the 211-S tanks, across an asphalt access road.

In the late 1970's, test well mockups were used to calibrate in-well radionuclide detectors. The calibration mockups were constructed of a steel container approximately 2.4 meters (8 feet) deep filled with soil. Tubes containing radioactive sources were inserted into the soil at distances of 2.5, 7.6, 15, 30, 46 and 61 centimeters from the well casing that was located in the center of the mockup. The mockup silo was buried so that a Radiological Logging System vehicle could drive up to the calibration silo and drop its logging probe into the center well casing.

The site was a small area marked with posts and chain, posted with Contamination Area signs. After being backfilled with gravel, the area was downposted to Underground Radioactive Material.

The site is located adjacent to the railroad track, west of 216-U-16 Crib and east of the stabilized 216-U-14 Ditch.
### Site 1: Spoils Pile/Berm

- **Code:** 200-W-80
- **Classification:** Accepted
- **Reclassification:** None
- **Names:** 200-W-80; Mound of Contaminated Soil Southwest of T Plant; Stabilized Contaminated Soil Area Southwest of T Plant
- **Type:** Spoils Pile/Berm
- **Status:** Inactive
- **Start Date:**
- **End Date:**

**Description:**
The site is a gravel area surrounded with post and chain and Underground Radioactive Material Area signs. The site had been a mound of soil surrounded with radiation rope and posted with Contamination Area signs. The mound was approximately 1.5 meters (5 feet) high, 8.2 meters (27 feet) long, and 3 meters (10 feet) wide. The mound of soil and the surrounding area contained many pieces of asphalt, similar to that in the adjacent parking lot of T Plant. The mound and surrounding area is covered by a thin growth of cheatgrass and tumbleweeds. About 3 meters (10 feet) east of the site is a small posted URM, with one capped well inside the posted area and one just outside. The capped well outside is locked and has a warning of potential contamination. Across the northern part of the contamination area are fence posts marking an underground pipeline, traveling east-west, posted as a URM. Another posted underground pipeline goes under the mound of soil, in a north-south direction, and is also posted as a URM.

**Location:** The site is located west of 221-T and northeast of the 241-T-361 settling tank. It is about 15 meters (50 feet) west of the steam pipeline.

### Site 2: Unplanned Release

- **Code:** 200-W-81
- **Classification:** Accepted
- **Reclassification:** None
- **Names:** 200-W-81; Contaminated Tumbleweed Fragments Along Railroad Track East of 218-W-3AE
- **Type:** Unplanned Release
- **Status:** Inactive
- **Start Date:**
- **End Date:**

**Description:**
The site was three posted Contamination Areas on the railroad track east of the burial ground, south of the 610 Gate of the 200 West Area fence. In 2009, each Contamination Area was radiologically surveyed and downposted to Soil Contamination Areas. Later, six inches of clean gravel was placed on the areas and the postings were changed Underground Radioactive Material Areas.

**Location:** The sites are located east of the 218-W-3AE Burial Ground along the railroad track, south of 12th Street.

### Site 3: Crib Unloading Station

- **Code:** 200-W-82
- **Classification:** Accepted
- **Reclassification:** None
- **Names:** 200-W-82; Crib Unloading Station; Risers East of 216-TY-201 and 216-T-26, 216-T-27 and 216-T-28 Cribs; Truck Unloading Station
- **Type:** Product Piping
- **Status:** Inactive
- **Start Date:** 1/1/1960
- **End Date:** 1/1/1966

**Description:**
The site consists of two concrete pads with flanged risers, surrounded by Contamination Area postings.
**Location:** The site is located east of Camden Avenue, east of the 216-TY-201 Flush Tank and 216-T-26, 216-T-27, and 216-T-28 Cribs.

**Related Sites/Structures:** The site is associated with the 216-T-27 and 216-T-28 Cribs. The pipeline associated with the unloading station is described in 200-W-188-PL.

**Process Description:** Based on the available information, it is believed that this site is a liquid waste truck unloading station. It is assumed that the short pipeline, shown on drawing H-2-2733, extended eastward to the risers. The unloading station was built to accommodate tanker trucks unloading 300 Area liquid wastes into the 216-T-27 and 216-T-28 cribs. The unloading station jetted waste from the trucks to the cribs and was capable of unloading two trucks at a time.

**Names:**

- **Type:** Unplanned Release
- **Status:** Inactive
- **Description:** The site had been a posted Contamination Area extending across the railroad track north of the 2727-W Sodium Storage building. In April 2007, the contamination was backfilled with clean dirt and the area posting was changed to Underground Radioactive Material. The railroad tracks are no longer used.

- **Location:** The site is located on the railroad tracks, north of the 2727-W building.

- **Related Sites/Structures:** The 2727-W Building, about 100 meters (100 yards) of this site, is posted with "Danger" signs for the sodium stored inside. It, and three nearby mobile trailers, are posted as Radiological Materials Areas.

- **Process Description:** No source of the contamination at this site is obvious from field conditions.

**Code:** 200-W-83

**Classification:** Accepted

**Reclassification:** None

**Start Date:**

**End Date:**

**Code:** 200-W-85

**Classification:** Accepted

**Reclassification:** None

**Start Date:**

**End Date:**

**Names:** 200-W-85; Soil Contamination Area East of 2727W

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The site was originally a posted Soil Contamination Area. The posting surrounded some growing rabbit brush and grass. No soil discoloration or disturbance was apparent. In December 2001, the area was covered with clean backfill material and downposted to an Underground Radioactive Material Area.

**Location:** The site is located approximately 30 meters (100 feet) east of the fenced 2727-WA equipment storage yard.

**Process Description:** It is not known what caused the contamination at this location. No radiological survey could be found to determine when the area was posted or the radiological conditions inside the posted area.

**Code:** 200-W-86

**Classification:** Accepted
**Names:** 200-W-86; Contamination Area Around Light Pole  
**Reclassification:** None

**Type:** Unplanned Release  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site was originally a small, graveled Soil Contamination Area around an active (in use) pole with a street light attached, near the intersection of the U plant railroad sour and Bridgeport Avenue. In December 2001, the utility pole was removed and the area was covered with clean backfill. The area was downposted to Underground Radioactive Material.

**Location:** The site is located northwest of 221-U, on a gravel road known as Bridgeport Avenue.

**Related Sites/Structures:** The light pole is related to the electrical utility facilities.

---

**Code:** 200-W-87  
**Classification:** Accepted

**Names:** 200-W-87; Unplanned Release on Chemical Spur Railroad Track Northwest of 221-U Plant  
**Reclassification:** None

**Type:** Unplanned Release  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site was originally a posted Contamination Area on a portion of the railroad spur. The spur is no longer active. In December 2001, the area was covered with clean backfill material and downposted to an Underground Radioactive Material Area.

**Location:** The site is located approximately 61 meters (200 feet) northwest of the 2714-U building and T-Hopper yard on the U Plant chemical spur railroad track.

**Related Sites/Structures:** UPR-200-W-118 is another unplanned release located on the same railroad spur, but closer to the 221-U building. This unplanned release was associated with material being transported to the 211-U Tank Farm area. The 211-U Chemical Unloading Station was removed and the area stabilized with gravel in 1998. The graveled area is posted with Underground Material Area signs. The demolished 2714-U was in this area.

**Process Description:** The chemical spur railroad track was used to transport chemicals to and from the 211-U Tank Farm and also to transport "T-Hopper" containers. The T-Hoppers contained calcined, uranium powder that had been processed in the 224-U Uranium Trioxide (UO3) plant. They were stored in a fenced area west of the 2714-U Building. However, the posting on this spur is the result of rail cars and engine parked here (see Site Comment).

---

**Code:** 200-W-89  
**Classification:** Accepted

**Names:** 200-W-89; 252-U; C8S17 Substation; U Plant Electrical Substation; U-Cat Substation  
**Reclassification:** None

**Type:** Foundation  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site was a posted, gravel Underground Radioactive Material (URM) area, located where the 252-U Electrical Substation had been located. The site is now located within the boundaries of the larger Underground Radioactive Material Area, known as 200-W-136. The 200-W-136 WIDS site includes the back side of 221-U and also the demolished 224-U, 224-UA, 203U, 203UX and the 272-U Hot Shop footprints.
**Location:** The site is located near the intersection of Beloit and 16th Street in 200 West Area, east of the (demolished) 224-U building.

**Related Sites/Structures:** The site is associated with 221-U and 224-U and 200-W-136.

**Process Description:** The 252-U Substation provided electric utility support to the 221-U and 224-U facilities.

**Waste Type:** Steam Condensate

**Waste Description:** The waste in this area is residual radioactive contamination in soil. After the electrical substation was decommissioned, a posted Underground Radioactive Material area remains. Laboratory analysis of metal, ceramic pieces and asbestos fibers (August 1998) identified cesium 134 and cesium 137. Some barium, cadmium, chrome and lead was also noted. No PCB's were identified. The radioactive contamination is assumed to have been deposited on the substation from U Plant and 224-U stack emissions.

---

**Code:** 200-W-90  
**Classification:** Accepted

**Names:** 200-W-90; Underground Radioactive Material Areas Posted Along 23rd Street in 200 West Area

**Reclassification:** None

**Type:** Unplanned Release  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site is comprised of three posted Underground Radioactive Material areas. Two are located on the south side of 23rd Street, across from the 218-W-2A Burial Ground. One is located further east, on the south side of 23rd Street, across from the 241-T Tank Farm.

**Location:** The posted areas are located along the south shoulder of 23rd Street, in 200 West Area, between Camden and Dayton Avenues.

**Related Sites/Structures:** It is possible the areas are related to UPR-200-W-63.

**Waste Type:** Misc. Trash and Debris

**Waste Description:**

---

**Code:** 200-W-92  
**Classification:** Accepted

**Names:** 200-W-92; Contaminated Mound of Soil and Debris, Soil Mound West of 241-TY Tank Farm

**Reclassification:** None

**Type:** Dumping Area  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The waste site is a mound of soil is approximately 1.5 meters (5 feet) high. It had been surrounded with chain and posted with Contamination Area signs. Several radiation flags were placed in the mound to identify significant contamination. Rocks, asphalt and chunks of cement were visible. Some vegetation, including rabbitbrush, had been growing on the mound. In April 2007, clean gravel was placed on top of the contamination and the site was down posted to Underground Radioactive Material.

**Location:** The mound is located west of an unnamed gravel road, west of the 241-TY Tank Farm.
**Waste Type:** Sanitary Sewage  
**Waste Description:** Maximum contamination levels of 1,600,000 disintegrations per minute per 100 square centimeters of beta gamma and 14,000 disintegrations per minute per 100 square centimeters of alpha were found on the soil and debris.

| Code: 200-W-101 | Classification: Accepted | Reclassification: None |
| Names: 200-W-101; Contaminated Material West of 216-S-12 Crib | |
| Type: Dumping Area | Start Date: |
| Status: Inactive | End Date: |
| **Description:** The waste site consisted of two large boxes and a rusted metal shaft surrounded with light post and chain. The area had been posted with Contamination Area and Radiation Area signs. The metal shaft was approximately 18 meters (60 feet) long and extends beyond (outside) the posted area chain. The radiological posting was changed to Contamination Area in April 2002. The debris and the radiological posting were removed in July 2011. | |

**Location:** The debris had been located west of Beloit Ave., west of the 216-S-12 Crib.

**Waste Type:** Chemicals  
**Waste Description:** The material inside the posted area consists of two large boxes and a long metal pipe (shaft).

| Code: 200-W-106 | Classification: Accepted | Reclassification: None |
| Names: 200-W-106; Soil Contamination Area Adjacent to 200-W-55 Dump Site | |
| Type: Unplanned Release | Start Date: |
| Status: Inactive | End Date: |
| **Description:** Soil contamination was found and posted on February 13, 2003. In March 2010, the area was surface stabilized and downposted to Underground Radioactive Material. | |

**Location:** The site is located west of the 241-TX Tank Farm, west of the 216-T-25 Trench and northeast of the 200-W-55 debris dump site.

| Code: 200-W-107 | Classification: Not Accepted (Proposed) | Reclassification: None |
| Names: 200-W-107; 222-U Building Stormwater Runoff; Miscellaneous Stream #685 | |
| Type: Injection/Reverse Well | Start Date: |
| Status: Inactive | End Date: |
| **Description:** This french drain structure has been covered with gravel and is no longer visible. It is part of the posted Underground Radioactive Material remediation stabilization area that was created when the 222-U building was demolished in 2005 (see sitecode 200-W-136). The yellow metal cover had a slot on one side and was level with the surrounding ground. In 2003, no aboveground pipes were visible extending from the building to the drain. The drain lid was posted with a "Contamination Area" sign and a label stating "This is Not a Confined Space". |
### Location:
The drain was located six feet east of the back wall of the 222-U Building, just west of 216-U-4B. It is now within the Underground Radioactive Material gravel area known as 200-W-136.

### Related Sites/Structures:
This site is associated with the 222-U Building and 200-W-136.

### Waste Type:
Water

### Waste Description:
Documentation states that the site received stormwater runoff from the east side or backside of the 222-U Building. During the site walkdown, however, it was unclear how the drain received stormwater because no pipes were observed extending from the building into the drain.

### Code: 200-W-108

**Names:**
200-W-108; 222-U Building Stormwater Runoff; Miscellaneous Stream #687

**Type:** Injection/Reverse Well

**Status:** Inactive

**Description:**
This french drain structure has been covered with gravel and is no longer visible. It is part of the posted Underground Radioactive Material remediation stabilization area that was created when the 222-U building was demolished in 2005 (see sitecode 200-W-136). The yellow metal cover had a slot on one side and was level with the surrounding ground. There were no postings on the yellow metal cover and no aboveground pipes were visible extending into the drain. The yellow drain lid was moved to the side, revealing a 0.76 meter (2.5 foot) diameter culvert, approximately 1.2 meters (4 feet) deep. The culvert was dry. No aboveground pipes were visible during the 2003 walkdown that extended to the french drain.

**Location:**
The site is located on the northeast corner (back side) of the 222-U Building. It is now within the gravel area known as 200-W-136.

**Related Sites/Structures:**
The drain is associated with the demolished 222-U building and the 200-W-136 remediation area.

**Waste Type:** Oil

**Waste Description:**
Documentation states that the site received stormwater runoff from the east side or backside of the 222-U Building. During the 2003 site walkdown, it was unclear how the drain received stormwater because no pipes were observed extending from the building into the drain and the top of the drain was even with the surrounding ground.

### Code: 200-W-109

**Names:**
200-W-109; 222-U Building Stormwater Runoff; Miscellaneous Stream #521

**Type:** Injection/Reverse Well

**Status:** Inactive

**Description:**
This french drain structure has been covered with gravel and is no longer visible. It is part of the posted Underground Radioactive Material remediation stabilization area that was created when the 222-U building was demolished in 2005 (see sitecode 200-W-136). The yellow metal cover has a slot on one side and is level with the surrounding ground. There are no postings on the yellow metal cover and no aboveground pipes were visible extending to the drain. When the cover was removed, the drain structure was found to be filled with sand.
Location: The site is located on the east side of the 222-U Building between the 200-W-107 and 200-W-108 french drains. It is now within the gravel area known as 200-W-136.

Related Sites/Structures: This site is associated with the 222-U Building and the 200-W-136 stabilized area.

Waste Type: Soil

Waste Description: Documentation states that the site received stormwater runoff from the east side or backside of the 222-U Building. During the site walkdown, however, it was unclear how the drain could have received stormwater because no pipes were observed extending from the building into the drain.

Code: 200-W-111

Classification: Not Accepted (Proposed)

Names: 200-W-111; 222-U Building Stormwater Runoff; Miscellaneous Stream #394

Type: Injection/Reverse Well

Status: Inactive

Description: This french drain structure has been covered with gravel and is no longer visible. It is part of the posted Underground Radioactive Material remediation stabilization area that was created when the 222-U building was demolished in 2005 (see sitecode 200-W-136). The site was a covered french drain. The yellow metal cover has a slot on one side and was level with the surrounding gravel covered ground. It was posted "Not a Confined Space". The cover had been placed over a 0.61 meter (2 feet) diameter vitrified clay pipe drain structure that was 0.91 meter (3 feet) deep. No underground piping was observed in the drain, nor aboveground pipes extending to the drain, however a steel drain pipe was observed extending downward on the 222-U building. The pipe had been cutoff approximately 0.61 meters (2 feet) above the ground.

Location: The site is located near the southeastern corner of the 222-U Building. It is now within the "Underground Radioactive Material Area" remediation stabilization gravel area known as 200-W-136.

Related Sites/Structures: The drain is associated with the 222-U Building and the 200-W-136 Underground Radioactive Material Area.

Waste Type: Chemicals

Waste Description: Documentation states that the site received stormwater runoff from the east side or backside of the 222-U Building. During the site walkdown, however, it was unclear how the drain received stormwater because no pipes were observed extending from the building into the drain.

Code: 200-W-118

Classification: Accepted

Names: 200-W-118; Miscellaneous Stream #141; Steam Condensate MSS-TRP-006

Type: Injection/Reverse Well

Status: Inactive

Description: The site is a 0.025 meter (one inch) diameter insulated pipe extending into a 1.22 meter (4 foot) diameter french drain structure.

Location: The site is located inside the northeastern corner of the 224-U facility fence. It is north of 16th Street and west of Beloit Ave.
**Process Description:**
Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion. This was a seasonal discharge.

**Waste Type:** Stormwater Runoff

**Waste Description:**
The drain received non-contaminated steam condensate.

Type: Burial Vault  
Status: Inactive  
Start Date: 1/1/1945  
End Date: 1/1/1952  
Description: Three underground vaults are contained in this site. The two original vaults are 3 by 3 by 3.7 meters (10 by 10 by 12 feet) deep, made of 5.1 by 30.5-centimeter (2 by 12-inch) wooden planking, with the tops 1.5 meters (5 feet) below grade. The third replacement vault is a concrete culvert pipe encasement 2.4 meters (8 feet) in diameter and 7.6 meters (25 feet) long and 1 meter (3.2 feet) below grade. The top of the encasement is a 23-centimeter (9-inch) precast concrete cover and the bottom is a 30.5-centimeter (12-inch) thick concrete floor. The disposal chutes for the wooden vault were removed.  
Location: The unit is located southeast of the 222-T Building.  
Waste Type: Not Specified  
Waste Description: This site contains laboratory process sample waste from the 222-T Building.  

---

Location: The site is located northwest of the 202-S Building and north of 216-S-7 Crib.  
Release Description: UPR-200-W-109 states that after repairing the buckled portions of the waste line near the 216-S-9 crib, a pressure test indicated another leak in the line. Additional hydrostatic testing finally forced the water to bubble to the surface. It surfaced inside the radiation zone marking the 218-W-9 burial trench. Dose rates of the liquid were 450 mR/hr, but as the water sank back into the soil, the dose rate dropped to 20 mR/hr. Excavation of the liquid bubble site disclosed a vertical buckle in the pipeline with a sizable break in the line at that point. The event occurred in 1969. (RHO-CD-673)  
Related Sites/Structures: The waste site is associated with pipeline 200-W-139-PL. The pipeline runs beneath the eastern edge of the 218-W-9 posted area. The Unplanned Release UPR-200-W-109 documents a break in the (200-W-139-PL) pipeline occurred inside the posted area of the 218-W-9 waste site.  

---

Type: Receiving Vault  
Status: Inactive  
Start Date: 1/1/1948  
End Date: 1/1/1974  
Description: The unit is a concrete vault partially underground with 3 steel risers and one vent structure.
protruding from holes in the top. The vault contains two tanks. It is posted with Contamination Area/Radiation Area signs and Restricted Access Unsafe Structure, Confined Space and IMUST signs.

Location: The site is located approximately 36.6 meters (120 feet) east of 231-Z building.

Release Description: In September 2002, alpha contamination was discovered on the concrete surface, around the riser. Maximum contamination levels were 210,000 disintegrations per minute (direct) and 420 disintegrations per minute removable.

Related Sites/Structures: The site is related to 231-Z building, 216-Z-5, 216-Z-6, 216-Z-7, 216-Z-10 and UPR-200-W-130. The pipelines from 231-Z to this vault are sitecode 200-W-199-PL. The pipeline from the vault to 216-Z-5 is sitecode 200-W-202-PL. The pipeline from the vault to 216-Z-7 is sitecode 200-W-203-PL. The pipeline from the vault to 216-Z-10 is 200-W-204-PL.

Process Description: The 231-W-151 vault tanks were installed to receive drainage from about 75 floor drains in Building 231-Z. Solids in the floor drainage would settle out leaving sludge and sediment in the bottom of the tanks. Waste was diverted to the 216-Z-5, 216-Z-6, 216-Z-7 cribs and the 216-Z-10 Reverse Well through this vault. The tanks were used for neutralizing 231-Z Building wastes prior to disposal to a crib. Since 231-Z was used to finish plutonium, any wastes or chemicals generated or used in the process may have conceivably been introduced to the 231-W-151 vault tanks.

Description: Tank 231-W-151-001 is located within the 231-W-151 Vault. It is a 15,140 liter (4000 gallon) stainless steel tank that received drainage from the 231-Z building floor drains. The drainage was routed to 231-W-151-002, which when filled, overflowed into 231-W-151-001. The solids would settle out into the tanks and the supernate was discharged to the 216-Z-7 crib. Tank operations began in 1948 and were discontinued in 1974. The inlet lines to the tank have been blanked off. In 1974, a sample was taken that indicated 231-W-151-001 contained only 0.001 grams of plutonium. The tank contents were reported to be 5,413 liters (1430 gallons) of supernate and no sludge.

### Tank 231-W-151-002

**Status:** Inactive  
**End Date:**  
**Description:** Tank 231-W-151-002 is located within the 231-W-151 Vault. It is a 3,596 liter (950 gallon) stainless steel tank that received drainage from the 231-Z building floor drains. The solids would settle out into the tanks and the supernate was discharged to the 216-Z-7 crib. Tank operations began in 1948 and were discontinued in 1974. The inlet lines to the tank have been blanked off. In 1974, a sample was taken that indicated 231-W-151-002 contained 228 grams of plutonium in the sludge and less than 0.001 grams of plutonium in the supernate. The tank contents were reported to be 3,615 liters (955 gallons) of supernate and 45 liters (12 gallons) of sludge.

### The SubSite is Part Of:

**Code:** 231-W-151  
**Names:** 231-W-151; 231-W-151 Sump; 231-W-151 Vault; 231-W-151-001 (Tank); 231-W-151-002 (Tank); 231-Z-151 Sump; IMUST; Inactive Miscellaneous Underground Storage Tank

### Tank 270-W

**Code:** 270-W  
**Names:** 270-W; 270-W Neutralization Tank; 270-W Tank; IMUST; Inactive Miscellaneous Underground Storage Tank  
**Classification:** Accepted  
**Reclassification:** None  
**Type:** Neutralization Tank  
**Start Date:** 1/1/1952  
**End Date:** 1/1/1960  
**Description:** There is no visual evidence for this tank. The tank is located beneath the cement foundation of the 2715-UA building. The 2715-UA building was removed in August 2005, leaving the foundation slab in place. The 270-W tank risers are protected with a cement block. A review of drawings indicated the 2715 UA building was placed over the 270-W tank. The 270-W consists of an underground, stainless steel tank that is 2.7 meters (9 feet) tall and 2.7 meters (9 feet) in diameter. The nominal capacity of the tank is 14,300 liters (3780 gallons).

**Location:** The unit is located under the northeast end of 2715-UA building, inside the 224-U facility fence.

**Related Sites/Structures:** The tank is associated with the 224-U facility and pipeline sites 200-W-42-PL and 200-W-151-PL.

**Process Description:** The tank was filled with limestone and used to neutralize acidic process condensate generated from the 224-U building. Following the pH adjustment, the waste was released to the 216-U-8 crib via a 15 centimeter (6 inch) VCP line. The 216-U-8 crib was taken out of service in 1960 and replaced with the 216-U-12 crib. A letter report, written in 1974, indicated that the 270-W tank was part of the waste line to the 216-U-12 crib. The report states that "the UO3 plant is scheduled to restart in 1977. Since the integrity of the 270-W tank could not be assured, a bypass line should be installed around the tank before the plant begins to discharge waste". The letter also states that based on the last liquid to flow through the tank, the liquid composition in the tank may include 2.64 X 10-9 curies/gallon of beta emitters, 9.69 X 10-5 grams/gallon of uranium and 1 X10-9 grams/gallon of plutonium.

### Tank 2607-W3

**Code:** 2607-W3  
**Names:** 2607-W3  
**Type:** Septic Tank  
**Status:** Inactive  
**Classification:** Accepted  
**Reclassification:** None  
**Start Date:** 1/1/1944  
**End Date:** 8/1/1998  
**Description:** The tank was filled with limestone and used to neutralize acidic process condensate generated from the 224-U building. Following the pH adjustment, the waste was released to the 216-U-8 crib via a 15 centimeter (6 inch) VCP line. The 216-U-8 crib was taken out of service in 1960 and replaced with the 216-U-12 crib. A letter report, written in 1974, indicated that the 270-W tank was part of the waste line to the 216-U-12 crib. The report states that "the UO3 plant is scheduled to restart in 1977. Since the integrity of the 270-W tank could not be assured, a bypass line should be installed around the tank before the plant begins to discharge waste". The letter also states that based on the last liquid to flow through the tank, the liquid composition in the tank may include 2.64 X 10-9 curies/gallon of beta emitters, 9.69 X 10-5 grams/gallon of uranium and 1 X10-9 grams/gallon of plutonium.
Description: In August 1998, under project W-396, the 2607-W3 Septic Tank was pumped, sampled, filled with sand and abandoned in place per WAC codes. The 2607-W3 Septic Tank was constructed of reinforced concrete. At one time, the eastern access was posted with a Radioactive Material warning sign. This system includes a drain field that was expanded in the 1950's.

Location: This unit lies northeast of the 241-T-361 Settling Tank, approximately 61 meters (200 feet) north of 23rd Street and 244 meters (800 feet) southwest of the 224-T Building.

Related Sites/Structures: The 2607-W3 Septic Tank as associated with the 221-T, the 222-T, the 224-T, and the 271-T Buildings.

Process Description: The 2607-W3 Septic Tank and associated drain field were designed to accept sanitary sewer effluent from the 221-T, the 222-T, the 224-T, and the 271-T Buildings. After being properly abandoned, the 2607-W3 effluent was redirected to the 2607-W1 system.

---

Code: 2607-W4  Classification: Accepted
Names: 2607-W4; T Plant Septic Tank and Drain Field  Reclassification: None
Type: Septic Tank  Start Date: 1/1/1944
Status: Inactive  End Date: 1/1/1998

Description: The 2607-W4 Septic Tank is a single compartment tank constructed of reinforced concrete. The drain field measures 3.1 by 9.2 meters (10 feet by 30 feet). The site is surrounded by a light chain barricade. At one time the area was marked with surface contamination warning signs. A site visit in October of 1998 indicates the area is no longer a Radiation Area. This system includes a drain field and receives sanitary wastewater and sewage from the 221-T Canyon Building.

Location: This unit lies northwest of the 221-T Canyon Building and southwest of the 216-T-1 Ditch.

Related Sites/Structures: The 2607-W4 Septic Tank is associated with the 221-T Canyon Building.

Process Description: The 2607-W4 Septic Tank and associated drain field are designed to accept sanitary sewer effluent from the 221-T Canyon Building.

---

Code: 2607-W5  Classification: Accepted
Names: 2607-W5; Septic Tank and Drain Field  Reclassification: None
Type: Septic Tank  Start Date: 1/1/1944
Status: Active  End Date: 12/31/1997

Description: The 2607-W5 Septic Tank is a single-compartment tank constructed of concrete and has three entry openings on the top, each protected by a wooden cover. A pipe connects the septic tank to a concrete diversion box, and then to a second concrete diversion box before entering the drainfield. The septic tank and diversion box are currently located within an Underground Radioactive Material (URM) area related to the 216-U-1, 216-U-2 cribs and the 241-U-361 stabilization. The septic system has two drain fields. The original drain field is located west and north of the septic tank, outside the URM area boundary. The replacement tile field is located north and east of the septic tank.

Location: This unit lies southwest of the 221-U Canyon Building and east of the 207-U Retention Basin. It is north of the 241-U-361 settling tank.
DOE/RL-88-30
Rev. 24

Release Description: UPR-200-W-19 occurred in 1953. The 241-U-361 tank overflowed and caused the ground to become contaminated. The Underground Radioactive Material area, located adjacent to the 2607-W5, is the result of the surface stabilization of this unplanned release.

Related Sites/Structures: The 2607-W5 Septic Tank is associated with the 221-U Canyon Building, the 222-U Laboratory, the 224-U Facility, the 271-U Building and UPR-200-W-19.

Process Description: The 2607-W5 Septic Tank and associated drain field were designed to accept sanitary sewer effluent from U Plant facilities. In 1998, the system was being used by MO-107 and MO-419.

The original tile field was built in 1944. A replacement tile field was built east of the original tile field in 1955.

Code: 2607-W6
Names: 2607-W6
Type: Septic Tank
Status: Active
Start Date: 1/1/1951
End Date:
Description: The 2607-W6 system was reconstructed in 1995. The unit has a sign correctly labeling it. A concrete structure with three metal manhole covers lies on the surface. The 2607-W6 Septic Tank is constructed of reinforced concrete and receives sanitary wastewater and sewage.

Location: This unit lies southwest of the 222-S Laboratory and southeast of the MO-291.

Related Sites/Structures: The 2607-W6 Septic Tank is associated with the 202-S, the 222-S, and the 2704-S Buildings and MO-037, MO-039, MO-028, MO-924, and MO-936.

Process Description: The 2607-W6 Septic Tank and associated drain field are designed to accept sanitary sewer effluent from the connected facilities.

Code: 2607-W7
Names: 2607-W7; Septic Tank
Type: Septic Tank
Status: Inactive
Start Date: 1/1/1954
End Date:
Description: The 2607-W7 Septic Tank was a small, 950 liter (350 gallon) tank constructed of reinforced concrete. Previous documentation stated the 2607-W7 Septic System includes a septic tank and drain field that lie within a radiation zone. A site visit done in 1999 found the septic tank to be located between two Underground Radioactive Material areas. The location of the drain field was visually not apparent. HNF-SD-LL-SP-001 shows the drain field west of the septic tank.

Location: This unit lies 14 meters (45.9 feet) north of the northernmost corner of the 221-U Canyon Building.

Related Sites/Structures: The 2607-W7 Septic Tank is associated with the 221-U Canyon Building.

Process Description: The 2607-W7 Septic Tank and associated drain field are designed to accept sanitary waste sewer effluent from the connected facility, a single restroom.

<td>Receiving Vault</td>
<td>None</td>
<td>Inactive</td>
<td>1/1/1952</td>
<td>1/1/1976</td>
<td></td>
</tr>
</tbody>
</table>

**Description:** The vault is a below grade, reinforced concrete structure. There are nine compartments arranged in two rows with a 189,000 liter (50,000 gallon) tank in each compartment. A concrete wall separates the two rows of tanks. In addition to the tanks, the vault contains miscellaneous agitators, pumps, and valves. It is marked and posted with Underground Radioactive Material area signs. The exhaust stack and dry well are included in this site. See sub-site descriptions.

**Location:** This site is located northeast of the 221-U Building, west of Beloit Ave.

**Release Description:** Tank leaks within the vault were noted in the 1960's. 241-WR-001 was reported to have collapsed during the TBP operation (1952-1958) and was observed to be empty in 1965. However, the 001 sump contained 51,786 liters (13,700 gallons) of liquid. Samples taken at that time indicated the liquid to be slightly contaminated water. All of the sumps and tanks were pumped out in 1965. The liquid was sent to the 216-U-12 crib. When tank 002 was pumped, it floated loose from its base, rupturing the lines connected to the tank. A significant clean up and repair effort was required to return the facility to service. Tanks WR-001, WR-002, WR-004 and WR-005 are suspected to have leaked. Individual specific occurrence reports were not issued. The "hot side" tanks have reportedly contaminated the "cold side" of the vault.

**Related Sites/Structures:**
- The vault is associated with the 296-U-6 Stack, 221-U Plant Uranium Recovery processes, Thorium Recovery process, 200-W-244-PL, 200-W-248-PL, 200-W-105-PL, 241-UX-154 and BC Cribs and Trenches.

**Process Description:** The 241-WR Vault received uranium and thorium slurry solutions (via underground encased pipelines) from the single shell tanks and prepared the waste to be fed into 221-U facility to extract the uranium and thorium. The 241-WR vault added chemicals and adjusted the pH before it was transferred to the 221-U canyon to be processed through the tributyl phosphate.
extraction columns. The 241-WR vault (WR-001) also received neutralized waste from the 221-U extraction process and stored it until it was transferred back to the tank farms.

During the WR vaults active operation, it stored uranyl nitrate hexahydrate, nitric acid, and tributyl phosphate wastes transferred into the vault storage tanks via underground pipelines. During U Plant Uranium Recovery Process operations (1952 to 1958), uranyl nitrate hexahydrate was stored and used as feed for 221-U. Recovered nitric acid was temporarily stored in WR vault to be used again. Tributyl phosphate wastes were stored in WR Vault before being routed to the BC cribs and trenches via the 241-UX-154 Diversion Box and the Cross Site Transfer line (600-284-PL). Following termination of uranium recovery operations in 1958, the vault was used to store nitric acid and thorium from the REDOX and PUREX processes.

In October 1965, contaminated water, including 3.14 kilograms of thorium, was discharged to 216-U-12 crib.

**Description:** The surface features of the stack were removed in 1986. The remaining below grade structure includes a 1.04 meter (3 foot 8 inch) octagonal concrete foundation extending 1.23 meters (4 feet) below grade, which encases a portion of the 45.72 centimeter (18 inch) stack that extends 0.31 meters below grade.

Above grade features included a 5.08 centimeter (2 inch) drain pipe exited northwest side of the stack, under the duct, and entered the ground at that point; a 1.9 centimeter (0.75 inch) drain pipe exited the duct just before meeting the stack, and flowed straight down, meeting the 5.08 centimeter (2 inch) drain below grade and a 2.54 centimeter (1 inch) fan drain pipe exited the concrete foundation below the fan, above grade. This pipe entered the ground and connected to the 5.08 centimeter (2 inch) pipe and a 60.96 centimeter (24 inch) dry well.

The 3.81 centimeter (18 inch) diameter, carbon-steel, 296-U-6 vault exhaust stack was mounted on a 1.04 meter (3 foot 8 inch) octagonal concrete foundation. The stack extended 14.63 meters (48 feet) above grade level. The stack was used to discharge unfiltered ventilation air from the storage of UNH for feed to 221-U, then from HNO3 storage, and later from the storage of thorium.

The SubSite is Part Of:

</tbody>
</table>
A 5.08 centimeter (2 inch) drain pipe ran from the north side of the concrete stack foundation, southeast to a 60.96 centimeter (24 inch) dry well. The exact location of the dry well is not known. The dry well is located southeast of where the stack once stood.

The basins were filled with high density grout in 2006. The site had been a concrete basin structure divided into two halves. The two sides were separated by a 0.3 meter (1 foot) thick concrete wall. Each basin contained a sump with a sump pump. A 1.8 meter (6 feet) high chain link fence used to surround the basins.

The concrete basins are located inside the Z Plant Exclusion Area fence, south of 236-Z building.

The retention basin is associated with the 241-Z and 234-5Z facilities. Pipelines associated with the basin are discussed in sitecode 200-W-209-PL.

The 216-Z-4 Trench is an inactive waste management unit. The unit was backfilled and deactivated in 1945. The original configuration was a large unlined excavation.

The trench was constructed in 1945 to temporarily receive liquid laboratory waste from the 231-Z Building. The 216-Z-4 Trench was deactivated and backfilled when it was discovered to be too small for the waste stream. The laboratory effluent was rerouted to the 216-Z-6 Crib. Since the 216-Z-6 crib was fed with an aboveground pipeline, it is likely the 216-Z-4 was also fed
The 216-Z-6 is a below grade, inactive waste management unit. The site consists of a rectangular wooden box set in the base of an excavation. The trench was fed by an above ground pipeline.

Location: The crib is located east of the 231-Z Building and north of Nineteenth Street.

Process Description: The 216-Z-6 Crib received process waste from the 231-Z Building, via an overground line from the 231-W-151 Sump. The site was only used for one month, and abandoned due to plugging of the surrounding soil by process sludge and precipitates.

The 216-Z-7 Crib is an inactive below grade waste management unit. The crib trench was backfilled upon retirement in 1967. The crib consists of two parallel wooden structures placed in two shallow parallel trenches within a single terraced excavation. Each wooden box consists of three timber tiers, with a perforated distribution box running the length of the second tier. The interior trenches are backfilled and covered with wood planks.

Location: The site is located east of the 231-Z Building and north of Nineteenth Street.

Process Description: Crib 216-Z-7 received process waste from the 231-Z Building from 1947 to 1967. The crib was built to replace Crib 216-Z-5. A riser on the west side of the crib received 300 Area liquid waste from tanker trucks.

The site consists of a two part drain system. The covered top of the upper french drain is visible on the surface, adjacent to a single cement marker post with a metal plate labeled 216-Z-13 (see 1985 photograph 122440-250cn).
Location: The french drain is located northeast of the 291-Z stack.

Related Sites/Structures: This french drain is associated with include two effluent discharge pipes, the ET-8 exhaust fan turbine, and the 291-Z Building. The pipeline to the french drain is 200-W-214-PL.

Process Description: The lower french drain is constructed of two tile culverts placed end-to-end, and backfilled beneath 9 feet (2.7 meters) of gravel. It is located approximately 6 meters (20 feet) south of the drain structure visible on the surface. Two pipes discharged to the lower french drain. The miscellaneous stream (#261) to the drain has been eliminated. The lower french drain received cooling water and steam condensate from the 291-Z ET-8 exhaust fan turbine, building steam condensate and drainage from the S-13 and S-14 coolers. The upper portion of the drain receives steam condensate from the 291-Z turbine exhaust stack. Due to the common nature of the discharge to the upper and lower drain systems, there is a potential for historical documentation related to the drains to be confusing. Due to the common nature of the waste discharged to the drains, the drains are treated as a single waste site.

Related Sites/Structures: This french drain is associated with include two effluent discharge pipes, the ET-8 exhaust fan turbine, and the 291-Z Building. The pipeline to the french drain is 200-W-214-PL.

Process Description: The lower french drain is constructed of two tile culverts placed end-to-end, and backfilled beneath 9 feet (2.7 meters) of gravel. It is located approximately 6 meters (20 feet) south of the drain structure visible on the surface. Two pipes discharged to the lower french drain. The miscellaneous stream (#261) to the drain has been eliminated. The lower french drain received cooling water and steam condensate from the 291-Z ET-8 exhaust fan turbine, building steam condensate and drainage from the S-13 and S-14 coolers. The upper portion of the drain receives steam condensate from the 291-Z turbine exhaust stack. Due to the common nature of the discharge to the upper and lower drain systems, there is a potential for historical documentation related to the drains to be confusing. Due to the common nature of the waste discharged to the drains, the drains are treated as a single waste site.

Location: The french drain is located northwest of the 291-Z Stack.

Related Sites/Structures: The lower french drain is associated with two effluent discharge pipes, the ET-9 exhaust fan turbine, and the 291-Z Building. The pipeline to the french drain is 200-W-215-PL.

Process Description: The lower french drain receives steam condensate from the turbine of the ET-9 exhaust fan and 291-Z floor drainage. The condensate discharged to the upper drain system has been disconnected and now discharges to the ground. Due to the common nature of the discharge to the upper and lower drain systems, there is a potential for historical documentation related to the drains to be confusing.

Location: The french drain is located northwest of the 291-Z Stack.

Related Sites/Structures: The lower french drain is associated with two effluent discharge pipes, the ET-9 exhaust fan turbine, and the 291-Z Building. The pipeline to the french drain is 200-W-215-PL.

Process Description: The lower french drain receives steam condensate from the turbine of the ET-9 exhaust fan and 291-Z floor drainage. The condensate discharged to the upper drain system has been disconnected and now discharges to the ground. Due to the common nature of the discharge to the upper and lower drain systems, there is a potential for historical documentation related to the drains to be confusing.

Location: The french drain is located northwest of the 291-Z Stack.

Related Sites/Structures: The lower french drain is associated with two effluent discharge pipes, the ET-9 exhaust fan turbine, and the 291-Z Building. The pipeline to the french drain is 200-W-215-PL.

Process Description: The lower french drain receives steam condensate from the turbine of the ET-9 exhaust fan and 291-Z floor drainage. The condensate discharged to the upper drain system has been disconnected and now discharges to the ground. Due to the common nature of the discharge to the upper and lower drain systems, there is a potential for historical documentation related to the drains to be confusing.
Location: The unit is adjacent to the southeast corner of the 2731-Z Building and north of the 291-Z Ventilation Building.

Related Sites/Structures: The french drain is associated with the 291-Z building. The pipeline to the french drain is 200-W-216-PL.

Process Description: The french drain used to receive condensate drainage from the 291-Z building S-12 Evaporator Cooler, but that source was re-routed to the 291-Z Sump, which is batch discharged to the PFP Low Level Waste Treatment Facility.

---

Code: 216-Z-16
Names: 216-Z-16; 216-Z-16 Crib
Type: Crib
Status: Inactive

Description: The site is a rectangular excavation with gravel filling the bottom third. A perforated pipe runs the length of the excavation. The gravel is covered with a polyethylene barrier. The excavation is backfilled to grade.

Location: The crib is located northwest of the 231-Z Building.

Related Sites/Structures: Eleven crib penetrating monitoring wells, one gage well, two monitoring wells adjacent to the crib, a vent riser, and the waste transfer line from 231-Z Building comprise structures associated with this trench. The crib pipeline is sitecode 200-W-200-PL.

Process Description: The crib was used to dispose of 231-Z laboratory waste in the soil column.

---

Code: 216-Z-17
Names: 216-Z-17; 216-Z-17 Ditch
Type: Trench
Status: Inactive

Description: The 216-Z-17 is an inactive waste site has been deactivated and backfilled. During operation this unit was configured as a long excavation that had sloped sides. The carbon steel effluent discharge pipe fed into a metering box that in turn discharged to the open trench.

Location: This unit is due east of the 231-Z Building, and immediately east of the 216-Z-6 Crib.

Related Sites/Structures: Structures associated with the 216-Z-17 Trench include the 231-W-151 Sump Tank, waste transfer lines, the metering box, and the effluent discharge pipe. The pipeline that fed the 216-Z-17 crib is sitecode 200-W-201-PL.

Process Description: The trench was used to dispose of laboratory waste from Laboratory operations in the 231-Z Building.

Code: 216-Z-21
Names: 216-Z-21; 216-Z-21 Seepage Basin; PFP Cold Waste Pond
Type: Pond

Classification: Accepted
Reclassification: Interim No Action (9/15/2005)

Start Date: 1/1/1980

Hanford Site Waste Management Units Report
February 2015

1306
**Site Description:** The site has been evaluated and determined to require No Action. It is a large, unlined soil berm depression. The basin is currently dry and is not radiologically posted.

**Location:** The site is located east of the Plutonium Finishing Plant, outside the security fence. It is southeast of the 216-Z-9 trench, on the west side of Camden Ave.

**Related Sites/Structures:** The site is associated with the 234-5 facility.

**Process Description:** The site is an unlined seepage basin that was constructed to receive PFP non-contact condensate and stormwater run off.

**Closure Info:** The No Action reclassification is documented on form 2005-040. The basin did not receive any radioactive or hazardous waste.

*Hanford Site Waste Management Units Report*

February 2015
Names: 600-70; Solid Waste Management Unit (SWMU)  
#2 - Miscellaneous Solid Waste  
Reclassification: None  
Type: Dumping Area  
Start Date: 1/1/1950  
Status: Inactive  
End Date:  
Description: The site is located on relatively flat terrain except for natural depressions and evidence that trenches may have been dug. Large amounts of construction materials such as concrete, wood, metal, cans, barrels and transite are visible. Numerous areas of burned materials were also observed.  
Location: The site is located 360 meters (1,181 feet) east of REDOX, outside the 200-W Area perimeter fence.  
Waste Type: Sanitary Sewage  
Waste Description: Transite  
Waste Type: Sanitary Sewage  
Waste Description: Suspected friable asbestos.  
Waste Type: Sanitary Sewage  
Waste Description: Metal lathe turnings, glass, lumber and tar.  
Waste Type: Sanitary Sewage  
Waste Description: Concrete, rebar.  
Waste Type: Sanitary Sewage  
Waste Description: Large piles of debris that includes concrete cover blocks, concrete chunks, wood, scrap metal, cans, buckets, barrels, glass and transite are spread over a large area.

Description: The release is not physically marked or posted.

Location: The contamination spread was located on the railroad tracks extending from the 221-T Canyon Building Tunnel to the Heavy Equipment Burial Ground.

Release Description: In 1949, contamination spread from a burial box that had been transported from the 221-T Canyon Building to the Heavy Equipment Burial Ground. After the box was buried, the bulldozer used to cover the trench was found to be contaminated with dust which had readings up to 10,000 counts/minute. A complete survey was made from the Canyon Building to the Heavy Equipment Burial Ground, which revealed a spread of contaminated particles. The most contamination was found in the vicinity northeast of the burial ground.

Waste Type: Equipment

Waste Description: Contamination specks were found along the RR track with readings averaging 7 millirem/hour.

</tbody>
</table>

Description: The Unplanned Release site is described as contamination on the surface above the waste line between the 242-T Evaporator and the 207-T Retention Basin (see 200-W-166-PL). Since the exact location of this 1952 Unplanned Release is not documented, it was considered possible that one of the areas stabilized in 2001 is in the same location as the 1952 line leak. The mapping coordinates for the 1952 contamination have been estimated from the limited information provided. A posted URMA with Bio Barrier signs is currently located at the location indicated in the 1952 hand drawn sketch.

Location: The 1952 release occurred in an underground pipeline causing water to be observed on the surface, east of the 241-TY Tank Farm. The exact location was not documented. A hand drawn sketch in HW-60807 places the release location near the 241-TY east fence. The mapping coordinates have been estimated.

Release Description: In October 1952, a steam coil in the 242-T waste evaporator tank caused ground contamination along the surface above the leaking cast iron pipe which carries cooling water and steam condensate from the waste evaporator building to the 207-T Retention Basin.

Related Sites/Structures: The release is associated with the 242-T Evaporator, 207-T Basin and pipelines 200-W-166-PL.

Process Description: H-2-44511 shows a cast iron pipeline that connects the 242-T Evaporator with the 207-T Retention Basin (see pipeline sitecode 200-W-166-PL). The pipeline carried steam condensate
from the building to the basin. The line runs north to south along the east side of the 241-TY Tank Farm, parallel to an encased waste transfer line.

**Waste Type:** Process Effluent

**Waste Description:** Cooling water and steam condensate from the 242-T waste evaporator that was routed to the 207-T retention basin through an underground cast iron pipeline. The contaminants were not identified, but since 242-T was the source of the stream, the material probably has a similar composition to the liquid discharged to the cribs.

---

**Code:** UPR-200-W-19  
**Classification:** Accepted  
**Reclassification:** None  
**Start Date:** 1/1/1953  
**End Date:**

**Names:** UPR-200-W-19; 241-U-361 Overflow; UN-200-W-19

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The site is an unplanned release. The area where the release occurred is covered with shotcrete and currently marked as a "Underground Radioactive Material" (URM) area that also contains the 216-U-1 Crib, 216-U-2 Crib, the 241-U-361 Settling Tank. A portion of the 2607-W5 tile field is also included in the URM area. In 2014, the posted area was expanded to the east due to growing contaminated vegetation. An area measuring approximately 36 by 36 feet, on the east side of a gravel road, was also included in this expansion.

**Location:** The release occurred north of 16th Street, near the 361-U Settling Tank and the 216-U-1&2 Cribs.

**Release Description:** In the Spring of 1953, organic wastes and cell drainage from the Tributyl Phosphate (TBP) process in 221-U and waste from 224-U (UO3) overflowed to the ground by way of the tank (241-U-361) and crib vents (216-U-1 and 216-U-2). Contamination readings of 11.5 rads per hour at a distance of 7.6 centimeters (3 inches) were reported over an area of approximately 4.6 square meters (50 square feet).

**Related Sites/Structures:** The release is associated with the 221-U, 224-U, 241-U-361 tank and the 216-U-1&2 Cribs.

---

**Waste Type:** Storage Tank

**Waste Description:** The release contained an unknown quantity of organic wastes and cell drainage from the Tributyl Phosphate (TBP) and Uranium Trioxide (UO3) plants with readings to 11.5 rads/hour at 7.6 centimeters (3 inches).

---

**Code:** UPR-200-W-23  
**Classification:** Accepted  
**Reclassification:** None  
**Start Date:** 1/1/1953  
**End Date:** 1/1/1953

**Names:** UPR-200-W-23; Waste Box Fire at 234-5Z; UN-200-W-23

**Type:** Unplanned Release

**Status:** Inactive

**Description:** A 1999 facility walkdown could not locate this unplanned release site. The approximate area is marked with a WIDS sign painted on the asphalt. The event occurred in June 1953.

**Location:** A sketch included in HW-60807 places this release near the south wall of 235-5Z, approximately 61 meters (200 feet) north of the 291-Z Stack.
Waste Type: Process Effluent
Waste Description: Plutonium contamination up to 10,000 disintegrations was spread by a fire in a waste box in June 1953.

Release Description: In June 1953, a fire in a waste box resulted in approximately 28 square meters (300 square feet) of ground contamination. The fire caused a spread of plutonium contamination with readings up to 10,000 disintegrations per minute.

Code: UPR-200-W-33
Names: UPR-200-W-33; Ground Contamination at 224-U; UN-200-W-33
Type: Unplanned Release
Status: Inactive
Description: The release site occurred inside the fenced 224-U facility boundary. The site is no longer marked or posted.
Location: The site is located approximately 28 meters (90 feet) east of the 224-U Building.
Release Description: In March 1955, a leaking flange of the C-5 Condensate Line from the 224-U Building caused a small area 3 by 4.5 meters (10 by 15 feet) of ground to become contaminated.
Related Sites/Structures: The release is associated with the Uranium Recovery process at the 224-U facility.
Waste Type: Process Effluent
Waste Description: A leaking flange in the C-5 condensate line at the 224-U building caused an area of ground contamination measuring approximately 0.9 meters by 0.9 meters (3 foot by 3 foot).

Code: UPR-200-W-36
Names: UPR-200-W-36; Groundwater Contamination at 216-S-1 and 216-S-2
Type: Unplanned Release
Status: Inactive
Description: The 216-S-1 & 2 cribs are currently bare ground, marked by concrete posts and a light chain, posted with "Underground Radiation Material" area and "Cave-in Potential" signs. The well is painted yellow and marked 299-W22-3.
Location: The release occurred at a well located near the east end of 216-S-1 & 2 cribs, east of the 241-SX Tank Farm.
Release Description: On August 2, 1955, process vapors were smelled near the 216-S-1 & 2 cribs. A Radiation Monitor investigated the area and found the well cap on test well 207-S-11 (alias 299-W22-3) to have a dose rate of 4 rad per hour on the well cap. A water sample was collected from the well on August 4, 1955 that resulted in a personnel contamination incident. The sampler also reported a gurgling sound coming from the well. It was concluded that the well casing had failed or ruptured. The rupture was apparently allowing process waste to bypass the crib soil column and flow directly into the groundwater. The well was promptly backfilled with sand.
Related Sites/Structures: The release is associated with the 216-S-1 & 2 cribs and well 299-W22-3.
Process Description: The test well originally consisted of a 20.3 centimeter (8 inch) steel casing driven to a depth of 45.7 meters (150 feet). In January of 1955, the well was extended an additional 50 meters (163 feet), beneath the groundwater table which was at a depth of about 65.5 meters (215 feet) in 1955.

Waste Type: Storage Tank

Waste Description: The 216-S-1 and 216-S-2 Cribbs received cell drainage from the D-1 Receiver Tank and redistilled condensate from the D-2 Receiver Tank in the 202-S Canyon Building. The inorganics found at the site include: aluminum, nitrate, nitric acid, and sodium. The radionuclides found at this site are: cobalt-60, americium-241, cesium-137, uranium, and plutonium. An unknown volume of this waste entered the groundwater beneath the crib through a rupture in the well casing. During the time between the last normal reading from the well (June 1955) and the time the incident was discovered, about 7,500,000 liters (2,000,000 gallons) of liquid waste, with an estimated gross beta activity of 7,500 curies had passed into the crib. Also, within this span of time about 40 grams (1.4 ounces) of plutonium had entered the crib.

Code: UPR-200-W-39
Names: UPR-200-W-39; 224-U Buried Contamination Trench; UN-200-W-39
Type: Unplanned Release
Status: Inactive
Classification: Accepted
Reclassification: None
Start Date: 1/1/1954
End Date: 1/1/1954
Description: The release site is not marked because the 224-UA Building was built over the release location.
Location: According to available references, the release occurred on the southeast side of the 224-U building. The disposal trench is located under the 224-UA (Calciner Building) addition.
Release Description: A leak from 224-U, during March 1954, spread to an area southeast of the 224-U Building. The contamination was placed in a trench that measured 3.1 meters (10 feet) wide by 15.2 meters (50 feet) long. The contamination was covered with 0.9 meters (3 feet) of clean soil.
Related Sites/Structures: The release is associated with the 224-U Facility.

Waste Type: Storage Tank

Waste Description: The release was described as a leak from 224-U. The effected soil was placed in a nearby trench. A later reference described the contamination as uranium, less than 10 nanocuries/gram. No volume estimate is provided.

Code: UPR-200-W-41
Names: UPR-200-W-41; Railroad Contamination; REDOX Railroad Cut Contamination; UN-200-W-41
Type: Unplanned Release
Status: Inactive
Classification: Accepted
Reclassification: None
Start Date: 1/1/1956
End Date: 
Description: The railroad track from the 202-S Tunnel to the first gravel road intersection has been covered with clean backfill material. The berms on the sides of railroad cut have been pushed in and posted as an "Underground Radioactive Material" area.
Location: The release occurred on the railroad right-of-way from the 202-S Railroad cut to the burial
ground. The railroad cut and the railroad track north of REDOX has been backfilled, stabilized and posted as Underground Radioactive Material.

**Release Description:** On July 7, 1956, during the transit of a box containing the J-5 Filter and miscellaneous equipment from the 202-S Building Canyon, spotty contamination up to 1,000 millirads/hour at surface was spread along the right-of-way from the 202-S Building railroad cut to the burrial ground presumably from liquid contained in the burial box. Six spots of 1,000 millirads/hour were found on the east side of the track on the blacktop at the 16th Avenue crossing. The area was immediately roped off and was eventually decontaminated to less than 1,000 counts per minute. Initial surveys indicated spotty contamination from 100 to 500 millirads/hour along the east side of the right-of-way diminishing in frequency from 19th Avenue to the burial ground. A check of the flat car used for the burial revealed low level contamination on all horizontal surfaces of 10,000 to 20,000 counts per minute and several areas on the paper in the southeast corner of the flat car to 3,000 millirads/hour at surface. Special fibreglass deposition filters placed along the tracks did not indicate a general contamination spread.

**Related Sites/Structures:** The site is associated with 202-S and UPR-200-W-42.

**Process Description:** Radiologically contaminated fuel rods were transported to the REDOX facility for processing by rail car. Contaminated material and equipment were transported to the burial grounds on the same rail road track. Over time the railroad track became contaminated.

**Waste Type:** Storage Tank

**Waste Description:** The waste was contaminated with beta/gamma with readings to 1,000 millirads/hour.

---

**Code:** UPR-200-W-44

**Classification:** Accepted

**Names:** UPR-200-W-44; Railroad Track Contamination; UN-200-W-44

**Reclassification:** Rejected (5/12/2014)

**Type:** Unplanned Release

**Start Date:** 1/1/1957

**Status:** Inactive

**End Date:**

**Description:** The waste site was evaluated and reclassified to Rejected in 2014. In 1954, a burial box in transit to a decontamination facility fell to the ground while the train was in motion and lodged against a steam line support. The exact location is unknown.

**Location:** The exact location is not known. Contamination occurred along the railroad track between REDOX and either U Plant or T Plant when the box containing failed equipment fell from the train. (Note: HW-53449 says the box was in route to U Plant, but other references state it was in route to T Plant. T Plant and U Plant were both used as equipment decontamination and repair facilities, but U Plant was used more in the 1960's. It is believed that T Plant is the correct destination).

**Release Description:** On October 24, 1957, a burial box, used to transport failed equipment from REDOX to the T Plant Canyon, was inadvertently pulled from the rail car when one of the box sling cables caught on a railroad tie, or possibly a switch frog. The area was contaminated up to 2 rads/hour. (Note: HW-53449 says the box was in route to U Plant)

**Waste Type:** Equipment

**Waste Description:** The release site is soil contaminated with beta/gamma with readings maximum readings up to 2 rads/hour.

<td>Description:</td>
<td>The railroad track from the 202-S Tunnel to the first gravel road intersection has been covered with clean backfill material. The railroad cut located inside the facility fence is posted as a &quot;Contamination Area.&quot; The section of covered track from the fence to the first gravel road intersection is posted as an &quot;Underground Radioactive Material&quot; area.</td>
<td>Location:</td>
<td>Burial operation of the H-2 Centrifuge from REDOX resulted in spotty contamination in the REDOX, 234-5Z, and 224-U Plant areas. General low level smearable contamination was also found along the railroad right-of-way to the burial ground.</td>
</tr>
<tr>
<td>Release Description:</td>
<td>Problems began when the H-2 Centrifuge was placed in a burial box in the REDOX Railroad Tunnel on December 30, 1957. After a short period of time fumes were observed coming from the centrifuge. Corrective measures to control the escape of fumes were attempted but were generally unsuccessful. After about four hours of this condition, fumes escaped the tunnel and began circulating throughout the REDOX Building via the ventilation system. By 4:30 A.M., December 31, 1957, respiratory protection was required for all personnel entering the north side of REDOX or the 233-S Building. Later, the respiratory protection requirements were extended to the south operating areas of REDOX. Considerable surface contamination was deposited in and around REDOX, including construction work areas outside the building. The centrifuge was transported by train to the burial ground. The burial box was observed to be &quot;puffing&quot; slightly as it proceeded to the burial site but no contamination was observed along the railroad right of way. It was buried at about 10:00 A.M on December 31, 1957. Dose rates related to the centrifuge burial were documented as 185 millirads/hour at 177 meters (580 feet), and about 2 millirads/hour at 0.8 kilometers (0.5 mile). Radiation fields averaging 1 rad/hour during backfilling of the centrifuge box in the burial ground prevented the box from being completely buried in one day. Two employees received face and nostril contamination during the backfill operation. Two days later, radiation surveys revealed a general low level smearable contamination along the railroad right-of-way.</td>

Code: UPR-200-W-51
Names: UPR-200-W-51; UPR-200-W-52; Release from 241-S Diversion Box; UN-200-W-51
Type: Unplanned Release
Status: Inactive
Description: The release site is not currently marked or posted. The area where this release had been located (in 1958) is near an area that was surface stabilized in 1992 (UPR-200-W-165).
Location: The contamination spread southward from the 241-S-151 Diversion Box (inside the 241-S tank farm) to approximately 91.4 meters (100 yards) beyond the 200 West Area fence. The plume was approximately 100 meters (300 feet) wide.
Release Description: On September 12, 1958, high pressure steam was applied to the D-8 line of the 241-S Diversion box in an attempt to unplug it. The pressure bled back into the diversion box and caused a release of contamination. A follow up survey revealed contamination readings up to 1 rad/hour immediately around the box. Contamination levels 30 meters (100 feet) south of the diversion box were 50 milirad per hour. A narrow strip of contamination extended southward, across Tenth Street, with contamination levels of 4,000 counts per minute. The contamination continued southward approximately 91.44 meters (100 yards) beyond the 200 West Area fence. The particles outside of the 200 West Area fence read on the order of 5,000 counts per minute. The contaminated areas were posted and the gross contamination was flushed with water.
Related Sites/Structures: The site is associated with the 241-S-151 Diversion Box, UPR-200-W-52, UPR-200-W-114 and UPR-200-W-165.

Waste Type: Storage Tank
Waste Description: Beta/gamma particulates with readings up to 50 millirads/hour within 100 feet (30.48 meters) of the diversion box and readings on Tenth Street to about 4,000 counts/minute and 5,000 counts per minute outside the fence were documented. Beta/gamma readings of up to 1 rad/hour were identified immediately around the 241-S-151 Diversion Box. Specific contaminants were not identified.

Code: UPR-200-W-55
Names: UPR-200-W-55; Uranium Powder Spill at 224-U; UN-200-W-55
Type: Unplanned Release
Status: Inactive
Description: The site is no longer marked or posted.
Location: The spill occurred at the 224-UA Building Loadout Room asphalt loading ramp. The nearby
roadway, and ground surface around the ramp were contaminated.

**Release Description:** On April 12, 1960, a 224-UA Loadout Room container overrun caused 1.36 metric tons (1.5 tons) of uranium powder to spill onto the asphalt loading ramp when a loading hose broke. This resulted in the contamination of the 224-UA Building asphalt loading ramp and a nearby roadway. During cleanup uranium was spread to nearby ground.

**Waste Type:** Chemicals

**Waste Description:** On April 12, 1960, 1.36 metric tons (1.5 tons) of uranium powder that had been separated from fission products spilled on the ground. Most of the powder was picked up and drummed.

**Code:** UPR-200-W-60  
**Classification:** Accepted

**Names:** UPR-200-W-60; Railroad Contamination; UN-200-W-60

**Type:** Unplanned Release

**Start Date:** 1/1/1966

**Status:** Inactive

**Description:** The U Plant Railroad had been surrounded with soil berms on the north and south sides of the track and posted with Contamination Area signs. The area was surface stabilized in 2001. The stabilization included the UPR-200-W-60 area. The entire area, including the railroad tracks, is now covered clean dirt and posted with Underground Radioactive Material Area signs.

**Location:** Spotty contamination extended from the 221-U tunnel door along the railroad tracks for a distance of about 68.6 meters (225 feet).

**Release Description:** On February 25, 1966, contaminated water dripped from a hole in the bottom of a PUREX equipment transfer box as the box was being pulled from the 221-U Building tunnel. Radioactivity along the railroad track ranged from a few thousand counts per minute to a maximum of 1 rad/hour. The release effected approximately 68 meters (225 feet) of rail road track.

**Related Sites/Structures:** The site is associated with the 221-U building and UPR-200-W-117.

**Waste Type:** Process Effluent

**Waste Description:** PUREX equipment was being transferred to U Plant in a rail car filled with water (for shielding). Beta/gamma contamination was found on the railroad tracks with readings ranging from a few thousand counts per minute to a maximum of 1 rad/hour.

<td>Release Description:</td>
<td>On October 27, 1969, contamination was found during a routine survey of the 221-T Plant railroad cut. Spots of contamination from 5,000 counts per minute to 150 millirads/hour were found between the rails of the spur line and adjacent to the spur line. One area, about 45.72 meters (50 yards) from the tunnel door, was generally contaminated over an area measuring 0.9 meters (3 feet) by 3 meters (10 feet). From this area west, the contamination spots were spaced a few inches to a few feet until approximately 114.3 meters (125 yards) from the tunnel door, where the contamination was non-detectable. The exact source of the contamination is unknown, but the location limits the cause to a rail car carrying radioactive material which was not effectively contained.</td>

</tr>
</tbody>
</table>
Location: The contamination was located on the north side of 2706-T Building adjacent to the MO433 trailer.

Release Description: On August 5, 1970, a contaminated electric lift was parked outside a radiation zone on the north side of the 2706-T building. Contamination from the vehicle affected the ground beneath the vehicle; an area of approximately 0.91 meters (3 feet) by 7.32 meters (24 feet). The ground was contaminated with a maximum of 20,000 counts per minute. The lift had been positioned outside of the radiation zone awaiting a radiological release survey. The electric lift was from 221-B Plant, but had not been properly surveyed before being moved to 2706-T.

Process Description: The 2706-T building is a vehicle and equipment decontamination facility.

Waste Type: Process Effluent

Waste Description: Beta/gamma with readings of 20,000 counts/minute on the ground. The contaminated electric lift read as high as 500 millirads/hour.

Location: Contamination was spread onto the road along the route from the 241-U Tank Farm to the 200 West Burial Ground, affecting 16th Street and Dayton Avenue.

Release Description: On January 24, 1974, contamination spread occurred along the roadways in 200 West Area. ARHCO personnel removed a heel-jet from the 241-U-102 Tank in the 241-U Farm. The jet was taken to the burial ground by truck. After the jet was removed from the truck and placed in the burial trench, the truck was found to be contaminated. A follow-up survey revealed contamination along the route of the truck. At the exit of the 241-U Farm, on 16th Street, spots to 600 millirads/hour were found. Numerous contaminated spots from 20,000 to 100,000 counts per minute were found along 16th Street to the intersection of 16th Street and Dayton Avenue, and on Dayton Ave. to the burial ground. The cause of the contamination spread included inadequate packaging of the failed equipment, inadequate surveillance of the load during transit, and transporting the equipment while it was raining, which made surveillance difficult.

Waste Type: Sanitary Sewage

Waste Description: The release dripped residue from a contaminated heel-jet removed from the 241-U-102 Tank. Beta-gamma contamination up to 600 millirads/hour was found on the road.

Location: The railroad cut adjacent to the 221-T tunnel is currently posted as a Contamination Area. The rail spur leading into the 2706-T facility is currently not posted. The Unplanned Release area is
not specifically marked or posted.

**Location:** The contamination was located on the railroad tracks that connect the 221-T Building Tunnel to the 2706-T Building.

**Release Description:** On October 16, 1974, a contamination spread from a leaking multi-purpose transfer box was discovered. During a routine survey in the 221-T Building Tunnel, on October 14, 1974, contamination levels up to 3,800 millirads/hour were detected on the bed of the multi-purpose transfer box railroad car. Decontamination of the rail car was scheduled for October 15, 1974. During the decontamination effort, a hair-line crack was observed in a weld of the outer shell of the transfer box. Radiation readings on the transfer box were reduced to 350 millirads/hour and 600 counts per minute smearable on October 16, 1974. The railcar was moved to the 2706-T Building so repairs could be made. A follow-up survey of the railcar at 2706-T indicated that additional contamination had seeped out. Radiation readings on the rail car had increased to 50,000 counts per minute smearable. A survey of approximately 365.76 meters (400 yards) of railroad track between 221-T Building Tunnel and the 2706-T Building revealed spots of contamination up to 40 millirads/hour. The cause of the leakage was migration of decontamination solution to the hair-line crack area and subsequent leaking due to rail movement of the transfer box.

**Process Description:** Contaminated equipment was transferred to T Plant on railcars for repair and decontamination.

**Waste Type:** Steam Condensate

**Waste Description:** Spotty beta/gamma contamination with readings to 40 millirads/hour on the ground.

**Code:** UPR-200-W-78  
**Classification:** Accepted

**Names:** UPR-200-W-78; UN-200-W-78; UO3 Powder Spill at 224-U

**Type:** Unplanned Release  
**Start Date:** 1/1/1970

**Status:** Inactive  
**End Date:**

**Description:** The site is no longer marked or posted.

**Location:** The release caused an area, located 36 meters (40 yards) south of the Uranium Tri-Oxide barrel storage area, to become contaminated.

**Release Description:** On August 21, 1970 a radiation survey done with a truck mounted road monitor. The equipment detected an area measuring approximately 3.72 square meters (40 square feet) contaminated with levels up to 20,000 counts/minute. It is assumed that some uranium powder spilled prior to March 1969, when the last pallets were moved from 224-U.

**Waste Type:** Process Effluent

**Waste Description:** Uranium trioxide powder was spilled on the ground. Contamination up to 20,000 counts per minute was found.

**Type:** Unplanned Release  
**Start Date:** 1/1/1966
### Rev. 24

**DOE/RL-88-30**

**Inactive Status:** 1/1/1966

**Description:** The waste site is the result of airborne contamination (in 1966) affecting the ground on both sides of Camden Ave. The area on the east of Camden Avenue, east of the 241-TX Tank Farm was stabilized with soil and grass. It is marked with "Underground Radioactive Material" signs.

**Location:** The release site is located east of the 241-TX Tank Farm, extending approximately 69 to 91 meters (75 to 100 yards) east of Camden Avenue.

**Release Description:** UPR-200-W-99 occurred on September 21, 1966. Two plumes of airborne contamination from the 241-TX-153 Diversion Box floated northeast and southeast. The releases contaminated the ground and road on both sides of Camden Avenue. The total length of contamination was identified to be 228 meters (750 feet) north and south along Camden Ave. The contamination extended a maximum of 91 meters (300 feet) east of Camden Ave. The maximum contamination found was 700 millirem per hour.

**Related Sites/Structures:** UPR-200-W-99 was associated with the 241-TX-153 Diversion Box and Camden Avenue.

**Waste Type:** Process Effluent

**Waste Description:** Airborne particulates containing approximately 1 curie of strontium-90, with maximum readings of up to 700 millirads/hour, contaminated a large area around the diversion box.

</tbody>
</table>
In November 2000, a posted Soil Contamination Area was located on the railroad spur leading into the 221-U railroad cut and tunnel. Most of the posted area is the railroad track on a bed of gravel. There is an unusual patch of asphalt across a portion of the railroad track, inside the posted Soil Contamination Area. In December 2001, the area was covered with clean backfill material and downposted to an Underground Radioactive Material Area.

The release site was the ground around the railroad cut northwest of the 221-U Building in the 200 West Area.

This site is the result of contaminated liquid and particulate matter dropping from railroad cars moving equipment and waste into and out of the 221-U Facility over time.

UPR-200-W-117 was associated with the 221-U Building and the railroad cars servicing that facility.

The track leads to the 221-U tunnel door. Material and equipment was transported in and out of the U Plant canyon via the tunnel entrance.

The contamination was primarily fission products and uranium from chemical processing operations.

The release site consisted of the ground outside the concrete unloading station at the 211-U Tank Farm. The unplanned release site is no longer marked or posted. The area around the 211-U tanks and railroad spur has been stabilized with gravel and is posted as an Underground Radioactive Material area.

UPR-200-W-118 was located on the railroad spur northwest of the 221-U Building, adjacent to the 211-U Chemical Tank Farm.

This contaminated area was the result of drips and spills from the reclaimed nitric acid unloading station at the 211-U Chemical Tank Farm. Wind-borne particulate matter spread to the ground surface outside the concrete unloading station, contaminating approximately 0.4 hectares (1 acre) of ground.

UPR-200-W-118 is associated with the 211-U and 211-UA Chemical Tank Farms.

The Uranium Recovery Process at 224-U received uranyl nitrate from REDOX and PUREX. After the uranium was removed, the reclaimed nitric acid was stored in the 211-UA tanks. It was transferred from 224-U to 211-UA via overhead lines. The slightly radioactive nitric acid
was recycled back to REDOX and PUREX. In the 1960's and 1970's it was returned to the separations facilities in railcars. It was pumped out of the 211-UA tanks into the railcars via underground lines and a pump pit. Some leakage was associated with the pumping process and caused low level radioactive contamination around the area. The reclaimed nitric acid storage was moved from 211-UA to a holding tank within the 224-U facility in the 1980's and the railcar unloading platform was abandoned. Some residual acid and waste water, contaminated above crib release limits, continued to be stored in the 211-UA tanks. All the acid and waste water was removed from the tanks prior to being transitioned to the new Environmental Restoration Contractor in 1994. Although the tanks were emptied, the acid pump pit and underground lines had not been flushed. Leaking valves and seals and residual contamination in the pump pit caused low level radioactive contamination to spread around the tanks and railcar unloading platform. The area was posted as a Contamination Area again in the early 1990's. The lines and pump pit were flushed in 1998 and the surface contamination was covered with gravel. The area was changed to an Underground Radioactive Material Area.

**Waste Type:** Equipment  
**Waste Description:** The waste consisted of radioactive reclaimed nitric acid that spilled to the soil.

Hanford Site Waste Management Units Report  
February 2015
**Type:** Unplanned Release  
**Start Date:** 1/1/1991  
**Status:** Inactive  
**End Date:**  
**Description:** The waste site was originally posted with "Surface Contamination" warning signs. The area has been backfilled with clean material from the 200 Area Ash Pit. The radiological posting was changed to "Underground Radioactive Material." In 2011, after the demolition of 224-U and 224-UA, the 200-W-136 Underground Radioactive Material Area was greatly expanded. It was extended to the back side of the 221-U building. This eliminated the need for a separate radiological posting for the UPR-200-W-162 waste site.  
**Location:** The release site is the area adjacent to and east of the 221-U Canyon Building from Section R-1 to R-19 in the 200 West Area.  
**Release Description:** The site consists of surface radiological speck contamination.  
**Related Sites/Structures:** UPR-200-W-162 was associated with the 221-U Canyon Building. The 200-W-136 posted area was expanded and now encompasses the area previously known as UPR-100-W-162. Also associated with UPR-200-W-101 and UPR-200-138 are located inside this larger Underground Radioactive Material Area.  
**Waste Type:** Equipment  
**Waste Description:** The site consists of surface speck contamination.  

---

**Code:** UPR-200-W-165  
**Classification:** Accepted  
**Reclassification:** Interim No Action (5/12/2014)  
**Type:** Unplanned Release  
**Status:** Inactive  
**End Date:**  
**Description:** The area was Interim Stabilized, over time from 1992 through 1995. The site was evaluated and reclassified to Rejected in 2014. It was originally a radiologically posted area that was scraped and the contaminated soil combined with other waste sites. The site had been a large area of posted Surface Contamination, located east of the 241-S Tank Farm, north of the steam line. The 216-S-23 and 216-S-9 cribs and the 216-S-18 excavation were inside the Surface Contamination Area posting. Some of the contaminated soil was placed on top of the 216-S-9, 216-S-8, 216-S-1 &2 and 216-S-23 cribs. Some was used to backfill the 216-S-18 depression. After collecting soil samples of the scraped area, portions of the area was removed from radiological control in 1993.  
**Location:** UPR-200-W-165 was located east of the 241-S, 241-SX, and 241-SY Tank Farms and west of the 216-S-9 Crib in the 200 West Area.  
**Release Description:** Radioactive surface contamination migrated from the 241-S, 241-SX, and 241-SY Tank Farms, eventually contaminating an area of approximately 4.7 hectares (11.5 acres).  
**Related Sites/Structures:** UPR-200-W-165 was associated with contamination migration from operational activities in the 241-S, the 241-SX, and the 241-SY Tank Farms.  
**Waste Type:** Storage Tank  
**Waste Description:** The waste consisted of contamination specks that migrated from the 241-S, 241-SX, and 241-SY Tank Farms.  
**Closure Info:** This waste site Interim Stabilization began in 1992, but no Reclassification form was processed.
at that time. The Reclassification form was processed in 2014.

The posted radiological surface contamination was divided into three sections, based on the locations of aboveground steamlines that restricted the earth moving equipment. Areas adjacent to the 241-S, SX and SY tank farm fences were not stabilized.

The contaminated surface soil in the northern section was scraped and consolidated onto the top of the 216-S-23 crib. A layer (18 to 24 inches deep) of clean soil was placed on top to cover the contaminated soil. Approximately 5.9 acres was decontaminated. The area decontamination was completed in July 1992.

The contaminated surface soil in the southern section was scraped and consolidated onto the top of the 216-S-1 &2 and 216-S-8 cribs. Some contaminated soil was placed inside the 207 Retention basin. A layer (18 to 24 inches deep) of clean soil was placed on top to cover the contaminated soil. Approximately 11.7 was decontaminated and another 2 acres were covered with clean dirt. This area was completed in September 1992.

The soil contamination area between the steamlines was found to be greater than 1 foot deep. From December 1994 through February 1995, approximately 5000 square feet was decontaminated and the radiological posting removed. Some of the contaminated soil was consolidated on top of the 216-S-9 crib and some was placed into the 216-S-18 depression and covered with clean dirt. Construction debris was uncovered in this area. The area under the steamline remained a posted contamination area until the steamline was removed.

The scraped areas were revegetated with wheatgrass. Approximately 60 acres inside 241-S and SX tank farm fences were treated with a soil fixative to prevent recontamination of areas outside the fence.

**Waste Type:** Process Effluent

**Waste Description:** The waste consisted of spotty contamination which is suspected to have originated from the 241-T Tank Farm.
### 300-FF-1

**Code:** 300 ASH PITS  
**Classification:** Accepted  
**Names:** 300 ASH PITS; 300 Area Ash Pits; 300 Ash Pits  
**Reclassification:** Closed Out (12/17/1997)  
**Type:** Coal Ash Pit  
**Start Date:** 1/1/1944  
**End Date:** 1/1/1994  
**Status:** Inactive

**Description:** In 1997, samples collected from test pits determined no further action was required. The unit consisted of two separate excavations that are 4.6 to 6.1 meters (15 to 20 feet) deep and 7,400 square meters (80,000 square feet) in area.

**Location:** The site is located in the 300 Area, south of the 316-1 Process Pond and west of the 300 Area Filter Backwash Pond (300 FBP).

**Process Description:** The 300 Area coal-fired power house generated coal ash starting in about 1944. The ash was suspended in a water slurry and sluiced to the South Process Pond (SPP) until 1951. When the coal fly ash was dry, it was hauled to several locations, including these disposal pit located west of the 300 Area. These pits received about 56,000,000 liters per year (15,000,000 gallons per year) of fly ash slurry during operations.

**Closure Info:** During the 300-FF-1 Phase 1 remedial investigations (RI), samples of ash showed that metals concentrations were below cleanup standards. However, the ash pits were constructed in an area that at one time was part of the South Process Pond (SPP). The Remedial Investigation did not collect samples from soils below the ash pit sediments that could contain contaminants from the SPP. Therefore, the 300-FF-1 Record of Decision required remedial action at the ash pits to verify no contaminants below the ash pits remained from previous SPP operations.

Six sample test pit locations were randomly identified at the ash pits. Samples were taken below the ash pit sediments, at a depth about 4.6 meters (15 feet) below surface grade. Field screening was performed at about 0.3 meter (1 foot) intervals in the ash, but did not identify any contaminants of concern above the cleanup levels. Samples were collected in August 1997 at a depth below the layers of ash, and the pits backfilled. Field screening did not identify any contaminants of concern. The sample results indicated no further action was required.

### 300 FBP

**Code:** 300 FBP  
**Classification:** Accepted  
**Names:** 300 FBP; 300 Area Filter Backwash Pond  
**Reclassification:** Interim No Action (11/7/2000)  
**Type:** Surface Impoundment  
**Start Date:** 1/1/1987  
**End Date:** 1/1/1998  
**Status:** Inactive

**Description:** This site has been reclassified as "No Action." The unit consists of two subsites; one is a single, rubber lined basin measuring 97.5 meters (320 feet) by 65 meters (213 feet), 7.6 meters (25 feet) deep. From 1987 to 1992, the basin operated as an unlined percolation pond, which is the second subsite. In 1992, the basin was lined with a synthetic liner on a concrete foundation.

**Location:** The site is located north of the 338 Building and east of the 300 Area Ash Pits, near the banks of the Columbia River. The basin is enclosed by a locked chain link fence.

**Related Sites/Structures:** The site is associated with the 384 Powerhouse and the 300 Area Treated Effluent Disposal Facility (TEDF).

**Process Description:** Before the pond was lined, filter backwash was discharged to it and allowed to percolate to groundwater. After 1995, the backwash was held in the lined pond to clarify. The clarified
water was sent to the 300 Area TEDF (Treated Effluent Disposal Facility). The Hanford Site Waste Management Units Report reports that the unit received water and nonhazardous alum from backwash filters used to filter water for sanitary and process use. Analysis of the backwash showed it to be nonhazardous. The accumulated sediment in the ponds is not regulated and could be disposed of in a landfill.

This Site has the Following SubSites:

| Code: 300 FBP:1 | Classification: Accepted |
| Names: 300 FBP:1; 300 FBP (Unlined) |

| Code: 300 FBP:2 | Classification: Accepted |
| Names: 300 FBP:2; 300 FBP (Lined) |

- **Classification**: Accepted
- **Reclassification**: Interim No Action (2/19/1998)
- **Type**: Surface Impoundment
- **Status**: Inactive
- **Description**: The subsite represents the unlined pond that operated from 1987 to 1992. This component of the 300 FBP is included as a "no action" site within the 300-FF-1/300-FF-5 Record of Decision.

**Closure Info**: No remediation was performed.

The SubSite is Part Of:

| Code: 300 FBP |
| Names: 300 FBP; 300 Area Filter Backwash Pond |

- **Classification**: Accepted
- **Reclassification**: Interim No Action (11/7/2000)
- **Type**: Surface Impoundment
- **Status**: Inactive
- **Description**: This subsite is the lined filter backwash pond. This site is not addressed within the 300-FF-1/300-FF-5 Record of Decision.

**Closure Info**: No remediation was performed.

The SubSite is Part Of:

| Code: 300 RFBP |
| Names: 300 RFBP; East Bay of South Process Pond; Pond 5; 300 Area Retired Filter Backwash Pond |

- **Classification**: Accepted
- **Type**: Pond
- **Status**: Inactive
- **Description**: The site has been remediated and closed out. When the South Process Pond became inactive in 1975, the east lobe started to be used by the 300 Area Water Treatment Facility as a filter.
backwash pond.

Location: The unit was located west of the 300 Area, in the east lobe of the 300 Area South Pond.

Related Sites/Structures: This site was associated with the South Pond (316-1); the Contaminated Soil West of the South Process Pond (300-262); and unplanned release (UPR) sites UPR 300-32, UPR-300-33, UPR-300-34, UPR-300-35, UPR-300-36, UPR-300-37, and UPR-300-FF-1.

Process Description: The 300 RFBP and the 316-1 South Process Pond, collectively referred to as the 316-1 South Process Pond site, are the site of former high-volume liquid waste disposal activities located north of the 300 Area complex, near the Columbia River. The easternmost boundary of the 316-1 South Process Pond is approximately 49 meters (160 feet) west of the shoreline of the Columbia River. The 316-1 South Process Pond site was built in 1943 and was the first 300 Area process liquid disposal unit. It was originally a single, large infiltration pond to which dikes were later added, forming three settling ponds and a large main infiltration pond. The east lobe of the site was used by the 300 Area water treatment plant as a filter backwash pond (WIDS site 300 RFBP). Combined process wastes discharged from the fuel fabrication facilities to the South and North Process Ponds ranged from 1,514,000 to 11,360,000 liters/day (400,000 to 3,000,000 gallons/day). During their operational life, the process ponds received thousands of kilograms of uranium as dissolved material and finely divided solids. Much of the uranium was carried with the infiltration water, but some remained in the pond soils. Discharging of waste to the process ponds ended in 1975.

Closure Info: Remediation activities at the 316-1 South Process Pond site began in 1997 with excavating trenches around the periphery of the 316-1 site. Trenching was performed to assess the lateral extent of contamination. The majority of remedial excavation and disposal activities were conducted in 1999 and 2000. Excavation at the site involved removing the overburden (scraped surface) soils and contaminated soils. The contaminated soil was transported to the ERDF for disposal. Based on field screening, overburden materials and comingled soil identified as potentially clean were placed in stockpiles for potential use as backfill. Soil samples were collected adjacent to utility poles located in the 316-1 site. Where these samples indicated contaminant concentrations above the cleanup criteria, the soil was removed and the area immediately backfilled and compacted with clean material to maintain the integrity of the utility pole. Excavation and disposal of the 316-1 South Process Pond remediation waste was completed in June 2000. The filter backwash pond (WIDS site 300 RFBP) was a lobe on east side of the process pond. During remediation, soil was primarily removed from the area on the west side of the process pond, near the pond inlet. The two north-south parallel soil berms inside the pond were removed. Areas to the south and west of the original pond boundaries were also removed during remediation. The general elevation at the bottom of the excavation used for analysis was 111.3 meters (365 ft) upon completion. The excavation depth was approximately 5.7 meters (19 ft).

Code: 300-3
Classification: Accepted
Names: 300-3; 300-FF-1 Aluminum Hydroxide
Reclassification: Interim No Action (7/17/1996)
Type: Burial Ground
Status: Inactive
Start Date:
End Date:
Description: The waste site was investigated and determined to require No Action per the Record of Decision for 300-FF-1. It was a wooden structure consisting of several horizontal (0.30 to 0.46 meters [1 to 1.5 ft] diameter) cedar logs forming a vertical wall. The structure contained a white, chalky substance.
Location: This site is about 100 meters (330 feet) northwest of the 316-1 South Process Pond.
Photos from 1956 indicate the site was possibly used to receive sodium aluminate/aluminum hydroxide scrapings from the South and North Process Ponds.

The structure was investigated by the site historical group. Photos from 1956 indicate the site was possibly used to receive sodium aluminate/aluminum hydroxide scrapings from the South and North Process Ponds. The white chalky substance was sampled and analyzed in October 1993.

According to page 50 of the Declaration of the Record of Decision for the 300-FF-1 and 300-FF-5 Operable Units (DOE Document Number 038509), remedial action is not needed at the 300-3 Aluminum Hydroxide Site. Regulator concurrence with supporting documentation eliminates the need for signatures on this form.

**Description:**

This site was located southwest of 618-4 Burial ground. It has been remediated and was closed out in 1997. It had been a posted Underground Radiological Material Area.

**Location:**

The site was near the southwest end of the 618-4 Burial Ground. The surface area was derived from a Global Position Survey (GPS) of the site boundary.

**Related Sites/Structures:**

The site is associated with WIDS sitecode UPR-300-FF-1.

**Closure Info:**

The waste site was approximately 159 square meters (1711 sq. ft). A layer of overburden ranging in depth from 0.3 to 0.9 meters (1 to 3 feet) was removed prior to the excavation and stockpiled. Only an additional 0.3 meters (1 foot) was removed to complete the excavation, based on radiological surveys. Contaminated soil was disposed at the Environmental Restoration Disposal Facility. Four verification samples were collected; two from the bottom of the excavation and two from the stockpiled overburden. The samples were analyzed for 300-FF-1 Operable Unit contaminants of concern.

**Description:**

The site has been remediated and closed out in July 1999. It was a large, rectangular area with visible debris on the surface and areas of subsidence. After excavation and closure activities the area was included in the 2004, 300-FF-1 Regrading Plan.

**Location:**

The site was located southeast of 618-5 Burial Ground, near the Columbia River bank.

**Related Sites/Structures:**

The site was associated with WIDS sitecode UPR-300-FF-1.

**Closure Info:**

The cleanup verification package (CVP-2000-00020) has documented that the 300-49 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals.
Site contaminants of concern (COCs) and contaminants of potential concern (COPCs) identified in the 300-FF-1 Remedial Design Report/Remedial Action Work Plan (1997 RDR/RAWP) consisted of the following: cobalt-60, uranium-234, uranium-235, uranium-238, polychlorinated biphenyls (PCBs). COPC's: arsenic, thallium, benzo(a)pyrene, chrysene. Of the PCBs analyzed, only Aroclor-1254 was detected in cleanup verification samples and was therefore evaluated as a site COC.

The COPC arsenic was not detected in cleanup verification samples at concentrations above Washington State background of 20 mg/kg (Washington Administrative Code 173-340) (the maximum detected value was 5.5 mg/kg) and is therefore not included as a COC in the evaluation of the site for cleanup verification. The COPCs thallium and the two polynuclear aromatic hydrocarbons (benzo[a]pyrene and chrysene) were not detected in cleanup verification samples at the detection limits specified in the RDR/RAWP and are therefore not included as COCs in evaluation of the site for cleanup verification.

An additional contaminant (lead) was identified from analysis of material excavated during remediation and evaluated as a site COPC. Lead was detected at levels above Hanford Site background of 10.2 mg/kg in cleanup verification samples and is therefore evaluated as an additional site COC for the Landfill 1A site.

Landfill 1A (300-49) and Landfill 1B (300-50) have been surface stabilized.

Cleanup verification samples were taken on June 28, 2000. The site excavation and overburden soil sample data were recorded in HEIS as SAF B00-037.

At the completion of the remedial action, the total excavation was approximately 6,906 square meters (74,340 square feet) in area with a maximum depth of approximately 3 meters (10 feet). Approximately 17,761 metric tons (19,578 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility. All visible debris was removed from the Landfill 1A site, and the site was excavated to native soil. An additional 5,644 metric tons (6,221 tons) of material (overburden) identified as potentially clean was stockpiled at the site for potential use as backfill.

Results of the sampling, laboratory analysis, and data evaluations of the Landfill 1A site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of Columbia River have been met.

</tr>
</tbody>
</table>
The site was associated with WIDS sitecode UPR-300-FF-1 and 300-49 (Landfill 1a).

**Related Sites/Structures:**

Remedial action objectives for the Landfill 1B site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These objectives are documented in the Record of Decision for the 300-FF-1 and 300-FF-5 Operable Units (ROD) (EPA, 1996) and the 300-FF-1 Remedial Design Report/Remedial Action Work Plan (1997 RDR/RAWP) (DOE/RL-96-70).

The selected remedial action for the Landfill 1B site included excavation to the extent required to meet specified soil cleanup levels and disposal of contaminated excavation materials at the Environmental Restoration Disposal Facility. The remedial action also included the removal and disposal of solid waste and all construction debris. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established in the 1997 RDR/RAWP and updated in the Remedial Design Report/Remedial Action Work Plan for the 300 Area (2002 RDR/RAWP) (DOE/RL-2001-47). Waste site contaminants of concern (COCs) and contaminants of potential concern (COPCs) identified from knowledge of the processes used in the 300 Area and previous 300-FF-1 Operable Unit investigations were listed in Table 2-1 of the 1997 RDR/RAWP.

Site excavation and waste disposal are complete, and the exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. At the completion of remedial action, the total excavation was approximately 10,498 square meters (113,000 square feet) in area with a maximum depth of approximately 3.1 meters (10 feet). Approximately 35,652 metric tons (39,300 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility. All visible debris was removed from the Landfill 1B site, and the site was excavated to native soil. Overburden material identified as potentially clean was stockpiled at the site for potential use as backfill at this waste site.

The results of the sampling, laboratory analysis, and data evaluations of the Landfill 1B site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of Columbia River have been met.

Cleanup verification samples were collected from the excavation and overburden soil and analyzed for the established contaminants of concern. The excavation soil sample were collected on July 5, 2000. The overburden soil samples were collected on June 28, 2000. The sample results can be located on the HEIS database under the SAF number B00-038.

The CVP demonstrates that remedial action at the Landfill 1B site has achieved the RAOs and corresponding RAGs established in the approved ROD, the 1997 RDR/RAWP, and the 2002 RDR/RAWP. The remaining soils at the Landfill 1B site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the Landfill 1B site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in remaining site soil will support future land uses that can be represented (or bounded) by the industrial land-use scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River. The CVP demonstrates acceptability for industrial land use; therefore, institutional controls limiting land use to industrial are required. Institutional controls preventing uncontrolled drilling or excavating are also required. The Landfill 1B site is verified to be remediated in accordance with the ROD and may be backfilled.

Hanford Site Waste Management Units Report
February 2015
Process Pond

Type: Pond  Start Date: 1/1/1943
Status: Inactive  End Date: 5/1/1975

Description: The site has been remediated and Closed Out. Approximately 47,600 square meters (512,000 sq. ft) of soil was excavated, to a depth of approximately 18 feet below ground surface.

The site is no longer marked or posted. The pond was a 32,000 square meter (8-acre), unlined infiltration pond containing five separate pond sections. Ponds 1, 2, and 3 were separated by two 9.1-meter (30-foot) dikes. Pond 4, the largest pond, was separated from Ponds 1, 2, and 3 to the west by a 4.9-meter (16-foot) dike and from Pond 5 to the east by 3.1 meters (100 feet) of land. The dikes were bulldozed into three sections, and the fill was used to cover loose material.

Location: The unit was located east of the 306 Building and west of the Columbia River.

Related Sites/Structures: This site was associated with Retired Filter Backwash Pond (300 RFBP); the Contaminated Soil West of the South Process Pond (300-262); and unplanned release (UPR) sites UPR 300-32, UPR-300-33, UPR-300-34, UPR-300-35, UPR-300-36, UPR-300-37, and UPR-300-FF-1.

Process Description: The 316-1 South Process Pond and 300 RFBP sites, collectively referred to as the 316-1 South Process Pond site, are the site of former high-volume liquid waste disposal activities located north of the 300 Area complex, near the Columbia River. The easternmost boundary of the 316-1 South Process Pond is approximately 49 meters (160 feet) west of the shoreline of the Columbia River. The 316-1 South Process Pond site was built in 1943 and was the first 300 Area process liquid disposal unit. It was originally a single, large infiltration pond to which dikes were later added, forming three settling ponds and a large main infiltration pond. The east lobe of the site was used by the 300 Area water treatment plant as a filter backwash pond (WIDS site 300 RFBP). Combined process wastes discharged from the fuel fabrication facilities to the South and North Process Ponds ranged from 1,514,000 to 11,360,000 liters/day (400,000 to 3,000,000 gallons/day). During their operational life, the process ponds received thousands of kilograms of uranium as dissolved material and finely divided solids. Much of the uranium was carried with the infiltration water, but some remained in the pond soils.

Discharging of waste to the process ponds ended in 1975.

Closure Info: Remediation activities at the 316-1 South Process Pond site began in 1997 with excavating trenches around the periphery of the 316-1 site. Trenching was performed to assess the lateral extent of contamination. The majority of remedial excavation and disposal activities were conducted in 1999 and 2000. Excavation at the site involved removing the overburden (scraped surface) soils and contaminated soils. The contaminated soil was transported to the ERDF for disposal. Based on field screening, overburden materials and comingled soil identified as potentially clean were placed in stockpiles for potential use as backfill. Soil samples were collected adjacent to utility poles located in the 316-1 site. Where these samples indicated contaminant concentrations above the cleanup criteria, the soil was removed and the area immediately backfilled and compacted with clean material to maintain the integrity of the utility pole. Excavation and disposal of the 316-1 South Process Pond remediation waste was completed in June 2000. The filter backwash pond (WIDS site 300 RFBP) was a lobe on east side of the process pond. During remediation, soil was primarily removed from the area on the west side of the process pond, near the pond inlet. The two north-south parallel soil berms inside the pond were removed. Areas to the south and west of the original pond boundaries were also removed during remediation. The general elevation at the bottom of the excavation used for analysis was 111.3 meters (365 ft) upon completion. The excavation depth was approximately 5.7 meters (19 ft).

Code: 316-2  Classification: Accepted
Names: 316-2; North (New) Pond; 300 Area North Process Pond

Type: Pond

Status: Inactive

Start Date: 1/1/1948

End Date: 5/1/1974

Description: The site was remediated and closed out in 1999. This site consisted of seven separate sections separated by 3.7-meter (12-foot) wide dikes. The whole pond was a 40,000-square meter (10-acre) area, surrounded by a dike 4.6 meters (15 feet) wide and approximately 3.0 meters (10 feet) high. The radiological posted was removed. The pond is no longer marked or posted.

Location: The unit was located northeast of the 306 Building and north of the 316-1 Pond.

Related Sites/Structures: Associated structures include: five 86-centimeter (34-inch) diameter by 7.3-meter (24-foot) long flumes. Two were filled with an unknown material and abandoned.

Process Description: The North Process Pond was constructed and activated in 1948, following a dike failure at the existing South Process Pond. Both ponds operated until 1975, when the units were replaced by the 300 Area Process Trenches (WIDS site 316-5). The site originally received cooling water and low-level liquid process waste from 300 Area fuel fabrication facilities and the early laboratory facilities in the 313, 314, 3706, and 321 Buildings. Later, laboratory facility waste was first routed to the 307 Retention Basins. Waste that was above discharge limits was diverted to holding tanks for shipment and disposal in the Hanford Site 200 Area. The North and South Process Ponds received laboratory waste via the 307 Retention Basins from 1963 to 1975. There was no effluent outlet from the North Process Pond. All of the effluent either infiltrated the soil column or evaporated. Lack of infiltration was a problem for the pond. Between 1948 and 1969, the basins were periodically dredged to improve infiltration when sludge in the bottom of the pond slowed the percolation rate. The sludge contained large amounts of uranium and copper and was deposited on the pond dikes and put in the Scraping Disposal Area or put into Landfill 1B (WIDS site 300-50) just north of the pond. During operation, there were several unplanned releases to the North Process Pond.

Closure Info: Remediation activities were initiated in May 1998 and continued into January 1999. On January 25, 1999 a decision was made to suspend excavation activities at the North Process Pond and mobilize work crews to the South Process Pond pending resolution of contractual issues with the remedial action subcontractor. Work crews remobilized to the North Process Pond and completed excavation activities in June 1999.

Based on data collected during the remedial investigation, the pond was divided into the Above Cleanup Level (ACL), Below Cleanup Level (BCL), and Undetermined Contamination Level (UCL) areas prior to excavation. The UCL area included the Scraping Disposal Area (sitecode 618-12). Four UPRs associated with the north pond were also associated with the south pond. UPR-300-34, UPR-300-35, UPR-300-36 and UPR-300-37 were addressed with the South Pond remediation (316-1). UPR-300-7 was closed out with the North Pond (316-2).
soil excavation was required in this area. The maximum excavation depth was 14 feet deep. The site was partly remediated through an expedited response action (ERA) in 1991. Remediation was completed in 1997. The site was clean closed through RCRA and closed out under CERCLA regulations.

**Location:** The unit is located north of the 300 Area.

**Release Description:** Sixteen unplanned releases are associated with this site: UPR-300-8, UPR-300-9, UPR-300-15, UPR-300-19, UPR-300-20, UPR-300-21, UPR-300-22, UPR-300-23, UPR-300-24, UPR-300-25, UPR-300-26, UPR-300-27, UPR-300-28, UPR-300-29, UPR-300-30, and UPR-300-47. These sites were closed out when the cleanup verification package for the Process Trenches was approved.

**Closure Info:** CERCLA remediation activities were initiated in July 1997 and completed in February 1998. Remediation of the 300 Area Process Trenches included removal and disposal of bird screens covering the trenches, demolition and disposal of the headworks structure located at the southern end of the trenches, demolition and disposal of the blockhouse structure, and excavation and disposal of contaminated soil that accounted for several unplanned release waste sites.

In 1991, an expedited response action (ERA) was performed to reduce the migration of radioactive and inorganic (heavy metals) contaminants to groundwater. This was accomplished by excavating contaminated sediments in the south end of the trenches, using them to fill in the north end of the trenches, and immobilizing them. The ERA uniformly excavated approximately 0.3 meters (1ft) and 1.3 meters (4 ft) of contaminated soil from the sides and bottom of each trench, respectively. The contaminated material was stockpiled in the northwest corner of the west trench and the north end of the east trench (referred to as a spoils area). Based on process history, the Part A submitted by the U.S. Department of Energy, Richland Operations Office (DOE-RL) assigned several listed waste codes to the ERA spoils pile.

**RCRA closure of the process trenches was performed in accordance with the 300 Area Process Trenches Modified Closure Post Closure Plan (DOE-RL 1995). An independent registered professional engineer was tasked to review the 300-FF-1 remedial action activities to ensure that the TSD closure met the WAC 173-303-610 performance standards. The permit was closed with post-closure requirements.**

**Description:** The site has been remediated and Interim Closed Out. The waste site was a solid waste disposal pit.

**Location:** The burial ground was located approximately 0.5 kilometers (1/3 mile) north of the 300 Area northern boundary fence.

**Related Sites/Structures:** This site was associated with UPR-600-15.
Process Description: The site received dry waste from the 300 Area operations.

Waste Type: Process Effluent

Waste Description: In 1998, drums of unknown material were uncovered during remedial action activities. It is suspected the drums contain depleted uranium filings and mineral oil.

Waste Type: Process Effluent

Waste Description: The site contains an unknown quantity of uranium-contaminated miscellaneous materials. During remedial activities, drums of depleted uranium packed in oil were uncovered. The presence of these drums was not previously known, therefore, the documented uranium inventory for this burial ground did not include these (estimated to be up to 1500) barrels of depleted uranium. The inventory contained in the drums has been estimated to be 110,600 kilograms (243,800 pounds) (Schwab 2000).

Closure Info: Excavation activities were performed in two phases, between 1998 and 2003. At the completion of field operations in 2003, the total excavation was approximately 7,342.6 square meters (79,043 square feet) in area with a maximum depth of approximately 11 meters (36 feet) below the surrounding grade. Approximately 46,585 metric tons (51,360 tons) of bulk soil and debris were excavated from the site and disposed of at ERDF. In addition, 786 drums containing depleted uranium waste were excavated from this site and transported to ERDF for interim staging and/or disposal. 266 drums containing depleted uranium oxide were grouted and disposed of at ERDF. In September 2003, 520 drums containing depleted uranium chips immersed in polychlorinated biphenyl-contaminated oil were transported from the ERDF staging area to Perma-Fix in Oak Ridge, Tennessee, for treatment. Overburden material and excavated soil identified as potentially clean were stockpiled at the site for subsequent use as backfill material.

Excavation operations were driven by remedial action objectives for removal of the burial ground contents as well as direct exposure limits, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals were established in the 300-FF-1 Remedial Design Report/Remedial Action Work Plan (DOE-RL 1997) and updated in the Remedial Design Report/Remedial Action Work Plan for the 300 Area (DOE RL 2004).

Because residual soil concentrations indicated that cleanup levels for more stringent land uses may have been achieved for the 618-4 Burial Ground, a supplemental evaluation was performed against the unrestricted land-use cleanup objectives established in the 300-FF-2 ESD (EPA 2004). Results of the evaluation demonstrated that remedial actions at the site have achieved all of the objectives for unrestricted land uses. Consequently, no institutional controls are required at the site.

</table>
Location: The North Process Pond Scraping Disposal Area extended approximately 61 meters (200 feet) south of the North Process Ponds.

Process Description: The scraping disposal area was used for disposal of uranium-contaminated soil from the bottom of the North Process Pond and from beneath the 321 Building during excavation for hydraulic core mockup.

Waste Type: Process Effluent

Waste Description: This site was used for disposal of uranium-contaminated soil that was scraped from the 316-2 Pond (North Process Pond) and some uranium-contaminated soil that was removed from beneath the 321 Building during excavation for hydraulic core mockup.

Closure Info: Remediation activities were initiated in May 1998 and continued into January 1999. On January 25, 1999 a decision was made to suspend excavation activities at the North Process Pond and mobilize work crews to the South Process Pond pending resolution of contractual issues with the remedial action subcontractor. Work crews remobilized to the North Process Pond and completed excavation activities in June 1999.

Based on data collected during the remedial investigation, the pond was divided into the Above Cleanup Level (ACL), Below Cleanup Level (BCL), and Undetermined Contamination Level (UCL) areas prior to excavation. The UCL area included the Scraping Disposal Area (sitecode 618-12). Four UPRs associated with the north pond were also associated with the south pond. UPR-300-34, UPR-300-35, UPR-300-36 and UPR-300-37 were addressed with the South Pond remediation (316-1). UPR-300-7 was closed out with the North Pond (316-2).

Names: 628-4; Landfill 1D

Type: Burn Pit

Status: Inactive

Description: The site has been remediated and Closed Out. The waste site was used as an alternate burning site, in conjunction with the burning in Burial Ground 5 (618-5), to allow the units to cool between burnings.

Location: The site was located just north of the west end of 300-52 (300 Area Sanitary Trenches).

Waste Type: Chemicals

Waste Description: The unit was used mainly for burning paper, wood, paint cans, and other operations debris; however, some incidental radioactive materials may have also been burned.

Closure Info: Remedial action at the Landfill 1D site began in 1999. Excavation at the site involved removing the overburden (scraped surface) soils, buried landfill waste and ash, and comingled soil. The buried landfill waste was sorted and sent to ERDF for treatment as necessary and disposal. During remediation, elevated concentrations of lead were identified in excavated soil. Because of the large volume of soil containing lead, a site-specific lead treatment standard was established for soil excavated from the Landfill 1D site through an Explanation of Significant Difference (ESD). Excavation and disposal of the Landfill 1D remediation waste was completed in June 2000.

The selected remedial action for the Landfill 1D site included excavation to the extent required to meet specified soil cleanup levels and disposal of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site. The remedial action also included the removal and disposal of solid waste and construction debris.
Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established in the 1997 RDR/RAWP and updated in the Remedial Design Report/Remedial Action Work Plan for the 300 Area (2002 RDR/RAWP) (DOE RL 2002).

At the completion of the remedial action, the total excavation was approximately 2,100 square meters (22,600 square feet) in area with a maximum depth of approximately 5.7 meter (19 feet). Approximately 5,635 metric tons (6,198 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility. All visible debris was removed and the site was excavated to native soil. Overburden material identified as potentially clean was stockpiled at the site for potential use as backfill.

The site meets cleanup standards and has been reclassified as "closed out" in accordance with the Hanford Federal Facility Agreement and Consent Order (Ecology et al. 1998) and the Waste Site Reclassification Guideline TPA-MP-14 (RL TPA-90-0001) (DOE-RL 1998).

**Code:** UPR-300-FF-1  
**Classification:** Accepted  
**Names:** UPR-300-FF-1; 300-FF-1 Hot Spots; Surface Radiation Survey for 300-FF-1; UN-300-FF-1  
**Reclassification:** Closed Out (7/23/2003)  
**Type:** Unplanned Release  
**Start Date:**  
**Status:** Inactive  
**End Date:**  
**Description:** The site has been remediated and closed out.  
**Location:** The posted release sites were widely spaced in the area north of the 300 Area fence.  
**Related Sites/Structures:** The release sites were located in the 300-FF-1 Operable Unit and associated with WIDS sites 300-44, 300-49, 300-50, 300-51, the 316-1 South Process Pond and 316-2 North Process Pond.  
**Waste Type:** Process Effluent  
**Waste Description:** Primarily, contamination was associated with the soil; however, some contaminated metal and other materials were also found. GM/P-11 instrument readings range from 100 to 50,000 counts/minute. Analysis of samples showed that the radiation levels were caused primarily by the presence of uranium. Some soil samples also contained relatively high concentrations of copper.  
**Closure Info:** Remediation activities at the 316-1 South Process Pond site began in 1997 with excavating trenches around the periphery of the 316-1 site. Trenching was performed to assess the lateral extent of contamination. The majority of remedial excavation and disposal activities were conducted in 1999 and 2000. Excavation at the site involved removing the overburden (scraped surface) soils and contaminated soils. The contaminated soil was transported to the ERDF for disposal. Based on field screening, overburden materials and comingle soil identified as potentially clean were placed in stockpiles for potential use as backfill. Soil samples were collected adjacent to utility poles located in the 316-1 site. Where these samples indicated contaminant concentrations above the cleanup criteria, the soil was removed and the area immediately backfilled and compacted with clean material to maintain the integrity of the utility pole. Excavation and disposal of the 316-1 South Process Pond remediation waste was completed in June 2000. The filter backwash pond (WIDS site 300 RFBP) was a lobe on east side of the process pond. During remediation, soil was primarily removed from the area on the west side of the process pond, near the pond inlet. The two north-south parallel soil berms inside the pond were removed. Areas to the south and west of the original pond boundaries were also removed during remediation. The general elevation at the bottom of the excavation
used for analysis was 111.3 meters (365 ft) upon completion. The excavation depth was approximately 5.7 meters (19 ft).

The spoils area was covered with plastic and aggregate to allow continued operation of the trenches without flushing residual contaminants into the groundwater. Post-excavation sample results indicated that the ERA successfully reduced contamination in all areas of the trenches, other than the spoils area.

RCRA closure of the process trenches was performed in accordance with the 300 Area Process Trenches Modified Closure Post Closure Plan (DOE-RL 1995). An independent registered professional engineer was tasked to review the 300-FF-1 remedial action activities to ensure that the TSD closure met the WAC 173-303-610 performance standards. The permit was closed with post-closure requirements.
**Description:** The site was a release that flowed into the 313 Process Sewer leading to the 316-5 Trench.

**Location:** UPR-300-15 was located at the end of the 313 Process Sewer at the 316-5 Trench.

**Release Description:** Uranium-bearing Acid Storage Tanks 3 and 4 in Building 313 overflowed the catch barrel and trickled over into the process sewer. Further inspection revealed that Tank 3 had discharged downward into Tank 4 through interconnected discharge lines. The discharge line for Tank 4 was wide open.

**Related Sites/Structures:** UPR-300-15 was associated with uranium-bearing acid storage Tanks 3 and 4, the overflow catch barrel in Building 313, and the 316-5 Process Trenches.

**Waste Type:** Storage Tank

**Waste Description:** The waste contained uranium-bearing acid.

**Closure Info:** CERCLA remediation activities were initiated in July 1997 and completed in February 1998. Remediation of the 300 Area Process Trenches included removal and disposal of bird screens covering the trenches, demolition and disposal of the headworks structure located at the southern end of the trenches, demolition and disposal of the blockhouse structure, and excavation and disposal of contaminated soil that accounted for several unplanned release waste sites.

<tr>
<td>Description:</td>
<td>The release originated at the 313 Building floor trenches and was confined to the 300 Area Process Trench.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>UPR-300-19 occurred in the 313 Building and was washed into the 300 Area Process Sewer. The 300 Area Process Sewer is routed to the 316-5 Trench.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Release Description: Two 14 gallon drums of incoming deoxidization chemicals (nitric-sulfuric-chromic acid mixture) were found to be leaking. After the leaks were discovered, the floor was washed off, resulting in discharge to the process sewer. The process sewer showed high nitrate, fluoride, and pH values as a result of this incident. The event is documented on Unusual Event Report SO-80-12.

Related Sites/Structures: UPR-300-19 was associated with the floor trenches in the 313 Building and the 300 Area Process Sewer (316-5).

Waste Type: Storage Tank
Waste Description: The waste contained nitric, sulfuric and chromic acid, followed by an ammonium bifluoride and sodium hydroxide discharge with incoming acid used in copper component deoxidizing.

Closure Info: CERCLA remediation activities were initiated in July 1997 and completed in February 1998. Remediation of the 300 Area Process Trenches included removal and disposal of bird screens covering the trenches, demolition and disposal of the headworks structure located at the southern end of the trenches, demolition and disposal of the blockhouse structure, and excavation and disposal of contaminated soil that accounted for several unplanned release waste sites.

In 1991, an expedited response action (ERA) was performed to reduce the migration of radioactive and inorganic (heavy metals) contaminants to groundwater. This was accomplished by excavating contaminated sediments in the south end of the trenches, using them to fill in the north end of the trenches, and immobilizing them. The ERA uniformly excavated approximately 0.3 meters (1ft) and 1.3 meters (4 ft) of contaminated soil from the sides and bottom of each trench, respectively. The contaminated material was stockpiled in the northwest corner of the west trench and the north end of the east trench (referred to as a spoils area). Based on process history, the Part A submitted by the U.S. Department of Energy, Richland Operations Office (DOE-RL) assigned several listed waste codes to the ERA spoils pile. The spoils area was covered with plastic and aggregate to allow continued operation of the trenches without flushing residual contaminants into the groundwater. Post-excavation sample results indicated that the ERA successfully reduced contamination in all areas of the trenches, other than the spoils area.

RCRA closure of the process trenches was performed in accordance with the 300 Area Process Trenches Modified Closure Post Closure Plan (DOE-RL 1995). An independent registered professional engineer was tasked to review the 300-FF-1 remedial action activities to ensure that the TSD closure met the WAC 173-303-610 performance standards. The permit was closed with post-closure requirements.
and sulfuric acid into the 316-5 Process Trench.

Waste Type: Storage Tank
Waste Description: Nitric and sulfuric acids with uranium in solution, quantity unknown.

Closure Info: CERCLA remediation activities were initiated in July 1997 and completed in February 1998. </table>
Description: The release was an overflow to the 334A Containment Pit. The UPR was routed to the 300 Area Process Trench.

Location: UPR-300-28 originated with an overflow into the 334A Containment Pit from the 334A Storage Tank. The UPR was routed to the 300 Area Process Trench.

Release Description: An open water fill line in the 333 Building caused the process tank to overflow into the 334A Storage Tanks, which overflowed into the containment pit. The pit then overflowed into the process sewer system. Overflow to the process sewer apparently began at 7:30 a.m. on June 3, 1978 and was discovered on the morning of June 5, 1978. The sewer pH monitor indicated the pH dropped from 7.4 to 6.8 after the solution from the pit entered the sewer, indicating very little acid was dumped into the sewer. In Fiscal Year 1998, the R-12 refrigerant in all eight chillers was replaced with R-134A, which is nonhazardous and non-ozone depleting.

Related Sites/Structures: UPR-300-28 was associated with the 334A Storage Tanks, 334A Containment Pit, and the 300 Area Process Trench.

Waste Type: Storage Tank

Waste Description: The release consisted of solution containing hydrofluoric, nitric, and sulfuric acids with copper, uranium, and zirconium in solution.

Closure Info: CERCLA remediation activities were initiated in July 1997 and completed in February 1998. Remediation of the 300 Area Process Trenches included removal and disposal of bird screens covering the trenches, demolition and disposal of the headworks structure located at the southern end of the trenches, demolition and disposal of the blockhouse structure, and excavation and disposal of contaminated soil that accounted for several unplanned release waste sites.

In 1991, an expedited response action (ERA) was performed to reduce the migration of radioactive and inorganic (heavy metals) contaminants to groundwater. This was accomplished by excavating contaminated sediments in the south end of the trenches, using them to fill in the north end of the trenches, and immobilizing them. The ERA uniformly excavated approximately 0.3 meters (1ft) and 1.3 meters (4 ft) of contaminated soil from the sides and bottom of each trench, respectively. The contaminated material was stockpiled in the northwest corner of the west trench and the north end of the east trench (referred to as a spoils area). Based on process history, the Part A submitted by the U.S. Department of Energy, Richland Operations Office (DOE-RL) assigned several listed waste codes to the ERA spoils pile. The spoils area was covered with plastic and aggregate to allow continued operation of the trenches without flushing residual contaminants into the groundwater. Post-excavation sample results indicated that the ERA successfully reduced contamination in all areas of the trenches, other than the spoils area.

RCRA closure of the process trenches was performed in accordance with the 300 Area Process Trenches Modified Closure Post Closure Plan (DOE-RL 1995). An independent registered professional engineer was tasked to review the 300-FF-1 remedial action activities to ensure that the TSD closure met the WAC 173-303-610 performance standards. The permit was closed with post-closure requirements.

*Hanford Site Waste Management Units Report*

February 2015
Area Process Trench.

**Location:** UPR-300-28 originated as leaks in the PVC chemical waste piping system in the 333 Building. The UPR was routed to the 300 Area Process Trench.

**Release Description:** Leak testing of the system revealed three leaks in the PVC piping system. In addition, one leak was found in the incoming nitric acid supply line.

**Related Sites/Structures:** UPR-300-29 was associated with the PVC chemical waste drain piping system in the 333 Building and the 300 Area Process Trench.

**Waste Type:** Storage Tank

**Waste Description:** The waste consisted of an unknown quantity of waste etch acids containing hydrofluoric, nitric, sulfuric, and chromic acids with copper, uranium, and zirconium in solution.

**Closure Info:** CERCLA remediation activities were initiated in July 1997 and completed in February 1998. Remediation of the 300 Area Process Trenches included removal and disposal of bird screens covering the trenches, demolition and disposal of the headworks structure located at the southern end of the trenches, demolition and disposal of the blockhouse structure, and excavation and disposal of contaminated soil that accounted for several unplanned release waste sites.

In 1991, an expedited response action (ERA) was performed to reduce the migration of radioactive and inorganic (heavy metals) contaminants to groundwater. This was accomplished by excavating contaminated sediments in the south end of the trenches, using them to fill in the north end of the trenches, and immobilizing them. The ERA uniformly excavated approximately 0.3 meters (1ft) and 1.3 meters (4 ft) of contaminated soil from the sides and bottom of each trench, respectively. The contaminated material was stockpiled in the northwest corner of the west trench and the north end of the east trench (referred to as a spoils area). Based on process history, the Part A submitted by the U.S. Department of Energy, Richland Operations Office (DOE-RL) assigned several listed waste codes to the ERA spoils pile. The spoils area was covered with plastic and aggregate to allow continued operation of the trenches without flushing residual contaminants into the groundwater. Post-excavation sample results indicated that the ERA successfully reduced contamination in all areas of the trenches, other than the spoils area.

RCRA closure of the process trenches was performed in accordance with the 300 Area Process Trenches Modified Closure Post Closure Plan (DOE-RL 1995). An independent registered professional engineer was tasked to review the 300-FF-1 remedial action activities to ensure that the TSD closure met the WAC 173-303-610 performance standards. The permit was closed with post-closure requirements.

**Code:** UPR-300-30

**Classification:** Accepted

**Names:** UPR-300-30; Acid Release to the Process Sewer

**Reclassification:** Closed Out (8/13/1998)

**Type:** Unplanned Release

**Start Date:** 1/1/1975

**End Date:** 1/1/1975

**Status:** Inactive

**Description:** The release originated at the Waste Acid System in the 333 Building and was routed to 300 Area Process Trench.

**Location:** UPR-300-30 originated in the 333 Building and was routed to the 300 Area Process Trench.

**Release Description:** A chemical reaction occurred when a carbonate-bearing solution was added to the waste acid solution. This caused foaming and eventually an overflow of the process tanks that discharged to the process sewer.
UPR-300-30 was associated with the waste receiving tank and chemical processing tanks in the 333 Building and the 300 Area Process Trench.

Waste Type: Process Effluent
Waste Description: The waste consisted of a small quantity of waste etch acids and spent film chemicals containing hydrofluoric, nitric, sulfuric, and chromic acids.

Closure Info: CERCLA remediation activities were initiated in July 1997 and completed in February 1998. Remediation of the 300 Area Process Trenches included removal and disposal of bird screens covering the trenches, demolition and disposal of the headworks structure located at the southern end of the trenches, demolition and disposal of the blockhouse structure, and excavation and disposal of contaminated soil that accounted for several unplanned release waste sites.

In 1991, an expedited response action (ERA) was performed to reduce the migration of radioactive and inorganic (heavy metals) contaminants to groundwater. This was accomplished by excavating contaminated sediments in the south end of the trenches, using them to fill in the north end of the trenches, and immobilizing them. The ERA uniformly excavated approximately 0.3 meters (1ft) and 1.3 meters (4 ft) of contaminated soil from the sides and bottom of each trench, respectively. The contaminated material was stockpiled in the northwest corner of the west trench and the north end of the east trench (referred to as a spoils area). Based on process history, the Part A submitted by the U.S. Department of Energy, Richland Operations Office (DOE-RL) assigned several listed waste codes to the ERA spoils pile. The spoils area was covered with plastic and aggregate to allow continued operation of the trenches without flushing residual contaminants into the groundwater. Post-excavation sample results indicated that the ERA successfully reduced contamination in all areas of the trenches, other than the spoils area.

RCRA closure of the process trenches was performed in accordance with the 300 Area Process Trenches Modified Closure Post Closure Plan (DOE-RL 1995). An independent registered professional engineer was tasked to review the 300-FF-1 remedial action activities to ensure that the TSD closure met the WAC 173-303-610 performance standards. The permit was closed with post-closure requirements.

UPR-300-32 was associated with piping, transfer pumps, the uranium mill tank at the 333 Building, and the 300 Area Process Pond.

Waste Type: Equipment
Waste Description: The waste consisted of an unknown quantity of uranium etch acids containing nitric and sulfuric acid with uranium in solution.
Closure Info: Remediation activities at the 316-1 South Process Pond site began in 1997 with excavating trenches around the periphery of the 316-1 site. Trenching was performed to assess the lateral extent of contamination. The majority of remedial excavation and disposal activities were conducted in 1999 and 2000. Excavation at the site involved removing the overburden (scraped surface) soils and contaminated soils. The contaminated soil was transported to the ERDF for disposal. Based on field screening, overburden materials and comingled soil identified as potentially clean were placed in stockpiles for potential use as backfill. Soil samples were collected adjacent to utility poles located in the 316-1 site. Where these samples indicated contaminant concentrations above the cleanup criteria, the soil was removed and the area immediately backfilled and compacted with clean material to maintain the integrity of the utility pole. Excavation and disposal of the 316-1 South Process Pond remediation waste was completed in June 2000. The filter backwash pond (WIDS site 300 RFBP) was a lobe on east side of the process pond. During remediation, soil was primarily removed from the area on the west side of the process pond, near the pond inlet. The two north-south parallel soil berms inside the pond were removed. Areas to the south and west of the original pond boundaries were also removed during remediation. The general elevation at the bottom of the excavation used for analysis was 111.3 meters (365 ft) upon completion. The excavation depth was approximately 5.7 meters (19 ft).

Code: UPR-300-33  Classification: Accepted
Type: Unplanned Release  Start Date: 1/1/1974
Status: Inactive  End Date: 1/1/1974
Description: The site has been remediated and closed out.
Location: UPR-300-33 occurred in the acid drain system and incoming acid fill line in the 333 Building and was routed to the 300 Area Process Pond.
Release Description: A leak test in the chemical waste drain system revealed 16 leaks from the 333 Building to the 334-A Building. Additionally, 5 leaks were found in the incoming acid fill lines (presumably nitric or sulfuric acid system).
Related Sites/ Structures: UPR-300-33 was associated with the acid drain system and acid fill lines in the 333 Building and the 300 Area Process Pond.
Waste Type: Storage Tank
Waste Description: The waste consisted of an unknown quantity of waste etch acids containing hydrofluoric, nitric, and chromic acids with copper, uranium, and zirconium in solution.
Closure Info: Remediation activities at the 316-1 South Process Pond site began in 1997 with excavating trenches around the periphery of the 316-1 site. Trenching was performed to assess the lateral extent of contamination. The majority of remedial excavation and disposal activities were conducted in 1999 and 2000. <tr>
<td>Location:</td>
<td>UPR-300-34 was the result of the failed limestone neutralization tank at the 333 Building causing the acid stream to be routed to the Process Pond, north of the 300 Area.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Release Description:</td>
<td>On August 1, 1973, failure of the limestone neutralization tank resulted in a discharge of acidic waste solutions to the ground beneath the tank (see 300-21) and the routing of the acid waste to the process pond. The spent etch acid solution potential contaminants are described in the Waste Characterization Report for Phase II of the Decontamination and Inspection Plan for the 333 Building and the 334-A Facility. Potential contaminants of concern are those generated by the 333 N-Fuels WATS processes. These can include nitrate and sulfate salts of hexavalent chromium, uranium, copper, aluminum, beryllium, nickel, manganese, hexafluorozirconates, and iron. The potential acids involved include nitric acid, sulfuric acid, and hydrofluoric acid.</td>
<td></td>
<td></td>
</tr>
<tr>

<td>UPR-300-34 was associated with the 333 Building, the limestone neutralization tank (see Site Code 300-21), the 300 Area Process Sewer, and the 316-1 Process Pond and UPR-300-32 through UPR-300-37.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>Prior to August, 1973, spent etch acids from the 333 N-Fuels manufacturing process drained via a polyvinyl chloride (PVC) line in the pipe trench (see 300-258) to an underground 14,380 liter (3800 gallon) tank (see WIDS 300-21) on the east side of the 333 Building. The waste acid was then pumped to an overhead waste acid storage tank (see WIDS 334 TFWAST) and from there it was pumped via a 5.1 centimeters. (2 inches.) PVC pipe in the Pipe Trench to the 313 Building for neutralization and waste disposal. On August 1, 1973, the spent etch acid waste solutions were rerouted to the process sewer which discharged to the 300 Area Process Pond pending the replacement of the failed underground waste acid receiving tank (WIDS 300-21). Sodium hydroxide was added to the Process Sewer during each discharge of spent acid solutions to neutralize (i.e. in-line) the waste acid solutions. pH control was used to maintain the discharges from the Process Sewer at a high pH. The 334-A Facility was put into service in January 1975 with two acid receiving tanks (see WIDS 334-A-TK-B and C). The 334-A Facility received the spent etch acid solutions from the 333 Building via drain pipes in the Pipe Trench. In-line neutralization in the Process Sewer was discontinued with the availability of the 334-A Facility. The site of the limestone neutralization tank was partially excavated during removal of the failed tank. It is assumed that some of the acid-contaminated soil beneath the tank was removed and the subsoil area was neutralized with water and sodium bicarbonate. Records for the leak cleanup activities are being sought. The subsoil site was partially excavated for the installation of the foundation of the 334-A Facility. The 334-A Facility included a below grade tank pit area with three tanks, pumps, and associated piping (see 334-A-TK-B and 334-A-TK-C).</td>

Code: UPR-300-47

Classification: Accepted

Reclassification: Closed Out (8/13/1998)

Names: UPR-300-47; 309 Building; Ethylene Glycol Release; Glycol Spill from the 309 Chiller System

Type: Unplanned Release

Status: Inactive

Start Date: 1/1/1993

End Date: 1/1/1993

Description: The release site was the sump in the machinery room at the 309 Building. The release site was cleaned up and waste generated during the cleanup was disposed of properly on May 7, 1993.

Location: UPR-300-47 originated at the number 3 water chiller, drained to the sump, and discharged to the process sewer in the 309 Building.

Release Description: On April 30, 1993 at approximately 1:30 a.m., a leak from the 309 Building cooling system was identified. About 2:00 a.m., the automatic sump pump in the 309 Building was turned off. The sump had collected the ethylene glycol and discharged approximately 800 gallons (3,030 liters) of 38 percent ethylene glycol solution to the process sewer before being turned off. At approximately 3:45 a.m. operations personnel observed green liquid coming from the process trench weir box. The release was due to failure of the expansion joint in the number 3 water chiller.

Related Sites/Structures: UPR-300-47 was associated with the 309 Building cooling system, sump, process sewer and process trenches (316-5).
Waste Type: Storage Tank
Waste Description: The waste consisted of 38 percent ethylene glycol solution.

Closure Info: CERCLA remediation activities were initiated in July 1997 and completed in February 1998. Remediation of the 300 Area Process Trenches included removal and disposal of bird screens covering the trenches, demolition and disposal of the headworks structure located at the southern end of the trenches, demolition and disposal of the blockhouse structure, and excavation and disposal of contaminated soil that accounted for several unplanned release waste sites.

In 1991, an expedited response action (ERA) was performed to reduce the migration of radioactive and inorganic (heavy metals) contaminants to groundwater. This was accomplished by excavating contaminated sediments in the south end of the trenches, using them to fill in the north end of the trenches, and immobilizing them. The ERA uniformly excavated approximately 0.3 meters (1ft) and 1.3 meters (4 ft) of contaminated soil from the sides and bottom of each trench, respectively. The contaminated material was stockpiled in the northwest corner of the west trench and the north end of the east trench (referred to as a spoils area). Based on process history, the Part A submitted by the U.S. Department of Energy, Richland Operations Office (DOE-RL) assigned several listed waste codes to the ERA spoils pile. The spoils area was covered with plastic and aggregate to allow continued operation of the trenches without flushing residual contaminants into the groundwater. Post-excavation sample results indicated that the ERA successfully reduced contamination in all areas of the trenches, other than the spoils area.

RCRA closure of the process trenches was performed in accordance with the 300 Area Process Trenches Modified Closure Post Closure Plan (DOE-RL 1995). An independent registered professional engineer was tasked to review the 300-FF-1 remedial action activities to ensure that the TSD closure met the WAC 173-303-610 performance standards. The permit was closed with post-closure requirements.

Code: UPR-600-15
Names: UPR-600-15; Contaminated Material found at 618-4; UN-600-15
Type: Unplanned Release
Status: Inactive
Classification: Accepted
Reclassification: Interim No Action (7/12/2004)
Start Date: 1/1/1979
End Date: 1/1/1979

Description: The release site was an area of soil outside the entrance to the 618-4 Burial Ground. A new fence around the 618-4 Burial Ground was built in 1974. However, the fence was installed in a new location that did not include the location of the fuel elements. The discovered release site was outside the new boundary of the 618-4 burial ground. The previous fenced area included the release site.

Location: UPR-600-15 occurred in an area of soil running north and south of the west boundary fence of the 618-4 Burial Ground in the 600 Area.

Release Description: Depleted uranium fuel elements were improperly discarded outside the entrance to the 618-4 Burial Ground. They were found 9/20/1979.

Related Sites/Structures: UPR-600-15 was associated with the 618-4 Burial Ground.

Waste Type: Process Effluent
Waste Description: The contamination came from buried fuel elements containing 0.15 percent uranium-235. A dose rate of 4,000 millirads/hour was detected on the soil surface.

Closure Info: Depleted uranium fuel elements were improperly discarded outside the entrance to the 618-4 Burial Ground. They were found 9/20/1979.

The 618-4 Burial Ground was excavated between 1998 and 2003. The remediation activity included the area where the fuel elements had been located.
300-FF-2

Code: 300 RLWS
Names: 300 RLWS; 300 Area Radioactive Liquid Waste Sewer; 300 Area RLWS
Type: Radioactive Process Sewer
Status: Inactive

Description: The inactive 300 Area Radioactive Liquid Waste Sewer (RLWS) consists of a network of underground, stainless-steel pipe, double-encased with reinforced-fiberglass or plastic pipe as secondary containment. In 2013, the sewer system was divided into two subsites. Subsite 1 is the portions of the RLWS sewer that are not associated with the 309 building. Subsite 2 is the portion of the sewer from the 309 building to the 340 facility.

The system drained into the 340 Vault facility. Leak detection systems were attached inside the outer encasement. Fifteen valve boxes were spaced along the gravity-drained pipeline between waste generating facilities and the 340 Vault. The west leg of the RLWS collected discharge from the 329, 326, 325, 325-A and 327 buildings. The east leg collected effluent from the 324 building. Both legs join at valve box VB-8, between the 307 basins and the 340 Building. From VB-8 the flow drained to VB-9, and from VB-9 effluent drained to the 340 Vault. Generating facilities were isolated from the RLWS by closed valves outside of each facility. The 340 Vault tanks and the 340-A tanks were also valve-isolated from the RLWS.

On October 1, 1998, the 300 RLWS was isolated from the 340 Complex and waste generating facilities. The 340 Complex was demolished in 2011.

Location: The underground pipeline segments are located beneath a large portion of the 300 Area, connecting the 325, 325-A, 324, 326, 327, and 329 Buildings with the 340 Facility Complex.

Release Description: An Occurrence Report was issued stating that on 04/26/12, at approximately 0951 hours, a Washington Closure Hanford (WCH) subcontractor tasked with removing and size reducing utility lines located near the 327 Building in the 300 Area was utilizing an excavator equipped with a shear attachment to reduce exposed, deactivated steam lines for their eventual disposal. Located near the steam lines being reduced was an exposed deactivated Radiological Liquid Waste System (RLWS) line. While size reducing the steam line into four and five foot sections, the excavator operator inadvertently cut the RLWS line. Although the immediate work area was posted as a Contamination Area (CA), the inadvertent breaching of the RLWS line was unanticipated; therefore, the applicable radiological controls were not in place for the RLWS line upon it being breached. Upon breaching the RLWS line, work was stopped and radiological control personnel responded to the area to conduct surveys and verify radiological boundaries.

Related Sites/Structures: Structures associated with the system include the 324, 325, 325-A, 326, 327, and 329 Buildings and the demolished 340 Complex. Valve boxes VB-1 through VB-15 regulate flow through the system. From VB-9, the RLWS flows into the 340 Vault tanks. At each generating facility, instrumentation and a valve connect the Retention Process Sewer (RPS) to the RLWS. Prior to RLWS isolation in 1998, if the instrumentation detected activities in RPS waste higher than the alarm point, the valve routed the RPS waste into the RLWS. A transfer station at the 307 retention basins was also available to route RPS waste to the RLWS.

Process Description: The sewer system was designed to transfer radioactive liquid wastes from various generating facilities to the 340 Complex. The 340 Complex received and sampled the effluent. High activity effluent was transferred to the 200 Area for storage and disposal.

This Site has the Following SubSites:
Subsite 1 is the segments of the process sewer throughout the 300 Area that are not associated with the 309 building (segments associated with the 309 building are described in 300 RLWS:2).

The system drained into the 340 Vault facility. Leak detection systems were attached inside the outer encasement. Fifteen valve boxes are spaced along the gravity-drained pipeline between waste generating facilities and the 340 Vault. The west leg of the RLWS collected discharges from the 329, 326, 325, 325-A and 327 buildings. The east leg collected effluent from the 324 building. Both legs join at valve box VB-8, between the 307 basins and the 340 Building. From VB-8 the flow drained to VB-9, and from VB-9 effluent drained to the 340 Vault. Generating facilities are isolated from the RLWS by closed valves outside of each facility. The 340 Vault tanks and the 340-A tanks are also valve-isolated from the RLWS.

On October 1, 1998, the 300 RLWS was isolated from the 340 Complex and waste generating facilities. The 340 Complex was demolished in 2011.

The underground pipeline is located beneath a large portion of the 300 Area, connecting the 325, 325-A, 324, 326, 327, and 329 Buildings with the 340 Facility Complex.

The 300 RLWS pipeline is associated with the 340 Facility and the Retention Process Sewer (300-214).

As part of the 1953 laboratory expansion projects, the 307 Retention Basins, the Retention Process Sewer (RPS) and the Radioactive Liquid Waste Sewer (RLWS) were constructed. The RPS drained to the 307 Retention Basins, and retention waste above discharge limits was diverted to the 340 vault tanks via the RLWS. In 1993, Project W-345 re-lined the basins and provided a batch release capability.

The 340 Complex received and sampled the 300 Area radioactive liquid waste. Waste routed by the RLWS was accumulated and stored in two underground tanks. The waste was stored for less than 90 days. It was transferred to the 200 Areas by rail car for storage and disposal. Retention process sewer waste is collected at the 340 complex in the 307 retention basins, sampled, and discharged to the process sewer. Waste exceeding discharge criteria is held for transport to the 200 Areas.
Names: 300 RLWS; 309 Contaminated Sewer; Radioactive Sewer from 309 Building to 340 Facility

Reclassification: None

Type: Radioactive Process Sewer

Start Date: 1/1/1954

End Date: 1/1/1975

Status: Inactive

Description: Subsite 2 is the segments of the Radioactive Liquid Waste Sewer (RLWS) associated with the 309 building. It was made a subsite because the 309 Contaminated Sewer system is similar to the Retired Radioactive Liquid Waste Sewer (RRLWS) in construction, but significantly older than the 300 RLWS. It is a separate system from the RRLWS and RLWS and handled a narrower range of contaminants than the RRLWS/RLWS.

Process Description: The 309 Contaminated Sewer is a network of single-walled steel and vitrified clay piping that connected 309 Building radioactive contaminated effluent to the 309 building tank farm (sitecodes 309-TW-1, 309-TW-2 and 309-TW-3). In 1960, a separate 8 centimeter (3-in.) diameter carbon steel line was installed to connected the 309 Building tank farm to the 340 facility tanks. Contaminated effluent from the 309 Building facility was designed to be directed to the PRTR transfer waste tank farm (also known as TW Tank or Holdup Tank). It was located to the northeast of the 309 Building reactor containment vessel. The tank farm consisted of three underground tanks on a buried concrete pad, an adjacent concrete valve pit, and underground piping. The tanks are commonly known as TW-1, TW-2, and TW-3. The 309 Retention Waste Sewer was designed to accommodate potentially contaminated effluent and is connected to the 300 Area RPS (300-214) west of the 324 Building.

The SubSite is Part Of:

Code: 300 RLWS

Names: 300 RLWS; 300 Area Radioactive Liquid Waste Sewer; 300 Area RLWS

Code: 300 RRLWS

Classification: Accepted

Reclassification: None

Name: 300 RRLWS; Contaminated Sewer; Crib Waste System; Intermediate Level Radioactive Liquid Waste System; 300 Area Retired Radioactive Liquid Waste Sewer System; 300 Area Retired RLWS

Type: Radioactive Process Sewer

Start Date: 1/1/1954

End Date: 1/1/1975

Status: Inactive

Description: The 300 Area Retired Radioactive Liquid Waste Sewer (RRLWS) is a network of 5-, 8-, 10-, and 15-centimeter (2-, 3-, 4-, and 6-inch) single-walled stainless steel piping and carbon steel fittings buried between 3 and 6 meters (10 and 20 feet) below grade. A separate 8-centimeter (3-inch) carbon steel transfer line installed in 1960 connected the 309 Building to the 340 Complex. No isolation valves, radiation monitors, or other leak detection capabilities were built into the RRLWS system. Since the potential for corrosion was low, the retired system was abandoned in place.

Location: The unit lies below grade in the 300 Area. Brass monuments locate several of the sewer clean outs.

Coordinates provided by Fluor Hanford as the main source to the pipeline system are: N115930.4 E594171.2. These coordinates are for a location on the south side of the 340 Building complex.
The unit is retired and does not receive effluent. While in service, the system transferred radioactive liquid waste from laboratories and facilities in the 300 Area to the 340 Complex for sampling and disposal.

| Code: | 300 VTS |
| Names: | 300 VTS; In-Situ Vitrification (ISV) Test Site; 300 Area Vitrification Test Site |
| Type: | Process Unit/Plant |
| Status: | Inactive |
| Start Date: | 1/1/1983 |
| End Date: | 1/1/1986 |

The site has been remediated and Interim Closed Out in 2006. It was considered Final Closed Out in 2014. The site consisted of a mobile pilot plant trailer, a Terra-Vit melter structure, Large-Scale ISV Off-Gas Assembly (hood), storage units, metal sheds, sea-land units, spare parts and other support structures, most of which were removed in 1999. The vitrified material and soil, miscellaneous equipment, empty barrels, crates, metal scaffolding, and pallets of miscellaneous materials were also removed. Five in-situ vitrified monoliths (up to 1000 tons) had been in the ground on the west side of the site. One of these monoliths was located below the Large-Scale Off-Gas Hood. Within the test site was a fenced concrete pad, where an electrical substation had been located. The electrical transformer pad had been a separate waste site, 300-231, Vitrification Test Site Transformer Pad, Substation C3-S15, but it was Consolidated with 300 VTS. The transformers have been removed.

The area was located west of Route Four South, across from the 300 Area and 9 meters (30 feet) south of 618-7 Burial Ground.

The site was associated with the 300 Area Thermal Treatment Research and Development Facilities and the 300-231 electrical transformers.

The site was used in the 1980's and 1990's as a field demonstration site for the melting of soils containing waste simulates. Tests using PCB's and limited tests with very low levels of radioactivity were conducted at the site.

In-situ vitrification (ISV) was a thermal treatment process that converted contaminated soils and sludges into a glass and crystalline product. An electrical current was passed among an array of four electrodes imbedded in the contaminated soil or sludge, melting and glassifying it. The process continued outward and downward until the appropriate vitrification depth was obtained.

Radioactive mixed waste (RMW) and dangerous waste constituents were stabilized in the glass and crystalline product. Organic contaminants were destroyed by pyrolysis, and the pyrolysis products oxidized as they migrated to the surface. An off-gas assembly was used to collect and treat off-gases to ensure complete containment of the waste materials. PNNL operated four
treatability testing units (bench-, engineering-, pilot-, and large-scale). The engineering and bench-scale units were located in the 324 Building. The pilot and large-scale units were transportable within the Hanford Site. The maximum design capacity of the large-scale unit (at the ISV site) was 64,345 liters (17,000 gallons) per day.

**Closure Info:** Interim

Remedial action at the 300 VTS site began in December 2004. The ISV melter structure was demolished using mechanical shears. The off-gas containment hood was sheared and sent to ERDF for disposal. The support frame was sheared and the scrap metal recycled. Test equipment and buried vitrified monoliths have been demolished or excavated, removed from the site, and recycled or disposed. The rubble was then sent to 600-246, (Gravel Pit #9, Inert/Demolition Waste Landfill) for disposal. All rubble met the requirements of the February 2005 inert landfill regulation (Washington Administrative Code [WAC] 173-350-410). Two test trenches were also excavated, the locations of which were based on historical information and geophysical anomalies. No soil contamination, except cesium-137, which was below the RAGs, was found in the test trenches. Debris included graphite electrodes that were sent to ERDF and pipe casings that were recycled.

Final cleanup verification samples were collected on August 22, 2005, to confirm acceptability of residual contaminant concentrations in the soil. Based on the overall footprint of the area and depth of excavation. The site was classified as one shallow zone decision unit.

A total of 83 metric tons (91 US tons) of structural steel was recycled from the demolition of the Terra-Vit melter and off-gas hood support structure. Disposal of the off gas containment structure resulted in 10 metric tons (11 US tons) of material being sent to ERDF. A total of 5,218 metric tons (5,752 US tons) of vitrified soil was excavated and sent to Gravel Pit #9, Inert/Demolition Waste Landfill (600-246) for disposal.

The Cleanup Verification Package for the 300 VTS Waste Site (CVP) has documented that the site was remediated in accordance with the Record of Decision for the 300-FF-2 Operable Unit, Hanford Site (ROD), as modified by the Explanation of Significant Differences for the 300-FF-2 Operable Unit Interim Record of Decision (ESD). Remedial action at the site has achieved the Remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) established in the ROD and the Remedial Design Report/Remedial Action Work Plan for the 300 Area (RDR/RAWP).

**Final**

The group of sites [300 VTS, 300-8, 600-243, 618-7, 618-9, 618-13, 600-290:1] were reclassified to Final Closed Out in 2014. They are listed in the 300-FF-2 Record of Decision and meet the criteria for unrestricted landuse.

</tbody>
</table>
technicians in late 1993, in preparation for excavations at the proposed EMSL site, which began in April 1994. During excavations, it was discovered that a Native American burial ground is in the area.

**Location:** The site is located east of the George Washington Way extension and south of the 300 Area fence line, inside the chained off area.

**Closure Info:** Interim

The reclassification is documented on form 98-081. Due to the culturally sensitive issues in this area, the decision makers associated with the 300-FF-2 Limited Field Investigation concluded that no further action would be necessary at this site.

Final

The site group of sites [300-1, 300-29, 600-22] are listed in the 300-FF-2 Record of Decision and meet the criteria for unrestricted landuse.

---

**Code:** 300-2

**Names:** 300-2; Contaminated Light Water Disposal; Potential Trench Location #1

**Type:** Trench

**Status:** Inactive

**Start Date:** 1/1/1965

**End Date:** 1/1/1966

**Classification:** Accepted

**Reclassification:** Final No Action (5/12/2014)

**Description:** The waste site has been evaluated and determined to require No Action. In 2014, the site was reclassified to Final No Action. It was an intentional release of contaminated water to soil in 1965.

**Location:** The exact location of the waste site is questionable. It is described as being located east of the 309 Building parking lot. 300-2 is one potential location, approximately beneath the demolished 3766 Building. An alternate location is described in sitecode 300-283. One estimated waste site dimensions is documented as 22.86 by 15.24 meters (75 by 50 ft). Another estimate is described in the Focused Feasibility Study for the 300-FF-2 Operable Unit as an irregularly shaped trench measuring 103.6 meters (340 ft) long by 85.3 meters (280 ft) wide. Both are estimated dimensions of a disposal event that would have had unknown, or at best, approximate boundaries. The dimensions reported were taken from separate source documents.

**Release Description:** About 189,250 liters (50,000 gallons) of secondary cooling water and other contaminated water containing 33 millicuries iodine-133 and 12 millicuries iodine-131 were disposed of to ground. About 10 microcuries of alpha emitters (calculated as Pu-239) and about 40 microcuries of non-volatile beta emitters plus rutheniums were transferred to the trench during the first 36 hours of the incident. A small number of short pumpings were made after that, however, the total gallonage and radioisotopic inventory are insignificant in comparison to those during the first 36 hours.

**Related Sites/Structures:** 300-2 is associated with sitecode 300-283, another potential location of the disposal trench. 300-283 was evaluated and reclassified to No Action in 2012. The contaminated light water came from the 309 Building also called the Plutonium Recycle Test Reactor (PRTR) - see H-3-11002.

**Process Description:** Radioactively contaminated water from a 1965 release at the Plutonium Recycle Test Reactor (309 Building) was pumped to the ground to avoid direct discharge to the Columbia River.

**Closure Info:** Interim

Because the exact location of the trench cannot be definitively determined, two suspected 300-2
waste site locations were investigated and sampled. The primary 300-2 waste site location is east of the 309 Building parking lot, beneath the location of the former 3766 Building, at Washington State Plane (WSP) coordinates N115607.4/E594192.2. The secondary location of the disposal of the contaminated liquid from this incident was described in the Compilation of Historical Information of 300 Area Facilities and Activities document as being located beneath the location of the former 3763 Building. This potential location is 24 meters (79 ft) east of the former 3766 Building at coordinates WSP N115612/E594216.

A third potential location is sitecode 300-283, Contaminated Light Water Disposal Site #2. A test pit for the 300-283 location was sampled at WSP coordinates N115596.6/E594258.2 on April 26, 2012. The 300-283 sample location is approximately 68 meters (223 ft) east of the primary 300-2 waste site coordinates given above. The 300-283 waste site was reclassified as Interim No Action in July 2012, as documented in the Remaining Sites Verification Package for the 300-283, Contaminated Light Water Disposal Site #2.

The confirmatory sampling instructions for the 300-2 waste site directed sampling at each of the two potential 300-2 waste site locations. Two test pits were dug on January 22, 2013. The first test pit was located in the footprint of the demolished 3766 Building at WSP coordinates N115607.4/E594192.2. One discrete soil sample was collected from the base of this test pit at 5.2 meters below ground surface (bgs). The second test pit was located in the footprint of the demolished 3763 Building at WSP coordinates N115612/E594216. One discrete sample was collected from the base of this test pit at 4.6 meters bgs.

Radiological surveying with field instrumentation did not indicate readings above background during excavation and confirmatory sampling of test pit 1 and test pit 2. No additional debris was observed during sampling and no soil staining was noted.

Final

Two suspected 300-2 waste site locations were investigated and sampled on January 22, 2013. The 300-2 waste site has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Evaluation of previous confirmatory sampling results show that the concentrations of COC's meet the CUL's for direct exposure and groundwater protection and river protection and support a residential land use scenario. Institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. In accordance with this evaluation, the confirmatory sampling results support a reclassification of the 300-2 waste site to Final No Action.
samples collected when the capacitors were removed showed PCB concentrations of less than 2 milligrams/kilogram. No spills to the soil have been documented by BPA. On October 18, 1990, the removal crew discovered radioactive yellow cake uranium clinging to the below ground portions of the footings.

**Process Description:**

The DOE 351 Substation was operated by the Bonneville Power Administration (BPA) from March 30, 1973 until February 11, 1991, when all BPA equipment was removed.

Mineral oil containing polychlorinated biphenyls (PCBs) and solvents were used during routine equipment maintenance. No spills to the soil were documented by the Bonneville Power Administration (BPA). Four capacitors (capacitors 3 and 31 north phase and capacitors 17 and 18 middle phase) were de-energized and removed in August 1989 because of insulating oil leaks. There is no evidence, however, that fluid leaked onto the ground from any of the removed capacitors. See analytical results for soil samples.

On October 17, 1990, removal of all BPA equipment was begun. On October 18, 1990 the removal crew discovered radioactive yellow cake uranium clinging to the below ground portions of the footings. The uranium is most likely associated with DOE-RL's fuel fabrication activities in the 300 Area and not any BPA related activities. Work was suspended until the area could be evaluated. Removal of the items (excluding the uranium contaminated footings) was completed on February 11, 1991.

---

**Code:** 300-5

**Names:** 300-5; 3709A Fire Station; 300 Area Fire Station Fuel Tanks

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The site was two underground fuel tanks, the pump island, ancillary piping, and contaminated soil. An unknown quantity of contaminated soil, under the fuel dispensing island at the 3709-A Building (300 Area Fire Station) was discovered on April 10, 1992. The fueling facility consisted of two 1893 liter (500 gallon) underground storage tanks (USTs), one containing unleaded gasoline (Tank 300-FS-15), the other diesel (Tank 300-FS-16), and approximately 9.1 meters (30 feet) of piping that lead to the fuel dispenser and island. The release was due in part to sections of corroded flex piping (with multiple pinhole size perforations) located directly under the pump island and also possibly from loose pipe/pump fittings. The pump island was removed immediately following the removal of the tanks and piping. Evidence that confirmed the release consisted of petroleum product odors that were detected by personnel immediately following the lifting of the pump island. The release was additionally confirmed by sampling performed during the site assessment. The system was undergoing permanent closure due to a failed tightness test conducted on August 26, 1991. These tanks were removed on April 14, 1992. The site is not marked in the field. Based on maps and descriptions, the site is under a paved portion of the access driveway on the southeast side of 3709A Building. A section of the asphalt has been patched where the tanks were dug up.

**Location:** The site is in the 300 Area, adjacent to the 3709A Fire Station on the south side, south and west of the east wall of 3709A. From this site it is approximately 28 meters (92 feet) to groundwater monitoring well #399-5-4B.

**Release Description:** The leaks are associated with two 1890 liter (500 gallon) tanks and were discovered during a tightness test of the tanks in August 1991. One of the tanks contained gasoline and the other, diesel fuel. The release was due in part to sections of corroded flex piping located directly under the pump island and also possibly from loose pipe/pump fittings.
Process Description: The gasoline and diesel tanks were used to refuel vehicles. The leaks were likely caused by corroded flex pipes and leaks in the fittings.

Location: The site is in the 300 area on the south side of the 3715 and 303-J buildings.

Related Sites/Structures: The site was associated with the 300 Area Fire Station, also known as building 3709A.

Process Description: Prior to excavation, the oil bunkers had consisted of four separate underground concrete fuel oil tanks (bunkers). It had been a large excavated area with soil staged adjacent to the excavation. The soil will eventually be used as fill. The area was isolated by a rope and orange safety fence.

Description: The waste site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. Prior to excavation, the oil bunkers had consisted of four separate underground concrete fuel oil tanks (bunkers). It had been a large excavated area with soil staged adjacent to the excavation. The soil will eventually be used as fill. The area was isolated by a rope and orange safety fence.

Location: The site is in the 300 area on the south side of the 3715 and 303-J buildings.

Related Sites/Structures: The site was related to the 384 Powerhouse, the 384 Powerhouse Fuel Oil Day Tanks #1 and #2 (WIDS Site 300-223), and ancillary piping (300-273).

Process Description: Prior to excavation, the oil bunkers had consisted of four separate underground concrete fuel oil tanks (bunkers). The site was north of a low berm wall (about 0.6 meters [2 feet] tall) and appeared on the surface as a rectangular concrete pad with manhole access plates and equipment and piping on the surface. Bunker 366 was under the west end of the concrete pad, and 366A was under the east end. Fuel oil tanks #1 and #2 were designated 366, while tanks #3 and #4 were designated as 366A.

The soil on the south side of the fuel bunkers appeared black, due to coal residue from the coal storage area that had been located here. Prior to 1964, the 384 Powerhouse was fueled with coal. The bunkers were installed to store fuel oil for the 384 powerhouse boilers when they were converted to oil burners. The first of the tanks was installed in 1964 to support the first oil-fired boiler at the 384 Powerhouse that same year. The additional three underground fuel oil tanks were constructed between 1970 and 1974 to support the conversion of coal fired boilers to oil. The tanks were originally unlined and used to store Bunker C Oil or Fuel Oil #6. A liner was installed in each tank when the decision was made to utilize #2 Diesel Oil in 1972. In approximately 1980, the powerhouse switched back to Bunker C Oil because of the increased cost of diesel. The liners were left in place.

During the time when #6 fuel was being used, the fuel from the underground tanks was continually heated using closed-loop steam lines in the tanks. The fuel oil was pumped from the main tanks (the bunkers) into the day tanks (site code 300-223) for additional heating prior to use for steam production in the powerhouse. The fuel oil becomes a very thick tar-like substance when left unheated and loses the ability to flow.

In 1991 the liner material had begun to deteriorate and sections of the liner were plugging up the suction heater, causing the pumps to cavitate. Also, the steam coils on the fuel bundles had deteriorated to the point that they were discharging steam into the fuel. There was also a significant build-up of sludge in the bottom of the tanks. A project was then completed to remove all of the sludge from the tanks and remove the liners and the river rock under the liners from the tanks. Several motors, heaters and other equipment pieces were also replaced under the same project. Since they were not required under regulation, neither the rock nor the liners
were replaced.

Closure Info: Interim

The 300-6 waste site (fuel oil bunkers) was expected to be excavated to groundwater, a depth of approximately 15.8 meters (52 ft) below ground surface (bgs), as necessary to remediate contaminated soil. Remediation of the waste site was performed from August 2 to December 8, 2010. The western portion of the 300-6 waste site excavation did reach the groundwater, and a pool of water remains in the floor of the excavation. The excavation was approximately 15 meters (49.5 ft) deep in the 300-6 west borehole location (when measured to the surface of the pool of water) and approximately 11.5 meters (37.7 ft) deep in the 300-6 east borehole location. The 300-6 and associated waste sites’ excavation resulted in approximately 34,770 bank cubic meters (45,477 bank cubic yards) of material removed for disposal at the Environmental Restoration Disposal Facility (ERDF).

Debris (piping and concrete) and soil from the remediation of the 300-6 and associated waste sites were direct loaded to ERDF. No overburden soil stockpiles were associated with the waste sites as a result of remediation, and no anomalies were noted.

The 300-123 UIC was identified as a WIDS waste site. The french drain was removed as part of the layback to remove the contaminated soil at the 300-6 waste site. The french drain consisted of soil and rock that extended to approximately 1.4 meters (4.5 ft) bgs. The existing floor of the 300-6 waste site excavation is approximately 11.3 m (37 ft) bgs.

The 300-65, 300-66, 300-122, and 300-124 UICs were located within the footprint of the 300-6 excavation layback and also removed during the 300-6 excavation. The 3715, 303E and 303J building slabs were removed during the 300-6 waste site excavation because they were located in the excavation layback as well.

The 300-268 site was located within the 300-6 layback area. It was excavated to a depth of 3.0 meters (9.8 ft).

During excavation of the 300-6 waste site, it was verified that the eastern half of the 300-273 waste site pipeline had been previously removed. In addition, as the project conducted test pits along the western half of the 300-273 waste site pipeline right-of-way on November 3, 2010, no pipeline structure was encountered at the elevations presented in the as-built drawings for the pipeline (USAEC 1974). Also in November 2010, the project excavated two test pits along the former 384 Powerhouse foundation within the UPR-300-42 waste site. No below-grade structure was noted, and no visible soil staining was observed, as was expected since the site was reportedly removed in 2009.

During excavation of the 300-6 waste site, it was verified that the eastern half of the 300-273 waste site pipeline had been previously removed. In addition, as the project conducted test pits along the western half of the 300-273 waste site pipeline right-of-way on November 3, 2010, no pipeline structure was encountered at the elevations presented in the as-built drawings for the pipeline. Also in November 2010, the project excavated two test pits along the former 384 Powerhouse foundation within the UPR-300-42 waste site. No below-grade structure was noted, and no visible soil staining was observed, as was expected since the site was reportedly removed in 2009 with the demolition of the 384 powerhouse structure.

Final

The 300 Area Fuel Oil bunkers and associated waste sites were remediated in 2010. The excavation extended to groundwater at a depth of 52 feet. The 300-6, 300-123, 300-268, 300-273, and UPR-300-42 waste sites were remediated and have been evaluated in accordance with
the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL’s for direct exposure and groundwater protection and river protection and support a residential land use scenario. Contamination that extended into the deep zone (greater than 4.6 meters [15 ft] bgs) has been removed; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-6, 300-123, 300-268, 300-273, and UPR-300-42 waste sites to Final Closed Out.

Reclassification:
- **Code:** 300-7
- **Names:** 300-7; Possible Early Burial Ground Site; Undocumented Solid Waste Burial Ground Adjacent to 618-8
- **Type:** Burial Ground
- **Status:** Inactive
- **Classification:** Accepted
- **Reclassification:** None

**Description:** The site is a small rise that extends to the north and west from the 300 Area North Parking Lot. It forms an irregular shaped polygon where the north edge of the parking lot is the south edge of the waste site. The site can be seen as a scarred area in several historical photographs (EMO-1026, pages A.26, A.30, A.34 labeled Burial Ground 8). Surface debris piles can be seen and subsurface disturbances have been identified with Ground Penetrating Radar. Currently, the site is covered with natural vegetation. Some of the visible surface debris consists of concrete, trash and cables. The area of subsurface anomalies is not marked.

**Location:** The site is located north of the 300 Area North Parking Lot, adjacent to and west of the north end of 618-8 Burial Ground. The results of a Global Positioning survey done in 1998 enlarged the footprint of the site.

---

Reclassification:
- **Code:** 300-8
- **Names:** 300-8; Aluminum Recycle Storage Area; Aluminum Shavings Area; North of Railroad and North of 618-8
- **Type:** Dumping Area
- **Status:** Inactive
- **Classification:** Accepted
- **Reclassification:** Final Closed Out (2/18/2014)

**Description:** The has been remediated and Interim Closed Out. The Aluminum Recycle Staging area consisted of six irregularly shaped Soil Contamination Areas located along the railroad track north of 300 Area. The contamination areas were on both sides of the railroad track and separated by unposted dirt roads.

**Location:** The site was located north of 300 Area and 618-8. It was west of the 316-5 Process Trenches. It consisted of a posted Soil Contamination Area adjacent to the rail spur. Another posted Soil Contamination Area was north of the rail road spur, across a dirt road.

**Process Description:** The site was used to stage scrap metal from the 300 Area. In 1962, recycling of aluminum scrap began. The material was staged until a sufficient quantity was collected for offsite salvage vendors to propose bids. The accumulated metal piles and the process of loading it onto rail cars scattered metal shavings over a large area. Some of the metal was radiologically contaminated with low levels of uranium and beryllium.

**Closure Info:** Interim
The remedial activity was conducted from December 2004 through May 2005. Initially, material within the site boundaries was removed to a depth of 0.3 meters (1 foot). Following excavation, geophysical surveys and ground-truthing excavations indicated that significant quantities of metal shavings, on the order of one to a few per square meter, remained at the site. Consequently, an additional 0.3 meters (1 foot) of material was removed from the entire area. Following this excavation, additional geophysical surveys were performed at thirty-five randomly located 3- by 3 meters (10 by 10 feet) test areas within the waste site boundaries. Within the 324 square meters (3,488 square feet) surveyed, fewer than 10 discrete pieces of metallic debris were detected. Based on these results and ground-truthing excavations, it was concluded that remediation was complete. Excavation of the site included the removal of small quantities of miscellaneous metal construction-type debris (e.g., nuts, bolts), aluminum metal shavings, and soil. No indications of liquid waste disposal or land disposal restricted materials were observed during excavation.

The Cleanup Verification Package for the 300-8 Waste Site (CVP-2005-00007), documented that remedial action objectives and goals have been achieved and meet the cleanup standards specified in the Record of Decision for the 300-FF-2 Operable Unit (ROD) and Remedial Design Report/Remedial Action Work Plan for the 300 Area (RDR/RAWP). Remedial actions were performed to support future industrial land use and to protect groundwater and the Columbia River.

The contaminated materials, approximately 39,750 metric tons (43,820 U.S. tons) of material, was removed for disposal at the ERDF. Results of post-remediation geophysical surveys demonstrated that only trace levels of metallic debris remained at the site. The remaining soil at the site has been sampled, analyzed, and evaluated. Results indicate that the site supports future land uses that can be represented (or bounded) by the industrial land-use scenario and poses no threat to groundwater or the Columbia River. Consequently, the 300-8 waste site is verified to be remediated in accordance with the ROD.

Because residual soil concentrations indicated that cleanup levels for more stringent land uses may have been achieved for the 300-8 waste site, a supplemental evaluation was performed against the unrestricted land-use RAGs established for the 300 Area in the ESD. This evaluation demonstrated that the results of verification sampling do not preclude any future uses (as bounded by the rural-residential scenario) and allow unrestricted use of shallow zone soils.

Final

The group of sites [300 VTS, 300-8, 600-243, 618-7, 618-9, 600-290:1] were reclassified to Final Closed Out in 2014. They are listed in the 300-FF-2 Record of Decision and meet the criteria for unrestricted landuse.

Hanford Site Waste Management Units Report
February 2015
1373
300-FF-2 Technical Baseline Report using a historical aerial photograph (negative #2530 taken in 1954), but additional review of the information determined that site to be a borrow pit. Other historical aerial photographs (negative #9619 taken in 1962) were studied and determined two other suspect areas. These locations were selected for geophysical surveys during the 300-FF-2 Operable Unit Limited Field Investigation activities. Later, an aerial photograph taken in 1948 was found (picture number 89711).

Location: The exact location of this site has never been confirmed. It was only described as a trench located 686 meters (750 yards) north of the 300 Area. Hand drawn sketches in two documents (HW-39076 and a letter report from AJ Stevens to AR Keen) indicate the location is north of the 300 area, east of the railroad tracks.

Code: 300-10
Names: 300-10; Burial Trench West of Process Trenches
Type: Burial Ground
Status: Inactive
Classification: Accepted
Reclassification: Final Closed Out (2/20/2014)
Start Date: 1/1/1950
End Date: 

Description: This waste site was remediated in 1997 and reclassified to Closed Out. The northwest corner terminates very near a dirt road that intersects the midpoint of the west 316-5 Process Trenches. A field walkdown done on 11/18/94 reported the site appeared as a soil covered field with natural vegetation. The site has been remediated and closed out, and revegetated with crested wheatgrass. It was considered Final Closed Out in 2014.

Location: The site is adjacent to the west side of the 316-5 Process Trenches.

Closure Info: Interim

Waste site 300-10 was initially excavated to a depth of 1.2 meters (4 ft) below grade based on the 300-FF-1 remedial design. The "Confirm as Clean" procedure documented in the RDR/RAWP (DOE-RL 1997) was then implemented to remove 0.3 meters (1 ft) lifts as necessary to complete the excavation. After completion of the 1.2 meter (4 ft) excavation and each subsequent 0.3 meter (1 ft) lift, a radiological survey of the remaining soil was performed to determine if additional removal was required. Only one additional 0.3 meter (1 ft) lift was required based on the radiological survey results. An initial set of verification samples was collected following the radiological survey results. Contaminated soil removed from waste site 300-10 was transported to the Environmental Restoration Disposal Facility for disposal. In addition to the radiological surveys, a metal detector was used to identify metal shavings in the soil. Although radiological screening instruments did not indicate soil contamination, the metallic anomalies were noted after completion of the 1.2 meter (4 ft) and 0.3 meter (1 ft) lifts. Metallic anomalies consisting of nails, iron scraps, and aluminum shavings were excavated by hand and transported to the Environmental Restoration Disposal Facility for disposal. None of the identified metallic objects were radiologically contaminated. After completion of the metal detector surveys, a second set of verification samples were collected.

Analysis of verification samples of the remaining soil show the area to be below cleanup standard levels. The area no longer poses a threat to human health or the environment and a December 17, 1997 (date approved) TPA change form (Control Number 116) lists the site as Closed Out.

Final

This group of sites [300-10, 300-45, 300-109, 300-259, 618-8] is considered Final Closed Out in the 300-FF-2 Record of Decision and meets the criteria for unrestricted landuse.

<tr>
<td>Description:</td>
<td>The site was released to the soil that were discovered following the removal of an underground gasoline tank in September 1992. The tank had failed a leak test. The tank was removed, however, the contaminated soil has not been cleaned up. The site is not marked in the field and currently appears as a graveled lot adjacent to the 382 Building. Originally, there were 3 tanks at this location, Tanks 382-1, 382-2, and 382-3. Tanks 382-2 and 382-3 were excavated and removed in 1994. A full site assessment (WAC 173-360-385) was performed for these tanks. There was no contamination found in the soil. (See Site Comment Section and Field Work - Analytical Sampling for these two tanks).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>
<td>The site is in the 300 Area, near the intersection of Wisconsin and Apple Streets. The three underground gasoline storage tanks were near the northwest corner of the 382 Pumphouse Building. The 382-1 tank was located at the northwest corner of the building. The 382-2 tank was located on the west side of the 382 Building about 3 meters (10 feet) south of the 382-1. The 382-3 tank was located on the west side of the 382 Building 4 meters (13 feet) west of the 382-2 fuel tank.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Release Description:</td>
<td>When tank 382-1 was removed, an unknown quantity of contaminated soil was discovered under the south end of the tank. The south end of the excavation corresponded to the fill-pipe end of the tank. Soil samples and field-screening samples were analyzed using an immunoassay field test kit for petroleum products. Soil collected from the south end of the tank excavation contained greater than 1,000 parts-per-million (ppm) Total Petroleum Hydrocarbons (TPH). Soil collected from the north end of the tank excavation was below the regulatory limit of 100 ppm TPH.</td>

<tr>
<td>Description:</td>
<td>The waste site is the underground process sewer that extends throughout the 300 Area for the disposal of process wastes such as steam condensate, cooling water and non-regulated liquids. The waste site was divided into subsites to accommodate a phased remediation strategy. The piping consists primarily of 20 centimeter (8 inch) vitrified clay pipes with acid-proof joints. Many other materials have been used in more recent retrofits and system modifications, including cast-iron, stainless-steel, carbon steel, and polyvinyl chloride. Large sections of the process sewer were re-lined with cured-in-place epoxy during the 1995 Project L-070 system upgrade. These process sewer feeder pipes join larger 46 centimeter (18 inch) diameter vitrified clay pipes that discharge to the Treated Effluent Disposal Facility (TEDF) Sump northeast of</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
306E Building. Prior to 1995, the system discharged to the 316-5 Process Trenches, which were constructed in 1975. Before 1975 the process sewers discharged to the north and south process ponds (WIDS Sitecodes 316-2 and 316-1).

Project L-070 upgraded the 300 Area process sewer and retention process sewer systems with a combination of vacuum, gravity and pressurized piping. The process sewer had the ability to discharge up to 760 liters per minute (200 gallons per minute), though rates of 4900 liters per minute (1300 gallons per minute) were observed during the late 1980's. Other ancillary systems are also part of the 300 process sewer. These systems include the flow monitoring stations, catch basins, sample ports, pumps, and the lift stations.

**Location:** The site is located in the 300 Area and is a network of underground piping extending throughout the area.

**Release Description:** In October 1950, a sub-contractor was excavating around the process sewer line from the Metal Fabrication Plant at a location between the fabrication plant and the instrument shop. The excavation work was necessary to encase the clay tile pipe in concrete. The excavator broke a sanitary line connected to a 20 centimeter (8 inch) 303 Area process waste line. During the line break investigation, a dose rate of 50 mr/hr was noted on an upright timber protruding from the soil, located northwest of the process line excavation. Work was stopped and inquiries were made regarding the wooden structure and contamination. It was determined that a temporary experimental autoclave had been installed at this location in 1944. It had a settling tank that had been connected to a small wooden crib. The structure was not recorded on any drawings and was not marked or posted. (See site code 300-282).

**Related Sites/Structures:** Unplanned Release site 300-34 and 300-282 are associated with this process sewer. A portion of this pipeline was co-located with the 618-1 Burial Ground.

Project L-070 disconnected the following buildings from the Process Sewer system: 303F, 303J, 303M, 304, 305B, 308, 311, 321, 331D, 331E, 331J, 334, 335, 3707C, 3708, 3716, 3717, 3717B, 3717F, 3722, 3732, 3802A, 3902A, 3902B.

Other facilities related to the process sewer include the retention process sewer, the 307 Retention Basins, the process ponds, the 316-5 process trenches, the 300 Area TEDF, the TEDF Sump, and the TEDF transfer lines. In September 2013, waste site 600-352-PL (related to 310 TEDF) was Consolidated with 300-15.

**Process Description:** There are three primary contributors to the 300 Area process sewer wastewater: purified potable water, equipment cooling water, and contributors with some chemical contamination. Flows from buildings are combined into one or two main waste pipes before exiting the building. Steam production activities accounted for a significant part of the waste water produced. These activities produced large quantities of waste cooling water and significant amounts of waste brine solution. A smaller portion of the flow is from laboratory sinks and drains connected to the sewer.

Past activities from the fuel fabrication facilities in the 313 and 333 Buildings were the most significant sources of chromium, copper, uranium, nitrate, sulfate, and fluoride ions, as well as caustics and degreasing solvents (e.g. perchloroethylene and 1,1,1-trichloroethane) entering the process sewer. In 1978, administrative controls were established that required the end-of-pipe discharge to meet drinking water standards. In 1985 additional administrative controls were placed into effect to gain greater control of the waste water. These included discontinuing...
chemical discharges from chemical and biological laboratories, fuels fabrication, photographic processing, and many maintenance operations. In 1995 discharges to the 316-5 trenches were halted. Instead, discharges were transferred via a new pipeline (see 600-352-PL) to the 300 Area TEDF (310 Facility) for treatment and discharge to the Columbia River.

Code: 300-15:2
Names: 300-15:2; 300 Area Process Sewer North of Apple St.
Type: Process Sewer
Status: Inactive
Classification: Accepted
Reclassification: Interim Closed Out (3/21/2013)
Start Date: None
End Date: None

Description: Subsite 2 has been remediated and Interim Closed Out. It was the inactive, excavated segments of the 300 Area Process sewer that were located north of Apple Street.
Location: This subsite is the network of underground piping extending throughout the 300 Area, located north of Apple Street.

Process Description: There are three primary contributors to the 300 Area process sewer wastewater: purified potable water, equipment cooling water, and contributors with some chemical contamination. Flows from buildings are combined into one or two main waste pipes before exiting the building. Steam production activities accounted for a significant part of the waste water produced. These activities produced large quantities of waste cooling water and significant amounts of waste brine solution. A smaller portion of the flow is from laboratory sinks and drains connected to the sewer.

Closure Info: Remediation of the 300-15:2 subsite was performed from July 17, 2012 through January 4, 2013. The subsite was divided into three decision units and a separate decision unit for the spoil pile areas. The majority of the soil within the footprint of the subsite was excavated to a depth of 0.5 to 4.9 meters (1.6 to 16 ft) below ground surface (bgs). The resulting 44,715.8 bank cubic meters (54,488.3 bank cubic yards) of soil was disposed at the Environmental Restoration Disposal Facility (ERDF). The 300-15 process sewer in or near the 351 substation were retained since they were not accessible. The segments of 300-15 pipelines located within the 618-1 Burial Ground boundary were previously removed and Interim Closed out with the 618-1 Burial Ground waste site (per CVP-2010-00001).

The lengths of excavated pipelines for each 300-15:2 decision unit are: Decision Unit 1 = 693.9 meters (2,276.6 ft); Decision Unit 2 = 1,285.7 meters (4,218.2 ft); Decision Unit 3 = 1,212.4 meters (3977.7 ft).

The SubSite is Part Of:

Names: 300-15; 300 Area Process Sewer System

Code: 300-15:3
Names: 300-15:3; 300 Area Process Sewer South of Apple St.
Type: Process Sewer
Status: Inactive
Description: Subsite 3 is the inactive portions of the 300 Area Process Sewer that are located south of Apple Street.
Location: This subsite is the network of underground piping extending throughout the 300 Area located south of Apple Street.
Process Description: There are three primary contributors to the 300 Area process sewer wastewater: purified potable water, equipment cooling water, and contributors with some chemical contamination. Flows from buildings are combined into one or two main waste pipes before exiting the building. Steam production activities accounted for a significant part of the waste water produced. These activities produced large quantities of waste cooling water and significant amounts of waste brine solution. A smaller portion of the flow is from laboratory sinks and drains connected to the sewer.

The SubSite is Part Of:
Code: 300-15
Names: 300-15; 300 Area Process Sewer System
Subsite 4 is the 3906 Lift Station and the 3906-B structures. The 3906 structure is divided into two separate systems by a wall of concrete. The northern portion of the structure served the sanitary sewer and contained two, 3 HP pumps that could operate at 190 liters per minute (50 gpm). The southern portion of the structure contained two 20 HP pumps rated at 2650 liters per minute (700 gpm) and was used for process sewer waste streams. In later years of operation, both portions received process sewer effluent as a result of temporary system reconfigurations that supported utility reroutes. The 3906-B Lift Station served as a gravity collection point and lift station for the sanitary and process sewer systems. The 3906 Lift Station provided a gravity drain collection point in the southeast part of the 300 Area for both the sanitary sewer system and the process sewer system. Waste water was pumped westward, where it could then flow by gravity to the end of the sewage systems.

The 3906 and 3906-B were both isolated and inactivated in late 2012.

Location: The 3906 Lift Station structure is located northeast of the location of the demolished 337 building, just south of Locust Road.

The 3906-B Lift Station structure is located just east of Riverview Loop, near the original 3906 Lift Station structure.

Related Sites/Structures: The lift station is associated with the 300-257 pipeline.

The 3906 Lift Station provided a gravity drain collection point in the southeast part of the 300 Area for both the sanitary sewer system and the process sewer system. Waste water was pumped westward, where it could then flow by gravity to the end of the sewage systems. The northern portion of the 3906 facility served the sanitary sewer system. In later years of operation, both portions received process sewer effluent as a result of temporary system reconfigurations that supported utility reroutes.

The SubSite is Part Of:

Code: 300-15
Names: 300-15; 300 Area Process Sewer System

The site consisted of three utility poles that surrounded the 314 Building. The poles were cutoff at ground level in 2005 and were no longer visible from the surface (per Excavation Permit DAN-2743). Three utilities poles were assigned to three separate subsites - 300-16:1, Utility Pole Northwest of 314 Building, 300-16:2, Utility Pole East of 314 Building and 300-16:3, Utility Pole Southeast of 314 Building. The subsites have been Interim Closed out, so the parent site is also considered Interim Closed Out. In 2014, the site and subsites were reclassified to
Final Closed Out.

**Location:** The utility poles were located around the 314 Building.

**Release Description:** In May 1994, subsurface contamination was discovered at the site when a damaged power pole was being replaced. A truck driver had backed into a utility pole located southeast of the 314 Building. The incident caused enough damage to require the pole to be replaced. Underground radiological contamination was discovered during the replacement of the damaged utility pole. When the pole was pulled from the ground, "yellow cake" (a combination of uranium and sulfuric acid) was found to be attached to the subsurface portion of the pole, indicating subsurface contamination at this location.

**Related Sites/Structures:** These incidents are associated with the contamination found along Ginko Street, recorded in 300-28 and also 300-24.

**Process Description:** The site was identified in 1994 during the development of the 300-FF-2 Operable Unit Technical Baseline Report (BHI-00012). The information was obtained from interviews was documented in an email (Email dated 5/5/1994). The interviewees reported that a driver backed into a steam utility pole and caused enough damage that the pole required replacement. When the old pole was pulled out of the ground it was discovered that "yellow cake" (uranium/sulfuric acid combination) was adhering to the subsurface portion of the pole. The exact location of the incident was unknown but was reported to be near the 314 Building. The technical baseline report identified the pole in Figure 3-65. This pole corresponds with the location of 300-16:3.

**Closure Info:** 300-16:1 is the Utility Pole Northwest of the 314 Building waste site. The 300-16:1 waste site was remediated and has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CULs for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Because the sample results do not meet the CULs for residential land use, the waste site requires institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-16:1 waste site to Final Closed Out

300-16:2 was addressed with 300-24, 300-80 and 300-218. Remediation occurred in 2009 and 2010 to a depth of 9.8 feet.

300-16:3, Utility Pole Southeast of 314 Building waste site was remediated with 300-28, 300-43 and 300-249.

**This Site has the Following SubSites:**

**Classification:** Accepted

**Reclassification:** Final Closed Out (5/12/2014)

**Start Date:**

**End Date:**
Description: The subsite has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. It consisted of the buried remains of a telephone pole located northwest of the 314 Building. A routine radiation survey for electrical upgrades in the 300 Area revealed contamination on a telephone pole on May 17, 1994 (Radiological Survey Report 165951). The radiation survey report indicated that the contamination level was 7,000 counts per minute on the top of the pole. The contamination at the bottom of the pole was measured at 3,500 counts per minute.

Location: The site was located 12 meters (39 feet) north of the 314 Building just south of 305-B Storage Facility at Washington State Plane (WSP) coordinates N116143.95 E593708.5.

Related Sites/Structures: 314 Building

Closure Info: Interim

Remediation in the vicinity of the 300-16:1 utility pole was conducted in the first quarter of calendar year 2011. The excavation extended approximately 1.5 meters (5 ft) below grade at the 300-16:1 utility pole. There was no waste staging pile area footprint or overburden soil stockpile associated with this waste site. All removed materials were disposed via direct loadout to the Environmental Restoration Disposal Facility.

Final

300-16:1 is the Utility Pole Northwest of the 314 Building waste site. The 300-16:1 waste site was remediated and has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CULs for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Because the sample results do not meet the CULs for residential land use, the waste site requires institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-16:1 waste site to Final Closed Out.

300-16:2 was addressed with 300-24, 300-80 and 300-218. Remediation occurred in 2009 and 2010 to a depth of 9.8 feet.

300-16:3, Utility Pole Southeast of 314 Building waste site was remediated with 300-28, 300-43 and 300-249.

The SubSite is Part Of:

<td>This subsite has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. The site consisted of the buried remains of a utility pole, located east of the 314 Building. One of three utility poles in the 300-16 waste site was located within the footprint of the current excavation for the 314 Buildings waste sites.</td>
<td>The site was located east of the 314 Building.</td>
</tr>
</tbody>
</table>
Process Description: On September 22, 1995 a telephone pole located on the east side of the 314 Building was removed. The lower four feet was found to be contaminated (Radiological Survey Report 194873). The radiation survey report indicated that the contamination level was 8,000 counts per minute on the base of the pole.

Related Sites/Structures: These incidents are associated with the contamination found along Ginko Street, recorded in waste sites 300-28 and 300-24 and the 314 building demolition.

Closure Info: Interim

Remedial action activities at the 300-16:2, 300-24, 300-80, and 300-218 waste sites were carried out from December 21, 2009 to May 20, 2010. The excavation reached a maximum depth of 3.0 meters (9.8 ft) near the center and southwest corner of the collective waste sites. Approximately 6,275 cubic meters or 14,995 tons of materials were removed from the waste site excavation and direct loaded for disposal at the ERDF. There was no waste staging pile area footprint or overburden soil stockpile associated with these waste sites. The utility pole that was associated with the 300-16:2 subsite was removed. The autoclave pit underlying the former 314A Building was removed. The structures associated with the 300-80 drain were removed. The concrete slabs associated with the 314, 314A, and 314B Buildings have been removed.

During remediation, a suspected french drain was found at the base of the exterior stairwell on the southwest edge of the 314 Building slab. Discussions with the EPA concluded that this drain could be remediated concurrently with the 314 Building waste sites. This suspected french drain was removed. Two pits within the main 314 Building extended below the level of the current excavation. Discussions with EPA concluded that the remaining portions of these pits could remain in place. The 300-285 (300FF2-018; FD 32), 300FF2-270 and 300-240 underground injection control (UIC), wells, were within the footprint of the 314 excavation layback. The listed UIC wells are not part of the waste site. They are listed for tracking purposes. The UIC wells have a "Not Accepted" classification status and are still present at the site.

All the foundation debris such as concrete, metal rebar, miscellaneous piping (e.g., steam, water, etc.), and electrical conduit was excavated and removed from the waste sites. No anomalous materials were observed during remedial activities.

Post-excavation radiological survey of the 314 Building slab was performed in June 2010. Additional radiological surveys of the 300-16:2 utility pole were performed in March 2011. The field radiological measurements survey results did not identify any residual radiological contamination above background levels.

Final

The 300-24, 300-80, 300-218, and 300-16:2 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Contamination at these waste sites did not extend into the deep zone soils. Because the remediation of the waste sites did not meet residential land use cleanup levels, the waste sites require institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-24, 300-80, 300-218, and 300-16:2 waste sites to Final Closed Out.

</tbody>
</table>

| Location:    | The site is located within the 300-28 waste sites. The site was located south of the 314 Building between the 303-A and 3722 buildings. |

| Related Sites/Structures: | These incidents are associated with the contamination found along Ginko Street, recorded in waste sites 300-28 and 300-24. |

| Process Description: | On March 6, 1992 a telephone pole, located south of the 314 Building was removed. The pole was found to be contaminated (survey RSR-37049). The radiation survey report indicated that the contamination level was 3,000 counts per minute. |

| Closure Info: | The 300-28, 300-43, 300-48, 300-249, and 300-16:3 excavation of building foundations, associated pipelines, and soils began on June 28 and was completed by July 29, 2010. Due to elevated radiologically contaminated soil found north of 303E Building, additional remediation was performed September 30, 2010, targeting specific locations with elevated readings. The excavation of the 300-28, 300-43, 300-48, 300-249, and 300-16:3 waste sites resulted in a total of approximately 2,914 bank cubic meters (BCM) (3,811 bank cubic yards [BCY]) of contaminated soil and debris. All material was direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). |

Remediation of the 300-28, 300-43, 300-48, 300-249, and 300-16:3 waste site excavations included removal of the 303A, 304, 304A, 303B, 3732, 303C, 3707D, and 303E Buildings concrete slabs. The manholes and intersections of the 300-15 process sewer were excavated and removed from within the excavation boundaries. All the foundation debris such as concrete, metal rebar, miscellaneous piping (steam, water, etc.), and electrical conduit was excavated and removed from the waste sites. No anomalous materials were observed during remedial activities. |

Although remediation and verification sampling was performed for the 300-161 waste site, it was then noted that 300-161 waste site was reclassified as a Rejected site and therefore did not require remediation or site closure process. The 300-161 waste site was removed from the RSVP. The 300-60, 300-61, 300-62, 300-161, 300-162, 300-176, 300-193 and 300-237 Rejected waste sites were located within the 300-28, 300-43, 300-48, 300-249, and 300-16:3 excavation layback. |

| Reclassification: Final Closed Out (2/18/2014) |

| Start Date: | |
| End Date:   | |
Description: The site has been remediated and Interim Closed Out. It was considered Final Closed Out in 2014. The site was identified during routine surveillance activities on April 23, 1993. Soil and metal shavings were identified with contamination levels of 3000 to 4000 disintegrations per minute. On April 26, 1993 six pieces of contaminated concrete reading 2000 to 4000 disintegrations per minute were found. An area approximately 4.5 meters (15 feet) by 6.1 meters (20 feet) was posted as a Soil Contamination Area. Approximately 0.46 meters (18 inches) to 0.61 meters (2 feet) of dirt was placed on the site. It was reposted as an Underground Radioactive Material Area.

Location: The site was located south of 600-117, the 300 Area Treated Effluent Disposal Facility.

Closure Info: Remedial action at the 300-18 site began in December 2004. Excavation of the site included the removal of small quantities of metal shavings, miscellaneous construction type debris, and soil. No indications of liquid waste disposal or land disposal restricted materials were observed during excavation. Remedial action excavation was completed in February 2005, with approximately 392 metric tons (432 U.S. tons) removed for transport to ERDF. The excavation covered an area of approximately 220 square meters (2,370 sq ft) with an average depth of approximately 1 meter (3 ft). Cleanup Verification Package CVP-2005-00004 documents that the waste site was remediated in accordance with the Record of Decision for the 300-FF-2 Operable Unit, (ROD). Remedial action objectives (RAOs) and remedial action goals (RAGs) for the site were documented in the ROD and the Remedial Design Report/Remedial Action Work Plan for the 300 Area (RDR/RAWP).

Because residual soil concentrations indicated that cleanup levels for more stringent land uses may have been achieved for the site, a supplemental evaluation was performed against unrestricted land-use cleanup objectives established in the Explanation of Significant Differences for the 300-FF-2 Operable Unit Record of Decision.

Excavation was driven by RAOs for direct exposure, protection of groundwater, and protection of the Columbia River. Preliminary waste site COCs were identified in the 300 Area Remedial Action (SAP). The site may be backfilled with clean soil to match surrounding grade elevation.

Final

This group of sites [300-18, 300-275, 600-47, 600-259, 618-5] are considered Final Closed Out in the 300-FF-2 Record of Decision and meet the criteria for Unrestricted Landuse.

</tr>
</tbody>
</table>
Process Description: The Plutonium Recycle Test Reactor (PRTR) was a heavy water moderated, light water cooled, nuclear reactor. The PRTR was operated in support of the Plutonium Utilization Program to develop an optimum reactor fuel design for recycling plutonium to stretch the uranium fuel supply for commercial nuclear reactors. The B-Cell was the 7.5 m (24.5 ft) wide area between the outer containment wall and the outer reactor shield wall on the northwest quadrant of the PRTR below the main floor (5 ft to 32 ft.) It contained the in-vessel rupture loop equipment, the gas loop equipment, and the cooling blowers for the Hot Fuel Exam Facility. The release occurred during a decontamination of the B-Cell.

Related Sites/Structures: The release is associated with the B-Cell of the 309 Building.

</tbody>
</table>

Description: The waste site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. The area around the 314 building was mostly paved with a few areas of exposed soil. A site visit in June 1995 found the area posted with Underground Radioactive Material signs and “Contact Radiological Control Group prior to excavating”. Later, the Underground Radioactive Material signs were moved to the 300 Area fence to eliminate the need for smaller individually posted areas inside 300 Area.

Location: The 314 building is located on the northeast corner of Alaska and Ginko Streets, inside 300 Area.

Release Description: Utility upgrades, being done by Power City Electric, required trenches to be excavated through the asphalt in the 300 Area. In June 1994, 600,000 disintegrations per minute beta/gamma and 350 disintegrations per minute alpha was found in the trench soil near the southwest corner of the 314 building. In June 2001, during an excavation on the south side of the building, radioactively contaminated soils containing approximately 557 picoCuries per gram of uranium were uncovered. Because of this, the size of this site was extended to the south.

Related Sites/Structures: The 314 Building is a separate WIDS site (sitecode: 300-218). Miscellaneous stream #268 (sitecode: 300-80) is located adjacent to the west wall of the 314 Building. Soil contamination in this area is documented in 300-16 and 300-28.

Process Description: The 314 building (and the 314B extension) served as a facility for several fuel fabrication processes. The processes included the metal extrusion process, uranium scrap recovery process, oxide burner operation, melt plant operations, research and craft services. The oxide burner operations caused contamination to spread and be deposited around the 314 Building area. Uranium metal dust from the fuel fabrication activities provided a pathway for heavy metal dust to become airborne and accumulated in the soils throughout the northern portion of the 300 Area.

Closure Info: Interim
Remedial action activities at the 300-16:2, 300-24, 300-80, and 300-218 waste sites were carried out from December 21, 2009 to May 20, 2010. The excavation reached a maximum depth of 3.0 meters (9.8 ft) near the center and southwest corner of the collective waste sites. Approximately 6,275 cubic meters or 14,995 tons of materials were removed from the waste site excavation and direct loaded for disposal at the ERDF. There was no waste staging pile area footprint or overburden soil stockpile associated with these waste sites. The utility pole that was associated with the 300-16:2 subsite was removed. The autoclave pit underlying the former 314A Building was removed. The structures associated with the 300-80 drain were removed. The concrete slabs associated with the 314, 314A, and 314B Buildings have been removed.

During remediation, a suspected french drain was found at the base of the exterior stairwell on the southwest edge of the 314 Building slab. Discussions with the EPA concluded that this drain could be remediated concurrently with the 314 Building waste sites. This suspected french drain was removed. Two pits within the main 314 Building extended below the level of the current excavation. Discussions with EPA concluded that the remaining portions of these pits could remain in place. The 300-285 (300FF2-018; FD 32), 300FF2-270 and 300-240 underground injection control (UIC) wells, were within the footprint of the 314 excavation layback. The listed UIC wells are not part of the waste site. They are listed for tracking purposes. The UIC wells have a "Not Accepted" classification status and are still present at the site.

All the foundation debris such as concrete, metal rebar, miscellaneous piping (e.g., steam, water, etc.), and electrical conduit was excavated and removed from the waste sites. No anomalous materials were observed during remedial activities.

Post-excision radiological survey of the 314 Building slab was performed in June 2010. Additional radiological surveys of the 300-16:2 utility pole were performed in March 2011. The field radiological measurements survey results did not identify any residual radiological contamination above background levels.

Final

The 300-24, 300-80, 300-218, and 300-16:2 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Contamination at these waste sites did not extend into the deep zone soils. Because the remediation of the waste sites did not meet residential land use cleanup levels, the waste sites require institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-24, 300-80, 300-218, and 300-16:2 waste sites to Final Closed Out.

---

**Code:** 300-28  
**Classification:** Accepted  
**Names:** 300-28; Contamination Found Along Ginko Street; Solid Waste Site Near 303-G Building  
**Reclassification:** Final Closed Out (5/12/2014)  
**Type:** Unplanned Release  
**Start Date:** 1/1/1994  
**Status:** Inactive  
**End Date:**  
**Description:** The site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. It was contaminated asphalt and soil beneath Ginko Street. Patches of new asphalt were visible where utility trenches were excavated. The dimensions of this waste site were estimated to be approximately 168 meters (551 ft) long and 6.5 meters (21.3 ft) wide.
The site was located inside the 300 Area, along Ginko Street.

During October 1994, radiological surveys documented the daily activities of the utility installations. The contamination along Ginko Street began southeast of the 314 Building and continued to the southwest corner of the 306-W Building. Contamination levels recorded ranged form 10,000 disintegration per minute to 200,000 disintegrations per minute (beta/gamma).

The contamination is associated with activities in the 314, 333, 3715, 304 and the 303 (A, B, C, G and K) Buildings.

The oxide burner operations caused contamination to spread and be deposited around the 314 Building area. Uranium metal dust from the fuel fabrication activities provided a pathway for heavy metal dust to become airborne and accumulated in the soils throughout the northern portion of the 300 Area.

The 300-28, 300-43, 300-48, 300-249, and 300-16:3 excavation of building foundations, associated pipelines, and soils began on June 28 and was completed by July 29, 2010. Due to elevated radiologically contaminated soil found north of 303E Building, additional remediation was performed September 30, 2010, targeting specific locations with elevated readings. The excavation of the 300-28, 300-43, 300-48, 300-249, and 300-16:3 waste sites resulted in a total of approximately 2,914 bank cubic meters (BCM) (3,811 bank cubic yards [BCY]) of contaminated soil and debris. All material was direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF).

Remediation of the 300-28, 300-43, 300-48, 300-249, and 300-16:3 waste site excavations included removal of the 303A, 304, 304A, 303B, 3732, 303C, 3707D, and 303E Buildings concrete slabs. The manholes and intersections of the 300-15 process sewer were excavated and removed from within the excavation boundaries. All the foundation debris such as concrete, metal rebar, miscellaneous piping (steam, water, etc.), and electrical conduit was excavated and removed from the waste sites. No anomalous materials were observed during remedial activities.

Although remediation and verification sampling was performed for the 300-161 waste site, it was then noted that 300-161 waste site was reclassified as a Rejected site and therefore did not require remediation or site closure process. The 300-161 waste site was removed from the RSVP. The 300-60, 300-61, 300-62, 300-161, 300-162, 300-176, 300-193 and 300-237 Rejected waste sites were located within the 300-28, 300-43, 300-48, 300-249, and 300-16:3 excavation layback.

---

**Code:** 300-29  
**Names:** 300-29; 305-B Berm; Source Location of UPR-600-11 Contaminated Soil  
**Type:** Unplanned Release  
**Status:** Inactive  
**Classification:** Accepted  
**Reclassification:** Final No Action (2/18/2014)  
**Description:** The site has been reclassified to No Action. It is a U shaped soil berm that surrounds the east wing of the 305-B Chemical Waste Storage Building. No radiological postings are currently present.

**Location:** The 305 building is on the east side of the Alaska Street inside the 300 Area. The berm was around the 305-B Chemical Waste Storage Building, east of the 305-B main building. The berm that surrounded the building covered a surface area of 184 square meters.

**Release Description:** On May 29, 1980, the JA Jones subcontractor workers had excavated 76.5 cubic meters (100 cubic yards) of soil from the 305-B berm before the contaminated rubble was detected and
The waste site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. It was the soil remaining after the demolition of the 333 building. The 333 building above grade structure was demolished in 2006. After demolition, the foundation slab remained and was posted as a Radiologically Controlled Area (RCA). The contaminated soil was beneath the building footprint. It included the concrete pad, the subgrade soil and piping. The Lowery Press Pit was in the center of the 333 building footprint.

Location: The 333 building had been located in the northeast corner of the 300 Area, north of Ginko St.

The 300-32 contaminated soil was beneath the building footprint.

Related Sites/Structures: The 333 Building is related to the 334-A Chemical Waste Receiving Station, the 334 Chemical Handling Building, 313 Sludge Recovery, and the Waste Acid Treatment System.

Process Description: The contamination in the 333 building includes all of the fuel components and chemicals used in the fuel rod fabrication process. Uranium Fuel for N Reactor was enriched to 95% uranium-235, and with 13% enriched to 1.25 uranium-235. A small amount of natural uranium was used. As well as beryllium, copper, zirconium, tin, iron, chromium and silicon. Nitric, sulfuric, hydrofluoric and other acids were used. TCE and other degreasers were used.

The co-extrusion process steps included the following steps. The components were inspected and cleaned with nitric, nitric-hydrofluoric, and Chronic-nitric-sulfuric acid (combined in a commercial product called Zinctone). The components were extruded in an extrusion press. The components were machined to create fuel sections. Nitric acid was used to remove copper-
silicon residues. Nitric-sulfuric acid was used to chemically mill excess uranium on fuel element ends. The element was etched with nitric-hydrofluoric acids and brazed with a specific beryllium-Zircaloy-2 alloy. The fuel supports or projections were welded on and the element underwent audi radiography. The element received a final etch with nitric-hydrofluoric acid. The element then underwent autoclave testing and inspection and was stored as finished fuel.

Closure Info: Interim

Demolition of the 333 Building above-grade structure was completed in September 2006. The 333 Building slab with press pit was removed to 1 meter (3.3 ft) below ground surface in July 2010. Confirmatory sampling at the 300-32 waste site was performed on January 9 and 10, 2012. Confirmatory sampling results indicated that additional remediation was required at sample location 15, due to total petroleum hydrocarbons (TPH) analyses exceeding the direct exposure clean up level. On January 2, 2013, remediation was performed at confirmatory focused sample location 15, with additional remediation surrounding the perimeter of the press pit concrete foundation. Verification sampling of the re-excavated area was performed on January 3, 2013.

Remediation at the 300-32 waste site was performed on January 3, 2013, and included removal of 1 meter (3.3 ft) of soil surrounding the entire perimeter of the remaining press pit concrete foundation. The removal extended 1 meter (3.3 ft) from the perimeter of the Loewy press pit concrete foundation. The final depth of removal for soil surrounding the concrete foundation was 2 meters (6.6 ft). All soil was direct loaded for disposal at ERDF. No stained concrete or soil was observed during additional remediation.

The excavation of the press pit area of the 300-32 waste site resulted in a total of approximately 398 bank cubic meters (521 bank cubic yards) of contaminated soil and debris being removed. All material was direct loaded for disposal at ERDF.

Final

The 300-32, 333 Building waste site is the footprint of the demolished 333 Building. On January 2, 2013, remediation was performed at this location, with additional remediation surrounding the perimeter of the press pit concrete foundation. Verification sampling of the re-excavated area was performed on January 3, 2013. The maximum remediation depth extended to 2 m (6.6 ft) below ground surface. The 300-32 waste site was remedi ated and has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support a residential land use scenario. Contamination at the waste site did not extend into the deep zone soils. Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-32 waste site to Final Closed Out.

<td></td>
</tr>
</tbody>
</table>
During remedial activities in 2009, the 300-33 and 300-256 combined waste sites were re-defined to include subsurface four pits ranging from 3 to 16 meters (12 to 45 ft) below the concrete slab surface of the 306 Building. The four pits included the tube pit located in Room 172 of the 306E Building, the assembly pit located in the western high bay of the 306E Building, the furnace pit located in the northwestern corner of the 306E Building, and the press pit located in the northeastern corner of the high bay. Because these are nonstandard structures, agreements were reached between the Department of Energy, Richland Operations Office, and the U.S. Environmental Protection Agency to document status and closure requirements for these pit structures in a separate closure report (Refer to 306E/W Below Grade Pits Closure Report, CCN 147876, Washington Closure Hanford, Richland, Washington).

Location: The site is located in the main 300 Area on the north side of Ginkgo Street between Wisconsin and California Streets.

Release Description: Multiple leaks and fires occurred over the years in and around the 306 building, in barrels and waste "load luggers" containing uranium, thorium, heavy metals, and other fuel component scrap. These fires oxidized and volatilized uranium and other wastes: long-lived contamination, which can be recirculated today, settled in building sumps, crevices, and nearby soil.

Related Sites/Structures: The site is related to the 306W Building, 333 building, 300 Area process sewer, and 300 area sanitary sewer.

Process Description: The 306W Building was completed in 1956 and named the Fuel Element Pilot Plant. The facility was constructed to support the 313 Building operations. It was expanded in 1960 to contain the co-extrusion fabrication processes for N Reactor fuels fabrication. In 1972, the east half, the new half, was designated as 306E and that portion of the building became the Hanford Engineering Development Laboratory (HEDL) operated by Westinghouse Electric Corporation. The west portion of the building, which is older, was named 306W and was allocated to Pacific Northwest Laboratories (PNL).

Closure Info: Interim

Demolition of the 306E, 306W, and 306E-BA facilities, which were located on top of the soil waste sites, was completed between November 2006 and December 2007. Remediation of the combined 300-33, 300-256, and 300-41 waste sites occurred between July 10 and November 9, 2009. The remediation activities included the removal of the neutralization tank, valve pit, soil, and other debris within the footprint of the 306E/W Building including the partial removal and backfill of the 306E Building assembly pit. All debris and excavation materials have been removed to the Environmental Restoration Disposal Facility.

The 300-33 and 300-256 combined waste sites included four pits ranging from 3 to 16 meters (12 to 45 ft) below the concrete slab surface of the 306 Building. The four pits included the tube pit located in Room 172 of the 306E Building, the assembly pit located in the western high bay of the 306E Building, the furnace pit located in the northwestern corner of the 306E Building, and the press pit located in the northeastern corner of the high bay. Because these are nonstandard structures, agreements were reached between the Department of Energy, Richland Operations Office, and the U.S. Environmental Protection Agency to document status and closure requirements for these pit structures in a separate closure report (Refer to 306E/W Below Grade Pits Closure Report, CCN 147876, Washington Closure Hanford, Richland, Washington).

Final

This group of sites is listed in the 300-FF-2 Record of Decision as Final Closed Out. Institutional Controls to maintain Industrial Landuse are required.

</tr>
<tr>
<td>Type: Unplanned Release</td>
<td>Start Date: 1/1/1995</td>
</tr>
<tr>
<td>Status: Inactive</td>
<td>End Date:</td>
</tr>
<tr>
<td>Description: The site was a release to soil that was discovered during excavation to install a new manhole (PS-87). PS-87 is a 0.7 meter (2.3 feet) diameter sewer opening with a round metal cover at grade. The cover is labeled &quot;Confined Space&quot; and &quot;Radioactive Material Internally Contaminated.&quot;</td>
<td></td>
</tr>
<tr>
<td>Location: Manhole PS-87 is located on the south side of Apple Street, inside the 300 Area. It is directly north of main entrance to 3506-B. The manhole is in a parking area for buildings 3506-A and 3506-B. A recent view of the manhole cover was obscured by sand and gravel.</td>
<td></td>
</tr>
<tr>
<td>Release Description: On December 12, 1995, during an excavation for the 300 Area Process Sewer Upgrade (Project L-070), contaminated soil was found at a depth of 3.6 meters (12 feet) near manhole PS-87. The maximum contamination identified in the dirt was 10,000 disintegrations per minute. Contaminated soil was removed from the excavation and placed into drums. After excavation and repairs were completed, the soil was put back in place. A leak from a cracked portion of the Process Sewer is suspected to have resulted in the contaminated soil. The cracked portion had been patched with grout a long time ago, possibly when it was originally installed. The broken pipe was replaced with a section of polyvinyl chloride (PVC) piping.</td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures: The site is associated with the 300 Area Process Sewer (300-15), and Manhole PS-87.</td>
<td></td>
</tr>
<tr>
<td>Process Description: The source of the contamination release is believed to be a crack in the 300-15 Process Sewer, a vitrified clay pipe that held radioactive liquid.</td>

<tr>
<td>Description: The waste site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. The waste site is potential soil contamination associated with the corroded process sewer piping near the demolished 303-F building and 311 tank farm. The site was an uneven gravel covered area. It was bounded by a concrete curb and concrete pad on the west and a rail spur on the east. The southern section of the site included the area around 303-F and the 311 Tank Farm. The northern end of the site had been covered by the demolished 3712 building.</td>
<td></td>
</tr>
<tr>
<td>Location: The site was located directly north of the 311 Tank Farm and south of the 3712 Building.</td>
<td></td>
</tr>
<tr>
<td>Release Description: During removal of the 311 Stillhouse in 1980, it was discovered that the vitrified clay process sewer line was severely corroded. The section between the neutralization pit and the 3712 manhole was corroded to a point where the entire lower half of the pipe was missing. It was estimated that at least 60 meters (200 feet) of the pipe is in similar condition. Documentation suggested that wastes were released to the soil column from badly corroded pipes.</td>
<td></td>

*Hanford Site Waste Management Units Report*
February 2015
sections of the process sewer piping between the 311 Tank Farm and 3712. The extent of soil contamination was unknown. No occurrence report has been located for this waste site.

**Related Sites/Structures:**

The site is associated with the 311 Tank Farm drains and the 300 Area Process Sewer, UPR-300-39, UPR-300-40 and UPR-300-45.

**Process Description:**

This section of pipe was part of the 300 Area process sewer until it was isolated. This leg of pipe collected rain water drainage from the 311 Tank Farm and the 303-F floor drains. The piping also collected effluent from the 311 Stillhouse.

**Closure Info:**

Interim

Remediation of the 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste sites was performed from May 24, 2010, through July 20, 2010. The soil within the waste site footprints was excavated to a depth of 1 meter (3.3 ft) below ground surface, and the resulted in 911 bank cubic meters (1,192 bank cubic yards) of soil being disposed at the Environmental Restoration Disposal Facility. On March 8, 2011, radiological field screening for beta and gamma activity was conducted in the 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste site areas. The radiological field screening surveys did not indicate any significant residual radiological activity.

**Final**

The 300-40, Corrosion of Vitrified Clay Process Sewer Pipe, UPR-300-40, Acid Release at the 303-F Pipe Trench, UPR-300-39, Sodium Hydroxide Leak at 311 Tank Farm, and UPR-300-45, 303-F Building Uranium-Bearing Acid Spill were located in close proximity. The southern section of the 300-40 waste site consists of the area around the footprint of the demolished 303-F Building and 311 Tank Farm. The northern section of the 300-40 waste site is within the footprint of the demolished 3712 Building. The UPR-300-40 waste site is associated with the drain pipe connections between the 303-F Building and the 300 Area process sewer. The waste consisted of uranium-bearing acid waste containing nitric and sulfuric acid with uranium in solution and chromic acids with copper and zinc in solution. The UPR-300-39 waste site is the soil adjacent to the caustic storage tanks in the 311 Tank Farm. The UPR-300-45 waste site is the soil beneath the former uranium-bearing acid transfer pipeline, adjacent to the 303-F Building. The uranium-bearing acid transfer pipeline ran through the pipe trench from the 333 Building to the valve box at the southeast corner of the 313 Building outside the Uranium Recovery Room. The leak contained uranium-bearing waste acids identified as nitric acid and sulfuric acid with uranium in solution. Remediation occurred in 2010 to a depth of 3 feet.

The 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that concentrations of COCs meet the CULs for direct exposure and groundwater protection and river protection and support a residential land use scenario. Contamination at the 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste sites did not extend into the deep zone (below 4.6 meters [15 ft]). Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not required. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste sites to Final Closed Out.

<td>300-41; 306E Neutralization Tank; Underground Lime Tank and Valve Pit</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type:</td>
<td>Neutralization Tank</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Description:** The site included a neutralization tank and valve pit. The valve pit was constructed of concrete and is covered by a 2.18 meter (7.15 foot) diameter metal lid. The top of the pit was flush with the ground surface on its north side and approximately 5 centimeters (2 inches) above grade on its south side. A rectangular hatch in the lid allowed access to the pit. The hatch is labeled "Confined Space." It appeared as though there are three ports in the lid where pipes or hoses could enter the pit. These three ports were closed.

The pit was surrounded by sand and four metal safety posts. All that is visible of the neutralization tank is a riser that appears to be made of metal; the riser appears to be discolored by rust. The riser is covered by a 0.72 meter (2.36 foot) diameter metal lid, that is greater in diameter than the riser itself. The lid is labeled "Neutralization Tank" in fading black paint. The lid is held in place by a metal bar, bolts and wing nuts. The metal bar has discolored the lid with rust. The top of the lid is 0.42 meters (1.4 feet) above the ground surface, which is sand.

**Location:** The site was located west-northwest of the northeast corner of the 306E Building.

**Release Description:** From 1956 to 1967, and once after 1967, the neutralization tank and valve pit intercepted and neutralized nitric acid-bearing chemical wastes before discharge to the process sewer. In 1976, the pit was inspected, along with the process waste sump, sewer manholes, and the inlet box to the process sewer leaching trenches, after several hundred gallons of slightly enriched uranyl nitrate hexahydrate solution was spilled in the sump. The investigation found that much uranium and thorium contamination lies in and beneath the entire 306 Building floor, slab, pipe trenches, and sewer lines. No significant accumulation was found in the pit and sewer manholes. In 1979, a HEDL Radiological Engineering report stated, among other things, "The lime pit...contain[s] uranium and thorium sludge." The soil contamination is addressed by WIDS Site 300-42.

**Related Sites/Structures:** The site is associated with the 306E Fabrication and Testing Laboratory Releases (WIDS Site 300-42) and 306E Building - HVAC Condensate, Miscellaneous Stream #454 (WIDS Site 300-71), and the process sewer (WIDS Site 300-15).

**Closure Info:** Interim

Demolition of the 306E, 306W, and 306E-BA facilities, which were located on top of the soil waste sites, was completed between November 2006 and December 2007. Remediation of the combined 300-33, 300-256, and 300-41 waste sites occurred between July 10 and November 9, 2009. The remediation activities included the removal of the neutralization tank, valve pit, soil, and other debris within the footprint of the 306E/W Building including the partial removal and backfill of the 306E Building assembly pit. All debris and excavation materials have been removed to the Environmental Restoration Disposal Facility.

The 300-33 and 300-256 combined waste sites included four pits ranging from 3 to 16 meters (12 to 45 ft) below the concrete slab surface of the 306 Building. The four pits included the tube pit located in Room 172 of the 306E Building, the assembly pit located in the western high bay of the 306E Building, the furnace pit located in the northwestern corner of the 306E Building, and the press pit located in the northeastern corner of the high bay. Because these are nonstandard structures, agreements were reached between the Department of Energy, Richland Operations Office, and the U.S. Environmental Protection Agency to document status and closure requirements for these pit structures in a separate closure report (Refer to306E/W Below Grade Pits Closure Report, CCN 147876, Washington Closure Hanford, Richland, Washington).

**End Date:**

**Status:** Inactive

<td>Unplanned Release</td>
<td>1/1/1972</td>
<td>1/1/1989</td>
</tr>
</tbody>
</table>

Description: The waste site has been remediated and Interim Closed Out. It was the uranium contaminated soil around the 304 building (formerly the 304 Concretion Facility). The site also included residual contamination remaining in the 304 Storage Area (304 SA). The 304 Building had been posted "Fixed Contamination Area." Sections of concrete and asphalt on the north side of the building were painted gray and posted "Fixed Contamination Area," including the fenced area. The painted and posted "Fixed Contamination Area" continued in a thin strip along the west side of the building, then grew to include a concrete or asphalt pad on the south side of the building. A thin strip of gray paint continued along the east side of 304, ending at the south wall of the change room. This painted area on the east side of the building was not posted "Fixed Contamination Area," but the unpainted asphalt further east was posted. The signs in the unpainted asphalt were approximately in line with the east edge of the 304 change room. A row of "Radiologically Controlled Area" signs runs along the south side of the 304 and 303A Buildings with the signs facing to the south.

Location: The contamination was on the east, south, and west sides of the demolished 304 Building.

Release Description: Until 1989, the walls of the facility were not sealed to the concrete pad and there were numerous small holes in the walls. During concretion operations the floors and walls of the facility were washed down daily. This washing and splashing against the walls may have carried contamination out of the building. Additionally, there was no provision to contain this wash water at either of the large door openings. The fenced north pad also has no containment system for spills, wash water, or precipitation runoff.

Related Sites/Structures: The site is related to operations in the 304 Building and Storage Area.

Process Description: During concretion operations, the 304 Facility floor was washed down daily with water. Because the steel walls of the main building were not sealed to the concrete wall base until 1989 (and there were numerous small holes in the walls) rinse water splashing against the steel walls might have carried contamination out of the building. In addition, there were no berms at the north and south doors to stop washdown water from leaving the building. The north fenced pad does not have a berm to contain spills or precipitation.

Closure Info: The 300-28, 300-43, 300-48, 300-249, and 300-16:3 excavation of building foundations, associated pipelines, and soils began on June 28 and was completed by July 29, 2010. Due to elevated radiologically contaminated soil found north of 303E Building, additional remediation was performed September 30, 2010, targeting specific locations with elevated readings. The excavation of the 300-28, 300-43, 300-48, 300-249, and 300-16:3 waste sites resulted in a total of approximately 2,914 bank cubic meters (BCM) (3,811 bank cubic yards [BCY]) of contaminated soil and debris. All material was direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF).

Remediation of the 300-28, 300-43, 300-48, 300-249, and 300-16:3 waste site excavations included removal of the 303A, 304, 304A, 303B, 3732, 303C, 3707D, and 303E Buildings concrete slabs. The manholes and intersections of the 300-15 process sewer were excavated and removed from within the excavation boundaries. All the foundation debris such as concrete, metal rebar, miscellaneous piping (steam, water, etc.), and electrical conduit was excavated and
removed from the waste sites. No anomalous materials were observed during remedial activities.

Although remediation and verification sampling was performed for the 300-161 waste site, it was then noted that 300-161 waste site was reclassified as a Rejected site and therefore did not require remediation or site closure process. The 300-161 waste site was removed from the RSVP. The 300-60, 300-61, 300-62, 300-161, 300-162, 300-176, 300-193 and 300-237 Rejected waste sites were located within the 300-28, 300-43, 300-48, 300-249, and 300-16:3 excavation layback.

| Code: 300-45 | Classification: Accepted |
| Names: 300-45; Location 3: Bird Droppings Area (Southwest Corner of the 316-5 Process Trenches Fence Line); SCA #1; Surface Contamination Area | Reclassification: Final Closed Out (2/20/2014) |
| Type: Unplanned Release | Start Date: |
| Status: Inactive | End Date: |
| Description: The waste site was remediated in 1997 and Closed Out. Heavy vegetation growth and anthills are in the area. The area has been downposted and released. It is no longer marked or posted. | |
| Location: The site was located adjacent to the southwest corner of the 316-5 Process Trench fence. | |
| Release Description: It has been determined the area consisted of contaminated soil caused by the spread of radioactive rabbit feces. | |
| Closure Info: Interim | |

One composite sample from the material was collected by the sampling team on 1/20/95, effectively removing much of the contamination. Scattered low-level contamination still remained. During the preparation of the Remedial Design Report/Remedial action Work Plan (RDR/RAWP) (DOE/RL-96-70), a decision was made to include this site with the remediation activities of the 316-5 Process Trenches in the 300-FF-1 Operable Unit work scope.

In 1997 the contaminated soil was removed and disposed of in the Environmental Restoration Disposal Facility (ERDF). Analysis of verification samples of the remaining soil show the area to be below cleanup standard levels. The area no longer poses a threat to human health or the environment and a December 17, 1997 (approval date) TPA change form (Control Number 118) lists the site as Closed Out.

Final

This group of sites [300-10, 300-45, 300-109, 300-259, 618-8] is considered Final Closed Out in the 300-FF-2 Record of Decision and meets the criteria for unrestricted landuse.

| Code: 300-46 | Classification: Accepted |
| Names: 300-46; Soil Contamination and French Drains Surrounding 3706 Building | Reclassification: Final Closed Out (5/12/2014) |
| Type: Unplanned Release | Start Date: |
| Status: Inactive | End Date: |
| Description: This waste site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. It consisted of the contaminated soil and nineteen french drains that | |
surround the 3706 building. The 3706 building was demolished in June 2007. The extent of uranium, transuranic and chemical contamination of the 3706 Building and the surrounding area was estimated. The ground surrounding the 3706 building was not posted as a radiologically controlled area. The 3706 Building was posted "Fixed Contamination Area." Numerous pipes were observed exiting the exterior walls on all sides of the building. Several of these pipes were associated with rust stains on the side of the building and the nearby ground. Several french drains were also observed on all sides of the building.

Nineteen recognized miscellaneous stream drains (WIDS sitecodes 300-131 through 300-149) were located within the boundary of the waste site and have been consolidated with 300-46. Eighteen underground injection wells located within the 300-46 area were excavated and removed. One underground injection well (WIDS sitecode 300-149) was not removed because of its close proximity to the active 399-6-5 monitoring well.

**Location:** The 3706 building was located in the 300 Area on the southeast corner of Apple Street and Alaska Street.

**Release Description:** Contamination of the area surrounding the 3706 Building is believed to have resulted primarily from the operations and associated spills and releases. Although radiological surveys near and around the 3706 Building have not detected any radiologically contaminated soil, subsurface contamination is suspected. Contamination within the 3706 building that may have contributed to outdoor contamination is described in the "Past Practices Technical Characterization Study - 300 Areas - Hanford Site", WHC-MR-388. According to the report, the 3706 Building is contaminated with both radiological and chemical constituents, including high-activity substances. These wastes are composed of all components of the bismuth phosphate, REDOX, PUREX, and RECUPLEX processes along with laboratory cleansers, reagents and drying agents, as well as plutonium, uranium, thorium, and beryllium. Mercury deposits from multiple laboratory uses also were very prevalent. Additional chemical wastes result from bioassay and environmental sample analyses. Among these substances were sodium thiosulfate, hydroxylamine hydrochloride, barium chloride, barium nitrate, magnesium perchlorate, sodium iodine, sodium carbonate, thenoyltrifluoroacetone, thenoyltrifluoroacetone-benzene solutions, boric acid, silver nitrate, cupric oxide, arsenic nitrate, zinc nitrate, ammonium chloride, tartaric acid, and cupferron. Other wastes result from the spread of irradiated metal dusts and fines from the machining and grinding of metallurgical test samples. Contamination results from both inadequate containment systems and from spills, overflows, vaporizations, spreads of radioactive dusts and fines, and other incidents involving the loss of control of radioactive materials. The 3706 Building was never connected to the RLWS. All non-sanitary wastes from the structure were disposed to the 300 Area process sewer system. In the case of uranium, as with early work with uranium in other HEW facilities, few special precautions for work with radioactive substances were taken. Uranium contamination, especially dusts and fines from metallurgical testing, was spread from the hands, shoes, hair, and clothing of personnel into the 300 Area sanitary sewer system.

**Related Sites/Structures:** The 3707C building was once connected to the 3706 building. The 3707C was demolished in 1996. Nineteen miscellaneous streams are documented around the 3706 and 3706A Buildings in the "Inventory of Miscellaneous Streams", Revision 3. These sites are identified in WIDS as site codes 300-131 through 300-149. It is also associated with an underground diesel tank - see sitecode 300-35.

**Process Description:** The original mission of the 3706 Building was to perform small-scale experiments with both low- and high-activity radioactive materials in support of all HEW production activities. The largest portion of staff and facilities in the building performed radiochemical trials aimed at improvements in the bismuth phosphate process. During the war years, some of the important variables and factors studied in the 3706 Building were the substitution of potassium permanganate for sodium dichromate as an oxidizing agent for plutonium, variations in acid strengths in several steps of the separations process, a decrease in the "digestion time" in the reduction step, methods for improving the centrifugability of lanthanum fluoride, the solubility...
of plutonium compounds and other substances in process solutions, methods of counting specific plutonium activity, characterization of fission products and plutonium decay products, the effects of hydrazine and lead in the dissolution process, and process equipment decontamination and corrosion studies. Other large sections of staff time and laboratories in the 3706 Building were devoted to metallurgical examination of irradiated fuel elements from the reactors, fuel development for the 313 Building, "physical technical" examination of graphite from the experimental levels of the 100 Area piles, special sample analyses from the 231 Plutonium Isolation Building in the 200 Areas separations plants, spectroscopy and radiocounting activities, and multifaceted sample analyses for the H. I. Division's environmental and personnel survey programs. In 1954, the 3706 Building underwent a major decontamination and remodeling effort, in which many of the laboratories were converted to offices. However, control (sampling) laboratories for fuel fabrication operations continued to operate in the building through the mid-1960's until they were transferred to the 3720 Building. Uranium fuel slugs, uranium powder, beryllium, and thorium continued to be handled, primarily in Laboratories 207-224, throughout this period. Rooms were renumbered in the building in early 1956, and the structure received a new roof in 1959. By 1964, the 3706 Building was called the General Services Building. Although it still contained some analytical laboratories, a majority of its space was devoted to mail services, duplicating, photographic, and drafting services, a first aid station, 300 Area patrol headquarters, and other administrative and clerical functions. During the 1970's and 1980's, the 3706 Building underwent several other minor remodelings as all laboratory work eventually was phased out. Today, the structure is unoccupied.

Closure Info: Interim

The demolition of the 3706 Building aboveground structures was completed in June 2007. The 300-46 excavation of building foundations, associated pipelines, and soils began on January 17, 2011, and was completed by April 19, 2012, to a depth of 1.5 meters (5 ft).

The excavation of the 300-46 waste site resulted in a total of approximately 6,445 bank cubic meters (BCM) (8,430 bank cubic yards [BCY]) of contaminated soil and debris. Based on historical drawings, approximately 300 meters (990 ft) of process sewer pipelines located within the 300-46 slab areas was also removed during excavation. All material was direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF).

Remediation of the 300-46 waste site excavation included removal of the 3706 Building concrete slab. All the foundation debris such as concrete, metal rebar, and miscellaneous piping (steam, water, etc.) was excavated and disposed at the ERDF. No anomalous materials or stained soil were observed during remedial activities.

Eighteen underground injection wells located within the 300-46 area were excavated and removed. One underground injection well (WIDS sitecode 300-149) was not removed because of its close proximity to the active 399-6-5 monitoring well.

On December 16, 2010, six characterization soil samples were collected from soils 0.5 meters (1.7 ft) below the slab area of the 3706 Building and from adjacent perimeter soils. On January 6, and 10, 2011, a total of 14 waste designation soil samples were collected from soils surrounding the 3706 Building. On February 10 through the 22, 2011, nine in-process soil samples were collected of the soil underlying the 300-15 pipeline surrounding the 3706 Building. Following sample analysis of the original excavation, it was determined that additional remediation was needed because one focused sample location (FS-131) exceeded groundwater and river protection RAGs for antimony and arsenic and could not be modeled to show protectiveness. This extra remediation, with agreement from the EPA was conducted on January 23, 2013. This remediation at the FS-131 area proceeded to a depth of approximately 3 meters (10 ft) below ground surface. Additional soil was removed from this location and
disposed at the ERDF.

Final

The 300-46, Soil Contamination and French Drains Surrounding 3706 Building waste site consisted of the remaining 3706 Building foundation and subgrade soils and structures including french drains. Remediation occurred in 2012 to a depth of 10 feet. Verification sampling was done in 2012 and 2013. The 300-46 waste site was remediated and has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Contamination at the waste site did not extend into the deep zone (below 4.6 meters [15 ft]). Because the sample results do not meet the CULs for residential land use, the waste site will require institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-46 waste site to Final Closed Out.

<tr>
<td>Closure Info:</td>
<td>The 300-28, 300-43, 300-48, 300-249, and 300-16:3 excavation of building foundations, associated pipelines, and soils began on June 28 and was completed by July 29, 2010. Due to elevated radiologically contaminated soil found north of 303E Building, additional remediation was performed September 30, 2010, targeting specific locations with elevated readings. The excavation of the 300-28, 300-43, 300-48, 300-249, and 300-16:3 waste sites resulted in a total of approximately 2,914 bank cubic meters (BCM) (3,811 bank cubic yards [BCY]) of contaminated soil and debris. All material was direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Remediation of the 300-28, 300-43, 300-48, 300-249, and 300-16:3 waste site excavations included removal of the 303A, 304, 304A, 303B, 3732, 303C, 3707D, and 303E Buildings</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
concrete slabs. The manholes and intersections of the 300-15 process sewer were excavated and removed from within the excavation boundaries. All the foundation debris such as concrete, metal rebar, miscellaneous piping (steam, water, etc.), and electrical conduit was excavated and removed from the waste sites. No anomalous materials were observed during remedial activities.

Although remediation and verification sampling was performed for the 300-161 waste site, it was then noted that 300-161 waste site was reclassified as a Rejected site and therefore did not require remediation or site closure process. The 300-161 waste site was removed from the RSVP. The 300-60, 300-61, 300-62, 300-161, 300-162, 300-176, 300-193 and 300-237 Rejected waste sites were located within the 300-28, 300-43, 300-48, 300-249, and 300-16:3 excavation layback.

**Description:**
The site was remediated in 1996 and reclassified to Closed Out in 1999. It was considered Final Closed Out in 2014. The site was contaminated soil that was discovered on the surface of soil erosion area located within a posted Underground Radioactive Material (URM) Area. The actual erosion was at the end of a concrete splash guard underneath the water discharge pipe. A test of the fire suppression system exposed sub-surface contamination that had been previously covered with clean soil.

**Location:**
The site is located on the east side of the 303-G Building, under the fire suppression water discharge pipe. On October 16, 1996, exposed contaminated soil was cleaned up and covered with clean soil.

**Release Description:**
The contaminated area was identified on October 8, 1996. Removable radiological contamination measuring up to 36,000 disintegrations per minute beta-gamma per 100 cubic centimeter were reported on the surface of some slightly eroded soil. The soil area measured about 0.3 meter by 0.9 meter (1 foot by 3 feet). The radiological contamination was exposed when water was discharged from the building's fire suppression system. The water was directed onto a concrete splash guard, but still had substantial velocity when it left the splash guard and contacted the soil. The contaminated soil was exposed because of erosion. The area was posted with Contamination Area signs.

**Closure Info:**
Interim

The WIDS Reclassification form 99-014 states that the exposed contaminated soil was cleaned up and covered with clean soil on October 16, 1996. The classification was changed to Closed Out in 1999.

Final

This site is listed in the 300-FF-2 Record of Decision. Institutional Controls to maintain industrial land use are required.

</tbody>
</table>
Inactive  

The waste site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. The drain structure was removed along with the 314 building foundation and soil. The site was a square concrete structure adjacent to the 314 Building and next to a fenced stairway leading down. The site was covered by a steel plate marked with a sign "Radioactive material, internally contaminated." The site does not appear to be a stormwater drain. It was above the surrounding grade and no drain pipes from the roof enter the site. The "Inventory of Miscellaneous Streams", Revision 3, says the stream has been eliminated because the source has been permanently abandoned and rerouted to the process sewer.

The responsible contractor agrees that the site did previously receive steam condensate, but is unable to verify stormwater discharges. Further inspection under the steel cover and the review of facility drawings are required to verify the function and site type.

The site was on the west side of the 314 Building, adjacent to the wall, 9 meters (27 feet) north of the southwest corner.

The french drain is related to the 314 Building (sitecode 300-218). An area of soil contamination exists outside the 314 Building. This unplanned release (sitecode 300-24) may be the source of the contamination within structure.

Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.

Remedial action activities at the 300-16:2, 300-24, 300-80, and 300-218 waste sites were carried out from December 21, 2009 to May 20, 2010. The excavation reached a maximum depth of 3.0 meters (9.8 ft) near the center and southwest corner of the collective waste sites. Approximately 6,275 cubic meters or 14,995 tons of materials were removed from the waste site excavation and direct loaded for disposal at the ERDF. There was no waste staging pile area footprint or overburden soil stockpile associated with these waste sites. The utility pole that was associated with the 300-16:2 subsite was removed. The autoclave pit underlying the former 314A Building was removed. The structures associated with the 300-80 drain were removed. The concrete slabs associated with the 314, 314A, and 314B Buildings have been removed.

During remediation, a suspected french drain was found at the base of the exterior stairwell on the southwest edge of the 314 Building slab. Discussions with the EPA concluded that this drain could be remediated concurrently with the 314 Building waste sites. This suspected french drain was removed. Two pits within the main 314 Building extended below the level of the current excavation. Discussions with EPA concluded that the remaining portions of these pits could remain in place. The 300-285 (300FF2-018; FD 32), 300FF2-270 and 300-240 underground injection control (UIC), wells, were within the footprint of the 314 excavation layback. The listed UIC wells are not part of the waste site. They are listed for tracking purposes. The UIC wells have a "Not Accepted" classification status and are still present at the site.

All the foundation debris such as concrete, metal rebar, miscellaneous piping (e.g., steam, water, etc.), and electrical conduit was excavated and removed from the waste sites. No anomalous materials were observed during remedial activities.
Post-excavation radiological survey of the 314 Building slab was performed in June 2010. Additional radiological surveys of the 300-16:2 utility pole were performed in March 2011. The field radiological measurements survey results did not identify any residual radiological contamination above background levels.

Final

The 300-24, 300-80, 300-218, and 300-16:2 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Contamination at these waste sites did not extend into the deep zone soils. Because the remediation of the waste sites did not meet residential land use cleanup levels, the waste sites require institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-24, 300-80, 300-218, and 300-16:2 waste sites to Final Closed Out.

| Code: 300-109 | Classification: Accepted |
| Names: 300-109; 333 Building Stormwater Runoff; Miscellaneous Stream #455 | Reclassification: Final Closed Out (2/20/2014) |
| Type: Injection/Reverse Well | Start Date: |
| Status: Inactive | End Date: |
| Description: The waste site was remediated and Interim Closed Out. The french drain and contaminated soil were removed and disposed into ERDF in January 2010. The site consisted of a 10-cm (4-in.) collection line and a french drain disposal system for stormwater collection and disposal north of the 333 Building. This system was designed and installed in 1990. | |
| Location: The Inventory of Miscellaneous Streams Report states it is located approximately 18.3 meters (60 feet) north of the 333 Building. | |
| Related Sites/Structures: The site is associated with the 333 Building and UPR-300-46. | |
| Process Description: The Inventory of Miscellaneous Streams Report states the injection well is below grade and drains a network of four catch basins. The network is known as SS-2 in document WHC-SD-L125-ES-001. A 300 Area Storm Water Engineering Study noted that the existing 10-cm (4-in.) collection pipe was undersized for the projected flow. A white PVC pipe emerged laterally from the asphalt in the approximate location described in the Inventory of Miscellaneous Streams (DOE-RL-95-82, Rev. 3). | |
| Closure Info: Interim | |

Remediation of the UPR-300-46 waste site was performed from April 28 through June 4, 2009. The soil within the waste site footprint was excavated to a depth of 1 meter (3 ft) below ground surface (bgs), and the resulting 75 bank cubic meters (BCM) (100 bank cubic yards [BCY]) of soil was disposed at the Environmental Restoration Disposal Facility (ERDF). Remediation of the 300-109 waste site was performed from April 28 through April 29, 2009. The soil and asphalt within the waste site footprint were excavated to an average depth of 2.6 meters (8.5 ft) bgs, with a maximum depth of 3.7 meters (12 ft) below ground surface at the location of the drain. The resulting 325 BCM (425 BCY) of soil was disposed at ERDF. The french drain and associated vitrified clay pipe was found and removed during the remediation. The PVC pipe noted in documentation from the 1990's was not found during remediation. A radiological survey was done to confirm the excavations were complete.
This report demonstrates that the 300-109, 333 Building Stormwater Runoff and UPR-300-46, Contamination North of 333 Building sites have met the rural-residential scenario RAOs established in the RDR/RAWP and the ROD. The evaluation shows that the sites have been successfully remediated and that there are no residual hazardous/dangerous materials present above the RAOS in the soil. Therefore, the 300-109 and UPR-300-46 waste sites are protective of human health, groundwater, and the Columbia River.

Final

This group of sites [300-10, 300-45, 300-109, 300-259, 618-8] is considered Final Closed Out in the 300-FF-2 Record of Decision and meets the criteria for unrestricted landuse.

<td>Description:</td>
<td>The 300-110 waste site was Interim Closed Out with the 618-1 site. Remedial actions at this site have been performed in accordance with remedial action objectives and goals established by the U.S. Environmental Protection Agency and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. The selected remedial action involved excavating the site to the extent required to meet specified soil cleanup levels and disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility. The site was a 0.41 meter diameter drain with a metal grate labeled &quot;Internal Radioactive Contamination&quot; due to its proximity to the WIDS Site 618-1 Burial Ground. The drain had a dirt bottom that is approximately 0.61 (2 feet) below the surface of the asphalt and an overflow line that drains to the process sewer.</td>
<td></td>
<td></td>
</tr>
<tr>

</tr>
</tbody>
</table>

The 618-1 Burial Ground, two subsites, three consolidated sites and four co-located sites were remediated as a group. This group included WIDS sitecodes 618-1, 618-1:1, 618-1:2, 333 LHWSA, UPR-300-13, UPR-300-14, 300-110, 303-M SA, 303-M UOF and 333 ESHWSA. Parts of waste sites 300-15, 300-259 and UPR-300-17 were also remediated along with 618-1. Several facilities were built over the top of portions of the 618-1 Burial Ground after it ceased to operate. These facilities were demolished and their debris taken to the Environmental Restoration Disposal Facility (ERDF) prior to the start of the burial ground remediation project. Field remediation activities at the 618-1 Burial Ground were performed between September 17, 2008 and September 10, 2009, in accordance with the RDR/RAWP. Approximately 47,332 metric tons (52,160 US tons) of soil and debris was excavated and disposed of at ERDF. No excavated soil will be used as clean, uncontaminated backfill. Waste encountered during excavation of the 618-1 waste site consisted mostly of contaminated soil, metal pipe, crucibles,
laboratory glassware, empty metal containers, and some LDR material. Twenty metal drums containing personal protective equipment (PPE) were removed from the trenches. The PPE was about 80% decomposed. Several bottles containing liquid and/or powder were also removed. One relatively large area on the south side of the burial ground was stained yellow presumably from acid leaks known to have occurred at the site.

Three sites (300-15 Process Sewer, 300-259 and UPR-300-17 Metal Shavings Fire) were partially remediated with the 618-1 remedial action.

Some land disposal restricted (LDR) materials, like lead solids contaminated with barium and chromium, were identified among the debris. The LDR material was segregated from the bulk soil and non-LDR debris for disposal. The bulk soil and non-LDR debris was sorted and segregated in the burial trenches. After sorting, the remaining bulk soil debris stockpiles were sampled to ensure that the material was in compliance with land disposal restrictions. The released stockpiled material was transported to ERDF for disposal. Land disposal restricted materials that had been segregated for treatment were transported to ERDF under a separate waste profile.

The remaining soil at the 618-1 site has been sampled, analyzed, and evaluated. Results indicate that the site supports future land uses that can be represented (or bounded) by the industrial land-use scenario and poses no threat to groundwater or the Columbia River. Institutional controls are required to prevent drilling or excavation into the deep zone. Cleanup Verification Package CVP-2010-00001 demonstrates that remedial action at the site has achieved the Remedial Action Objectives and corresponding Remedial Action Goals established for the industrial land-use scenario in the Record of Decision (EPA 2001), the Explanation of Significant Differences for the 300-FF-2 Operable Unit (EPA 2004), and the RDR/RAWP (DOE-RL-2001-47, Rev 3).

Final

This group of sites [300-33, 300-41, 300-110, 300-256] is listed in the 300-FF-2 Record of Decision as Final Closed Out. Institutional Controls to maintain Industrial Landuse are required.

---

**Code:** 300-121  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 300-121; 3621D Building Stormwater Runoff; Injection Well #26; Miscellaneous Stream #403  
**Type:** French Drain  
**Status:** Inactive  
**Start Date:**  
**End Date:**  

**Description:** The site is a french drain with a concrete base. The site is on a slope so the top of the drain rises between 8 to 27 centimeters (3.1 to 10.6 inches) above the ground surface. Approximately 20 centimeters (7.9 inches) from its top, the drain starts to narrow. The drain is covered by a 1.37 meter (4.49 foot) metal lid. The lid appears to fit flush with the concrete base. The lid is labeled "Confined Space" and has "FD 26" written on it. The site is surrounded by sandy soil and rocks.

**Location:** The site is west of the southwest corner of the 3621D Building. It is outside the fence that surrounds the building. The 3621D building is located southeast of the intersection of Locust Street and the George Washington Way extension.

**Related Sites/Structures:** The site is associated with the 3621D Building.
Process Description: The drain received effluent from floor drains inside the 3621-D building. All the floor drains inside the 3621-D building have been plugged.

**Code:** 300-123  
**Classification:** Accepted

**Reclassification:** Final Closed Out (5/12/2014)

**Names:** 300-123; 366 Building Fuel Oil Bunker Loading Station Steam Condensate French Drain; Miscellaneous Stream #342

**Type:** French Drain  
**Status:** Inactive

**Start Date:**  
**End Date:**

**Description:** The waste site has been remediated and Interim Closed Out with the 300-6 waste site. In 2014, the site was reclassified to Final No Action. The site was a french drain that received steam condensate from the 366 Building fuel oil bunker loading station. The french drain was removed between August 24 and September 14, 2010 during the excavation of waste site 300-6 (D4-300-018). The french drain was a metal culvert that is covered with a 0.69 meter (2.25 foot) diameter diamond plate metal cover with four 1.9 centimeter (0.75 inch) holes in the cover. The lid is discolored by rust. Inside the french drain, there is soil and rock about 1.4 meters (4.5 feet) from the top of the culvert. There are also granular ash deposits on the ground in the general area east northeast of the 384 powerhouse. The soil on the south side of the French drain has eroded into the excavation for 300-6 exposing the metal culvert.

**Location:** The site is located southwest of the southeast corner of the 3715 building.

**Related Sites/Structures:** The site received effluent steam condensate from the 366 Building fuel oil bunker loading station. In the area were also ancillary piping 300-273 and 300-6, 366/366A Fuel Oil Bunkers.

**Process Description:** Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.

**Closure Info:** Interim

The 300-6 waste site (fuel oil bunkers) was expected to be excavated to groundwater, a depth of approximately 15.8 meters (52 ft) below ground surface (bgs), as necessary to remediate contaminated soil. Remediation of the waste site was performed from August 2 to December 8, 2010. The western portion of the 300-6 waste site excavation did reach the groundwater, and a pool of water remains in the floor of the excavation. The excavation was approximately 15 meters (49.5 ft) deep in the 300-6 west borehole location (when measured to the surface of the pool of water) and approximately 11.5 meters (37.7 ft) deep in the 300-6 east borehole location. The 300-6 and associated waste sites' excavation resulted in approximately 34,770 bank cubic meters (45,477 bank cubic yards) of material removed for disposal at the Environmental Restoration Disposal Facility (ERDF).

Debris (piping and concrete) and soil from the remediation of the 300-6 and associated waste sites were direct loaded to ERDF. No overburden soil stockpiles were associated with the waste sites as a result of remediation, and no anomalies were noted.

The 300-123 UIC was identified as a WIDS waste site. The french drain was removed as part of the layback to remove the contaminated soil at the 300-6 waste site. The french drain consisted of soil and rock that extended to approximately 1.4 meters (4.5 ft) bgs. The existing floor of the 300-6 waste site excavation is approximately 11.3 m (37 ft) bgs.
The 300-65, 300-66, 300-122, and 300-124 UICs were located within the footprint of the 300-6 excavation layback and also removed during the 300-6 excavation. The 3715, 303E and 303J building slabs were removed during the 300-6 waste site excavation because they were located in the excavation layback as well.

The 300-268 site was located within the 300-6 layback area. It was excavated to a depth of 3.0 meters (9.8 ft).

During excavation of the 300-6 waste site, it was verified that the eastern half of the 300-273 waste site pipeline had been previously removed. In addition, as the project conducted test pits along the western half of the 300-273 waste site pipeline right-of-way on November 3, 2010, no pipeline structure was encountered at the elevations presented in the as-built drawings for the pipeline (USAEC 1974). Also in November 2010, the project excavated two test pits along the former 384 Powerhouse foundation within the UPR-300-42 waste site. No below-grade structure was noted, and no visible soil staining was observed, as was expected since the site was reportedly removed in 2009.

During excavation of the 300-6 waste site, it was verified that the eastern half of the 300-273 waste site pipeline had been previously removed. In addition, as the project conducted test pits along the western half of the 300-273 waste site pipeline right-of-way on November 3, 2010, no pipeline structure was encountered at the elevations presented in the as-built drawings for the pipeline. Also in November 2010, the project excavated two test pits along the former 384 Powerhouse foundation within the UPR-300-42 waste site. No below-grade structure was noted, and no visible soil staining was observed, as was expected since the site was reportedly removed in 2009 with the demolition of the 384 powerhouse structure.

Final

The 300 Area Fuel Oil bunkers and associated waste sites were remediated in 2010. The excavation extended to groundwater at a depth of 52 feet. The 300-6, 300-123, 300-268, 300-273, and UPR-300-42 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support a residential land use scenario.

Contamination that extended into the deep zone (greater than 4.6 meters [15 ft] bgs) has been removed; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-6, 300-123, 300-268, 300-273, and UPR-300-42 waste sites to Final Closed Out.

---

**Code:** 300-175

**Description:** The site was a 36 centimeter (14.2 inch) diameter, concrete french drain with a metal cover on the west side of the demolished 3714 building. The inside had been dry and filled with cobbles. There are no steam lines entering the site, and no steam lines are visible inside the drain. In August 2011, the drain structure was filled with grout.

**Location:** The 300-174 french drain is located on the west side of the 3714 Building.

---

**Names:**

**Status:** Inactive

**Start Date:** 1/1/1995

**End Date:** None

**Classification:** Accepted

**Reclassification:** None

Hanford Site Waste Management Units Report
February 2015
Process Description: Steam was produced from sanitary water that has been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites receive steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.

Related Sites/Structures: The site was related to the 3714 Building.

Code: 300-214
Names: 300-214; 300 Area Retention Process Sewer; 300 RPS
Type: Radioactive Process Sewer
Start Date: 1/1/1953
End Date:
Status: Active
Classification: Accepted
Reclassification: None
Description: The waste is an underground carbon steel and polyvinyl chloride pipeline connecting the 300 Area laboratory facilities (308, 324, 325, 326, 327, and 329 buildings) to the 307 Retention Basins. The Retention Process Sewer (RPS) provides radioactive monitoring and transport of nonhazardous, potentially radioactive process waste.
Location: The RPS lies below grade in the 300 Area. The system connects the 324, 325, 326, 327, 329, and 309 Buildings, discharging to the 307 Retention Basins.
Related Sites/Structures: The retention process sewer includes four diverter stations, a sample pit northwest of basin 1, and the 3707-F control shack. The system is related to the 340 Waste Handling Complex, the process sewer, and the 300 RLWS.
Process Description: The Retention Process Sewer (RPS) collects non-hazardous, potentially radiologically-contaminated waste from the 324, 325, 326, 327, and 329 buildings. When the 308 building was active, it also generated effluent discharged to the RPS. The potentially contaminated effluent is discharged to the 307 Retention Basins. The retention basins are periodically sampled and analyzed. Waste below a predetermined level (5,000 picocuries per liter) is discharged from the basins through the Process Sewer to the 300 Area Treated Effluent Disposal Facility (TEDF). Waste above the discharge criteria is held for transport to the 200 Area double shell tanks. Beta-gamma detectors in the four diverters at the laboratory buildings monitor the RPS waste activity. Prior to October 1,1998, if the RPS waste was contaminated, it was diverted to the Radioactive Liquid Waste Sewer (RLWS). During normal operations the waste from the RPS is held in one of the 307 Retention Basins for sampling and discharge. If the facility beta-gamma detector alarm trips, all waste flowing in the RPS is rerouted to a different one of the 307 retention basins. This waste will be sampled, analyzed and disposed of accordingly. The 324 and 327 Buildings have opted not to use this method of containment. In the event that the facility RPS beta-gamma detector alarms at either of these facilities, the waste transfer to the RPS is halted and contained at the facility.

Code: 300-218
Names: 300-218; 314; 314A and 314B Buildings; Engineering Development Laboratory
Type: Fabrication Shop
Start Date: 1/1/1943
End Date: 1/1/1996
Status: Inactive
Classification: Accepted
Reclassification: Final Closed Out (5/12/2014)
Description: The waste site has been remediated and Interim Closed Out. In 2014, the site was reclassified to

Hanford Site Waste Management Units Report
February 2015
Final Closed Out. It consisted of the 314 Building and the associated 314A and 314B Buildings. Both the 314A and 314B buildings were attached to the 314 Building. Because the 314A building was demolished some time ago, the remaining 314 and 314B buildings were often referred to as the 314 facilities, or collectively as the 314 Building. The 314 and 314B facilities were demolished down to the slab October thru December 2005. The buildings have been demolished down to the slab.

The 314A Autoclave Pit was attached on the northeast corner of the 314 Building. The 314A Building included a basement which became radiologically contaminated by the autoclave operations. The above ground portion of the building was previously demolished, in the 1950s. The history and details of the 314A Building and its demolition are not well documented. The basement was left in place, filled with dirt and covered with concrete. The concrete slab was fenced off.

The 314B Stress Rupture Test Facility was attached to the northwest corner of the building and consisted of eight small rooms with blow out roof panels and blast doors for the purpose of conducting high pressure experiments. The facility was placed in standby in June of 1996. The water and sprinkler systems were drained, and the ventilation was shutdown and capped where needed. The facility was cleaned out with the exception of a few large pieces of equipment, which were excessed in place or have storage agreements with the owners.

**Location:** The 314 and 314A buildings were located in the northwest section of 300 Area, near the corner of Alaska and Ginko Streets.

**Release Description:** A number of known releases occurred at the 314 building during the period from 1943 to 1971 when the building was used for reactor fuel manufacturing. Many were associated with sludge or turnings fires and autoclave explosions. Others resulted from the lathe and machining operations, extrusion press work, outgassing and other fuel fabrication operations.

A fire occurred in the high bay area during the 1950's. The fire spread contamination through the high bay area. Water used to fight the fire contaminated soil around the facility. The smoke permanently contaminated the inside of the building. Another large fire occurred several years later and is known to have contaminated the exterior grounds with washdown run off. Historical practices were also known to include washing the floor with hoses and directing the flow outdoors. Other operations with uranium also are known to have contributed to exterior soil contamination. Historical documents have noted underground radioactive contamination on the west side of the building. Efforts to decontaminate the site included removal of a concrete slab, water drainage trench, and supporting lumber and soil under the slab. Documents also indicate uranium contamination embedded in the concrete walls, floors and overhead piping inside the building, principally in the high bay area.

**Related Sites/Structures:** The building is associated with 300-16, 300-24 and 300-28.

**Process Description:** The 314 "Press Building", built in 1944, had numerous uses before being retired. The original mission of the 314 Building was fabrication of uranium metal fuel for single pass production reactors. Processes included uranium casting machining, and chemical milling, however in 1944 the facility was used for outgassing and straightening of fuel rods that were extruded offsite. In 1945, the onsite fuel rod extrusion process began in the 314 Building. The uranium billets arrived at the 314 building for extrusion, outgassing and straightening. Then they were sent to the 313 building for machining, canning and inspection. The rods were returned to the 314 building for autoclaving and radiographic testing. Other related operations included chip recover, melt plant operations, and oxide burner operations for uranium recovery from scraps and dust. Later, the facility was used for testing of zirconium fuel cladding alloys.

After the closure of the single pass reactors, the 314 building housed several research and craft
activities. These included space for test equipment and mockups. The space was used for housing autoclaves, high-pressure and high temperature loops and prototype equipment that was in development and testing. A combined shop and repair area were located in the building. Charging machines and reactor auxiliary equipment were developed in the building. Since the 1970's, laboratory work was done by PNL's Materials Department.

This building was one of the original World War II era 300 Area, MED/DuPont structures. Several rectangular additions have been constructed along the north side of both 314 and 314B. The building frame work was bolted steel. The gable roof was constructed of corrugated asbestos. Exterior walls and partitions were concrete block. The floor was reinforced concrete with test pits and a basement room at the west end. A small second floor or mezzanine existed at the west end of the building. The principal utilities were sanitary water and sewer, steam, normal building power, compressed air and process sewer. The building had a wet sprinkler system. Air conditioning and heating was provided in the office areas along the north side of the building and in the second floor mezzanine through the use of heat pump systems. Evaporative cooling and heating by steam space heaters was provided within the high/open bay area. Electric service was provided from a 1000 KVA transformer outside the building. Service voltage was 480/277 V. Distribution voltage within the building from dry transformers, was 120/208 V and 120/240 V. A 7.5 ton bridge crane serves the high bay on the south side.

The 314B Stress Rupture Test Facility was attached to the northwest corner of the building and consisted of eight small rooms with blow out roof panels and blast doors for the purpose of conducting high pressure experiments. The facility was placed in standby in June of 1996. The water systems and sprinkler systems were drained and the ventilation was shutdown and capped where needed. The facility was cleaned out with the exception of a few large pieces of equipment, which were excessed in place or have storage agreements with the owners. Power remained connected to the facility. Some interest was shown in possibly leasing the facility to a private enterprise. However, the legacy contamination remaining in the high bay prevented this from occurring.

**Closure Info:** Interim

Remedial action activities at the 300-16:2, 300-24, 300-80, and 300-218 waste sites were carried out from December 21, 2009 to May 20, 2010. The excavation reached a maximum depth of 3.0 meters (9.8 ft) near the center and southwest corner of the collective waste sites. Approximately 6,275 cubic meters or 14,995 tons of materials were removed from the waste site excavation and direct loaded for disposal at the ERDF. There was no waste staging pile area footprint or overburden soil stockpile associated with these waste sites. The utility pole that was associated with the 300-16:2 subsite was removed. The autoclave pit underlying the former 314A Building was removed. The structures associated with the 300-80 drain were removed. The concrete slabs associated with the 314, 314A, and 314B Buildings have been removed.

During remediation, a suspected French drain was found at the base of the exterior stairwell on the southwest edge of the 314 Building slab. Discussions with the EPA concluded that this drain could be remediated concurrently with the 314 Building waste sites. This suspected French drain was removed. Two pits within the main 314 Building extended below the level of the current excavation. Discussions with EPA concluded that the remaining portions of these pits could remain in place. The 300-285 (300FF2-018; FD 32), 300FF2-270 and 300-240 underground injection control (UIC), wells, were within the footprint of the 314 excavation layback. The listed UIC wells are not part of the waste site. They are listed for tracking purposes. The UIC wells have a "Not Accepted" classification status and are still present at the site.

All the foundation debris such as concrete, metal rebar, miscellaneous piping (e.g., steam, water, etc.), and electrical conduit was excavated and removed from the waste sites. No
anomalous materials were observed during remedial activities.

Post-excavation radiological survey of the 314 Building slab was performed in June 2010. Additional radiological surveys of the 300-16:2 utility pole were performed in March 2011. The field radiological measurements survey results did not identify any residual radiological contamination above background levels.

Final

The 300-24, 300-80, 300-218, and 300-16:2 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Contamination at these waste sites did not extend into the deep zone soils. Because the remediation of the waste sites did not meet residential land use cleanup levels, the waste sites require institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-24, 300-80, 300-218, and 300-16:2 waste sites to Final Closed Out.

<tr>
<td>Description:</td>
<td>This site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. It included the transfer lines connecting the various components of the 300 Area Waste Acid Treatment System (WATS) and the 300 Area Uranium Recovery Operations. The piping, located in the Pipe Trench (300-224), included the 333 N Fuels process transfer lines connected to the process acid waste solution storage tanks in the 333 and 334-A Facilities, the waste transfer lines to the waste treatment facilities in the 313 Uranium Recovery/WATS Neutralization Room, the transfer lines to/from the 313 Building to the neutralized acid waste storage tanks in the 311 Tank Farm, the ethylene glycol supply and return lines in the Pipe Trench between the 333 Building and the 313 Building used to heat this portion of the Pipe Trench, the fresh acid (nitric and sulfuric) lines from the 334 Tank Farm to the 333 Building, and the caustic lines from the Tank Farm to the 313 WATS/URO Room. As of 11/1/98, all process and waste piping inside the associated facilities had been disconnected from the Pipe Trench. Only the piping inside the Pipe Trench or outside the facilities (e.g. tank farm piping) remained for pipes associated with the 300 Area Waste Acid Treatment System or the 300 Area U-Bearing Acid Treatment System. The 300 Area Waste Acid Treatment System was closed in phases. It was totally closed on 10/30/2005.</td>
</tr>
<tr>
<td>Location:</td>
<td>The WATS transfer lines were located inside the Pipe Trench. Some portions of the transfer lines, located inside the 334-A Facility, the 313 WATS and URO, and the 303-F Building, were removed during the Decontamination and Inspection Plans for Phases I and II of the closure plan.</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The Pipe Trench (300-224), the 333 Building, the 334 Tank Farm, the 334-A Building, the 303-F Building, the 311 Tank Farm, and the Uranium Recovery Operations in the 313 Building.</td>
</tr>
<tr>
<td>Process Description:</td>
<td>WATS Process Drain: The 333 N-Fuels spent etch acid drain lines in the Pipe Trench to the 334-A Facility (storage tanks) are 10.2 cm. and 7.6 cm. (4 in. and 3 in.) PVC lines. Upstream WATS Acid Transfer: Batches of WATS waste acid solutions were pumped from the 334-A tanks through 5.1 cm. (2 in.) PVC lines in the Pipe Trench to the 313-TK-2</td>
</tr>
</tbody>
</table>
neutralization tank in the 313 Building.

WATS Neutralized Acid Waste Transfer: After neutralization with caustic, the batch of neutralized acid waste solution was pumped through 5.1 cm. (2 in.) lines in the Pipe Trench to storage tanks in the 311 Tank Farm. In 1995, recycle piping was installed in the Pipe Trench from the 311 Tank Farm waste storage tanks to the 313 Building to allow additional solids removal if required.

URANIUM-BEARING ACID transfer: The U-bearing waste acid solutions were collected in the Interim Storage/Blending Tank 333-TK-24 in the 333 Building and batch transferred via 5.1 cm. (2 in.) stainless steel lines in the Pipe Trench to Storage Tanks 1 and 2 in the 333 West Tank Farm. The stored U-bearing acid was transferred through a 2 in. stainless steel line in the Pipe Trench back into the 333 Building to a valving manifold where it was routed west through stainless steel piping in the Pipe Trench, south and east to the 303-F Building and then on to the acid storage tanks 313-TK-3 and 313-TK-4 in the 313 Uranium Recovery Operation (300 URO).

URANIUM RECOVERY: The U-bearing waste acid solutions were neutralized, filtered, and transferred through pipes in the Pipe Trench to the same waste storage tanks in the 311 Tank Farm as used to store the WATS neutralized acid waste solution.

Closure Info: Interim

Note that the portions of the WATS trench that were inside the 333 Building and east of the 333 Building are not part RSVP-2011-106 interim closeout document. The portion of the 300-219 and 300-224 waste sites that were in the 618-1 Burial Ground were clean closed as part of the 300 Area WATS Resource Conservation and Recovery Act of 1976 (RCRA) treatment, storage, and disposal unit (TS-3-1). The portions of the 300-219 and 300-224 waste sites addressed in the RSVP-2011-016 document are the portions of the WATS trench from the 313 Building to the 333 Building.

Remediation of the 300-219 and 300-224 waste sites was performed from December 14, 2009, through May 23, 2011. The majority of the soil within the waste sites footprints were excavated to a depth of 0.5 to 1.0 meters (1.6 to 3.3 ft) below ground surface (bgs). The soil under the 300-224 loading area was excavated to a depth of over 1.5 meters (4.9 ft) bgs. Remediation of the 333 WSTF waste site was performed on December 14, 2009. The soil within the waste site footprint was excavated to a depth of 1.0 meter (3.3 ft) bgs, resulting in 40 BCM (52 BCY) of soil was being disposed at the ERDF. The resulting 581 bank cubic meters (BCM) (760 bank cubic yards [BCY]) of soil was disposed at the Environmental Restoration Disposal Facility (ERDF).

Final

The 300-219 waste site consists of the transfer lines inside the 300-224 Waste Acid Treatment System (WATS) trench. The 300-224 WATS trench ran between the 313 Building, 303-F Building, 311 Tank Farm, 333 Building, 334-A Building, and 334 Tank Farm. The 333 WSTF waste site, located on the west side of the former 333 Building, was an above-grade tank farm with a concrete containment basin. Remediation occurred from 2009 through 2011 with a maximum depth of 4.9 feet. The 300-219, 300-224, and 333 WSTF waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CULs for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Because the sample results do not meet the CULs for residential land use, the waste sites require institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of
the 300-219, 300-224, and 333 WSTF waste sites to Final Closed Out.

### Description:
This site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. It was a subsurface, concrete pipe trench with concrete block and metal plate covers. The pipe trench had several sections which allowed piping connections to be made between process operations in the 313 Building, the 303-F Building, the 311 Tank Farm, the 333 Building, the 334-A Building, and the 334 Tank Farm.

The portions of the 300-219 and 300-224 waste sites addressed in the RSVP-2011-016 document are the portions of the WATS trench from the 313 Building to the 333 Building.

The west part of the concrete pipe trench, that connected the 333 Building and the 313 Building, was approximately 188 meters (617 ft) long with internal dimensions of about 45.7 cm by 45.7 cm (18 in by 18 in). This section of the pipe trench had ethylene glycol heating lines used for freeze protection. An access box or valve box with a metal lid connected to the west wall of 333 where the pipe trench emerges from the building. The pipe trench was covered by concrete lids, each measuring 1.21 meters by 0.64 meters (4 ft by 2.1 ft). The concrete covers were numbered, with # 1 being the closest to the west wall of 333. Some of the covers adjacent to 333 and the 333 West Tank Farm were posted "Fixed Contamination Area." The entire length of the pipe trench was posted "Radioactive Material, Internally Contaminated." The pipe trench ran south along the west side of the 333 Bldg. and made a 90 degree turn to the west at the building's southwest corner. It crossed the street and made another 90 degree turn to the south and ran along the east side of the 3712 Building. A metal access lid was found on the east side of 3712, between the covers numbered # 65 and # 66. This allowed access to the pipe trench and the helium lines that ran between 306W and 3712.

### Location:
The pipe trench runs between the 313 Building, the 303-F Building, the 311 Tank Farm, the 333 Building, the 334-A Building, and the 334 Tank Farm, as shown in the attached scanned schematic diagram.

### Related Sites/Structures:
The pipe trench is associated with the 300-258 pipe trench, the 334-A Acid Treatment Facility, 300-64, the 333 U-bearing acid storage area, the 311 Tank Farm, the 303-F building, the 313 Uranium Recovery Operations and Waste Acid Neutralization Operations, and (after about 1977) the process sewer. The site was associated with the 618-1:2 Neutralization Pit.

### Process Description:
The 333 Building portion of the pipe trench contains chemical process transfer piping for the 300 Area Waste Acid Treatment System including the waste etch acids drains to the 334-A Building (WATS) and the transfer lines from 333-TK-24 to the additional U-bearing waste acid storage tanks in the 333 West Tank Farm. The pipe trench also contains transfer piping for fresh acids and for fresh oil and waste oil (for the 333 co-extrusion press). Until 1977, the concrete pipe trench on the east side of 333 drained into a limestone pit (618-1:2) located over the 618-1 Burial Ground. This end of the pipe trench was sealed in July 1975 and a drain was installed to the process sewer.

The 313 Building portion of the pipe trench contains transfer piping for the 300 Area WATS, for the 313 Uranium Recovery Operation (URO), for fresh caustic for neutralization, for the neutralized acid waste (WATS) stream, and the neutralized U-bearing acid waste (URO) stream between 313 Building and the neutralized waste storage tanks in the 311 Tank Farm.
Note that the portions of the WATS trench that were inside the 333 Building and east of the 333 Building are not part RSVP-2011-106 interim closeout document. The portion of the 300-219 and 300-224 waste sites that were in the 618-1 Burial Ground were clean closed as part of the 300 Area WATS Resource Conservation and Recovery Act of 1976 (RCRA) treatment, storage, and disposal unit (TS-3-1). The portions of the 300-219 and 300-224 waste sites addressed in the RSVP-2011-016 document are the portions of the WATS trench from the 313 Building to the 333 Building.

Remediation of the 300-219 and 300-224 waste sites was performed from December 14, 2009, through May 23, 2011. The majority of the soil within the waste sites footprints were excavated to a depth of 0.5 to 1.0 meters (1.6 to 3.3 ft) below ground surface (bgs). The soil under the 300-224 loading area was excavated to a depth of over 1.5 meters (4.9 ft) bgs. Remediation of the 333 WSTF waste site was performed on December 14, 2009. The soil within the waste site footprint was excavated to a depth of 1.0 meter (3.3 ft) bgs, resulting in 40 BCM (52 BCY) of soil being disposed at the ERDF. The resulting 581 bank cubic meters (BCM) (760 bank cubic yards [BCY]) of soil was disposed at the Environmental Restoration Disposal Facility (ERDF).

Final

The 300-219 waste site consists of the transfer lines inside the 300-224 Waste Acid Treatment System (WATS) trench. The 300-224 WATS trench ran between the 313 Building, 303-F Building, 311 Tank Farm, 333 Building, 334-A Building, and 334 Tank Farm. The 333 WSTF waste site, located on the west side of the former 333 Building, was an above-grade tank farm with a concrete containment basin. Remediation occurred from 2009 through 2011 with a maximum depth of 4.9 feet. The 300-219, 300-224, and 333 WSTF waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CULs for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Because the sample results do not meet the CULs for residential land use, the waste sites require institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-219, 300-224, and 333 WSTF waste sites to Final Closed Out.

| Code: | 300-251 | Classification: | Accepted |
| Names: | 300-251; Unplanned Release Outside the 303-K Building | Reclassification: | Final Closed Out (5/12/2014) |
| Type: | Unplanned Release | Start Date: | 1/1/1943 |
| Status: | Inactive | End Date: | |
| Description: | The site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. It consisted of uranium contaminated soil around and under the 303-K Building (also known as the 303-K Contaminated Waste Storage). The 303-K building was removed and the TSD was clean closed on July 22, 2002. The soil remediation activity occurred in 2010 and 2011. |
| Location: | The unit is located in the 300 Area, on the north side of Ginko Street between the 313 and 314 Buildings. |
| Release Description: | Releases may have occurred during decontamination activities within the facility or the storage of materials outside the facility. Individual events were not always documented. |
The building was constructed of cinder blocks that rested on a concrete slab. The building was constructed in 1943 for storage to support uranium fuel production. In 1953, building modifications and outdoor storage pads (concrete and asphalt) were constructed to support the decontamination of aluminum reactor spacers. From 1953 to 1977, decontamination operations were conducted at this site. From 1977 to 1982, the building was used to cure and test concreted billets of uranium chips and fines from the 303 Concretion facility. Since 1953, radioactive waste has been stored at the facility including the outdoor areas. From 1986 to 1995, low-level radioactive waste and mixed waste was stored within the building and the outdoor area.

Initial remediation of the waste site was performed June 21 to 22, 2010. The waste site was excavated to a depth of 0.5 meters (1.6 ft) below ground surface, resulting in approximately 432 bank cubic meters (BCM) (565 bank cubic yards [BCY]) of soil disposed at the Environmental Restoration Disposal Facility (ERDF). Concrete and asphalt were also found within the excavation and were removed for disposal. All material was direct loaded from the excavation; therefore, no waste staging piles were created. No overburden soil stockpiles are associated with the waste site.

A post-excavation radiological survey for gamma and beta activity was conducted following the completion of remedial action to confirm that waste site excavation was complete. No elevated gamma activity was detected. The radiological field screening survey identified two locations with elevated beta activity, with one judged to be potentially above cleanup levels. This location is on the southeast margin of the excavation. Additional soil from the southeast location (approximately 8 BCM [10.5 BCY]) was removed by hand shoveling and was disposed at ERDF. A focused sample was collected from each of the two locations exhibiting elevated beta activity.

A supplemental remedial action at the 300-251 waste site was done on June 1, 2011. Approximately 42 BCM (55 BCY) of additional soil was removed for disposal to ERDF. The supplemental remedial action was due to a total petroleum hydrocarbons (TPH) result greater than direct exposure RAGs for a verification soil sample (J1DWL3) taken at sample location EXC-9.

The 300-251, Unplanned Release Outside the 303-K Building waste site, consisted of potentially contaminated soil around and under the former 303-K Contaminated Waste Storage Building. Remedial action was performed in June 2010 and June 2011. The waste site was excavated to a depth of 1.6 feet. The 300-251 waste site was remediated and has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Contamination at this waste site did not extend into the deep zone soils. Because the remediation of the waste site did not meet residential land use cleanup levels, the waste site requires institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-251 waste site to Final Closed Out.
Names: 300-253; 384-W Original Brine Pit; 384-W Original Salt Dissolving Pit and Brine Pump Pit

Reclassification: Final Closed Out (3/10/2014)

Type: Sump

Start Date: 1/1/1977

Status: Inactive

End Date: 3/10/2014

Description: The waste site had been evaluated and determined to require No Action. In 2014, the site was reclassified to Final Closed Out. It was a two-chambered concrete brine pit. No surface features were noted at the structure's location except a patch of asphalt that was darker than the surrounding material.

The structure was located partially below grade with the top 83 centimeters (33 inches) visible. It had either a concrete or metal lid (see Site Comment). The larger chamber, was the salt dissolving pit, also identified as the "Salt Storage Pit" on drawing H-3-36240. This section held the salt that was dissolved to make the brine. Typically, the salt dissolving pit was connected to the brine pump pit by a piece of perforated pipe located at the bottom of the structure. The pipe was covered by layers of gravel and sand. The smaller chamber was the brine pump pit, also identified as "brine" on drawing H-3-36240. This chamber held the filtered brine for use in powerhouse operations. The pump pit was connected to the powerhouse by a 5.1 centimeter (2 inch) line and a 2.5 centimeter (1 inch) line.

Location: The original 384 brine pit was located approximately 0.6 meters (2 feet) south of the 384 Building's southwest corner. The brine pit's west wall was in line with the west wall of the 384 Building.

Related Sites/Structures: The site is related to the 384 Powerhouse. It was replaced by another brine pit, WIDS Site Code 300-222.

Process Description: The steam system used "soft" water. Brine was used to regenerate the ion exchange demineralizers in the water softeners. The brine was created by distributing water across the surface of the salt. As the water passed through the salt, the solution became saturated. The brine solution passed through layers of sand and gravel which filtered out salt crystals and other particles. The filtered brine passed into the pump pit via a pipe that connected the chambers. Flow through the brine pit was achieved by the addition of new water into the salt dissolving pit and the removal of brine from the pump pit.

Closure Info: Interim

The reclassification status of No Action is documented of form 99-042. Any remaining material will be addressed as part of decommissioning the 384 Powerhouse.

Final

In 2014, the site was reclassified to Final Closed Out on form 2014-012 and requires Institutional Controls.

---

Names: 300-255; 309 Tank Farm Contaminated Soil

Type: Unplanned Release

Start Date: 1/1/1960

Status: Inactive

End Date: 1/1/1969

Description: The site is contaminated soil located inside the 309 Building Tank Farm fenced area. The source of the contamination was probably the piping related to tanks 309-TW-1, 309-TW-2 and 309-TW-3. The 309 Tank Farm houses three underground holdup tanks (WIDS Sites 309-
TW-1, 309-TW-2 and 309-TW-3) covered by a protective concrete pad, an underground concrete covered valve pit, above and below ground transfer pipelines, an ion exchange vessel, a control panel, and a large access area of mixed sand and gravel. In 1996, the Tank Farm area and associated hardware and fixtures were surveyed, sampled, assayed, video taped, or otherwise characterized. The purpose of this work was to establish the radiological status of the Tank Farm as preparatory work to cleanup actions.

**Location:**
The site is located northeast of the 309 Building and inside the 309 Tank Farm fence.

**Process Description:**
The underground tanks were constructed in conjunction with the Plutonium Recycle Test Reactor (PRTR) (a.k.a. 309 Building) in the late 1950's. The tanks are described in WIDS Sites 309-TW-1, 309-TW-2, and 309-TW-3. The 309-TW-3 tank typically collected liquid waste from the storage basin overflow and drain system, the Rupture Loop Annex Cell sump, contaminated floor drains, Loadout Facility drains, exhaust fan pit drain, stack and duct drains, and the exhaust air filter drain. Tank 309-TW-2 was used as a backup for 309-TW-3. Tank 309-TW-1 was used as a process holding tank where liquid from the other two tanks was treated or prepared for pumping liquid waste to the 340 Complex. Sometime after the initial installation of the tanks, an ion exchange column was installed between tanks 309-TW-2 and 309-TW-1. The ion exchange column was used to treat liquid from Tanks 309-TW-2 and 309-TW-3 before sending the liquid to the 340 Complex for disposal (contaminated stream). If the contamination was removed by the ion exchange resin processing, it was sent through the 300 Area Retention Process Sewer to the 307 Retention Basins.

**Related Sites/Structures:**
The site was related to operations at the 309 Building (PRTR - Plutonium Recycle Test Facility), 309 Tank #1 (WIDS Site 309-TW-1), 309 Tank #2 (WIDS Site 309-TW-2), 309 Tank #3 (WIDS Site 309-TW-3), an underground concrete covered valve pit, above and below ground transfer pipelines, an ion exchange vessel, and a control panel.

<td></td>
<td></td>
</tr>
</tbody>
</table>

During remedial activities, the 300-33 and 300-256 combined waste sites were re-defined to include four subsurface pits ranging from 3 to 16 meters (12 to 45 ft) below the concrete slab surface of the 306 Building. The four pits included the tube pit located in Room 172 of the 306E Building, the assembly pit located in the western high bay of the 306E Building, the furnace pit located in the northwestern corner of the 306E Building, and the press pit located in the northeastern corner of the high bay. Because these are nonstandard structures, agreements were reached between the Department of Energy, Richland Operations Office, and the U.S. Environmental Protection Agency to document status and closure requirements for these pit structures in a separate closure report (Refer to 306E/W Below Grade Pits Closure Report, CCN 147876, Washington Closure Hanford, Richland, Washington).

**Location:**
The 306E Building was on the north side of Ginko Street, in the northeast corner of the 300 Area.

**Release Description:**
Without distinguishing between the 306E and 306W Buildings, Gerber, WHC-MR-0388, states the following. Airborne dust and particulate contamination in and near this facility included uranium and thorium, as well as all of the components of the beryllium-Zircaloy-2 brazing.
Process Description:
The original 306 Building was completed in 1956 and named the Fuel Element Pilot Plant. The facility was constructed to support the 313 Building operations. It was expanded in 1960 to contain the co-extrusion fabrication processes for N Reactor fuels fabrication. In 1972, the new eastern half was designated as 306E and became the Hanford Engineering Development Laboratory (HEDL) operated by Westinghouse Electric Corporation. The original western portion of the building, was designated as 306W and was allocated to Pacific Northwest Laboratories (PNL).

Closure Info: Interim

Demolition of the 306E, 306W, and 306E-BA facilities, which were located on top of the soil waste sites, was completed between November 2006 and December 2007. Remediation of the combined 300-33, 300-256, and 300-41 waste sites occurred between July 10 and November 9.
2009. The remediation activities included the removal of the neutralization tank, valve pit, soil, and other debris within the footprint of the 306E/W Building including the partial removal and backfill of the 306E Building assembly pit. All debris and excavation materials have been removed to the Environmental Restoration Disposal Facility.

The 300-33 and 300-256 combined waste sites included four pits ranging from 3 to 16 meters (12 to 45 ft) below the concrete slab surface of the 306 Building. The four pits included the tube pit located in Room 172 of the 306E Building, the assembly pit located in the western high bay of the 306E Building, the furnace pit located in the northwestern corner of the 306E Building, and the press pit located in the northeastern corner of the high bay. Because these are nonstandard structures, agreements were reached between the Department of Energy, Richland Operations Office, and the U.S. Environmental Protection Agency to document status and closure requirements for these pit structures in a separate closure report (Refer to 306E/W Below Grade Pits Closure Report, CCN 147876, Washington Closure Hanford, Richland, Washington).

Final

This group of sites [300-33, 300-41, 300-110, 300-256] is listed in the 300-FF-2 Record of Decision as Final Closed Out. Institutional Controls to maintain Industrial Landuse are required.

<td>Status</td>
<td>Inactive</td>
<td>End Date:</td>
<td></td>
</tr>
<tr>
<td>Description:</td>
<td>The waste site has been evaluated and determined to require No Action. In 2014, the site was reclassified to Final Closed Out. It is the underground process sewer piping that was originally connected to the 309 Building's Rupture Loop Holding Tank. The rupture tank was removed in the late 1970's. The pipeline extended to a 36 inch diameter corrugated pipe that emptied into the Columbia River. All connections to the Radioactive Liquid Waste Sewer (300 RLWS) were severed and plugged. The area where the Rupture Loop Holding Tank was located is now covered with asphalt and is being used as a parking lot. No pipeline is visible on the river bank or the edge of the river.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location</td>
<td>The pipeline begins southeast of the location of the 309 Rupture Loop Holding Tank (WIDS Site 300-55) and joins other process sewer lines. It runs due east to a sump (overflow structure) at the top of the river bank.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The site was related to the Rupture Loop Holding Tank (WIDS Site 300-55), 3906 lift station, a valve box, the Radioactive Liquid Waste Sewer (WIDS Site 300 RLWS), manhole #3 and contributory piping coming into manhole #3, an overflow structure at the east end of the site, and piping that exits into the Columbia River.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>Liquid waste from the 309 Building (Plutonium Recycle Test Reactor) was routed to the Rupture Loop Holding Tank for sampling. If it was contaminated it was sent to the 340 Complex through a 7.6 centimeter (3 inch) underground pipeline. If the waste was not contaminated, it was diverted to the Columbia River via a 1 meter (3 foot) diameter pipeline to the outfall. The holding tank had a set of incoming piping that included a 7.6 centimeter (3 inch) steel process sewer pipeline and a 10.2 centimeter (4 inch) steel vent pipeline. The outgoing piping was more complex, with two outgoing pipelines being interconnected inside a valve box. One 7.6 centimeter (3 inch) steel pipe run started at the pump on the center top of the tank and ran to...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
the valve box. This pipeline was for pump discharge and was the means of lowering the tank level. The second pipe was a 15 centimeter (6 inch) steel overflow pipe that drained to manhole #3. This pipe exited the tank 22.9 centimeters (9 inches) from the top of the tank.

The valve box (pit) was a 1.8 meter by 1.8 meter (6 foot by 6 foot) mostly below grade concrete box with a gravel bottom. The valve box had a manhole and ladder for direct access to the valves. There were also three grade level openings in the top of the valve box for access to the valves with a gate key. It is unknown if the valve box remains in place. The valve box was located approximately 2.1 meters (7 feet) from the Rupture Loop Holding Tank. It may have been removed at the same time as the tank.

There was one 7.6 centimeter (3 inch) incoming pipeline to the valve box and two 7.6 centimeter (3 inch) exit pipelines. Contaminated waste water was diverted at the valve box to the high level waste pipeline that went to the 340 Complex. Uncontaminated water was sent to the process sewer where it teed into the overflow pipeline. At manhole #3, five pipelines converge and flow into a 1 meter (36 inch) 10 gauge corrugated steel pipeline that flowed to the Columbia River. The five pipelines that enter manhole #3 are all process sewer piping with the following sizes and descriptions: (1) a 15.2 (6 inch) steel pipeline from the Rupture Loop Holding Tank overflow line and the valve box, (2) a 30.5 centimeter (12 inch) vitrified clay pipe coming from the 309 Building, (3) a 30.5 centimeter (12 inch) steel line with a 5.1 centimeter (2 inch) condensate drain above the steel pipeline from the 309 Reactor, (4) a 0.76 meter (2.5 foot) steel line from the Condenser Facility (demolished), and (5) a 15.2 centimeter (6 inch) vitrified clay pipe from the 309 Building. According to DOE/EIS-0113, the streams from the 309 Building included cooling water from air conditioning chillers and floor drains from the south basement service area.

The corrugated steel pipe enters a manhole (overflow structure) at the top of the river bank. The structure is 3.8 meters (12.5 feet) deep with the invert to the structure at 1.9 meters (6.2 feet) from the top of the open grate cover. The pipe exits at a depth of 3.8 meters (12.5 feet) on the opposite side of the structure (going towards the river). No pipeline is visible on the river bank or at the edge of the river. DOE/EIS-0113 shows the top view and the profile of this pipeline. The pipeline from the overflow structure (concrete box) is covered by 3.15 meters by 3.15 meters by 0.9 meters (10 feet by 10 feet by 3 feet) deep riprap. Additional riprap has been placed at the terminus of the pipe. At the pipeline terminus there is a minimum of 1.2 meters (4 feet) of riprap cover over the pipeline. This pipeline was identified as discharge No. 014 309 Building Outfall Structure Columbia River Mile 344.5.

According to the Water Utilities group, the corrugated pipe had collapsed (due to deterioration) in some places causing subsidences that were filled with dirt.

**Closure Info:** Interim

Characterization sampling was performed, and the analytical results indicate that the residual concentrations of COPCs at this site meet the RAOs for industrial direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the characterization sampling and modeling results support a reclassification of the 300-257 waste site to Interim No Action. The waste site is evaluated using the human health direct exposure cleanup levels for industrial land use and applicable standards for groundwater and river protection in the shallow zone (i.e., surface to 4.6 meters [15 ft] deep).

Final

The 300-257, 309 Process Sewer to River waste site consisted of process sewer piping that originally connected to the 309 Building Rupture Loop Holding Tank and extended to the Columbia River bank. Sediment samples were collected at two locations on February 19 and...
March 7, 2013. The 300-257 waste site has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). RESRAD modeling predicts that the radionuclide characterization sampling results meet the excess cancer risk and allowable radiation dose and are protective of groundwater and the Columbia River under an industrial land use scenario. Sample concentrations of nonradionuclides COC's meet the CUL's for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Because the sample results do not meet the CUL's for residential land use, the waste site requires institutional controls to maintain industrial land use. In accordance with this evaluation, the site sampling results support a reclassification of the 300-257 waste site to Final Closed Out.

Interim

The northern portion of the 300-258 waste site that was addressed in the 618-1 Burial Ground excavation is interim closed out within this document based on the results presented in the Cleanup Verification Package for the 618-1 Burial Ground. The 618-1 Burial Ground excavation occurred from September 17, 2008, to September 10, 2009. Two focused, in-process samples were collected from the southern portion of the pipe trench. After sampling, the southern portion of the pipe trench of soil and debris were removed (August 6, 2009) and sent to the Environmental Restoration Disposal Facility (ERDF).

Final
The 300-258, Abandoned Pipe Trench between 334 Tank Farm and 306E waste site was a concrete pipe trench between the 306E Development Fabrication Test Laboratory and the 334 Tank Farm facilities where it joined the 300-224 pipe trench. The northern portion of the 300-258 waste site was removed with the 618-1 Burial Ground remediation, which occurred from September 17, 2008, to September 10, 2009 (WCH 2010). The southern portion of the pipe trench was removed on August 6, 2009. Verification sampling of the southern portion of the 300-258 waste site was conducted on June 9, 2011. The 300-258 waste site was remediated and has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results of the 300-258 waste site shows that the site meets the CUL's for direct exposure and groundwater protection and river protection and support a residential land use scenario. Institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-258 waste site to Final Closed Out.

</tbody>
</table>

Remediation of the 300-259 waste site was performed from March 18 through May 18, 2009. Approximately 6,600 metric tons (7,300 U.S. short tons) of debris and soil were removed. The soil within the waste site footprint was excavated to a depth of 1 m (3 ft) below ground surface (bgs), and the resulting 3,000 bank cubic meters (4,000 bank cubic yards) of soil was disposed at ERDF. Observations during excavation supported the findings of the geophysical survey that indicated the 300-259 waste site contamination was limited to the surface, as the soil below the gravel added in 1991 appeared undisturbed.

In accordance with the Remaining Sites Verification Package, RSVP-2009-059, the verification sampling results supports a reclassification of the 300-259 waste site to Interim Closed Out. The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 300 Area (RDR/RAWP) (DOE-RL-2001-47, Rev. 3) and in the 300-FF-2 Interim Action ROD.

Remedial actions were performed to support future industrial land use and to protect groundwater and the Columbia River. Further, the residual contaminant concentrations achieved do not preclude any future uses (as bounded by the rural-residential scenario) and...
allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep).

Final

This group of sites [300-10, 300-45, 300-109, 300-259, 618-8] is considered Final Closed Out in the 300-FF-2 Record of Decision and meets the criteria for unrestricted landuse.

Related Sites/Structures: This site was associated with the South Pond (316-1); the Retired Filter Backwash Pond (300 RFBP) and unplanned release (UPR) sites UPR 300-32, UPR-300-33, UPR-300-34, UPR-300-35, UPR-300-36, UPR-300-37, and UPR-300-FF-1.

Closure Info: Interim

Remediation activities at the 316-1 South Process Pond site began in 1997 with excavating trenches around the periphery of the 316-1 site. Trenching was performed to assess the lateral extent of contamination. The majority of remedial excavation and disposal activities were conducted in 1999 and 2000. Excavation at the site involved removing the overburden (scraped surface) soils and contaminated soils. The contaminated soil was transported to the ERDF for disposal. Based on field screening, overburden materials and comingle soil identified as potentially clean were placed in stockpiles for potential use as backfill. Soil samples were collected adjacent to utility poles located in the 316-1 site. Where these samples indicated contaminant concentrations above the cleanup criteria, the soil was removed and the area immediately backfilled and compacted with clean material to maintain the integrity of the utility pole. Excavation and disposal of the 316-1 South Process Pond remediation waste was completed in June 2000. The filter backwash pond (WIDS site 300 RFBP) was a lobe on east side of the process pond. During remediation, soil was primarily removed from the area on the west side of the process pond, near the pond inlet. The two north-south parallel soil berms inside the pond were removed. Areas to the south and west of the original pond boundaries were also removed during remediation. The general elevation at the bottom of the excavation used for analysis was 111.3 meters (365 ft) upon completion. The excavation depth was approximately 5.7 meters (19 ft).

Final

The site is listed in the 300-FF-2 Record of Decision. Institutional Controls to maintain industrial land use are required.

<td>Names:</td>
<td>300-263; 324 Building Diversion Tank</td>
</tr>
<tr>
<td>Type:</td>
<td>Catch Tank</td>
</tr>
<tr>
<td>Status:</td>
<td>Inactive</td>
</tr>
<tr>
<td>Description:</td>
<td>This is an underground, 77,071-liter (20,360-gallon), cylindrical tank. It is approximately 36 feet long and 10 feet deep. The top of the tank is approximately 60 inches below ground surface.</td>
</tr>
<tr>
<td>Location:</td>
<td>The tank is located in the 300 Area, east of the 3718G Building.</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>Originally, the tank was associated with the 324 Building. There are three supporting caissons (valving, pump and ion exchange).</td>
</tr>
<tr>
<td>Process Description:</td>
<td>The site is an inactive catch tank. The tank was set up to hold contaminated process solutions that were too hot to send directly to the crib (316-3) without additional treatment. After the tank was put on line, it was intended to be used as a diversion tank in the event of a radioactive release from the facility (324 Building).</td>
</tr>
</tbody>
</table>

Shortly after the tank was installed, the 340 Complex came on line. At that time, the piping system to the diversion tank in the 324 yard was bypassed and capped. Since that time, the 324 Building has transferred its waste to the 340 Complex. Drawing H-3-28455 shows the isolation of the system and has been visually verified at the caissons.
**Reclassification:**

**300-265; Pipe Trench Between 324 and 325 Buildings**

**Type:** Radioactive Process Sewer

**Status:** Inactive

**Start Date:** 1/1/1971

**Description:** The site is a 5 centimeter (2 inch), underground encased stainless-steel waste transfer line encased within a 10 centimeter (4-inch) fiberglass-reinforced epoxy pipe. The pipeline has a downward slope of about 0.5% from the 325 Building to the 324 Building. Inside the pipeline are two other stainless-steel Schedule 40 pipes, one is 3/8 inch and the other is 3/4 inch. The inner pipes were driven through the 5 centimeter (2 inch) pipe several years after the larger pipe was installed. The route of the pipeline is marked at the ground surface and is totally within the exclusion area to prevent accidental excavation. The depth of the pipeline ranges from 1 to 4 meters (3 to 12 feet) underground. The encasement surrounding the two smaller pipelines was used both for secondary containment and as a route for transfer of the process off-gas for discharge through the 324 Building stack. Before venting through the stack, it flowed into B Cell and was treated with the B Cell ventilation exhaust.

**Location:** The transfer line runs in an east-west direction, north of the 324, 308 and 325-A buildings, inside the 300 Area.

**Related Sites/Structures:** This pipeline connects the 324 and 325 Buildings.

**Process Description:** This stainless steel transfer system allowed liquefied High Level Waste (HLW) to be pumped back and forth from the 324 and 325 Buildings for vitrification experiments for spent nuclear fuel waste.

**Code:** 300-268

**Classification:** Accepted

**Reclassification:** Final Closed Out (5/12/2014)

**Names:** 300-268; 3741 Building Foundation; Box Storage Building Foundation; Special Machine Shop

**Type:** Foundation

**Status:** Inactive

**Start Date:** 1/1/1944

**End Date:** 1/1/1956

**Description:** The waste site has been remediated and Interim Closed Out with the 300-6 waste site remediation. In 2014, the site was reclassified to Final No Action. The building has been removed. The building foundation was covered with gravel. There were no visual signs or markers to indicate where the building footprint had been located. The site cannot be precisely located without geophysical scans or excavation. The entire 300 Area is a posted Underground Radioactive Material area. There is no separate radiological posting for this site.

**Location:** The 3741 Building was east of where the 384 Power Plant and south of the 303-J buildings had been located. The mapped location was adjusted in 2009, based on drawing research.

**Process Description:** The building was used to store and prepare samples of irradiated graphite, flux wires, and uranium from the 305 Test Pile, in cardboard boxes. The word "box" in the name Box Storage Building was derived from these boxes. The building was also used as a Special Machine Shop. It contained lathes, drills, saws and other machinery for cutting and preparing metal samples for analysis.

**Closure Info:** Interim

The 300-6 waste site (fuel oil bunkers) was expected to be excavated to groundwater, a depth of
approximately 15.8 meters (52 ft) below ground surface (bgs), as necessary to remediate contaminated soil. Remediation of the waste site was performed from August 2 to December 8, 2010. The western portion of the 300-6 waste site excavation did reach the groundwater, and a pool of water remains in the floor of the excavation. The excavation was approximately 15 meters (49.5 ft) deep in the 300-6 west borehole location (when measured to the surface of the pool of water) and approximately 11.5 meters (37.7 ft) deep in the 300-6 east borehole location. The 300-6 and associated waste sites’ excavation resulted in approximately 34,770 bank cubic meters (45,477 bank cubic yards) of material removed for disposal at the Environmental Restoration Disposal Facility (ERDF).

Debris (piping and concrete) and soil from the remediation of the 300-6 and associated waste sites were direct loaded to ERDF. No overburden soil stockpiles were associated with the waste sites as a result of remediation, and no anomalies were noted.

The 300-123 UIC was identified as a WIDS waste site. The french drain was removed as part of the layback to remove the contaminated soil at the 300-6 waste site. The french drain consisted of soil and rock that extended to approximately 1.4 meters (4.5 ft) bgs. The existing floor of the 300-6 waste site excavation is approximately 11.3 m (37 ft) bgs.

The 300-65, 300-66, 300-122, and 300-124 UICs were located within the footprint of the 300-6 excavation layback and also removed during the 300-6 excavation. The 3715, 303E and 303J building slabs were removed during the 300-6 waste site excavation because they were located in the excavation layback as well.

The 300-268 site was located within the 300-6 layback area. It was excavated to a depth of 3.0 meters (9.8 ft).

During excavation of the 300-6 waste site, it was verified that the eastern half of the 300-273 waste site pipeline had been previously removed. In addition, as the project conducted test pits along the western half of the 300-273 waste site pipeline right-of-way on November 3, 2010, no pipeline structure was encountered at the elevations presented in the as-built drawings for the pipeline (USAEC 1974). Also in November 2010, the project excavated two test pits along the former 384 Powerhouse foundation within the UPR-300-42 waste site. No below-grade structure was noted, and no visible soil staining was observed, as was expected since the site was reportedly removed in 2009.

During excavation of the 300-6 waste site, it was verified that the eastern half of the 300-273 waste site pipeline had been previously removed. In addition, as the project conducted test pits along the western half of the 300-273 waste site pipeline right-of-way on November 3, 2010, no pipeline structure was encountered at the elevations presented in the as-built drawings for the pipeline. Also in November 2010, the project excavated two test pits along the former 384 Powerhouse foundation within the UPR-300-42 waste site. No below-grade structure was noted, and no visible soil staining was observed, as was expected since the site was reportedly removed in 2009 with the demolition of the 384 powerhouse structure.

Final

The 300 Area Fuel Oil bunkers and associated waste sites were remediated in 2010. The excavation extended to groundwater at a depth of 52 feet. The 300-6, 300-123, 300-268, 300-273, and UPR-300-42 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL’s for direct exposure and groundwater protection and river protection and support a residential land use scenario. Contamination that extended into the deep zone (greater than 4.6 meters [15 ft] bgs) has been removed; therefore, institutional controls to prevent uncontrolled drilling or excavation into the
deep zone are not required. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-6, 300-123, 300-268, 300-273, and UPR-300-42 waste sites to Final Closed Out.

---

**Reclassification:**

**300-269; 331-A Virology Laboratory Foundation**

**Type:** Foundation

**Status:** Active

**Start Date:** 1/1/1972

**End Date:** 1/1/1995

**Description:** The site is a rectangular concrete building foundation. New air conditioner units are installed on the concrete foundation to support the adjacent 331 facility.

**Location:** The 331-A foundation is located adjacent to the northwest side of the existing 331 Building.

**Related Sites/Structures:** The 331-A Building was part of the original 331 Building complex.

**Process Description:** The 331-A Building was a roughly T-shaped, one-story, concrete-block building with a sloped wood frame roof. The building was originally used for biological research to investigate radiation effects of animals. The purpose of the research was to investigate radiation damage to tissue from plutonium and fission products. Animals that were contaminated were held in other areas of the 331 complex until their feces showed no significant contamination. In the early 1980s, the facility was converted to a virology laboratory to study bacterial and viral growth in animals. Virology research continued until 1995.

---

**Reclassification:**

**300-270; Unplanned Release at 313 Building**

**Type:** Unplanned Release

**Status:** Inactive

**Start Date:** 1/1/2000

**End Date:** 1/1/2000

**Classification:** Accepted

**Reclassification:** Final Closed Out (5/12/2014)

**Description:** The Unplanned Release site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. The 300-270 waste site was an unplanned release of a milky-white flow of water that came out of a pipe located below the loading dock on the east side of the 313 Building. The pipe drained storm water from the roof of the 313 Building. The release was on the surface of the ground in an area of compacted gravel and soil.

**Location:** The release occurred on the east side of the 313 Building.

**Related Sites/Structures:** The release of whitish stormwater came from a pipe under the loading dock on the east side of the 313 Building. The pipe drains the roof of the 313 Building, according to the e-mail summarizing the sampling activities.

**Process Description:** The source of the stormwater was the roof of the 313 Building, but the reason for the discoloration was not determined. The liquid tested and found to be nonradioactive and nondangerous. The matter was not pursued further.

**Closure Info:** Interim

The UPR-300-38 waste site consisted of contaminated soil beneath the 313 Building, as well as the foundation. The contamination resulted from multiple unplanned release events. The 313 ESSP (East Side Storage Pad) waste site was the footprint of a large concrete pad adjacent to the southeastern side of the former 313 Building, with an asphalt ramp that connected the pad to
Ginko Street. The 300-270 waste site was the area of a release of whitish storm water that came from a pipe under the loading dock on the east side of the former 313 Building. The pipe drained the roof of the former 313 Building.

Remediation of the UPR-300-38 waste site was performed from January 10, 2010, through June 2, 2011. The soil within the northern portion of the waste site footprint was excavated to an approximate average depth of 1 meter (3.3 ft) below ground surface (bgs). The southern area of the waste site was excavated to an approximate average depth of 2 meters (6.6 ft) bgs, with limited areas of deeper soil contamination to 5 meters (16.4 ft) bgs. The resulting 15,204 bank cubic meters (BCM) (19,887 bank cubic yards [BCY]) of soil was disposed at the Environmental Restoration Disposal Facility (ERDF).

Remediation of a large portion of the 313 ESSP waste site was performed by the excavation of concrete, asphalt, and underlying soil during the remediation of the UPR-300-38 waste site and the adjacent area near the footprint of the former 303-F Building. This work was performed on July 8, 2011. The soil within the waste site footprint was excavated to a depth of 1 meter (3.3 ft) bgs, and the resulting 153 BCM (205 BCY) of soil was disposed at ERDF. Approximately 98 BCM (128 BCY) was associated with the UPR-300-38 excavation; the remainder (55 BCM [72 BCY]) was associated with the 313 ESSP excavation near the footprint of the former 303-F Building. An additional 38 BCM (50 BCY) was removed from the northeast corner and the southern edge of the 313 ESSP waste site on August 26, 2011, resulting in a total of 191 BCM of debris and soil removed from the 313 ESSP waste site.

Remediation of the 300-270 waste site was performed May 23, 2011. The soil within the waste site footprint was excavated to a depth of 0.5 meter (1.6 ft) bgs, and the resulting 40 BCM (52 BCY) of soil was disposed at ERDF.

A total of 15,435 bank cubic meters (20,194 bank cubic yards) of soil and debris from the remediation of all three waste sites was disposed at the Environmental Restoration Disposal Facility.

Final

The UPR-300-38, Soil Contamination Beneath the 313 Building; 313 ESSP, 313 East Side Storage Pad; and 300-270, Unplanned Release at 313 Building waste sites were either within or immediately adjacent to the footprint of the demolished 313 Building. The UPR-300-38 waste site consisted of contaminated soil beneath the 313 Building, as well as the foundation. The contamination resulted from multiple unplanned release events. The 313 ESSP waste site was the footprint of a large concrete pad adjacent to the southeastern side of the former 313 Building, with an asphalt ramp that connected the pad to Ginko Street. The 300-270 waste site was the area of a release of whitish storm water that came from a pipe under the loading dock on the east side of the former 313 Building. The pipe drained the roof of the former 313 Building. Remediation of the UPR-300-38 waste site was performed from January 2010 through June 2011. Remediation of a large portion of the 313 ESSP waste site occurred July 8 and August 26, 2011 and included excavation of concrete, asphalt, and underlying soil. Remediation of the 300-270 waste site was performed May 23, 2011. The maximum depth of the remediation at the UPR-300-38 waste site was 5 meters (16.4 ft) below ground surface. The 313 ESSP and 300-270 waste sites were remediated to 1 meters (3.3 ft) bgs.

The 300-270, 313 ESSP, and UPR-300-38 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Site-specific RESRAD modeling predicts that the radionuclide verification focused sampling results meet the excess cancer risk and allowable radiation dose and are protective of groundwater and the Columbia River under an industrial land use scenario. The remaining verification sampling results show that the site meets the CUL's for
direct exposure and groundwater protection and river protection and support an industrial land use scenario. Contamination at these waste sites did not extend into the deep zone soils. Because the remediation of the waste sites did not meet residential land use cleanup levels, the waste sites require institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-270, 313 ESSP, and UPR-300-38 waste sites to Final Closed Out.

The 300-6 waste site (fuel oil bunkers) was expected to be excavated to groundwater, a depth of approximately 15.8 meters (52 ft) below ground surface (bgs), as necessary to remediate contaminated soil. Remediation of the waste site was performed from August 2 to December 8, 2010. The western portion of the 300-6 waste site excavation did reach the groundwater, and a pool of water remains in the floor of the excavation. The excavation was approximately 15 meters (49.5 ft) deep in the 300-6 west borehole location (when measured to the surface of the pool of water) and approximately 11.5 meters (37.7 ft) deep in the 300-6 east borehole location. The 300-6 and associated waste sites' excavation resulted in approximately 34,770 bank cubic meters (45,477 bank cubic yards) of material removed for disposal at the Environmental Restoration Disposal Facility (ERDF).

Debris (piping and concrete) and soil from the remediation of the 300-6 and associated waste sites were direct loaded to ERDF. No overburden soil stockpiles were associated with the waste sites as a result of remediation, and no anomalies were noted.

The 300-123 UIC was identified as a WIDS waste site. The french drain was removed as part of the layback to remove the contaminated soil at the 300-6 waste site. The french drain consisted of soil and rock that extended to approximately 1.4 meters (4.5 ft) bgs. The existing floor of the 300-6 waste site excavation is approximately 11.3 m (37 ft) bgs.

The 300-65, 300-66, 300-122, and 300-124 UICs were located within the footprint of the 300-6 excavation layback and also removed during the 300-6 excavation. The 3715, 303E and 303J building slabs were removed during the 300-6 waste site excavation because they were located in the excavation layback as well.
The 300-268 site was located within the 300-6 layback area. It was excavated to a depth of 3.0 meters (9.8 ft).

During excavation of the 300-6 waste site, it was verified that the eastern half of the 300-273 waste site pipeline had been previously removed. In addition, as the project conducted test pits along the western half of the 300-273 waste site pipeline right-of-way on November 3, 2010, no pipeline structure was encountered at the elevations presented in the as-built drawings for the pipeline (USAEC 1974). Also in November 2010, the project excavated two test pits along the former 384 Powerhouse foundation within the UPR-300-42 waste site. No below-grade structure was noted, and no visible soil staining was observed, as was expected since the site was reportedly removed in 2009.

During excavation of the 300-6 waste site, it was verified that the eastern half of the 300-273 waste site pipeline had been previously removed. In addition, as the project conducted test pits along the western half of the 300-273 waste site pipeline right-of-way on November 3, 2010, no pipeline structure was encountered at the elevations presented in the as-built drawings for the pipeline. No below-grade structure was noted, and no visible soil staining was observed, as was expected since the site was reportedly removed in 2009.

Final

The 300 Area Fuel Oil bunkers and associated waste sites were remediated in 2010. The excavation extended to groundwater at a depth of 52 feet. The 300-6, 300-123, 300-268, 300-273, and UPR-300-42 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RRAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support a residential land use scenario.

Contamination that extended into the deep zone (greater than 4.6 meters [15 ft] bgs) has been removed; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-6, 300-123, 300-268, 300-273, and UPR-300-42 waste sites to Final Closed Out.

### Code: 300-274  Classification: Accepted

| Names: 300-274; Surface Debris | Reclassification: Final Closed Out (5/12/2014) |
| Type: Dumping Area | Start Date: |
| Status: Inactive | End Date: |

**Description:** The waste site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. A field walkdown of the 300-FF-1 Operable Unit was done in July and December of 2004 to identify remaining debris, hazards and potential new waste sites. Miscellaneous surface debris found consisted mostly of transite, wood, asphalt, metal and broken glass. For remediation purposes, the site was evaluated as three areas. Area 1 was the Miscellaneous Debris Area. Area 2 was the Glass Bottle Location and Area 3 was the PCB Stained Soil Area.

**Location:** The 300-FF-1 Operable Unit boundary extends north of the northeast corner of 300 Area to south of the Treated Effluent Disposal Facility (TEDF). It is bounded on the east by the Columbia River. The western edge is irregularly shaped. The majority of the debris was located in the southern portion of the 300-FF-1 Operable Unit, south of the filter backwash ponds.
The 300-274 - Area 1 Surface Debris locations were found along the western and southern boundary of the 300-FF-1 Operable Unit (OU). They extended from near the Filter Backwash pond in the southeast corner of the OU northwest to in the vicinity of the northern border of the 300-FF-1 OU. The majority of the debris was located in the southern portion of the 300-FF-1 OU, south of the 300 Area Filter Backwash Pond.

The 300-274 - Area 2 Glass Bottle location was identified at Washington State Plane coordinates N117054 E593840.

The 300-274 - Area 3 Soil Staining was identified northwest of the 618-4 Burial Ground, north of the 300-289 waste site and southeast of the 300 Area Treated Effluent Disposal Facility.

Process Description:
Various forms and sizes of potentially hazardous or dangerous surface debris waste was created during 300 Area construction and operation and during decommissioning and remedial action activities.

Closure Info: Interim

For remediation purposes, the site was evaluated as three areas. Area 1 was the Miscellaneous Debris Area. Area 2 was the Glass Bottle Location and Area 3 was the PCB Stained Soil Area.

Area 1 Surface Debris consisted of noncontiguous debris areas with no observable impact to the surrounding soil or vegetation. Materials observed scattered at most of the locations included transite, wood, asphalt, metal, and broken glass. Surface debris was picked up by hand. Items that visually indicated potential asbestos were marked with paint. A team trained in asbestos removal collected these items. The debris items were visually evaluated to determine if they contained potential hazardous or dangerous constituents. Locations were evaluated for contamination in the soil. No soil contamination was identified and no samples were collected. The debris was disposed in ERDF.

Area 2 Glass Bottle location resulted in the bottle and .03 cubic meters (1 cubic ft) of soil being placed in an plastic bag and disposed in ERDF.

Area 3 was a stained soil site that measured approximately 12 meters (39 ft) by 13 meter (43 ft). Area 3 PCB Stained soil resulted in several phases of excavation and sampling. A test pit excavation extended to groundwater (46 feet deep) in one area. A total of 2330 bank cubic meters of soil was taken to ERDF.

Final

The 300-274 Surface Debris waste site consisted of Area 1, surface debris areas, Area 2, a glass bottle location, and Area 3, a polychlorinated biphenyl (PCB)-stained soil area. Remedial action at the 300-274 Area 1 surface debris areas was remediated by hand pickup and removal of surface debris. Area 2 glass bottle location was remediated by removing the glass underlying soil. A verification sample was collected on October 12, 2009. The Area 3 PCB-stained soil area was remediated during several phases of excavation. The verification samples collected on October 12, 2009 indicated elevated PCB contamination was present. Additional remediation was performed and a second verification sampling was performed on September 19, 2011. Elevated PCBs were measured at the location of sample EXC-7. Additional remediation was performed at this location to approximately 7.5 meters (25 ft) below ground surface (bgs). Characterization samples of groundwater and sediment were collected from a test pit extending to groundwater at approximately 11.9 meters (39 ft) bgs.

The 300-274 waste site was remediated and has been evaluated in accordance with the 300
Area Final Action ROD (EPA 2013) and the RDR/RAWP (DOE-RL 2014). Contamination in portions of this site extended to groundwater. Verification sampling results show that the residual site soil meets the CUL's for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Because the remediation of the waste site did not meet residential land use cleanup levels, the waste site requires institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-274 waste site to Final Closed Out.

### Code: 300-275

**Classification:** Accepted  
**Reclassification:** Final Closed Out (2/18/2014)

**Names:** 300-275; Potential Landfill on River Edge  
**Type:** Sanitary Landfill  
**Status:** Inactive

**Description:** The waste site has been remediated and Interim Closed Out. Before remediation the site consisted of seven areas of debris in two regions, a northern and southern one. There were three surface debris areas and four subsurface debris areas.

**Location:** There were two separate regions of debris. The northern region was approximately 40 meters (131 feet) west of the Columbia River shoreline and 140-meters (459-feet) north of the remediated 300-49, Landfill 1a site. The southern region with one surface debris area and two subsurface areas was located 9 meters (29.5 feet) northeast of 300-49.

**Closure Info:** Interim

The first phase of remediation of the 300-275 waste site was accomplished by hand pick up and removal of surface debris. Surface debris identified at both the northern and southern regions of the site included small fragments of potentially asbestos-containing shingles (transite), metal fragments, concrete pieces, porcelain jar fragments, rusted cans, metal fragments, insulated electrical cable, broken glass, pieces of copper tubing, a broken graduated cylinder, and other trash. Materials removed were disposed at ERDF. The second phase involved excavation of subsurface debris in the northern and southern regions if the site. Excavation occurred between July 25, 2007, and August 9, 2007. Transite and other possible asbestos-containing materials were found in the subsurface debris at both regions of the 300-275 waste sites.

A total of 1,148 bank cubic meters (1,502 bank cubic yards) of material were excavated from the overall site, resulting in approximately 2,754 metric tons (3,036 tons) of material disposed at the Environmental Restoration Disposal Facility (ERDF). The soil directly below items of surface debris was visually evaluated during removal of the debris. If staining or other evidence of a release of contaminants (e.g., impacted vegetation) to the underlying soil had been observed, the impacted soil would have been removed and verification soil samples collected. None of the soil underlying surface debris collected exhibited evidence of a release of contaminants such as staining or impacted soil. In accordance with this evaluation, the verification sampling results support a reclassification of the site to Interim Closed Out. The Remaining Sites Verification Package (RSVP-2008-059) has documented that the current site conditions achieve the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 300 Area (RDR/RAWP) and in the 300-FF-2 Interim Action ROD.

**Final**

This group of sites [300-18, 300-275, 600-47, 600-259, 618-5] are considered Final Closed Out in the 300-FF-2 Record of Decision and meet the criteria for Unrestricted Landuse.
**Code:** 300-276

**Classification:** Accepted

**Names:** 300-276; 3607 Sanitary Sewer System; 3607 Sanitary System Miscellaneous Components; 3707; 300 Area Sanitary Sewer Disposal System

**Reclassification:** Final Closed Out (5/12/2014)

**Type:** Sanitary Sewer

**Status:** Inactive

**Start Date:** 1/1/1943

**End Date:** 1/1/1996

**Description:** The waste site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. It consisted of the components of the original septic system which processed sanitary effluent from the 300 Area Sanitary Sewer System (300 SSS) piping. The site included the surface and subsurface sewer system components of manhole SS6, the influent diversion box, the effluent diversion box, the sludge pumping equipment, the sludge pit, the system's original septic tank, the system's original tile field, a retention basin and the measuring weir/diversion trenches.

**Location:** The components of 300-276 were located in the northeast section of 300 Area, east of the 333 building.

**Process Description:** The original, gravity flow 300 Area Sanitary Sewer System operated from 1944 through 1996. In 1996, the ground disposal portion of the system was replaced with a pressurized system and routed to the City of Richland sewer system. This WIDS site is the pre-1996 sewer system, downstream of Manhole SS6.

The original sanitary sewer system (1943) consisted of one septic tank that received effluent via manhole SS6 and a tile field. In 1951, two more septic tanks, two diversion boxes, and a sludge pit and pumping system were added. The tile field was replaced by two large leaching trenches. (WIDS site 300-52 represents the two 1951 septic tanks and two leaching trenches) More improvements were made in 1960. A chlorination station was added in 1972.

**Release Description:** WHC-MR-088 states the Sanitary Sewer System may have received undocumented contamination via cross contamination from other waste systems and from connections to change houses, lunchrooms, restrooms and First Aide stations populated by contaminated workers. A 1948 Health Instrument division report stated significant increases of uranium were found in the 300 Area sanitary water due to seepage from the process waste ponds. A 1991 radiological survey of the septic tank sludge pump displayed readings of 25,000 counts per minute.

**Related Sites/Structures:** This site is associated with 300-52 and 300 SSS.

**Closure Info:** Interim

The demolition of the three septic tanks, associated equipment, the liquid chlorine bottle storage facility foundation, and the loadout of demolished debris and soil, began on November 8, 2010. It was completed February 3, 2011. Debris from the demolition and excavation of the septic system included concrete, rebar, piping, valves, sand (used for tank fills), and residual sludge.

Excavation at the 300-276 waste site resulted in a total of approximately 2,228 bank cubic meters (2,914 bank cubic yards) of contaminated soil and debris. All material was direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). A post-excavation radiological survey for gamma activity was conducted following the completion of remedial action to confirm that no radiological contamination was present. No elevated gamma activity was detected.

**Final**
The 300-276, 3607 Sanitary System Miscellaneous Components waste site consisted of surface and subsurface sewer system components downstream from the sanitary sewer manhole SS6, including piping, an influent diversion box, sludge pumping equipment, septic tanks, tile field, and the former locations of a sludge pit, a retention basin, and a measuring weir/diversion trench facility. The foundation for an adjacent liquid chlorine bottle storage facility (chlorination station) was considered part of the 300-276 waste site for the remedial action. The demolition of the septic tanks, associated equipment, and the foundation of the former chlorination station, began in November 2010 and was completed in February 2011. The excavation extended to a maximum depth of approximately 4.5 meters (15 ft) below ground surface.

The 300-276 waste site was remediated and has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that concentrations of COCs meet the CUL's for direct exposure and groundwater protection and river protection and support a residential land use scenario. Contamination at the 300-276 waste site did not extend into the deep zone (below 4.6 meters [15 ft]). Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not required. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-276 waste site to Final Closed Out.

| Description:  | The 303-M SA waste site was Interim Closed Out with the 618-1 Burial Ground CERCLA remediation activities. Remedial actions were performed in accordance with remedial action objectives and goals established by the U.S. Environmental Protection Agency and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. The selected remedial action involved excavating the site to the extent required to meet specified soil cleanup levels and disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility in the 200 Area of the Hanford Site. This site was a RCRA TSD (part of 303-M Oxide Facility) that was transferred into the CERCLA remediation scope. The 303-M Storage Area was an inactive, curbed, concrete pad adjacent to the west side of the 303-M Uranium Oxide Facility (UOF). The concrete surface was painted with a heavy gray paint as a fixative. Several "fixed radioactive contamination" signs were on the surface. The area was used for storage of pyrophoric uranium and Zircaloy-2 chips and fines awaiting treatment in the 303-M UOF. The metal turnings were stored underwater in 114-L (30-gal) metal drums. The drums of fines were stored in a spaced array defined by painted yellow circles on the pad. Location: The unit is 21 feet (6.4 meters) east of the 333-N Building and enclosed within a 6-inch high concrete curb adjacent to the west wall of the 303-M Uranium Oxide Facility. Related Sites/Structures: Structures associated with this unit include the 333-N Building, the 303-M Building, the remnants of the 303-L Building, and the 618-1 Burial Ground. Process Description: The storage area was used to store drums of uranium and zircaloy-2 chips and fines, prior to oxidation in the 303-M Uranium Oxide Facility. Lift trucks with barrel clamps were used to
transport the drums of uranium metal turnings from the 333-N Fuels Fabrication Building to a designated storage spot (a solid yellow circle painted on) the storage pad. Water levels in the drums were maintained within six inches of the top of the drum, well above the level of the fines in the drum. Barrel clamps were used to pick up a drum and take it into the 303-M Uranium Oxide Facility for processing.

**Closure Info:** Interim

The 618-1 Burial Ground, two subsites, three consolidated sites and four co-located sites were remediated as a group. This group included WIDS sitecodes 618-1, 618-1:1, 618-1:2, 333 LHWSA, UPR-300-13, UPR-300-14, 300-110, 303-M SA, 303-M UOF and 333 ESHWSA. Parts of waste sites 300-15, 300-259 and UPR-300-17 were also remediated along with 618-1. Several facilities were built over the top of portions of the 618-1 Burial Ground after it ceased to operate. These facilities were demolished and their debris taken to the Environmental Restoration Disposal Facility (ERDF) prior to the start of the burial ground remediation project.

Field remediation activities at the 618-1 Burial Ground were performed between September 17, 2008 and September 10, 2009, in accordance with the RDR/RAWP. Approximately 47,332 metric tons (52,160 US tons) of soil and debris was excavated and disposed of at ERDF. No excavated soil will be used as clean, uncontaminated backfill. Waste encountered during excavation of the 618-1 waste site consisted mostly of contaminated soil, metal pipe, crucibles, laboratory glassware, empty metal containers, and some LDR material. Twenty metal drums containing personal protective equipment (PPE) were removed from the trenches. The PPE was about 80% decomposed. Several bottles containing liquid and/or powder were also removed. One relatively large area on the south side of the burial ground was stained yellow presumably from acid leaks known to have occurred at the site.

Three sites (300-15 Process Sewer, 300-259 and UPR-300-17 Metal Shavings Fire) were partially remediated with the 618-1 remedial action.

Some land disposal restricted (LDR) materials, like lead solids contaminated with barium and chromium, were identified among the debris. The LDR material was segregated from the bulk soil and non-LDR debris for disposal. The bulk soil and non-LDR debris was sorted and segregated in the burial trenches. After sorting, the remaining bulk soil debris stockpiles were sampled to ensure that the material was in compliance with land disposal restrictions. The released stockpiled material was transported to ERDF for disposal. Land disposal restricted materials that had been segregated for treatment were transported to ERDF under a separate waste profile.

The remaining soil at the 618-1 site has been sampled, analyzed, and evaluated. Results indicate that the site supports future land uses that can be represented (or bounded) by the industrial land-use scenario and poses no threat to groundwater or the Columbia River. Institutional controls are required to prevent drilling or excavation into the deep zone. Cleanup Verification Package CVP-2010-00001 demonstrates that remedial action at the site has achieved the Remedial Action Objectives and corresponding Remedial Action Goals established for the industrial land-use scenario in the Record of Decision (EPA 2001), the Explanation of Significant Differences for the 300-FF-2 Operable Unit (EPA 2004), and the RDR/RAWP (DOE-RL-2001-47, Rev 3).

**Final**

This group of sites [303-M SA, 303-M UOF, UPR-300-17, UPR-300-46, 333 ESHWSA] are listed in the 300-FF-2 Record of Decision. Institutional Controls to maintain industrial land use are required.
The 303-M Building was demolished in March 2006, and the debris shipped to the ERDF as described in Facility Status Change Form D4-300-008. This site was a RCRA TSD that was transferred into the CERCLA remediation scope.

The site was a reinforced concrete structure containing a high bay area and a one-story extension on the north side of the building. The 303-M SA is located on the west side of the building. The building was used to oxidize pyrophoric uranium metal turnings and chips and Zircaloy-2 fines generated during fuel fabrication machining operations in the 333 Building. During the 4 years that it was operational (1983 to 1987), the 303-M UOF converted 115 metric tons of uranium scrap into oxide form.

The unit is located in the north central 300 Area, east of the 333 Building. All contaminated surfaces have been fixed by paint.

Structures related to the 303-M Building include the 303-M Storage Area (WIDS Site Code 303-M SA), the 333 Building, the 618-1 Burial Ground, and the remnants of the 303-L Building.

The facility was used to oxidize pyrophoric uranium metal turnings and chips and zircalloy-2 fines generated during fuel fabrication machining operations in the 333 Building. The metal turnings were received in 30 gallon drums filled with water for fire prevention. The metal turnings were removed, screened, hand fed into a shredder/chopper, and small bags of metallic fines were placed inside a burner chamber for oxidation.

The 618-1 Burial Ground, two subsites, three consolidated sites and four co-located sites were remediated as a group. This group included WIDS sitecodes 618-1, 618-1:1, 618-1:2, 333 LHWSA, UPR-300-13, UPR-300-14, 300-110, 303-M SA, 303-M UOF and 333 ESHWSA. Parts of waste sites 300-15, 300-259 and UPR-300-17 were also remediated along with 618-1. Several facilities were built over the top of portions of the 618-1 Burial Ground after it ceased to operate. These facilities were demolished and their debris taken to the Environmental Restoration Disposal Facility (ERDF) prior to the start of the burial ground remediation project.

Field remediation activities at the 618-1 Burial Ground were performed between September 17,2008 and September 10,2009, in accordance with the RDR/RAWP. Approximately 47,332 metric tons (52,160 US tons) of soil and debris was excavated and disposed of at ERDF. No excavated soil will be used as clean, uncontaminated backfill. Waste encountered during excavation of the 618-1 waste site consisted mostly of contaminated soil, metal pipe, crucibles, laboratory glassware, empty metal containers, and some LDR material. Twenty metal drums containing personal protective equipment (PPE) were removed from the trenches. The PPE was about 80% decomposed. Several bottles containing liquid and/or powder were also removed. One relatively large area on the south side of the burial ground was stained yellow presumably from acid leaks known to have occurred at the site.

Three sites (300-15 Process Sewer, 300-259 and UPR-300-17 Metal Shavings Fire) were partially remediated with the 618-1 remedial action.

Some land disposal restricted (LDR) materials, like lead solids contaminated with barium and chromium, were identified among the debris. The LDR material was segregated from the bulk
soil and non-LDR debris for disposal. The bulk soil and non-LDR debris was sorted and segregated in the burial trenches. After sorting, the remaining bulk soil debris stockpiles were sampled to ensure that the material was in compliance with land disposal restrictions. The released stockpiled material was transported to ERDF for disposal. Land disposal restricted materials that had been segregated for treatment were transported to ERDF under a separate waste profile.

The remaining soil at the 618-1 site has been sampled, analyzed, and evaluated. Results indicate that the site supports future land uses that can be represented (or bounded) by the industrial land-use scenario and poses no threat to groundwater or the Columbia River. Institutional controls are required to prevent drilling or excavation into the deep zone. Cleanup Verification Package CVP-2010-00001 demonstrates that remedial action at the site has achieved the Remedial Action Objectives and corresponding Remedial Action Goals established for the industrial land-use scenario in the Record of Decision (EPA 2001), the Explanation of Significant Differences for the 300-FF-2 Operable Unit (EPA 2004), and the RDR/RAWP (DOE-RL-2001-47, Rev 3).

Final

The tank was removed August 30, 1989. The 311 MT1 tank and two others (311 MT2 and 313 MT) were taken to the Nonradioactive Dangerous Waste Landfill (NRDWL) for storage.

The tank impressions from all three tanks were surveyed with a photo ionization organic vapor detector (HNU Model P1-101). There were no readings. Narrow holes were bored into the sand at suspicious locations. There were no readings. There was no stained soil. Samples (random) were collected at four locations around the tank. The excavation was backfilled on the completion of the tank removal.
Review of the results of soil tests from 311 MT1, 311 MT2, and 313 MT excavations indicate that none of the tanks had leaked.

The reclassification is documented on form 99-06.

Final

This group of sites [311 MT1, 311 MT2, 313 MT, UPR-300-41, 600-46] is listed in the 300-FF-2 Record of Decision.

<tr>
<td>Description:</td>
<td>The 313 East Side Storage Pad (ESSP) has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. The 313 ESSP waste site previously staged radiological waste from 313 Building operations and, during fuel fabrication operations, staged mixed waste from the 313 Building centrifuge and uranium waste from the 313 Building filter press. The unit was also used to stage raw materials received by rail cars. It was a large concrete pad with an asphalt ramp that connected the pad to Ginko street. The Waste Acid Treatment System pipe trench (WIDS Site 300-224) passed east-west through the site and was posted as internally contaminated with radioactive material. Two areas of the pad, located adjacent to the east wall near the southern end of the 313 building had been painted gray. Signs were placed at the base of the walls, just above the painted areas that read &quot;Fixed Contamination - Contamination Under Grey Paint on Ground&quot;.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location:</td>

<tr>
<td>Closure Description:</td>
<td>The UPR-300-38 waste site consisted of contaminated soil beneath the 313 Building, as well as the foundation. The contamination resulted from multiple unplanned release events. The 313 ESSP (East Side Storage Pad) waste site was the footprint of a large concrete pad adjacent to the southeastern side of the former 313 Building, with an asphalt ramp that connected the pad to Ginko Street. The 300-270 waste site was the area of a release of whitish storm water that came from a pipe under the loading dock on the east side of the former 313 Building. The pipe drained the roof of the former 313 Building. Remediation of the UPR-300-38 waste site was performed from January 10, 2010, through June 2, 2011. The soil within the northern portion of the waste site footprint was excavated to an approximate average depth of 1 meter (3.3 ft) below ground surface (bgs). The southern area of the waste site was excavated to an approximate average depth of 2 meters (6.6 ft) bgs, with limited areas of deeper soil contamination to 5 meters (16.4 ft) bgs. The resulting 15,204 bank cubic meters (BCM) (19,887 bank cubic yards [BCY]) of soil was disposed at the Environmental Restoration Disposal Facility (ERDF). Remediation of a large portion of the 313 ESSP waste site was performed by the excavation of concrete, asphalt, and underlying soil during the remediation of the UPR-300-38 waste site and the adjacent area near the footprint of the former 303-F Building. This work was performed on July 8, 2011. The soil within the waste site footprint was excavated to a depth of 1 meter (3.3 ft) bgs, and the resulting 153 BCM (205 BCY) of soil was disposed at ERDF. Approximately 98 BCM (128 BCY) was associated with the UPR-300-38 excavation; the remainder (55 BCM [72 BCY]) was associated with the 313 ESSP excavation near the footprint of the former 303-F Building.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Building. An additional 38 BCM (50 BCY) was removed from the northeast corner and the southern edge of the 313 ESSP waste site on August 26, 2011, resulting in a total of 191 BCM of debris and soil removed from the 313 ESSP waste site.

Remediation of the 300-270 waste site was performed May 23, 2011. The soil within the waste site footprint was excavated to a depth of 0.5 meter (1.6 ft) bgs, and the resulting 40 BCM (52 BCY) of soil was disposed at ERDF.

A total of 15,435 bank cubic meters (20,194 bank cubic yards) of soil and debris from the remediation of all three waste sites was disposed at the Environmental Restoration Disposal Facility.

Final

The UPR-300-38, Soil Contamination Beneath the 313 Building; 313 ESSP, 313 East Side Storage Pad; and 300-270, Unplanned Release at 313 Building waste sites were either within or immediately adjacent to the footprint of the demolished 313 Building. The UPR-300-38 waste site consisted of contaminated soil beneath the 313 Building, as well as the foundation. The contamination resulted from multiple unplanned release events. The 313 ESSP waste site was the footprint of a large concrete pad adjacent to the southeastern side of the former 313 Building, with an asphalt ramp that connected the pad to Ginko Street. The 300-270 waste site was the area of a release of whitish storm water that came from a pipe under the loading dock on the east side of the former 313 Building. The pipe drained the roof of the former 313 Building. Remediation of the UPR-300-38 waste site was performed from January 2010 through June 2011. Remediation of a large portion of the 313 ESSP waste site occurred July 8 and August 26, 2011 and included excavation of concrete, asphalt, and underlying soil. Remediation of the 300-270 waste site was performed May 23, 2011. The maximum depth of the remediation at the UPR-300-38 waste site was 5 meters (16.4 ft) below ground surface. The 313 ESSP and 300-270 waste sites were remediated to 1 meters (3.3 ft) bgs.

The 300-270, 313 ESSP, and UPR-300-38 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Site-specific RESRAD modeling predicts that the radionuclide verification focused sampling results meet the excess cancer risk and allowable radiation dose and are protective of groundwater and the Columbia River under an industrial land use scenario. The remaining verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Contamination at these waste sites did not extend into the deep zone soils. Because the remediation of the waste sites did not meet residential land use cleanup levels, the waste sites require institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-270, 313 ESSP, and UPR-300-38 waste sites to Final Closed Out.

| Code:  | 313 MT | Classification: Accepted |
| Names: | 313 MT; 313 Building Underground Methanol Storage Tank; 313 Methanol Tank | Reclassification: Final Closed Out (2/18/2014) |
| Type:  | Storage Tank | Start Date: 1/1/1955 |
| Status: | Inactive | End Date: 1/1/1971 |
| Description: | The waste site was reclassified to Closed Out in 1999. It was considered to be Final Closed Out in 2014. The 313 Methanol Tank was emptied in 1987 and removed in 1989. The excavation was backfilled and the floor was patched with concrete. Prior to removal the site consisted of a steel cylindrical tank lying horizontally. The tank was below the floor of the 313 Building. |

Hanford Site Waste Management Units Report
February 2015

1438
The tank was located below the floor in the southeast portion of the 313 Building.

No releases have been identified.

Structures associated with the tank include the 311 Methanol Tank 1 (WIDS Site 311 MT1), the 311 Methanol Tank 2 (WIDS Site 311 MT2), transfer piping, and the 313 Building.

Prior to removal, the tank was used as an emergency dump tank. In case of a fire in the 313 Building, the methanol from the dehydration tanks could be released to the underground tank. The tank was never used for an emergency dump.

The tank was removed August 30, 1989. The 313 MT tank and two others (311 MT2 and 311 MT2) were taken to the Nonradioactive Dangerous Waste Landfill (WIDS Site NRDWL) for storage.

The tank impressions from all three tanks were surveyed with a photo ionization organic vapor detector (HNU Model P1-101). There were no readings. Narrow holes were bored into the sand at suspicious locations. There were no readings. There was no stained soil. Samples (random) were collected at four locations around the tank. The excavation was backfilled on the completion of the tank removal.

Review of the results of soil tests from 311 MT1, 311 MT2, and 313 MT excavations indicate that none of the tanks had leaked.

The reclassification is documented on form 99-08.

This group of sites [311 MT1, 311 MT2, 313 MT, UPR-300-41, 600-46] is listed in the 300-FF-2 Record of Decision.

The waste site was evaluated and determined to require No Action. The trenches were backfilled in 1965 and are no longer visible. A large portion of the location has been paved and fenced. The site consisted of two trenches, each 180 meters (600 feet) long, 9.1 meters (30 feet) wide at the east end, tapering to 3.0 meters (10 feet) wide at the west end. The depth varied from 3.7 meters (12 feet) to 8.2 meters (27 feet). The trenches ran in an east and west direction, approximately 6.1 meters (20 feet) apart. Each contained a 13 centimeter (5 inch) vitrified clay pipe that ran the entire length of the unit.

The trenches were located east of 300 Area, southeast of the 340 Facility. Most of the waste site lies inside the 324 building fence.

The trenches are associated with the 340 Complex. Facilities that discharged to the 307 trenches via the retention basins, included 324, 325, 326, 327, 329, and the 308 buildings.
From 1953 to 1963, effluent below discharge limits was released from the 307 Retention Basins and discharged to these trenches. Effluent above discharge limits was transported to the 200 Area for disposal. The 316-3 waste site received wastes from the 300 Area Laboratory expansion facilities including the 329 Biophysics Laboratory, 327 Radiometallurgy Building, 324 Radiochemistry Building, 326 Pile Technology Building, and 329 Mechanical Development Building.

In 1987, the west end of the 316-3 waste site was used to test a grout liquid waste solidification process. A 15.2 by 6.1 by 3.0 meters (50 by 20 by 9 ft) trench was excavated immediately west of the former 3718E Building, and contaminated material was encountered. The Geiger/Mueller radiological detector measured maximum radiological activities of 378 picocuries per gram (pCi/g) beta and 234 pCi/g alpha.

Subsurface investigation sampling for the 316-3 waste site was conducted between August 13 and September 11, 2012. Samples were collected from seven test pits. Due to buried utilities in the area, the test pits locations were adjusted to minimize the potential impact of encountering active utility lines. Because the waste site had potentially contaminated backfill material, it was planned to perform sampling at 2 meter (6.6-ft) depth intervals to analyze potential vertical contamination and the soil underlying the backfill material.

Test pit 1 was excavated on September 11, 2012 to a depth of 20 feet.

Test pit 2 excavation was performed on August 20, 2012 to a depth of 20 feet.

Test pit 3 excavation began on August 23, 2012. A layer of asphalt was discovered at approximately 0.33 meter (1 ft) depth. Several utility interferences were encountered to a depth of 6.6 feet.

Test pit 4 excavation was performed on August 14, 2012 to a depth of 20 feet.

Test pit 5 excavation was performed on August 15, 2012 to a depth of 20 feet.

Test pit 6 excavation was performed on August 21, 2012. A buried asphalt pad was discovered at approximate depth of 0.5 meter (1.6) bgs. Due to the close proximity of interferences, such as RLWS line and 300-15 process sewer line, the test pit could not be excavated safely. Therefore, only one surface soil sample was collected at the TP-6 location.

Test pit 7 excavation was performed on August 13, 2012 to a depth of 20 feet.

<tbody>
<tr>
<td>Crib</td>
<td>The crib structures were removed in 2004. The crib consisted of two bottomless tanks, buried 3 meters (10 feet) below grade, resting on gravel strata. A waste influent line extended from 0.6 meters (2 feet) above the bottom of one of the tanks and continued, at an angle, to grade level. A vent riser extended from the top of the tank to 2.4 meters (8 feet) above grade. The tanks were 0.6 meters (2 feet) apart, with a stainless steel overflow pipe connecting them just below the top of each tank. (see H-3-5305) The area was marked with AC-540 markers marked &quot;Crib 316-4&quot;. A 1995 Geophysical Investigation survey verified the tanks had concrete footings and sat on a bed of gravel. It also states the tanks are believed to be 8 foot in diameter, 7 ft tall, with</td>
</tr>
</tbody>
</table>
the tops of the tanks being located approximately 10 feet below the surface.

The crib excavation was backfilled in 2005 with 4221 meters of clean dirt.

**Location:** The site is located northwest of the 300 Area, approximately 45 meters (150 feet) southeast of the 618-10 (300 North) Burial Ground.

**Release Description:** A cumulative total of 895 kgs (1974 pounds) of uranium was discharged into the cribs as U-bearing organic wastes from the 321 Building from 1948 through June 23, 1954.

**Process Description:** The site received hexone-bearing uranium wastes and limited amounts of other uranium-bearing wastes from the 321 Building. Calculations up to and including July 1955 indicated liquid wastes containing a total of 550 kg (1,230 lbs) of uranium had been discharged to this site. Additional documentation has been found indicating 12,040 L (3,182 gal) of liquid organic waste was being shipped to the 300 North Cribs in 1962.

---

**Code:** 331 LSLDF  
**Classification:** Accepted  
**Reclassification:** Interim Closed Out (3/10/2014)  
**Names:** 331 LSLDF; 331 Life Sciences Laboratory Drainfield; 331 LSL Drain Field  
**Type:** Drain/Tile Field  
**Start Date:** 1/1/1970  
**End Date:** 1/1/1974  
**Description:** In 2008, The 331 LSLDF waste site was evaluated and determined to require No Action. In 2014, it was reclassified to Final Closed Out. It is a septic system consisting of a diversion chamber, two (dual-chambered) septic tanks, a distribution box, and a drain field connected to the 331 complex. The 331 LSLDF septic system was operational from 1970 to 1974, at which time the sanitary sewer connections were rerouted to the 300 Area Sanitary Sewer. The 331 LSLDF septic system was fully isolated and abandoned in place in 1974. The waste line has been capped west of the septic tanks. The drainfield is marked with a single sign at the site center.

**Location:** The unit is located southeast of the 331 Building.

**Related Sites/Structures:** The drainfield is associated with the 331 Life Sciences Laboratory.

**Process Description:** The septic system was designed to receive sanitary wastewater associated with animal studies from the 331-A and 331-B Buildings for discharge into the soil column. However, field observations and testing suggest this system did not receive any discharges. It is probable that all of the animal study discharges were routed to the 331 Life Sciences Laboratory Trenches 1 and 2 (331 LSLT1 and 331 LSLT2), the 331 LSLT1 Animal Waste Pit, the 300 Area Sanitary Sewer, or transported to the 100 Area. The animal studies involved the use of radioisotopes, and the animal waste was segregated on the basis of radiological activity. Solid animal waste exceeding 200 pCi/g specific activity was transported to the 100 F Area trenches. Other solid animal waste (less than 200 pCi/g specific activity) was allowed to flush into the 331 waste system(s). The 331 Building, located in the Hanford Site's 300 Area, was constructed in 1970. The largest portion is a three story facility, consisting of laboratories on the first and third floors. The first floor laboratory area initially contained a multi-room, inhalation toxicology, and exposure suite. The third floor laboratories included small animal facilities, and related animal physiology and inhalation toxicology laboratories, low-level and high-level radiochemistry laboratories, as well as tissue culture, virology, histology, hematology, biochemistry, histochemistry, pathology, and microbial physiology laboratories. Two smaller ancillary structures, 331-A and 331-B, made up another segment of the 331 Building. The 331-A Building is detached and located on the northwest side of the 331 Building and contained 15 pen areas for large animals (e.g., swine). The 331-B Building, connected to the west and
southwest portion of the 331 Building, is a one-story concrete block structure with long, narrow, animal runs. The run area originally contained 110 concrete living units for dogs. The north section was comprised of an animal clinic, hospital, food preparation room, and change room. An equipment room and a metabolism room were located at the south end of the animal runs. The dog runs were built as a wing adjacent to 331-B. It also contained dog habitat areas. A semi-high bay building, 331-D, was erected southeast of the 331 Building in 1974. The 331-D Building was to serve as an Animal Waste Treatment Facility. It contained a 94,625 liters per day (25,000 gallons per day) capacity waste treatment plant, which was designed to chemically treat, mechanically flocculate, settle, and gravity filter animal wastes. A sludge dryer also was installed to heat and dry 54.4 kilograms per hour (120 pounds per hour) of sewage sludge product from the treatment facility.

**Closure Info:** Interim

This septic system was designed to receive sanitary wastewater associated with animal studies from the 331-A and 331-B Buildings for discharge into the soil column. However, field observations and testing suggest this system did not receive any discharges. Similar to the septic tanks, all of the drain field laterals were found to be clean, almost new in appearance. Sediments within the laterals were only sparingly available, and the little that could be collected (from the fifth and sixth laterals in the northern trench and the sixth lateral in the southern trench) had to be combined to achieve a sufficient sample size for fixed laboratory analysis.

During the RSVP evaluation field radiological surveys were performed to evaluate the presence of radioisotopes from the animal studies. No radiological activity was detected in the field or in the samples analyzed at the laboratories. The sample results did indicate detections for 17 non-radioactive COPCs. It is probable that all of the animal study discharges were routed to the 331 Life Sciences Laboratory Trenches 1 and 2 (331 LSLT1 and 331 LSLT2), the 331 LSLT1 Animal Waste Pit, the 300 Area Sanitary Sewer, or transported to the 100 Area.

Confirmatory sampling of the drain field and of the soil around the distribution box was performed in April 2007. Similar to the septic tanks, all of the drain field laterals were found to be unexpectedly clean, and almost new in appearance. Sediments within the laterals were only sparingly available, and the little that could be collected from each lateral was combined to achieve a sufficient sample size for fixed laboratory analysis.

**Final**

This site is listed in the 300-FF-2 Record of Decision. Institutional Controls to maintain industrial land use are required.

**Code:** 331 LSLT1

**Names:** 331 LSLT1; 331 Life Sciences Laboratory Trench #1; 331 LSL Trench 1

**Type:** Trench

**Status:** Inactive

**Description:** The trench is currently marked with a single sign at the site centerline and surrounded with Underground Radioactive Material signs. The 331 Life Sciences Laboratory Trench 1 (LSLT1) is an abandoned leaching trench that has been backfilled. The site was a rectangular excavation. The site includes connecting waste transfer lines.

**Location:** The unit was located underneath or near the east end of the 331 Building. The north leaching trench has been arbitrarily designated as the 331 LSLT1 unit. The site is located just north of...
the 331 LSLT2.

**Related Sites/Structures:** The structures associated with this site include the 331 LSLT2 trench immediately to the south, the No. 1 and No. 2 Diversion Chambers, the animal waste unloading pit, the 331-B Sanitary Septic Tank, the 331-B (and possibly 331-A) Building, and the waste transfer lines. Other associated structures are the 331 Life Sciences Laboratory Drain Field and the 331-D Animal Waste Treatment Facility.

**Process Description:** The 331 Leaching Trenches disposed of sanitary and animal wastes to the soil column. Sanitary waste flowed from the 331-B Septic Tank and animal waste flowed from the animal waste unloading pit, entered Diversion Chamber No. 1, and was subsequently discharged to the leaching trenches.

**Code:** 331 LSLT2  
**Names:** 331 LSLT2; 331 Life Sciences Laboratory Trench #2; 331 LSL Trench 2  
**Type:** Trench  
**Status:** Inactive  
**Start Date:** 1/1/1966  
**End Date:** 1/1/1974  
**Classification:** Accepted  
**Reclassification:** None

**Description:** The trench is currently marked with a single sign at the site centerline and surrounded with Underground Radioactive Material signs. The 331 LSLT2 is an abandoned leaching trench that has been backfilled. The site was a rectangular excavation. The site includes connecting waste transfer lines.

**Location:** The unit was located underneath or near the east end of the 331 Building. The south leaching trench has been arbitrarily designated as the 331 LSLT2 Unit. The site is located just south of the 331 LSLT1.

**Related Sites/Structures:** The structures associated with this site include the LSLT1, the No. 1 and No. 2 Diversion Chambers, the animal waste unloading pit, the 331-B Sanitary Septic Tank, the 331-B (and possibly 331-A) Buildings, and the waste transfer lines. Other associated structures are the 331 Life Sciences Laboratory Drain Field and the 331-D Animal Waste Treatment Facility.

**Process Description:** The 331 Leaching Trenches disposed of sanitary and animal wastes to the soil column. Sanitary waste flowed from the 331-B Septic Tank and animal waste flowed from the animal waste unloading pit, entered Diversion Chamber No. 1, and was subsequently discharged to the leaching trenches.

**Code:** 333 ESHWSA  
**Names:** 333 ESHWSA; 333 Building East Side Hazardous Waste Storage Area; 333 East Side HWSA  
**Type:** Storage  
**Status:** Inactive  
**Start Date:** 1/1/1964  
**End Date:**  
**Classification:** Accepted  
**Reclassification:** Final Closed Out (2/18/2014)

**Description:** The 333 East Side Hazardous Waste Storage Area is part of the asphalt paved area near the northeast corner of the 333 Building, within the building fence line. No barrels of hazardous waste are stored here anymore, only miscellaneous non-hazardous materials. Currently, several large trash dumpsters are at this location.

**Location:** The unit is located northeast of the 333 Building, in the northern part of the 300 Area.
Related Sites/Structures: The unit is associated with the 333 Building Operations. This site was located adjacent to the 618-1 Burial Ground.

Process Description: The unit provided temporary storage for miscellaneous hazardous wastes.

Closure Info: Interim

The 618-1 Burial Ground, two subsites, three consolidated sites and four co-located sites were remediated as a group. This group included WIDS sitecodes 618-1, 618-1:1, 618-1:2, 333 LHWSA, UPR-300-13, UPR-300-14, 300-110, 303-M SA, 303-M UOF and 333 ESHWSA. Parts of waste sites 300-15, 300-259 and UPR-300-17 were also remediated along with 618-1. Several facilities were built over the top of portions of the 618-1 Burial Ground after it ceased to operate. These facilities were demolished and their debris taken to the Environmental Restoration Disposal Facility (ERDF) prior to the start of the burial ground remediation project.

Field remediation activities at the 618-1 Burial Ground were performed between September 17, 2008 and September 10, 2009, in accordance with the RDR/RAWP. Approximately 47,332 metric tons (52,160 US tons) of soil and debris was excavated and disposed of at ERDF. No excavated soil will be used as clean, uncontaminated backfill. Waste encountered during excavation of the 618-1 waste site consisted mostly of contaminated soil, metal pipe, crucibles, laboratory glassware, empty metal containers, and some LDR material. Twenty metal drums containing personal protective equipment (PPE) were removed from the trenches. The PPE was about 80% decomposed. Several bottles containing liquid and/or powder were also removed. One relatively large area on the south side of the burial ground was stained yellow presumably from acid leaks known to have occurred at the site.

Three sites (300-15 Process Sewer, 300-259 and UPR-300-17 Metal Shavings Fire) were partially remediated with the 618-1 remedial action.

Some land disposal restricted (LDR) materials, like lead solids contaminated with barium and chromium, were identified among the debris. The LDR material was segregated from the bulk soil and non-LDR debris for disposal. The bulk soil and non-LDR debris was sorted and segregated in the burial trenches. After sorting, the remaining bulk soil debris stockpiles were sampled to ensure that the material was in compliance with land disposal restrictions. The released stockpiled material was transported to ERDF for disposal. Land disposal restricted materials that had been segregated for treatment were transported to ERDF under a separate waste profile.

The remaining soil at the 618-1 site has been sampled, analyzed, and evaluated. Results indicate that the site supports future land uses that can be represented (or bounded) by the industrial land-use scenario and poses no threat to groundwater or the Columbia River. Institutional controls are required to prevent drilling or excavation into the deep zone. Cleanup Verification Package CVP-2010-00001 demonstrates that remedial action at the site has achieved the Remedial Action Objectives and corresponding Remedial Action Goals established for the industrial land-use scenario in the Record of Decision (EPA 2001), the Explanation of Significant Differences for the 300-FF-2 Operable Unit (EPA 2004), and the RDR/RAWP (DOE-RL-2001-47, Rev 3).

Final

This group of sites [303-M SA, 303-M UOF, UPR-300-17, UPR-300-46, 333 ESHWSA] are listed in the 300-FF-2 Record of Decision. Institutional Controls to maintain industrial land use are required.
The 340 Complex was completed in 1953 along with the initial Radioactive Liquid Waste Sewer (RLWS) piping system, the 307 Basins and the Retention Process Sewer (RPS) piping system. These systems represented an attempt to deal with radioactive effluents from several new laboratories in a modern, controlled manner. The 340/307 system was fed by pipelines from the 325, 326, 327, and 329 Buildings in a system known as the Radioactive Liquid Waste Sewer (RLWS) piping system, the 307 Basins and the Retention Process Sewer (RPS) piping system. These systems represented an attempt to deal with radioactive effluents from several new laboratories in a modern, controlled manner. The 340/307 system was fed by pipelines from the 325, 326, 327, and 329 Buildings in a system known as
the Retention Process Sewer (RPS) or the Diversion Waste System. Liquid process wastes that had the potential to be contaminated were disposed to the RPS and routed to the 307 Basins for sampling. If radioactivity was not detected above release limits, these wastes were disposed to the 307 Trenches. If levels proved to be above release limits, the effluents were pumped into the 340 Building RLWS tanks.

The 340 Complex received and sampled the 300 Area radioactive liquid waste. Waste routed by the RLWS was accumulated and stored in two underground tanks. The waste was stored for less than 90 days. It was transferred to the 200 Areas by rail car for storage and disposal. Retention process sewer waste is collected at the 340 complex in the 307 retention basins, sampled, and discharged to the process sewer. Waste exceeding discharge criteria is held for transport to the 200 Areas.

Description: This site appears on aerial photos as a large, asterisk-shaped area. It is a vegetation-free area that is not marked or easily distinguished on the ground from the surrounding terrain. The vegetation in the area was removed in the 1940's to create a visual practice target for military airplanes. Some vegetation has grown back over the years and the site is not as distinct as it once was. However, the surrounding terrain has a more diverse mix of vegetation than exists in the area of the target. A pre-Hanford fence bisects part of the site. An area at the southeast corner of the site has green steel posts, but no warning signs or barricade chains are present. Within the area marked by the steel green posts is an inactive telephone pole. The site is littered with several large pieces of "practice bombs". The site was nicknamed "UFO Landing Site" because of its appearance from the air. It's shape and the presence of dead vegetation suggest that herbicides were used to create the shape. A site visit as part of an ecological review on October 29, 1994 indicated the vegetation abnormalities appear to be caused from a combination of mechanical disturbance and a fire that occurred in 1985. There are no Hanford records of herbicides being used at this site.

Location: The site is located southwest of the former 618-9 Burial Ground and west of the 300 Area.

Waste Type: Process Effluent

Waste Description: Bomb fragments are scattered throughout the site, but are concentrated at the site's southeastern corner. No unexploded bombs have been found in the area. Practice bombs are constructed of thin sheet metal which can be easily bent with manual pressure and appear to be the size of 113.6 kilogram (250 pound) bombs. The items are completely hollow. There are no nose or tail fuses nor evidence of the use of spotting charges in the nose. In some cases, the items collapsed upon impact without fragmenting leaving recognizable tailfins and noses. Also, filler caps were found in the nose which were possibly used to fill the practice bombs with sand or water.

Closure Info: Interim

Bomb fragments are scattered throughout the site, but are concentrated at the site's southeastern corner. No unexploded bombs have been found in the area. Practice bombs are constructed of thin sheet metal which can be easily bent with manual pressure and appear to be the size of 113.6 kilogram (250 pound) bombs. The items are completely hollow. There are no nose or tail fuses nor evidence of the use of spotting charges in the nose. In some cases, the items collapsed upon impact without fragmenting leaving recognizable tailfins and noses. Also, filler caps were found in the nose which were possibly used to fill the practice bombs with sand or water.

Based on aerial photographs that were available and a surface topographic map, the sample points were selected prior to going to the field. The locations were visually confirmed by the samplers prior to sampling. A sample location on the outer edge of one of the "spokes" was
selected for the first sample location. The remnants of a fence line to the south, as shown on the
topographical map, and a distinct break in the vegetation growth pattern on the north suggested
that the correct location had been found. In addition, the area of the spoke had a slightly raised
appearance. Upon arriving at the location of the center of the site, the second sample location,
the samplers observed the surrounding area. The surface appeared to be physically disturbed, as
the surface soils had been removed leaving a surface of scattered gravels. Vegetation has grown
up amongst the gravels. To the north, it appeared as though the surface dirt had been piled up or
pushed into several areas. To the west and northwest, the faint outlines of at least two other
spokes could be inferred by changes in the vegetation patterns. In the center of the area, which
was chosen as the sample location, an area had a raised "pitcher's mound" appearance much like
a bull's-eye for a target. The area was surveyed. Approximately 8 to 10 remnants of dummy
bombs were found to the west and southwest of the sampling location. These remnants ranged
from pieces of rusted sheet metal to bombs that were almost completely intact; several had tail
fins, nose cone, and other distinct features clearly visible. Several photographs were taken of
the bomb fragments. On August 17, 1995, sampling was completed at the 600-22 site (the UFO
Landing Site) and the indicate that all herbicide values were nondetects and not near MTCA
Method B limits; gross alpha and beta values were typical of background values. Values typical
of background, found in the Phase I RI report for the 300-FF-2 Operable Unit.

Final

The site group of sites [300-1, 300-29, 600-2] are listed in the 300-FF-2 Record of Decision and
meet the criteria for unrestricted landuse.

removed from the site were shipped offsite to a waste transfer company for ultimate disposal to a Toxic Substances Control Act landfill.

**Waste Type:** Process Effluent  
**Waste Description:** The site contained one empty 208-liter (55-gallon) drum.

**Waste Type:** Process Effluent  
**Waste Description:** The site contained wood debris.

**Closure Info:** Interim

On June 15, 1995, cleanup actions began with the removal of the miscellaneous surface debris, including a section of irrigation pipe and valving which was found just north of the oil stained area. On June 20, 1995, sampling and removal of oil-stained soil was initiated. Miscellaneous surface debris and approximately 10 cubic meters of soil contaminated with petroleum hydrocarbons and polychlorinated biphenyls (PCBs) were removed from the site. Field screening and laboratory analytical results indicated that the excavated soils were contaminated with PCBs at levels up to 55 parts per million (ppm) and TPH levels up to 350 parts per million. No other contaminants were detected above natural background levels.

On August 16, 1995, 84 waste drums containing the PCB-contaminated soil removed from the site were shipped off site to a waste transfer company for ultimate disposal to a Toxic Substances Control Act (TSCA) landfill. Following cleanup activities, the site was revegetated with native shrubs and grasses.

**Final**

This group of sites [311 MT1, 311 MT2, 313 MT, UPR-300-41, 600-46] is listed in the 300-FF-2 Record of Decision.

**Code:** 600-47  
**Classification:** Accepted  
**Names:** 600-47; Dumping Area North of 300-FF-1  
**Reclassification:** Final Closed Out (2/18/2014)  
**Type:** Dumping Area  
**Start Date:**  
**Status:** Inactive  
**End Date:**  
**Description:** The site has been remediated and interim closed out. This site consisted of several areas of debris and Underground Radioactive Material Areas.

**Location:** This site was located north of the 300 Area above the bank of the Columbia River west of Johnson Island.

**Related Sites/Structures:** The 600-210 Outfall Structure and pipeline are also located in this area.

**Waste Type:** Vegetation  
**Waste Description:** Debris found at the site includes concrete, brick, cinder block, glass, stainless steel, steel millings/filings, plastic, tar roofing paper, wire, pipe, bottles, sheet metal, screen, clay pipe, irrigation pipe, etc. Concreted soils were found during test diggings, burned wood was found on top of the rise. A "Danger Area" sign was located on the ground just north of the rise. A photo of the area from 1950 shows soil disturbance in the area.
Debris found at the site included wood, concrete, bricks, glass, steel, plastic, paper, wire, piping, broken bottles, and clay pipe. Contaminated material identified in field surveys included four areas of soil, wood, nuts, bolts, and other metal debris. The four areas of contaminated soil and debris were covered with approximately 0.6 to 0.9 meters (2 to 3 ft) of soil for surface stabilization. The area within and around the 600-47 waste site is considered culturally sensitive based on proximity to the river and the historical location of the pre-Hanford Fruitvale community. Some of the debris at the site may have pre-dated Hanford Site operations.

Remedial action activities at the 600-47 site began in December 2004. The site was divided into seven subareas, based on observed occurrences of contamination. Material in the radiologically posted and surface stabilized subareas (1, 3, 5, and 7) was sorted as it was excavated and stockpiled within the area of contamination pending sampling and subsequent disposal. Excavated material consisted of contaminated soil and small quantities of metal shavings and miscellaneous construction-type debris. No land disposal restriction materials (e.g., lead solids), anomalies, or liquid wastes were identified in the bulk soil and debris during the excavation process. In addition to the remedial action activities performed in radiologically posted areas, visible surface debris was removed by hand from the unposted, nonstabilized subareas (2, 4, 6). Remedial action excavation was completed in February 2005. Approximately 2,159 metric tons (2,380 U.S. tons) of material from the site were removed and disposed of at ERDF.

The cleanup verification package, CVP-2005-00005, documented that the site has been remediated in accordance with the Record of Decision for the 300-FF-2 Operable Unit (ROD), as modified by the Explanation of Significant Differences for the 300-FF-2 Operable Unit Interim Record of Decision (ESD). Remedial action objectives and goals established for the site in the ROD and ESD are reflected in the Remedial Design Report/Remedial Action Work Plan for the 300 Area (RDR/RAWP).

The contaminated excavation materials were disposed at the Environmental Restoration Disposal Facility (ERDF) in the 200 Area of the Hanford Site, and the site was backfilled with clean soil to the average adjacent grade elevation. Cleanup objectives were based on the 300 Area unrestricted land-use scenario established by the ESD. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

Final

This group of sites [300-18, 300-275, 600-47, 600-259, 618-5] are considered Final Closed Out in the 300-FF-2 Record of Decision and meet the criteria for Unrestricted Landuse.

| Code:  | 600-63 | Classification: | Accepted |

| Type:  | Experiment/Test Site | Start Date: | 1/1/1984 |
| Status: | Active | End Date: | 1/1/1994 |
| Description: | The site is enclosed within a chain link fence with barbed wire top and a locked gate. The fenced area is posted with "Restricted Area - Contact PNL Radiological Office" and "Underground Radioactive Material" signs. Outside the fence there is a considerable amount of... |
debris. Two large wooden cabinets, pallets, piping and a fire extinguisher were noted.

**Location:**
The unit is located southeast of 400 Area, west of Route 4 South. It is southeast of the 618-10 Burial ground.

**Related Sites/Structures:**
The site is associated with 600-259. In 1999, programmatic responsibility for the lysimeter site was split between PNNL and ERC. PNNL retained responsibility for the active Buried Waste Lysimeter (see 600-63). The inactive Grout Waste Lysimeter facility and the Special Waste Form lysimeter were transitioned to the Environmental Restoration Contractor. A chain link fence had been previously added to physically separate the active portion of the site from the inactive portion.

**Process Description:**
The Buried Waste Test Facility is located in the northeast corner of the fenced area. A solar panel, some metal scaffolds and a concrete cover are visible. In 1998, the west side of the site had a large amount of blown-in tumbleweeds collected along the fence. The tumbleweeds had been removed before the 1999 site visit. The BWTF was established in 1978 to investigate recharge and radionuclide migration in Hanford soil. Six drainage lysimeters (7.6 meters deep) and two weighing lysimeters (1.5 meters deep) were installed. A trace amount of Co-60 was mixed in one centimeter of soil and placed 60 centimeters below the surface of two of the drainage lysimeters. Trace amounts of tritium was placed in two other lysimeters. The migration of the contaminants was monitored. The columns were sampled in 1990. No tritium or cobalt was found at the 180 centimeter level using hand-held instruments and field level screens.

**Waste Type:** Chemicals

**Waste Description:** A trace amount of Co-60 was mixed in one centimeter of soil and placed 60 centimeters below the surface of two of the drainage lysimeters. Trace amounts of tritium were placed in two other lysimeters. The migration of the contaminants was monitored.

**Code:** 600-243

**Classification:** Accepted

**Names:** 600-243; Bioremediation Pad Inside Gravel Pit #6; Oil Contaminated Soil; Petroleum Contaminated Soil Bioremediation Pad; Pit 6

**Reclassification:** Final Closed Out (2/18/2014)

**Type:** Surface Impoundment

**Start Date:**

**Status:** Inactive

**End Date:**

**Description:** The site has been remediated and Interim Closed Out. It was a treatment facility for petroleum contaminated soil. It was a rectangular shaped area, 48.5 meters (159 feet) long by 38.7 meters (127 feet) wide. A 0.9 meters (3 foot) berm surrounds the site. The site was lined with heavy black plastic. The contaminated soil had visible rust stains and pieces of clear plastic mixed into the soil. Tumbleweeds and cheatgrass were growing on the surface. No petroleum odors were observed at the site. The site is posted Keep Out - Petroleum Contaminated Soil - For Entry Contact 376-7053 and WIDS Site 600-243.

**Location:** The site is located approximately 300 meters (984 ft) west of the 300 Area and south of a dead end dirt road that heads west from Route 4 South. The site boundaries as identified in the remedial action design drawing are E593130.19, N116110.00; E593125.56, N116156.22; E593181.25, N116158.01; E593179.63, N116118.95.

**Related Sites/Structures:** The bioremediation pad is located within the original boundaries of Gravel Pit #6 (site code 600-244).

**Process Description:** The site was used as a bioremediation pad for petroleum-contaminated soils. The soil originated from remediation activities performed in 1994 as part of the L-044 Project. The project
generated contaminated soils during the removal of underground storage tanks at the 300 Area Fire Station (300-5) and in the 1100 Area. Petroleum tanks removed from these areas during the L-044 project included those that stored gasoline, diesel and waste oil. Moisture and nutrients were periodically added to the site to facilitate bioremediation of the hydrocarbons. Eight samples were collected in 1995 and analyzed for gasoline, diesel, and heavy oils. Eleven samples were collected in 2001 and analyzed for diesel and heavy oils. The results indicated that the soil still exceeded Model Toxics Control Act (MTCA) 1996 Method A cleanup levels for soil (200 mg/kg TPH based on protection of groundwater). Motor oil range hydrocarbons were detected as high as 3700 mg/kg. Diesel range hydrocarbons were not detected.

Waste Type: Process Effluent

Waste Description: The waste is petroleum contaminated soil from Project LO-44, Underground Storage Tank Removals. The contaminants of potential concern (COPCs) for the 600-243 waste site were petroleum hydrocarbons in the diesel and motor oil ranges, benzo(k)fluoranthene, chrysene, fluoranthene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, PCBs, and lead.

Closure Info: Interim

The 600-243 waste site was remediated in August 2007. Approximately 2,134 BCM (2,791 BCY) of soil and plastic was removed via direct loadout and disposed to the Environmental Restoration Disposal Facility (ERDF). Visual observation of the area surrounding the 600-243 waste site established that this area was used for placement of coal ash. As expected based on the geophysical investigation and observations of the soil surrounding the waste site, a significant amount of coal ash was found below the plastic liner of the waste site during remediation. A Global Positioning Environmental Radiological Surveyor (GPERS) with instrumentation specific to the detection of radiation associated with beta- and gamma-emitting radionuclides was used to perform final radiological surveys of the site after remediation.

The Remaining Sites Verification Package (RSVP-2007-033) demonstrates that the 600-243 petroleum-contaminated soil bioremediation pad meets the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 300 Area (RDR/RAWP) and the Interim Action Record of Decision for the 300-FF-2 Operable Unit, (ROD). While a limited sampling of surrounding coal ash was undertaken, a full evaluation of the coal ash underlying and surrounding the waste is outside the scope of this remaining sites verification package. Radiological field surveys were performed to ensure that radiological contamination was not present at the waste site.

A comparison against ecological risk screening levels was made for the site contaminants of concern and other constituents. Screening levels were exceeded for antimony, barium, boron, cadmium, copper, lead, manganese, selenium, vanadium, and zinc. Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. Because concentrations of antimony, manganese, and vanadium are below Hanford Site background levels, it is believed that the presence of these constituents does not pose a risk to ecological receptors. The remaining metals that exceed ecological risk screening levels are due to coal ash, which is ubiquitous in the general area of the 600-243 waste site. The bioremediation pad had been placed directly on coal ash, and the verification sample results reflect the composition of the coal ash. A more complete quantitative ecological risk assessment will be presented in the baseline risk assessment for the river corridor portion of the Hanford Site and will be used to support the final closeout decision for this site.

Final

The group of sites [300 VTS, 300-8, 600-243, 618-7, 618-9, 618-13, 600-290:1] were reclassified to Final Closed Out in 2014. They are listed in the 300-FF-2 Record of Decision
and meet the criteria for unrestricted landuse.

<td>Description:</td>
<td>The entire site has been remediated and interim closed out. The waste site consisted of The Grout Waste Test Facility (subsite 1) which was exhumed in 1994. The Special Waste Form lysimeter (subsite 2) was remediated in 2005.</td>
<td>Location:</td>
<td>The unit was located southeast of 400 Area, just west of Route 4 South. It was southeast of the 618-10 Burial ground.</td>
</tr>
<tr>
<td>Release Description:</td>
<td>On January 25, 1991, it was concluded that the lysimeter may have been damaged during backfilling causing a reportable quantity of effluent to leak into the soil. It was estimated that over a 3 year period, as much as 300 liters of contaminated liquid may have leaked. It was noted that one of the Grout Waste Test Facility lysimeter caissons (B1) was not collecting recharge water. The caisson was not exhumed to determine the cause, but it was speculated that the weld at the bottom of the caisson had been compromised when it was filled with gravel. It was decided that the buried caisson had probably leaked into the underlying sediments, contaminating them with radioactive materials. The release was estimated to have occurred over a 3 year period. The maximum concentration of contaminates in the sediments was estimated to be 6E-05 microcuries/milliliter to 1.3E-04 microcuries/milliliter of Technetium-99. When the Grout Lysimeter Facility was removed in September 1994, extensive sampling was conducted for all constituents identified in the caissons. Background samples were collected and compared to the sample results. It was concluded that no radiological constituents had leaked from either caisson during the lysimeter test. Although there was clear evidence that the B1 Lysimeter did have a large seam weld crack at the bottom, the leak contained only atmospheric moisture. No final report was issued for the sample analysis due to</td>

Approximately 950 metric tons (1,050 U.S. tons) of contaminated material was removed and disposed of at the ERDF. The remaining soil was sampled, analyzed, and evaluated. Results indicated that the site supports future land uses that can be represented (or bounded) by an unrestricted land-use scenario and that residual concentrations throughout this site pose no threat to groundwater or the Columbia River.

The 600-259 (subsites 1 and 2), waste site has been verified to be remediated in accordance with the ROD and the ESD and may be backfilled.

Final

This group of sites [300-18, 300-275, 600-47, 600-259, 618-5] are considered Final Closed Out in the 300-FF-2 Record of Decision and meet the criteria for Unrestricted Landuse.
Description: The lysimeters were exhumed in September 1994. The Grout Waste Test Facility consisted of four large lysimeters designed to test the leaching and migration rates of grout solidified low level radioactive waste. The four caissons were placed vertically in the ground, forming a square. The four lysimeters were designated as A1, A2, B1 and B2. A2 and B2 were never used. Lysimeter A1 contained phosphate/sulfate waste and B1 contained Cladding Removal Waste. Twenty four radioactive waste forms were placed on each lysimeter. The waste forms were placed in layers, separated by soil and gravel. Routine monitoring and leachate collection activities were conducted until January 1989.

Location: The unit is located southeast of 400 Area, just west of Route 4 South. It is southeast of the 618-10 Burial ground, and adjacent to 600-63.

The SubSite is Part Of:

Code: 600-259
Names: 600-259; Grout Waste Test Lysimeter; Inactive Lysimeter Site East End; Special Waste Form Lysimeter
The Special Waste-Form Lysimeter was constructed in the summer of 1983 and consisted of ten soil filled caissons (1.83 meters [6 feet] in diameter by 3.05 meters [10 feet] deep) placed concentrically around a central access caisson that measured 3.65 meters (in diameter, 3.65 meters deep. Each lysimeter is equipped with a gravity drain attached to the central caisson for leachate collection. The central caisson also provides access to the ten lysimeters through horizontal sample ports. A 15 centimeter diameter monitoring well is installed adjacent to each lysimeter caisson to allow for downwell gamma scanning and neutron probe measurements of the caissons. Each of the ten lysimeter caissons contains one waste-form sample that is in direct contact with the soil. Samples of commercial reactor waste was obtained and solidified in cement, bitumen or vinyl-ester styrene to create a waste form. Information was collected regarding the amount and types of contaminants that leached into the soil over time. Test data was collected between 1984 and 1992.

**Status:** Inactive  
**End Date:** 1/1/1950

**Description:** Both subsites have been reclassified. In 2014, the subsites were reclassified to Final Closed Out and Final No Action. Therefore the parent site is considered Final Closed Out. The foundation and loading dock were remediated in 2009. Prior to remediation, the concrete pad had been posted as a radiological fixed contamination area. The site consists of two subsites. Subsite 1 included the contaminated foundation and loading dock. It was remediated and Interim Closed Out. Subsite 2 is the rest of the waste site boundary and is known as the 300 West Storage Area. It was evaluated and determined to be a No Action site.

**Location:** The concrete foundation had been located due west of 300 Area, at the end of a gravel road. It is approximately 730 meters (0.45 miles) west of Stevens Drive.

**Related Sites/Structures:** The concrete foundation is associated with the excavated 618-9 burial ground, the 618-13 soil mound and the 321 building.

**Process Description:** The 300 Area was constructed between June 1943 and January 1945. At that time, the area surrounding the 600-290 waste site was inconspicuous except for a dirt road that ran along the north side of the gravel pit. A 1948 aerial photograph (IDMS-N2139826) shows a disturbed tear drop shaped area similar to the present condition. Two structures are visible in the photograph. One is at the center of the tear drop shape and the other borders the dirt road on the north side. The structure to the north is surrounded by a square feature resembling a fence. WHC-MR-0388 states that a 500 gallon Columbian stainless steel tank and several agitators, used by Du Pont in the early 321 Building bismuth phosphate tests, was buried in 1947 west of 300 Area. The area west of 300 Area was later used to bury solvent waste from 321 Building. The burial site (618-9) is known as the "300 West Burial Ground" and the "Dry West Burial Site No. 9". Dried hexone from solvent extraction studies in the 321 Building was placed in black iron drums and moved to a fenced storage area near the desert dry chemical storage hut in March 1950 (HW-17410). The 321 Building sustained significant damage from a hexone explosion on January 23, 1949 (HW-13812). The facility management would have been particularly sensitive to the dangers of hexone following the explosion. The location of this remote area was ideal for storing dangerous materials, away from buildings and personnel. In October 1950 all hexone from the 321 Building tanks was removed to provide room for the less-flammable Shell Deodorized Spray Base Solvent. The hexone was dried and stored in black metal drums for use in subsequent Redox studies (HW-15843 and HW-19325). Top soil from the 303 Area was removed in 1950 and piled approximately one-half to three quarters of a mile northwest of the 300 Area, and covered with two feet of clean soil. Total activity buried here is not known. The 618-13 soil mound of covered contaminated material has been posted as a
radiation zone (HW-39076). This waste site, is visible in aerial photographs as early as April 30, 1951 (350-NEG). Contaminated soil was reportedly found inside the 300 Area, on October 23, 1950, during construction of the new Instrument Division Building. The new building was being located between the existing Instrument Shop and the Metal Fabrication Plant (313 Building). The activities involved excavating the earth around two existing tile pipe lines (one sanitary and one liquid process waste line from the Metal Fabrication Plant). The incident report (DDTS-Generated-3822) speculated that the contaminated soil was from a wooden French Drain or crib installed on this site in 1944 to temporarily receive wastes from experimental autoclaves. The soil had a maximum dosage-rate of 50 mrep/hr (HW-19325).

Facility personnel, in 1971, identified the soil mound (618-13) as the location that received soil from the excavation near the 313 Building (in 1952) (Richmond 1971). The evidence from aerial photographs and historical documents appears to indicate that the soil mound was constructed shortly after October 23, 1950. The facility personnel, in 1971, also described the earth mound as having been constructed to serve as a blast shield for any explosions which might result from solvent storage in the [300-W] Equipment Storage Yard. The 1951 training manual for the 321 Building identified one of the related facilities as the "300 West Area Storage for chemicals and solvents" (HW-19791). Aerial photography from this period shows only one location (near the mound) fitting this description. An aerial photograph (2406-PHOTO), dated December 1, 1953, has features that resemble objects contained in a fenced area north of the soil mound. This is the same location where a square feature resembling a fence was observed in a 1948 aerial photograph (IDMS number N2139826). It appears that the dry chemical storage was located just north of the 600-290 waste site, near the location of the 300 West Burial Ground (618-9). The 300 West Burial Ground was constructed in June 1954 when about 18,927 liters (5,000 gallons) of solvent waste from the 321 Building, contained in 208 liter (55 gallon) drums, was buried and covered with about 1.2 meters (4 feet) of clean soil (HW-39076). The burial ground is also described in document WHC-MR-0388. This report states that nearly 100 drums that had been generated in 1949 to 1950. The drums were stored on an outdoor pad for nearly 5 years. The drums were later placed in the 300 West Burial Ground (sitecode 618-9). The fence that surrounded the soil mound (618-13) is visible in a May 15, 1956 aerial photograph (3746-PHOTO). Two large structures are also visible in the photograph that resemble huts. The area (fence, roads, storage buildings and earth barricade) is depicted in drawing M-3600 sheet 46, originally drawn in 1958. The mound, fence, hutments and various objects inside the fence are also visible in aerial photographs taken in 1962 and 1968 (29033 and 48300-20-CN). The fenced area is identified in the 1975 Final Environmental Statement (ERDA-1538) as a "Contaminated Equipment Storage Area". This report states that all of the equipment had been removed and that the ground was slightly contaminated. The purpose of the concrete pad and loading dock was described in the 300-FF-2 Operable Unit Technical Baseline Report (Reference: Appendix A of BHI-00012, Letter from Keene, A. R., 02/03/1961, "Burial of Solid Wastes in the Vicinity of the 300 Area"). The report states that the pad and dock were used for the storage of depleted solvents that were subsequently buried in the nearby 618-9 burial ground. The soil mound, and the pad and loading dock, was all that remained by 1976 (aerial photograph 74962-11CN). The fence, hutments and fenced in objects had all been removed.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: The waste is the remains of the concrete pad (apron), the loading dock and surrounding soil. The loading dock was obviously stained with rust colored and yellow staining. Contaminants of potential concern may include uranium and nitric acid (uranyl nitrate). Volatile organic compounds (including hexone), semi-volatile organic compounds, polychlorinated biphenyls, chlorinated hydrocarbons, and lead. Five areas of fixed radiological contamination were identified during a radiological survey on 5/1/2006 (RSR-300PS-06-0808).

Closure Info: 600-290 was remediated with waste sites 300 VTS, 300-8, 600-243. 618-7, 618-9, 618-13 in 2006. In 2014, the group of sites was reclassified to Final Closed Out.
The 600-290:2, 300 West Storage Area waste subsite consisted of the remaining areas within the 600-290 waste site boundary, excluding the previously remediated 618-13 Burial Ground waste site and the 600-290:1 subsite. The majority of the 600-290:2 area was enclosed by a fence and was used for storage of contaminated equipment. Confirmatory sampling of the 600-290:2 subsite was performed on April 3, 2012. Samples were collected up to 1 meters (3.3 ft) below ground surface to account for revegetation work performed after the previous remediation.

The 600-290:2 subsite has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Previous sampling results show that the concentrations of COCs meet the CULs for direct exposure and groundwater protection and river protection and support a residential land use scenario. Institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. In accordance with this evaluation, the previous sampling results support a reclassification of the 600-290:2 subsite to Final No Action.

Description: This subsite has been remediated and Interim Closed Out. A gravel road leads to the concrete pad on the north side of the soil mound. The area was designed to allow a truck to back up onto the concrete pad adjacent to the loading dock and offload drums of waste. Circular rust colored patterns, in the size and shape as 308 liter (55 gallon) drums, suggest that drums were once stored on the loading dock. The foundation and loading dock were remediated in 2009. Prior to remediation, the concrete pad had been posted as a radiological fixed contamination area.

Closure Info: Interim

The concrete pad and loading dock were remediated in 2009. Field remediation of the 618-13 Burial Ground and the 600-290:1 concrete pad and loading dock occurred between January 5 and February 2, 2009. The activity removed the soil mound, concrete pad, and loading dock. The mound and concrete pad were removed to ground surface level. No sub-grade excavation was required. The excavated material was maintained within the waste site footprint, therefore, no staging piles were generated outside of the waste site boundary. Contaminated soil, pieces of decayed wood, and concrete were the only materials found during remediation of the site. A radiological survey of the 618-13 footprint was done on February 12, 2009. The results indicated the soil beneath the excavated mound was less than two times the background for beta-gamma radionuclides.

Cleanup Verification Package CVP-2009-00005 demonstrates that remedial action at the 618-13 Burial Ground and the collocated 600-290:1 Pad and Loading Dock Near 618-13 has achieved the remedial action objectives (RAOs) and corresponding remedial action goals.
(RAOs) established for the unrestricted landuse scenario in the Interim Action Record of Decision (EPA 2001), the Explanation of Significant Differences for the 300-FF-2 Operable Unit (EPA 2004), and the Remedial Design/Remedial Action Work Plan for the 300 Area (DOE/RL 2009b).

The contaminated materials from the site have been excavated and disposed at ERDF. The remaining soil at the 618-13 and 600-290:1 sites have been sampled, analyzed, and evaluated. Results indicate that the site supports future land uses that can be represented (or bounded) by the residential land-use scenario and poses no threat to groundwater or the Columbia River.

Final

The group of sites [300 VTS, 300-8, 600-243, 618-7, 618-9, 618-13, 600-290:1] were reclassified to Final Closed Out in 2014. They are listed in the 300-FF-2 Record of Decision and meet the criteria for unrestricted landuse.

**Description:** This subsite was evaluated and determined to require No Action. In 2014, the subsite was reclassified to Final No Action. It included the remaining area covered by the WIDS boundary that was not addressed in subsite 1. The majority of the area had been enclosed by a fence and was used for storage of contaminated equipment. A portion of the subsite extends north of the fence where anomalies were visible in an old aerial photograph.

**Process Description:** The majority of the 600-290:2 area was enclosed by a fence and was used for storage of contaminated equipment.

**Closure Info:** Interim

Confirmatory sampling for the 600-290:2 subsite was conducted on April 3, 2012, to support a determination that residual contaminant concentrations at these sites meet the cleanup criteria specified in the 300 Area RDR/RAWP (DOE/RL 2009) and the 300-FF-2 ROD (EPA 2001). Twelve statistical discrete soil samples were collected on the grid within the footprint of the site. A soil sample was collected at each of the identified sample locations at a depth of 0.3 meter (1 ft) to 1 meter (3 ft) below ground surface. During excavation and sampling, radiological field screening was performed as specified in the confirmatory work instruction. No radiological contamination was detected above background levels. Field screening for the presence of volatile organic compounds (VOCs) was also negative.

The confirmatory sampling and the analytical results indicate that the residual concentrations of COPCs at this site meet the remedial action objectives for direct contact, groundwater protection, and river protection. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. Institutional controls to prevent uncontrolled drilling or excavation are not required.
Accordingly, a reclassification to No Action is supported for the 600-290:2 subsite.

Final

600-290:1 was remediated with waste sites 300 VTS, 300-8, 600-243, 618-7, 618-9, 618-13 in 2006. In 2014, the group of sites was reclassified to Final Closed Out.

The 600-290:2, 300 West Storage Area waste subsite consisted of the remaining areas within the 600-290 waste site boundary, excluding the previously remediated 618-13 Burial Ground waste site and the 600-290:1 subsite. The majority of the 600-290:2 area was enclosed by a fence and was used for storage of contaminated equipment. Confirmatory sampling of the 600-290:2 subsite was performed on April 3, 2012. Samples were collected up to 1 meters (3.3 ft) below ground surface to account for revegetation work performed after the previous remediation.

The 600-290:2 subsite has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Previous sampling results show that the concentrations of COCs meet the CULs for direct exposure and groundwater protection and river protection and support a residential land use scenario. Institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. In accordance with this evaluation, the previous sampling results support a reclassification of the 600-290:2 subsite to Final No Action.

Description: This burial ground was excavated and remediated in 2008 and 2009. The 618-1 Burial Ground, two subsites, three consolidated sites and four co-located sites were remediated as a group and reclassified to Interim Closed Out. This group included WIDS sitecodes 618-1, 618-1-1, 618-1-2, 333 LHWSA, UPR-300-13, UPR-300-14, 300-110, 303-M SA, 303-M UOF and 333 ESHWSA. Three sites (300-15 Process Sewer, 300-259 and UPR-300-17 Metal Shavings Fire) were partially remediated with the 618-1 remedial action.

Drawing H-3-1172 shows the Burial Ground consisted of at least two trenches running north-south, that measure 5 meters (16 feet) wide by 61 meters (200 feet) long and are 2.4 meters (8 feet) deep. The south end of the burial ground contained a series of pits that are estimated to be 6.1 meters (20 feet) deep and possibly two shorter, east-west trenches. The burial ground had been marked with yellow, concrete AC-540 markers and radiation area chain on three sides. Five other Buried Radioactive Material medallions, inserted flush with the asphalt pavement along the east side of the 333 Building, marked the western extent of the burial ground. In 1998, the burial ground was located within a larger area posted as a Contamination Area.

Over time, multiple facilities and portions of operational support structures were placed on top of the backfilled burial ground footprint. The 303-M Building was built over a portion of the original burial ground.
Location: The site was located in the northeast corner of the 300 Area, adjacent to the east side of the 333 Building.

Related Sites/Structures: The burial ground is associated with early 300 Area facility operations. Several facilities had been constructed over the top of portions of the burial ground. The 303-M facility was built over the top of the north end of the west trench (Burial Trench 1). The 334 building, the 334-A building, and the 334 Waste Acid Tanks (above ground tank farm) were also placed over portions of the west side of the burial ground. WIDS SubSites 618-1:1 (aka 333 ESHTSSA) and 618-1:2 (aka Limestone Neutralization Pit) are associated with the site since they were physically located on or immediately adjacent to the burial ground. The burial ground is associated with acid releases, WIDS Site UPR-300-13 and WIDS Site UPR-300-14, and two storage areas, 333 LHWSA and 333 ESHTSSA (see the consolidated sites under the Regulatory tab). WIDS Site 300-259 (Contaminated Soil East of 618-1 Burial Ground) surrounded 618-1 Burial Ground.

Process Description: The burial ground received waste from early 300 Area facility operations, including the 305 Reactor, 3706 Laboratory and the 3741 Building. Conflicting operational dates have been cited in various documentation. HW-39076 states the operational dates of 618-1 were 1945 through 1951, when it was replaced by 618-2. Historical photograph (Negative number 2406) is dated December 1953. The 618-1 Burial Ground appears to be backfilled and inactive in this aerial photograph. The 618-2 Burial Ground is also visible in this photograph and indicates multiple burial trenches are open and active. Other documents and letters indicate the end date for this burial ground as 1956 or 1957.

Waste Type: Process Effluent

Waste Description: WIDS Site 333 ESHTSSA stored above ground containers of solidified heat-treat salt waste from the fuels fabrication facility. The waste consisted of sodium chloride, potassium chloride, sodium nitrite, sodium nitrate, and potassium nitrate. Approximately, thirty to fifty 208 liter (55 gallon) drums accumulated each year (1964-1987).

Waste Type: Process Effluent

Waste Description: Additional waste from unplanned releases (WIDS Site UPR-300-13) from facilities that were constructed over the burial ground would have contributed additional chemicals to the soil column as a liquid release. Sample results showed that 2015 kilograms (4432 pounds) of nitric acid, 44 kilograms (96 pounds) of fluoride, 217 kilograms (477 pounds) of copper and 1.4 kilograms equivalent to 0.0005 curies of uranium were lost to the ground. 870 kilograms (1910 pounds) of caustic was added to the leaking tank and allowed to leak into the soil to neutralize the acid that had escaped into the ground. The leak rate of the tank was 582.9 liters (154 gallons) per hour. A release on July 18, 1975 (WIDS Site UPR-300-14) of 4,540 liters (1,200 gallons) of 93% sulfuric acid solution from the 334 Tank Farm drained to a limestone pit (WIDS Site 300-246). Since the pit had an open bottom and was located over the 618-1 Burial Ground, the release drained to the burial ground.

Waste Type: Process Effluent

Waste Description: 618-1 was estimated to contain large quantities of uranium (~16 tons [14,500 kilograms]) from the fuel fabrication activities and small quantities of plutonium and fission products from laboratory operations. Specific items include contaminated gloves, miscellaneous equipment, bronze crucibles, and solid laboratory waste. A 1946 report states that lead sink traps from the 321 laboratory were removed and taken to the burial ground. Radiological readings on the sink traps indicated 6,000 d/m alpha and 15 mr/hr beta/gamma. A monthly report from August 1946 mentions the burial of a bronze crucible that read 170 millireps/hour (179 millirads/hour) and 5.5 mr/hr (millirads/hour) at a distance of 0.2 centimeters (4 inches). UPR-300-13 contributed process acid that included 4,432 pounds (2,012 kilograms) of nitrate, 447 pounds (202.9 kilograms) of copper, and 3 pounds (1.4 kilograms) of uranium. During the burial ground remediation, in 2008 and 2009, items found in the burial ground included metal drums, iron and
bronze crucibles, metal boxes, glass laboratory flasks and bottles. Some of the bottles contained unknown liquids and powders. One drum was labeled Poison Waste. Some drums were leaking oily liquid.

**Closure Info:** The 618-1 Burial Ground, two subsites, three consolidated sites and four co-located sites were remediated as a group. This group included WIDS sitecodes 618-1, 618-1:1, 618-1:2, 333 LHWSA, UPR-300-13, UPR-300-14, 300-110, 303-M SA, 303-M UOF and 333 ESHWSA. Parts of waste sites 300-15, 300-259 and UPR-300-17 were also remediated along with 618-1. Several facilities were built over the top of portions of the 618-1 Burial Ground after it ceased to operate. These facilities were demolished and their debris taken to the Environmental Restoration Disposal Facility (ERDF) prior to the start of the burial ground remediation project.

Field remediation activities at the 618-1 Burial Ground were performed between September 17, 2008 and September 10, 2009, in accordance with the RDR/RAWP. Approximately 47,332 metric tons (52,160 US tons) of soil and debris was excavated and disposed of at ERDF. No excavated soil will be used as clean, uncontaminated backfill. Waste encountered during excavation of the 618-1 waste site consisted mostly of contaminated soil, metal pipe, crucibles, laboratory glassware, empty metal containers, and some LDR material. Twenty metal drums containing personal protective equipment (PPE) were removed from the trenches. The PPE was about 80% decomposed. Several bottles containing liquid and/or powder were also removed. One relatively large area on the south side of the burial ground was stained yellow presumably from acid leaks known to have occurred at the site.

Three sites (300-15 Process Sewer, 300-259 and UPR-300-17 Metal Shavings Fire) were partially remediated with the 618-1 remedial action.

Some land disposal restricted (LDR) materials, like lead solids contaminated with barium and chromium, were identified among the debris. The LDR material was segregated from the bulk soil and non-LDR debris for disposal. The bulk soil and non-LDR debris was sorted and segregated in the burial trenches. After sorting, the remaining bulk soil debris stockpiles were sampled to ensure that the material was in compliance with land disposal restrictions. The released stockpiled material was transported to ERDF for disposal. Land disposal restricted materials that had been segregated for treatment were transported to ERDF under a separate waste profile.

The remaining soil at the 618-1 site has been sampled, analyzed, and evaluated. Results indicate that the site supports future land uses that can be represented (or bounded) by the industrial land-use scenario and poses no threat to groundwater or the Columbia River. Institutional controls are required to prevent drilling or excavation into the deep zone. Cleanup Verification Package CVP-2010-00001 demonstrates that remedial action at the site has achieved the Remedial Action Objectives and corresponding Remedial Action Goals established for the industrial land-use scenario in the Record of Decision (EPA 2001), the Explanation of Significant Differences for the 300-FF-2 Operable Unit (EPA 2004), and the RDR/RAWP (DOE-RL-2001-47, Rev 3).

Hanford Site Waste Management Units Report
February 2015
1463
Area; 333 ESHTSSA

Type: Burial Ground  
Status: Inactive

Description: This area has been remediated and reclassified to Interim Closed Out with the 618-1 Burial Ground. The 333 ESHTSSA was an inactive storage area. The unit included various locations inside the 333 Building fence where heat-treat salts were stored. The heat-treat salts were stored on the paved area near the southeast corner of the building or in the adjacent area located over a portion of the 618-1 Burial Ground. Several areas of the asphalt pavement have been painted over and posted fixed radiological contamination (see WIDS Site UPR-300-17). The area stored containers of solidified heat-treat salt waste from the fuels fabrication facility. The waste consisted of sodium chloride, potassium chloride, sodium nitrite, sodium nitrate, and potassium nitrate. Approximately, thirty to fifty 208 liter (55 gallon) drums accumulated each year (1964-1987).

Description: The neutralization pit has been remediated and reclassified as Interim Closed Out with the 618-1 Burial Ground. The centerline of the Pit was 26.8 meters (88 feet) south of the centerline of the 333 Building East Pipe Trench, aligned with where the pipe trench exited the east wall of the 333 Building (see H-3-18520). The upper wooden covers for the Limestone Neutralization Pit had been removed and the pit had been backfilled with soil. It was no longer visible at the surface. The concrete pipe trench branch to the pit was visible prior to remediation (see photos). The drain line from the concrete pipe trench to the pit was sealed and the neutralization pit shut down in 1975, following a large acid spill (WIDS Site UPR-300-14). This incident caused concern for the groundwater. The original pit was constructed of a 0.46 meter (1.5 foot) deep bed of limestone with 7.6 centimeter (3 inch) rock on top of a 0.3 meter (1 foot) deep bed of washed gravel. The top of the limestone bed was 15.2 centimeters (6 inches) above grade and 1.2 meters (4 feet) above the surface of the limestone bed. The Limestone Neutralization Pit received drainage from the WATS pipe trench and the 334 Tank Farm sump trench. The pit was filled with limestone rocks used to neutralize acidic aqueous solutions draining from the pipe trench. The pit had an open top to allow the addition of limestone rocks as needed. It was open at the bottom to drain to the soil column. The soil column effected part of the of the 618-1 Burial Ground, located beneath the neutralization pit. The 334 Tank Farm had four elevated tanks, two for storing concentrated nitric acid, one to store concentrated sulfuric acid, and one tank to store waste etch acid. A sump trench beneath the elevated acid tanks collected leaks from tanks, valves, and piping. The acid transfer lines from the 334 Tank Farm to the 333 Building were installed in the Pipe Trench. Rainwater collected in the sump trenches and the pipe trench drained to the pit.

The SubSite is Part Of:
**Code:** 618-1  
**Names:** 618-1; Solid Waste Burial Ground No. 1; 300 Area Burial Ground No. 1; 318-1

**Code:** 618-2  
**Classification:** Accepted  
**Names:** 618-2; Solid Waste Burial Ground No. 2; 318-2  
**Reclassification:** Interim Closed Out (12/28/2006)  
**Type:** Burial Ground  
**Start Date:** 1/1/1951  
**End Date:** 1/1/1954  
**Status:** Inactive  
**Description:** The site has been remediated and interim closed out. The burial ground contained three or four trenches running east-west. The largest trench was 54 meters (175 feet) long and 18 meters (60 feet) wide.

**Location:** The unit was located north of the 333 Building, on the north side of the 300 Area Exclusion Area.

**Process Description:** The site received solid waste from the 300 Area operations. This included waste from the 325 and 327 laboratory facilities, which began operations in 1953. A 1995 Ground Penetrating Radar survey found the northern most trench to be 49 meters (160 feet) long and 9 meters (30 feet) wide. The southern most trench was 55 meters (180 feet) long and 15 meters (50 feet) wide. The center trench was 54 meters (175 feet) long and 18 meters (60 feet) wide. The discrepancy of whether there were three or four trenches could be due to the fact that the geometry of the middle trench was broken into two pieces at the east end.

**Waste Type:** Process Effluent  
**Waste Description:** The unit was used for disposal of uranium-contaminated equipment and materials, plutonium, and fission products. The uranium waste was typically solid metallic uranium oxides in the form of metal cuttings from Reactor Fuel Fabrication facilities in the 300 Area. The plutonium and fission products came from 300 Area laboratory facilities, that began to operate in 1953. The burial ground may also contain tin from the triple dip canning process and lead from the lead dip process. In December 2004, during remedial excavation of this burial ground, a combination lock safe was unearthed. A plutonium contaminated cup, a one gallon jug containing liquid waste, a 250 milliliter flask and several metal cans were found inside the safe.

**Closure Info:** Remedial action activities at the 618-2 waste site initially began in November 2004 and were completed in August 2006. Excavation of contaminated soil and debris was performed until native soil was reached at the floor of each trench. The determination of native soil was based on the absence of debris materials, plus radiological surveys and visual observations of the soil at the base of the excavation. The total excavated depth was approximately 6 meters (19.7 feet), with the shallow zone consisting of the excavation sidewalls to a depth of 4.6 meters (15 feet) and the deep zone consisting of the excavation sidewalls below 4.6 meters (15 feet) together with the floor of the excavation. In-process radiological field screening was conducted during the site remedial actions to guide the excavation and quickly assess the presence and level of contamination. The radiological survey results indicated the presence of isotopes of uranium and plutonium, as well as cesium-137. The buried waste consisted primarily of a wide variety of laboratory and construction type debris. Excavation activities found no indication of bulk liquid waste disposal at this waste site. During the initial excavation phase, contaminated soil and debris were excavated from the burial ground and transported to a designated "stockpile" area for sorting and sampling. Sorting and sampling of the excavated soil and debris was performed in a designated staging pile area. This staging pile area supported the 618-2, 618-3, and 618-8 Burial Ground excavations and is included with the closure of the 618-2 waste site.

Excavation and load-out operations were suspended from December 2004 to December 2005, due to the discovery of higher than anticipated levels of plutonium-contaminated waste. When operations resumed in December 2005, the first materials designated for load-out were the
existing sorted stockpiles located on the east side of the designated stockpile sorting area. Following a sampling campaign to ensure compliance with Land Disposal Restrictions (LDRs), these sorted stockpiles were loaded into ERDF containers and transported to ERDF for disposal. Concurrent with the load-out of the existing sorted stockpile material, additional stockpiles of previously unsorted and unsampled 618-2 material, located on the west side of the designated stockpile/sorting area, were thoroughly sorted and subsequently sampled. Upon receipt of sample results confirming compliance with LDR restrictions, these stockpiles were also loaded into ERDF containers and transported to ERDF for disposal. In January 2006, excavation and sorting operations resumed at the 618-2 Burial Ground trenches utilizing a revised material handling strategy that eliminated the requirement for hauling the excavated material to a designated stockpile area. The revised strategy provided a mechanism for direct sorting and stockpiling of the excavated material inside the boundaries of the existing trenches. After sorting, the "in-trench" stockpiles were then sampled to ensure compliance with LDR restrictions. Upon receipt of sample results confirming compliance with LDR restrictions, the "in-trench" stockpiles were loaded into ERDF containers and transported to ERDF for disposal.

Land disposal restriction (LDR) materials, primarily consisting of lead solids, were identified and separated from the bulk soil and debris during excavation and sorting operations. All excavated materials were disposed of at ERDF. Approximately 71,203 metric tons (78,488 U.S. tons) of material from the site was removed and disposed of at ERDF. Excavated material consisted of contaminated soil and a wide variety of miscellaneous debris. Some Land Disposal Restriction (LDR) materials, primarily lead solids, were identified among the debris and were subsequently segregated from the bulk soil and non-LDR debris, then designated for separate load-out as LDR material. Subsequent to sorting, the remaining bulk soil and non-LDR debris material stockpiles were sampled to ensure that the material was in compliance with LDR restrictions. Upon receipt of sample results confirming compliance with LDR restrictions, the released stockpile material was loaded into ERDF containers and transported to ERDF for disposal. LDR materials that had been segregated for treatment were subsequently loaded-out and transported to ERDF under a separate waste profile.

In June 2006, an area of discolored soil, exhibiting high plutonium contamination, was located in the eastern portion of the middle trench at a depth of 8 meters (26.2 ft) below grade. This location likely corresponds with the "high activity" waste disposal area of the middle trench that is discussed in a historical memo concerning the February 17, 1954 fire at the 618-2 Burial Ground. An additional 1 meter (3.3 ft) of soil was removed from this area and a soil sample collected at a depth of 9 meters (29.5 ft) below grade. The sample results indicated residual plutonium activities decreasing with depth, but not at a rate that would support an evaluation of protection of groundwater. A review of historical groundwater levels in the vicinity of the 618-2 site indicated a groundwater low of 104 meters (341.2 ft) above sea level (15 m [49.2 ft] below grade) and a groundwater high of 107.5 meters (352.7 ft) above sea level (11.5 m [37.7 ft] below grade). Considering this information, a test pit was excavated to groundwater in August 2006, to remove the contaminated soil and to collect discrete soil samples for laboratory analysis to support further evaluation of protection of groundwater. A grab sample of water at the base of the test pit was also collected. Four additional potholes were dug, surrounding the test pit location. Discolored soil and residual contamination indicated additional excavation was needed.

Remediation activities were conducted in accordance with the RDR/RAWP. Remediation involved excavation and removal of buried waste and contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs.

The cleanup verification package (CVP), CVP-2006-00010, has documented that remedial action objectives (RAOs) and remedial action goals (RAGs) for the site have been achieved as established for the industrial land-use scenario in the Interim Action Record of Decision for the 300-FF-2 Operable Unit, Hanford Site, (ROD), as modified by the Explanation of Significant
Differences for the 300-FF-2 Operable Unit Interim Record of Decision (ESD), and the Remedial Design Report/Remedial Action Work Plan for the 300 Area (RDR/RAWP).

| Code:      | 618-3                          | Classification: | Accepted                 |
| Names:     | 618-3; Burial Ground #3; Dry Waste Burial Ground No. 3; Solid Waste Burial Ground No. 3; 318-3 | Reclassification: | Interim Closed Out (9/5/2006) |
| Type:      | Burial Ground                   | Start Date:     | 1/1/1954                 |
| Status:    | Inactive                       | End Date:       | 1/1/1955                 |
| Description: | The site has been remediated and interim closed. Prior to remediation the site was fenced and posted with Underground Radioactive Material signs. The original surface dimensions were 107 meters (350 feet) long by 50 meters (165 feet) wide. An extension to the north end of the burial ground appeared on Drawings H-6-933 and H-6-939, lengthening the site by 15 meters (50 feet). A 1995 Ground Penetrating Radar survey indicated that this burial ground was dominated by one continuous north-south trending trench. Within the interpreted trench boundary, areas of debris were readily identified continuously covering an area of about 335 feet by 90 feet. |
| Location:  | The site was located north of the 300 Area Exclusion Fence, adjacent to and west of the 618-2 Burial Ground. |
| Process Description: | This disposal site was first used in the summer of 1954. It received mostly contaminated waste from the remodeling of the 313, 303-J and 303-K Buildings and the construction of the 311 Facility. |
| Waste Type: | Process Effluent               |
| Waste Description: | The site consisted of uranium-contaminated waste, primarily building materials from the remodeling of the 313 Building. It may have also contained waste from the 303-J and K upgrades. In 1986, the volume of contaminated soil was estimated to be 12,549 cubic meters (443,160 cubic feet), with 12,643 cubic meters (446,480 cubic feet) of overburden. |
| Closure Info: | Remedial action activities at the 618-3 waste site were conducted from September 9, 2004, to October 28, 2004. Remediation activities were conducted in accordance with the RDR/RAWP. Remediation involved excavation and removal of buried waste and contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs. In-process radiological field screening was conducted during the site remedial actions. Field screening was used to guide the excavation to quickly assess the presence and level of contamination. The radiological survey results were consistent with the presence of uranium, at relatively low concentrations. There was no indication of additional radioactive contamination beyond the low levels of uranium. The buried waste consisted primarily of a wide variety of construction-type debris. Excavation activities found no indication of bulk liquid waste disposal at this waste site. Land disposal restriction materials, primarily consisting of lead solids, were identified and separated from the bulk soil and debris during excavation and sorting operations. Sorting and sampling of the excavated soil and debris was performed in a designated staging pile area. This staging pile area supported the 618-2, 618-3, and 618-8 Burial Ground excavations and will be closed out with the 618-2 waste site. No overburden piles were created during the waste site excavation. All excavated materials were disposed at ERDF. A total of approximately 30,878 metric tons (34,037 U.S. tons) of material was removed and disposed at ERDF. |
| Final cleanup verification sampling was conducted on January 31, 2006, to confirm acceptability of residual contaminant concentrations in the soil. Based on the overall footprint... |
of the area and depth of excavation, the site was classified as one shallow zone decision unit. The final verification samples were submitted to offsite laboratories for analysis using approved U.S. Environmental Protection Agency (EPA) analytical methods as required per the SAP.

The cleanup verification package (CVP) has documented that the waste site was remediated in accordance with the Interim Action Record of Decision for the 300-FF-2 Operable Unit, (ROD) (EPA 2001), as modified by the Explanation of Significant Differences for the 300-FF-2 Operable Unit Interim Record of Decision (ESD) (EPA 2004). Remedial action objectives (RAOs) and remedial action goals (RAGs) for this site were documented in the ROD and the Remedial Design Report/Remedial Action Work Plan for the 300 Area (RDR/RAWP).

For the exceedance of uranium, the biased samples were taken from below the biologically active zone (a maximum depth of 2.7 meters [8.9 feet]) per Table 2-2 of the 100 Area Burial Grounds Focused Feasibility Study. As such, these concentrations of uranium will not be accessible to ecological receptors. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final ROD for these sites.

The cleanup verification package has demonstrated that remedial action at the waste site has achieved the RAOs and corresponding RAGs established for the industrial land-use scenario in the ROD, the ESD, and the RDR/RAWP. The remaining soil at the site has been sampled, analyzed, and evaluated. Results indicate that the site supports future land uses that can be represented (or bounded) by the industrial land-use scenario and poses no threat to groundwater or the Columbia River. The waste site was verified to be remediated in accordance with the ROD and the ESD. This site has no deep zone; therefore, no institutional controls are required.

---

**Code:** 618-5  
**Classification:** Accepted  
**Reclassification:** Final Closed Out (2/18/2014)  
**Names:** 618-5; Burial Ground No. 5; Regulated Burning Ground; 318-5  
**Type:** Burial Ground  
**Status:** Inactive  
**Start Date:** 1/1/1945  
**End Date:** 1/1/1962  
**Description:** The site was remediated in 2003 and interim closed out in 2004.  
**Location:** The unit was located north of the 300 Area. It was north of the remediated 316-2 Pond and east of the 316-5 Process Trenches. The site was approximately 1.6 kilometers (1 mile) north of the Richland City limits.  
**Process Description:** The site received 300 Area waste from 1945 through 1962. The site was one large (single) pit. It was also used as a burn pit.  
**Waste Type:** Chemicals  
**Waste Description:** HW-39076 states the area was a burning trench as well as a storage area for aluminum silicate containing 17% uranium and bronze crucibles with radiation levels up to 200 mR/hr. The site was used for the disposal of uranium-bearing trash. Characterization test pits dug in 1992 encountered radiologically contaminated lead bricks, steel pipes, wood fragments and other garbage. Asbestos was found in Test Pit 2.  
**Closure Info:** Interim  

Remedial activities occurred between March and August 2003. Historical information documenting operation of the 618-5 Burial Ground as a burn pit was consistent with the type and condition of waste observed during the excavation process. In addition to the major waste
streams encountered, smaller quantities of asbestos, wood debris, intact bottles, dried paint, tar, and other items were unearthed in discrete areas of the burial ground. A detailed listing of waste unearthed from the burial ground and managed as no bulk material was maintained in the 300 Area project files (i.e., waste tracking sheet). At the completion of field operations in 2003, the total excavation was approximately 8,110 square meters (87,300 square feet) in area with a maximum depth of approximately 7.5 meters (24.6 feet) below the surrounding grade. Approximately 46,300 metric tons (50,930 tons) of bulk soil and debris were excavated from the site, put into adjacent staging pile areas, and subsequently transported to the Environmental Restoration Disposal Facility for disposal. Overburden material and excavated soil identified as potentially clean was stockpiled (below cleanup level soil stockpile) at the site for subsequent use as backfill material.

Remedial action objectives and goals for the 618-5 Burial Ground were established by the U.S. Environmental Protection Agency and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives were based on industrial land use and are documented in the Record of Decision for the 300-FF-2 Operable Unit (ROD).

Excavation operations were driven by remedial action objectives for removal of the burial ground contents as well as direct exposure limits, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals were established in the ROD and the Remedial Design Report/Remedial Action Work Plan for the 300 Area.

Because residual soil concentrations indicated that cleanup levels for more stringent land uses may have been achieved for the 618-5 Burial Ground, a supplemental evaluation was performed against the unrestricted land-use cleanup objectives established in the 300-FF-2 ESD. Results of the evaluation demonstrated that remedial actions at the site have achieved all of the objectives for unrestricted land uses. Consequently, no institutional controls are required at the site.

Final

This group of sites [300-18, 300-275, 600-47, 600-259, 618-5] are considered Final Closed Out in the 300-FF-2 Record of Decision and meet the criteria for Unrestricted Landuse.
Process Description: Most of the waste in this burial ground originated from the 313 and 333 buildings (operated by Douglas United Nuclear [DUN]). Some waste was generated by the JA Jones, Battelle Northwest and Westinghouse companies, located in the 300 Area. Between 1962 and 1973, hundreds of drums of zircaloy chips (slightly contaminated with Beryllium) were disposed at this burial ground. The zircaloy chips are waste from the process of machining the ends of zircaloy clad fuel elements. The chips vary in size, but are generally 0.14 millimeters (4 to 5 mils) thick and 0.6 centimeters (0.25 inches) wide. The chips may be contaminated with beryllium and uranium. The material was considered to be pyrophoric and was placed in 114 liter (30 gallon) iron drums, filled with water. No records were kept to identify the exact quantities and locations of these drums. The practice was discontinued in June, 1973.

Waste Type: Chemicals

Waste Description: Materials buried at this site were primarily from the 321, 313, 333, 3722 and 3732 Buildings. Miscellaneous contaminated equipment and hundreds of 114 liter (30 gallon) drums of zircaloy chips contaminated with moderate amounts of beryllium and uranium were buried in the trenches from 1960 to 1973. Since the zircaloy was considered pyrophoric, the drums were filled with water to avoid spontaneous combustion. It is highly possible the water has leaked out of the drums. It has been suggested the waste remain undisturbed to avoid oxidation. An explosive hazard may be present. Other low-level material, slightly contaminated with uranium and thorium, was also buried in the trenches. A 1972 memo states that from January through August 1972, 91 cubic meters (3024 cubic feet) of waste contaminated with uranium was placed in Burial Ground 7. It also states that during that same period, 55 cubic meters (1848 cubic feet) of thorium contaminated waste, 25 cubic meters (848 cubic feet) of thorium oxide and 30 cubic meters (1000 cubic feet) of non-radioactive beryllium contaminated waste was placed in Burial Ground 7.

Closure Info: Interim

Remedial action activities at the 618-7 Burial Ground began January 4, 2008, and were completed on November 15, 2008. Remediation activities involved excavation and removal of buried waste and contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs. In-process radiological field screening was conducted during the site remedial actions to guide the excavation and quickly assess the presence and level of contamination. Waste encountered during excavation of the trenches was consistent with the types of material anticipated based on its reported use for disposal of contaminated equipment from the 300 Area Facilities and drums of Zircaloy chips.

A total of 117 drums containing Zircaloy packed in water-soluble oil were removed. Because these drums contained PCBs and other contaminants, they were sent to an off-site treatment facility. Approximately 20 stainless steel tanks (2 to 3 meters [8 to 10 ft] in diameter and 1 to 3 meters [4 to 10 ft] in length) and a solvent extraction column (1 meter [3 ft] in diameter and 9 meters [30 ft] tall) were also recovered from the thoria trench. The tanks and solvent extraction column were associated with the Plutonium Uranium Reduction Extraction (PUREX) prototype facility that operated in the 321 Building. Several of the tanks contained cooling coils filled with an ethylene glycol solution. Process furnaces and hundreds of empty five gallon buckets from the thoria target fabrication line (located in the 3722 Building) were also found in the thoria trench. The north and middle trenches, collectively referred to as the main trench, contained a large volume of aluminum turnings mixed with soil. A total of 200 drums were recovered that contained aluminum turnings and aluminum rods. Approximately 200 drums containing vermiculite were recovered. The vermiculite was slightly contaminated with low levels of uranium and was suspected to have been used as an absorbent. Approximately 50 drums containing different types of oil were removed. Approximately 200 bottles ranged in size from 100 mL to 20 liters were recovered from the three trenches. In August 2008, a silvery powder was unearthed that ignited when it was exposed to air. The fire was immediately extinguished with pre-staged soil.
Contaminated debris and soil were segregated and sorted within the trench excavation boundaries. Excavation was performed until native soil was reached at the floor of each trench. The determination of native soil was based on the absence of debris materials, radiological surveys, and visual observations of the soil at the base of the excavation. In total, approximately 160,920 metric tons (177,380 US tons) of material from the site was removed and disposed. All excavated materials were disposed at the ERDF, with the exception of the radiologically contaminated oil and the Zircaloy, which were sent for treatment and/or disposal at an approved off site facility. Approximately 18,140 metric tons (20,000 US tons) of aluminum turnings and solids contained lead above land disposal restriction (LDR) levels and required solidification prior to disposal at ERDF. Aluminum turnings and aluminum rods from approximately 200 drums were mixed with soil and sent to ERDF. The contaminated vermiculite was also mixed with soil for disposal at ERDF. The bottles recovered from the 3 trenches (approximately 200) were emptied and the bottles were disposed at ERDF. The contents of the bottles were sent to an analytical laboratory for characterization prior to disposal.

Final

The group of sites [300 VTS, 300-8, 600-243. 618-7, 618-9, 618-13. 600-290:1] were reclassified to Final Closed Out in 2014. They are listed in the 300-FF-2 Record of Decision and meet the criteria for unrestricted landuse.

Remedial action activities at the 618-8 waste site began on November 1, 2004, and were completed on November 8, 2004. Remediation involved excavation and staging of clean overburden material and removal of contaminated soil to the extent required to satisfy the RAQ's and corresponding RAG's. The excavated material consisted of soil and a wide variety of construction-type debris. Some land disposal restricted materials (primarily three metal drums) were identified and separated from the bulk soil and debris during excavation and sorting operations. Sorting and sampling of the excavated soil and debris was performed in a designated staging pile area. After sorting and receiving of sampling results, the released
material was loaded into ERDF containers and transported to the ERDF for disposal. Material designated as land disposal restricted materials were loaded out and transported to the ERDF under a separate waste profile.

The staging pile area used for the 618-8 waste site also supported the 618-2 and 618-3 Burial Ground excavations. In December 2004, load-out operations at the 618-8 Burial Ground staging piles were suspended, due to the discovery of plutonium-contaminated waste at the 618-2 Burial Ground. Part of mitigation actions was to stabilize the excavated, staged waste and debris. A soil cover was placed on all the stockpiled material from the 618-8 Burial Ground. Load-out of the 618-8 stockpiled material resumed on September 1, 2005. The activity was completed on September 13, 2005. Final cleanup verification sampling was conducted on January 31, 2006.

Approximately 6,462 metric tons (7,125 U.S. tons) of material from the site was removed and disposed at the ERDF.

Geophysical, ground-penetrating radar (GPR) surveys were performed in 1987 and additional characterization in 2002. These GPR surveys identified two distinct areas containing substantial amounts of buried waste in the areas located north of the parking lot (inside the area previously delineated by the "post and chain" boundaries). The GPR surveys could not identify a traditional trench configuration or evidence of buried waste under the area delineated by the medallions in the parking lot. Subsequent test excavations and trenching performed at the parking lot area did not expose any evidence of buried waste or debris in that area. A total of eight soil samples were collected from soil removed during the trenching and test excavations. These samples were analyzed for Resource Conservation and Recovery Act of 1976 metals and a wide range of radionuclides. Analytical results showed all results were either undetected or detected below lookup values. As a result, the area under the parking lot was not excavated further.

Site excavation and waste disposal are complete, and the exposed surfaces have been sampled and analyzed to verify attainment of the remedial action goals. Results of the sampling, laboratory analyses, and data evaluations for the site indicated that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met for industrial land use.

Because residual soil concentrations indicated that cleanup levels for more stringent land uses may have been achieved for the site, a supplemental evaluation was performed against unrestricted land-use cleanup objectives established in the Explanation of Significant Differences for the 300-FF-2 Operable Unit Record of Decision.

The cleanup verification package (CVP) 2006-00006 documents that the waste site has been remediated in accordance with the Interim Action Record of Decision for the 300-FF-2 Operable Unit, (ROD) (EPA 2001) and has met the remedial action objectives (RAOs) and remedial action goals (RAGs) for this site for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 300 Area (RDR/RAWP).

Final

This group of sites [300-10, 300-45, 300-109, 300-259, 618-8] is considered Final Closed Out in the 300-FF-2 Record of Decision and meets the criteria for unrestricted landuse.

</table>
**Type:** Burial Ground  
**Status:** Inactive  
**Start Date:** 1/1/1950  
**End Date:** 1/1/1956  
**Description:** The site was remediated and Closed Out. It was a burial ground composed of a single trench and enclosed within a fence measuring 105 by 95 meters (344 by 312 feet). The waste site was exhumed during an Expedited Response Action in 1991-1992. The empty trench was backfilled and revegetated. The site was released from Radiological Control and the fence was removed.  
**Location:** The site was located northwest of the 300 Area and southwest of the 618-7 Burial Ground.  
**Waste Type:** Chemicals  
**Waste Description:** Historical reports indicated 6,000 kilograms (13,200 pounds) of tributyl phosphate, 10,000 kilograms (22,000 pounds) of paraffin hydrocarbon, and 19,000 liters (5,000 gallons) of uranium-contaminated organic solvents were disposed of in the burial trench. In 1991, this burial ground was excavated. Approximately 2,600 liters (700 gallons) of methyl isobutyl ketone, aka hexone, and 3,400 liters (900 gallons) of kerosene solvent were recovered from 120 drums in the trench's western end. The kerosene solvent was normal paraffin hydrocarbon and tributyl phosphate, known as NPH/TBP. Severely corroded drums were also found at the eastern end of the trench. Approximately 39.6 cubic meters (1,400 cubic feet) of debris was also found, including more than 80 empty drums, a wheelbarrow, scrap process equipment, construction debris, two breached bags of ammonium nitrate, unidentified white powders, and several lead bricks. Debris and soil were removed to the 200 Area Low-level Radioactive Burial Ground. Liquid wastes were sent to licensed off site waste handling facilities.  
**Closure Info:** Interim  
An Expedited Response Action was approved to remove hazardous and radioactive material from this trench. Excavation of the 618-9 Burial Ground began on February 28, 1991. Digging originated at the center of the trench over an area showing anomalies in the geophysical survey. To avoid breaching the drums, soil was machine excavated, leaving 0.3 to 0.6 meters (1 to 2 feet) of overburden. Hand digging was performed on the remaining soil. Approximately 2,650 liters (700 gallons) of methyl isobutyl ketone (hexone) and 3,400 liters (900 gallons) of kerosene were recovered from 42 drums. Over 80 empty barrels were removed, along with a significant amount of scrap process equipment and debris. The initial excavation uncovered a variety of debris covered by 1.2 meters (4 feet) of backfill. The debris included empty waste drums, a wheelbarrow, construction debris (corrugated siding, process vessels, and piping) and two bags of ammonium nitrate fertilizer. Extensive follow-up soil gas and soil sampling showed only insignificant amounts of kerosene. Hexone was not detected. The Expedited Response Action was considered complete in October 1992.  
**Final**  
The group of sites [300 VTS, 300-8, 600-243, 618-7, 618-9, 618-13, 600-290:1] were reclassified to Final Closed Out in 2014. They are listed in the 300-FF-2 Record of Decision and meet the criteria for unrestricted landuse.

| Code: 618-10 | Classification: Accepted |
| Names: 618-10; 300 North Solid Waste Burial Ground; 318-10 | Reclassification: None |
| Type: Burial Ground | Start Date: 3/1/1954 |
**Description:** The site consists of 12 trenches and 94 vertical pipe units. The trenches range in size from 97 meters (320 feet) long by 21 meters (70 feet) wide, 7.6 meters (25 feet) deep to 15 meters (50 feet) long by 12 meters (40 feet) wide, 7.6 meters (25 feet) deep. The vertical pipe units are 56 centimeter (22 inch) diameter, 4.6 meter (15 feet) long waste receptacles constructed by welding five 55-gal (208 L) bottomless drums together. The column of drums were buried vertically. When they reached their waste capacity level, they were backfilled and topped with concrete. The site perimeter is fenced and marked with concrete AC-540 Markers numbered 3-64-1 through 3-64-68. The site has been surface stabilized and vegetated with grasses. The site is posted with Underground Radioactive Material signs.

**Location:** The site is located approximately 4 miles northwest of the 300 Area, west of Route 4 South.

**Release Description:** See UPR-600-1, UPR-600-2 and UPR-600-3.

**Related Sites/Structures:** The site is associated with the 300 Area facilities and the 618-11 Burial Ground.

**Process Description:** The burial ground received a variety of waste from the 300 Area operations. Low level activity waste and large items were placed in the burial trenches. Some high activity waste liquid waste or plutonium contaminated liquid was placed inside barrels and sealed with concrete. The "concrete barrels" were also disposed of in the trenches. Intermediate waste consisted of waste containing between 10 and 1000 curies per cubic foot. High level waste contained greater than 1000 curies per cubic foot. The intermediate and high level wastes were remotely deposited into the vertical pipe units.

**Waste Type:** Chemicals

**Waste Description:** The site contains a broad spectrum of low- to high-level dry wastes, primarily fission products and some transuranic (TRU) from the 300 Area. Low-level wastes are buried in trenches, and medium- to high-level beta/gamma wastes are mostly in the vertical pipe units. Some higher activity wastes were placed in concrete shielded drums and disposed in the trenches. Following a Plutonium Nitrate spill in the 305-B Building (3-3-61) miscellaneous contaminated debris was taken to the 300 North Burial Ground. A plutonium contaminated glove box was shipped to the 300 North Burial Ground on 6-8-60. Document D&D-23840 found evidence of high dose rate waste being placed in the trenches, some dose rates exceeding 20 rad per hour. One 1964 radiation survey provides a hand drawing map of 619-10 and shows where barrels of depleted uranium were placed.

---

**Code:** 618-11  **Classification:** Accepted

**Names:** 618-11; Y Burial Ground; 300 Wye Burial Ground; 318-11  **Reclassification:** None

**Type:** Burial Ground  **Start Date:** 1/1/1962

**Status:** Inactive  **End Date:** 1/1/1967

**Description:** The burial ground perimeter is marked with concrete AC-540 markers numbered 2-68-1 through 2-68-28. The site surrounded by an 2.4 meter (8 foot) chain link fence with a locked gate. The fence labeled 618-11 Burial Ground and posted with Underground Radioactive Material signs. The site consists of three "V" shaped trenches, 2 large diameter caissons and 50 vertical pipe storage units. The trenches are 270 meters (900 feet) long by 15 meters (50 feet) wide (surface dimensions) and 7.6 meters (25 feet) deep. The 50 vertical pipe storage units were made by welding five 208-liter (55-gallon) drums together. The welded drums formed a cylinder 56 centimeters (22 inches) in diameter, 4.6 meters (15 feet) long that was buried.

---

*Hanford Site Waste Management Units Report*
February 2015 1474
vertically. The bottoms of the units were 4.6 meters (15 feet) below ground surface. The units were open to the soil at the bottom. The two large diameter caissons were constructed of 2.4 meters (8 feet) diameter corrugated metal pipe, 3.0 meters (10 feet) long, with the top of the caisson being 4.6 meters (15 feet) below grade, connected to the surface by an offset 91-centimeter (36-inch) diameter pipe with a dome type cap. The caissons were open to the soil at the bottom. The bottoms of the caissons were 7.6 meters (25 feet) below ground surface. An additional 0.6 meters (2 feet) of topsoil was added to the site when it was surface stabilized in 1983.

Location: The site is northwest of the 300 Area, directly west of the Energy Northwest commercial power plant (formerly known as the Washington Public Power Supply System (WPPSS) Plant # 2).

Release Description: There are seven documented Unplanned Releases associated with this burial ground. They are UPR-600-4, UPR-600-5, UPR-600-6, UPR-600-7, UPR-600-8, UPR-600-9, and UPR-600-10.

Related Sites/Structures: The burial ground is associated with 300 Area operations and the 618-10 Burial Ground.

Process Description: The burial ground received a variety of waste from the 300 Area operations. Low level activity waste and large items were placed in the burial trenches. Some high activity waste liquid waste or plutonium contaminated liquid was placed inside barrels and sealed with concrete. The "concrete barrels" were also disposed of in the trenches. Intermediate waste consisted of waste containing between 10 and 1000 curies per cubic foot. High level waste contained greater than 1000 curies per cubic foot. The intermediate and high level wastes were remotely deposited into the vertical pipe units. Contaminants included fission products, plutonium and beryllium.

Waste Type: Oil

Waste Description: The site contains a broad spectrum of low to high level dry wastes, including fission products and plutonium. Low-level wastes in cardboard boxes and large pieces of equipment were buried in the trenches. The trenches also include 55 gallon drums with high activity or small amounts of liquid, encased in cement. Most of the high activity wastes were remotely placed into the pipe storage units and caissons. These wastes were contained in small cans. Historical research related to the burial ground waste inventory resulted in the review of many Radiological Shipment Records (RSR's) and Radiological Survey Records. Document D&D-23840 identifies larger items with significant dose rates were placed in the trenches, as well as drums containing depleted uranium and material contaminated with beryllium, thorium and plutonium. Many of these records were copied and bound into miscellaneous report documents. A summary is included in the 618-11 Expedited Response Proposal. One 1963 memorandum, authored by EA Berreth, indicates that all plutonium waste from the 325 building was to be sent to the 200 Area burial grounds. 325 building waste with high dose rates would be sent to 618-11 burial pipes.

Code: 618-13
Names: 618-13; 618-13 Burial Ground; 303 Building Contaminated Soil Burial Site; 318-13
Type: Burial Ground
Status: Inactive
Description: The 618-13 waste site was remediated in 2009 and Interim Closed Out. The waste site had been of a mound of soil approximately 4.6 to 6.1 meters (15 to 20 feet) high by 38 meters (125 feet) long by 15 meters (50 feet) wide, covered with 0.6 meters (2 feet) of clean soil.
Location: The waste site was located west of the 300 Area, across Route 4 South, adjacent to the excavated 618-9 Burial Ground.
The site was originally a single use disposal site for contaminated soil removed from the 303 Building perimeter in 1950. It is believed that the large mound of soil was added later and served as a safety shield (blast shield) for drums of hexone stored in buildings on the west side of the berm, prior to being buried in the 618-9 Burial Trench in 1954. A concrete building foundation and loading dock remained directly west of the mound (see sitecode 600-290:1).

**Process Description:**

The site was a release to the soil in the area between the 307 Retention Basins and the 340 Hanford Site Waste Management Units Report February 2015

**Waste Type:** Animal Waste

**Waste Description:** This site presumably received uranium contaminated topsoil removed from around the 303 Building area. Total activity buried in the site is not known. During remediation, only soil and a small amount of wood debris was identified. No other debris was found in the soil pile.

**Closure Info:**

The concrete pad and loading dock were remediated in 2009. Field remediation of the 618-13 Burial Ground and the 600-290:1 concrete pad and loading dock occurred between January 5 and February 2, 2009. The activity removed the soil mound, concrete pad, and loading dock. The mound and concrete pad were removed to ground surface level. No sub-grade excavation was required. The excavated material was maintained within the waste site footprint; therefore, no staging piles were generated outside of the waste site boundary. Contaminated soil, pieces of decayed wood, and concrete were the only materials found during remediation of the site. A radiological survey of the 618-13 footprint was done on February 12, 2009. The results indicated the soil beneath the excavated mound was less than two times the background for beta-gamma radionuclides.

Cleanup Verification Package CVP-2009-00005 demonstrates that remedial action at the 618-13 Burial Ground and the collocated 600-290:1 Pad and Loading Dock Near 618-13 has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAOs) established for the unrestricted landuse scenario in the Interim Action Record of Decision (EPA 2001), the Explanation of Significant Differences for the 300-FF-2 Operable Unit (EPA 2004), and the Remedial Design/Remedial Action Work Plan for the 300 Area (DOE/RL 2009b).

The contaminated materials from the site have been excavated and disposed at ERDF. The remaining soil at the 618-13 and 600-290:1 sites have been sampled, analyzed, and evaluated. Results indicate that the site supports future land uses that can be represented (or bounded) by the residential land-use scenario and poses no threat to groundwater or the Columbia River.

**Final**

The group of sites [300 VTS, 300-8, 600-243, 618-7, 618-9, 618-13, 600-290:1] were reclassified to Final Closed Out in 2014. They are listed in the 300-FF-2 Record of Decision and meet the criteria for unrestricted landuse.

---

**Code:** UPR-300-1  
**Classification:** Accepted  
**Reclassification:** Consolidated (10/16/2014)  
**Start Date:** 12/1/1969  
**End Date:** 12/1/1969  
**Description:** The site was a release to the soil in the area between the 307 Retention Basins and the 340 Hanford Site Waste Management Units Report February 2015

1476
Building. There is no readily apparent sign of subsurface contamination beneath the gravel covered area. UPR-300-1, UPR-300-2, and UPR-300-11 sites are adjacent to the 340 facility. Demolition of the facility and remediation of the soil waste site includes the areas of these unplanned release sites. It is not practical to distinguish these sites from the larger site. The UPR sites have been reclassified to Consolidated.

Location: UPR-300-1 occurred in the soil between the 307 Retention Basins and the 340 Building in the 300 Area.

Release Description: A long-duration leak was discovered in the cast iron transfer line between the 307 Retention Basins and the 340 Vault. On December 9, 1969, operators experienced difficulty transferring retention waste from the 307 Basins to the 340 Vault. The next day the pump was tried again and it continued to work at reduced output. Eventually the pump was stopped when water appeared at ground surface between the basins and the 340 building. After stopping the pump, the area of the flooding was excavated and the bottom half of the Retention Basin transfer line adjacent to the junction of the transfer line with the Radioactive Liquid Waste Sewer (RLWS) line was found to be severely corroded. The corroded section of carbon steel pipe discharged approximately 900 curies of short-lived radionuclides (including 10 curies each of strontium-90 and cesium-137) to the soil column over a period as long as a year. Investigation suggested that the cause of the corrosion was RLWS waste backing up into the section of transfer line near the junction.

Related Sites/Structures: UPR-300-1 was associated with the 340 Building/307 Retention Basins transfer line, and the Radioactive Liquid Waste Sewer (RLWS). Well 399-3-8 is also associated with this site. This well was drilled through the middle of the contamination to determine if the plume had reached groundwater in 1970. Review of the site shows that this well has been "missing" for some time. Numerous drawing searches have been performed, aerial photographs have been reviewed, a geophysical study was performed, and site personnel have been interviewed in attempts to locate and determine what happened to the well. The presumed location of the well coincides with the location of RLWS valve box number 8. Construction of valve box number 8 took place in 1970, the last date of well sampling. It is possible that construction activities disturbed the well. Thus, it is possible that the well casing was cut off below grade, or completely removed.

Process Description: The 307 Retention Basins are fed by the Retention Process Sewer (RPS) and discharge to the Process Sewer. In the event that effluent in the 307 Retention Basins does not meet release criteria for the process sewer, the waste is transferred to the 340 Tank vault for storage until it can be transported to the 200 Area Tank Farms.

Waste Type: Storage Tank

Waste Description: The waste discharged to the soil column consisted of process effluent contaminated by transuranic fission products including 900 curies of short-lived radionuclides (mainly promethium-147) and 10 curies each of strontium-90 and cesium-137.

This Site Was Consolidated With:

Code: 340 COMPLEX

Hanford Site Waste Management Units Report
February 2015 1477
Description: The waste site is the result of multiple releases from ongoing decontamination and waste handling activities, starting in January 1954, that affected the soil around the 340 facility. UPR-300-1, UPR-300-2, and UPR-300-11 sites are adjacent to the 340 facility. Demolition of the facility and remediation of the soil waste site includes the areas of these unplanned release sites. It is not practical to distinguish these sites from the larger site. The UPR sites have been reclassified to Consolidated.

Location: UPR-300-2 affected the soil within 3 to 6 meters (10 to 20 feet) of the north, east, and south walls of the 340 Building.

Release Description: Several leaks have occurred that contributed significant amounts of radioactivity to the soil around 340 Building. Soil contamination that extends several feet down adjacent to the 340 Building south wall suggests that the sump (truck tanker loadout) overflowed during the tanker truck era. Strontium-90 has been identified in the soil. The short-lived radionuclides are gone, and the ground surface is stabilized. However, contamination is known to extend several feet into the soil. In the same vicinity, a drain was exposed to allow the draining of tanker trucks for maintenance on the tanker valves. Minor leakage occurred around the drain pipe. This area is also covered and stabilized, but contamination is known to extend several feet into the soil.

A major leak on a retention waste line was discovered December 9, 1969 (See WIDS Site UPR-300-1). The last known ground contamination found in the same area occurred during the V-659 project on October 31, 1977. A leaking tee on the 15.2 centimeter (6 inch) radioactive liquid waste line had gone undetected until the line was uncovered (See WIDS Site UPR-300-11). Known contamination is also present on the north side of the vault. The most affected area is near the northwest corner of the vault (near the control room). A HEPA filter in the vault exhaust system was located there, and condensation from the vault atmosphere collected in the filter enclosure and dripped on the ground. The condition was corrected with the V-677 project, and the surface soil was removed. A potential for low level nuisance contamination is present in the yard, especially downwind (east-northeast) of known problem areas. A systematic search was made for this contamination in 1979, and none was found. Soil samples were taken and surface surveys were made.

Related Sites/Structures: UPR-300-2 is associated with 340 Building processes.

Process Description: The 340 facility was completed in 1953 along with the initial Radioactive Liquid Waste Sewer (RLWS) piping system, the 307 Basins and the Retention Process Sewer (RPS) piping system. These systems represented an attempt to deal with radioactive effluents from several new laboratories in a modern, controlled manner. The 340/307 system was fed by pipelines from the 325, 326, 327, and 329 Buildings (and later the 308 and 325 Buildings) in a system known as the Retention Process Sewer (RPS) or the Diversion Waste System. Liquid process wastes that had the potential to be contaminated were disposed to the RPS and routed to the 307 Basins for sampling. If radioactivity was not detected above release limits, these wastes were disposed to the 307 Trenches. If levels proved to be above release limits, the effluents were pumped into the 340 Building RLWS tanks.

Waste Type: Storage Tank

Waste Description: 10 millicuries of cesium-137 is provided in the original source document and is designated as an estimate only. It is unknown if this was related to a single event or all events over the time period (1954 to date).

This Site Was Consolidated With:
Code: 340 COMPLEX
Names: 340 COMPLEX; 340 Radioactive Liquid Waste Handling Facility; 340 Vault
Reclassification: Final Closed Out (5/12/2014)

Start Date: 1/1/1945
End Date: 1/1/1955

The waste site has been remediated and Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. It consisted of the soil beneath and south of the 321 Building. The 323 building was also known as 321-A. The waste site represents numerous releases that occurred from 1945 to 1988 related to operations in this facility. This time period covers the development of the REDOX, PUREX, RECUPLEX, Metal Recovery and the bismuth phosphate processes, and numerous other pilot operations. No specific occurrence reports have been identified.

UPR-300-4 was located beneath and south of the 321 Building.

Uranium, thorium and uranyl nitrate have been associated with the processes performed in the 321 canyon and basement shop areas. Significant detectable uranium contamination was etched into the concrete of the canyon walls and on cranes, decks, and overhead areas. Modification of the facility over the years required cleaning and painting to contain the contamination. However, drilling or otherwise breaching the surface area released residual uranium/thorium contamination. The use of small quantities of plutonium in the early operations has not been substantiated.

More recent history (radiation surveys) indicated that contamination in and around 321 and 321-A (323 Building) was significant and extensive. Excavation inside the canyon area for the HEDL (FFTF) Hydraulic Core Mock-Up (HCM) uncovered higher concentrations of uranium waste than had been previously reported. A yellow substance (presumably uranyl nitrate) measured 20 millirad per hour and extended 4.6 - 6.1 meters (15 - 20 feet) under the canyon floor and beyond. Cleanup stopped at the depth needed for the HCM. Excavation south of the building also uncovered significant quantities of uranium contamination (25 millirad per hour) and was covered with 0.9 - 1.2 meters (3 - 4 feet) of backfill. A manhole between 321 and 321-A (323 Building) read approximately 75 millirad per hour.

Specific contamination events in the 321 Building included a large explosion of a hexone/nitric acid mixture on January 23, 1949. The explosion occurred in E-Cell when a spark from an electric motor being used to test a turbine pump bearing arced through the air and touched off the mixture. The actual volume was only about 20 gallons of liquid in a 55 gallon drum. The explosion spread uranium powder and solution throughout the canyon and lifted the roof because there were no blow-out panels in the building. Ceilings and floors cracked, but the hard concrete walls did not. The aqueous makeup room in the north portion of the building and the back/south dock that held building process solutions were severely jarred by the event, and some chemicals and process solutions splattered and spilled. An entire drum of uranyl nitrate hexahydrate flew through the air on the back dock, spilling its contents. The cleanup consisted of large and repeated water flushings that spread the contamination to surrounding soils and to the Process Ponds.

Other contamination events in the 321 Building included an explosion and resultant fire in dissolver vessel A-5, in A-Cell in May 1957. The vessel contained enriched (0.95% uranium-235) uranyl nitrate solution. In January 1962, a concentrator experienced overpressurization and sprayed uranyl nitrate hexahydrate as far as the roof of 3706 Building. A release of iodine-131 both within the building and out of the stack occurred during a chlorine gas-scrubbing experiment in 1964. There were many smaller leaks and contamination incidents in addition to these more serious events.
Process Description:
The 321 facility was originally constructed as a pilot scale plant for testing chemical process improvements using unirradiated or low-activity substances. The facility was ultimately used to troubleshoot, research, and develop radioactive processes associated with REDOX, PUREX, RECUPLEX, the Metal Recovery process, and the bismuth phosphate process. Additionally, reactor fuel development and miscellaneous support of the other 300 Area laboratories also took place in the 321 Building.

Over the years, a long list of unplanned releases associated with the 321 Building was compiled. Among these were several sizeable explosions, one of which lifted the building concrete slab roof and cracked the floor of this heavily reinforced structure. The same explosion spread uranium powder around the facility, spilled and splattered various process solutions, and sent a drum of uranyl nitrate hexahydrate hurtling through the air and onto the back dock spilling its contents. In another event, a dissolver vessel over pressurized and sprayed a solution of uranyl nitrate hexahydrate as far as 30.5 meters (100 ft), onto the roof of the 3706 Building.

The primary cleanup method for contaminant releases in and around the 321 Building was to flush the contamination with water and into the surrounding soils, thus accounting for much of the near surface contamination in the soils around the 321 Building. Uranyl nitrate is a yellow substance that is produced during the processing of spent nuclear fuel in preparation for isotopic separation of the uranium and was a major part of the research conducted within the 321 Building.

The 323 Building was also known as 321-A. It provided feed storage in below grade tanks (see 323 Tanks) and lay down space and storage above grade. Four stainless steel tanks (323 Tanks 1, 2, 3, 4) were approximately 14.6 meters long by 3.05 meters in diameter (48 feet long by 10 feet in diameter) located under the 323 Building. They contained uranium/thorium sludge. The tanks were filled with water to reduce corrosion of the tanks. Total quantities of radionuclides and tank volumes were unknown. Reference Drawing H-75032 has details on tank locations, size and elevation. An access door is located in the northeast corner of 323 under a stairwell. Building 323 also contains a shielded cell used for stress analysis of various irradiated fuel cladding materials. Stringent contamination control measures were applied for specimens prepared in 327 Building and transferred to 323. No significant problems have been associated with shielded cell. However, the exhaust duct, primary HEPA filter and downstream exhaust fans and filter plenum located on the south side of 323 have a potential for low level mixed fission product and activation product contamination.

Related Sites/Structures:
This site is associated with the 321 Building and possibly 323 (321-A) Building. It is also associated with the four 323 Tanks.

Five documented miscellaneous stream drains are located around the 321 Building (see "Inventory of Miscellaneous Streams", Revision 3). These sites are identified in WIDS as site codes 300-81, 300-82, 300-83, 300-84 and 300-92. They have been consolidated into the UPR-300-4 waste site.

Waste Type: Storage Tank
Waste Description: Because the 321 Building was a pilot plant, the Building's mission changed a number of times. These mission changes altered the potential contaminants that may have contributed to the soil contamination. Wastes and contamination include all of the components of the many chemical
Processes tested in this facility over the years and result from both waste management practices and from unplanned contamination events and accidents.

Components of the bismuth phosphate process included many acids (nitric, phosphoric, hydrofluoric, oxalic, and others), bismuth nitrate, sodium dichromate, potassium permanganate, calcium, lanthanum and sodium fluorides, ammonium fluorosilicate, peroxide, sodium hydroxide, and other substances. Components of the REDOX process and its development include methyl isobutyl ketone (hexone), aluminum nitrate, ammonium nitrate, many acids (including nitric, sulfuric, oxalic, and others), ferrousulfamate, sodium hydroxide, mercury, resins and other substances.

Components of the Metal Recovery process and the PUREX process were quite similar to each other and included tri-butyl phosphate, normal paraffin hydrocarbon, acids (including nitric, oxalic, and others), ammonium fluoride, ammonium nitrate and other substances.

The RECUPLEX process used tri-butyl phosphate, carbon tetrachloride, many acids (including nitric, oxalic, hydrofluoric, and others), sodium fluoride, sodium hydroxide, and other substances. All of these chemicals became waste constituents, along with trace isotopes of plutonium, uranium, thorium, strontium, cesium, aluminum, iron, copper, and zinc.

Additionally, cell and equipment decontamination reagents, cleansers, and drying materials, including carbon tetrachloride, trichloroethylene, acetone, A-butanone, and many commercial products, became a part of the 321 waste stream.

**Closure Info:** Interim

Remediation of the UPR-300-4 waste site was conducted between February 22, 2011, and January 16, 2013. This included the removal of the 321, 321B, 321C, 321D, 323, and 3718-S building foundations. The four 323 underground tanks and five steam condensate drywells and storm drains (300-81, 300-82, 300-83, 300-84, and 300-92) were also completely removed.

Approximately 24,108 bank cubic meters (BCM) (31,532 bank cubic yards [BCY]) of soil, rock, building debris, and piping were removed from the UPR-300-4 excavation. Of that, approximately 1,945 BCM (2544 BCY) was sampled and designated for use as backfill under a separate agreement with the U.S. Environmental Protection Agency (EPA). The balance of the material removed from the UPR-300-4 excavation was disposed to the Environmental Restoration Disposal Facility (ERDF)

The four 323 tanks, located beneath the 323 building foundation were completely removed as part of the UPR-300-4 scope. This included emptying the 323 waste tanks, removing all the associated debris and the potentially impacted soils surrounding the tanks. Approximately 613,719 L (162,145 gal) of water were removed and disposed to the Effluent Treatment Facility (ETF) in September 2012. Approximately 6,623 BCM (8,663 BCY) of soil, rock, building debris, and piping were removed and disposed to ERDF in 2012. A decontamination pad, located on the west side of the excavation, was remediated on February 14, 2013. Approximately 0.30 meter (1 ft) of soil and rock were removed and disposed to ERDF. This resulted in the removal of approximately 114 tons, or 51.8 BCM (67.8 BCY), of soils.

The excavation of the UPR-300-4 waste site extended to groundwater, at a depth of approximately 15 meters (50 ft) below ground surface (bgs). The design for the excavation facilitated the removal of the structure of the 321 Building down to that level. A concrete footing remains at and below groundwater. During the initial excavation groundwater was uncovered near the concrete footing. Fill material was used, with the concurrence of EPA, to cover groundwater and facilitate the ongoing excavation. During this excavation a visible yellow stain was identified on the south sidewall. The stain was found to contain significant
uranium and is thought to be the result of a release of uranyl nitrate. Uranyl nitrate is specifically listed in the documentation of several of the unplanned released that occurred in and around the 321 facility. The plume associated with the yellow stain was excavated and removed down to the level of groundwater. Contamination extending into the groundwater is beyond the scope of the UPR-300-4 waste site and will be addressed as part of the 300-FF-5 operable unit.

Final

The UPR-300-4, Contaminated Soil Beneath the 321 Building waste site, consisted of contaminated soil around and below the 321 Building including soils below the adjacent 323 Building where waste tanks received liquids via underground piping from operations within the 321 Building. Remediation of the UPR-300-4 waste site, which included removal of the 323 waste tanks and associated piping, was conducted between February 2011, and January 2013 to a maximum depth of 14 meters (46 ft) below ground surface. Verification sampling for the UPR-300-4 waste site was conducted on March 18 and 19, 2013.

The UPR-300-4 waste site was remediated and has been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL's for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Because the remediation of the waste site did not meet residential land use cleanup levels, the waste site requires institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the UPR-300-4 waste site to Final Closed Out.

Description: The site was a release that contaminated the storage basin area, the filter vault, the stack base, the truck stall, and the truck ramp outside the 309 Building. Currently, the truck ramp is paved with asphalt. No radiological postings or markers are present to identify the location of this release.

Location: UPR-300-5 occurred in the 309 Building filter pit, stack base and the truck stall, and the outside truck ramp located on the east side of the 309 Building. The release extended approximately 4 feet (1.2 meter) outside the 309 Building on the truck ramp. The width was the full width of the truck ramp.

Release Description: The release occurred on August 31, 1973. The 309 Fuel Storage Basin water level was found to be slightly low. Water was added to prevent the exposed walls of the basin from drying and causing possible airborne contamination in the basin room. The operator opened the fill line, but became distracted by other activities in the Fuel Basin Storage area. The employees forgot the water supply line was turned on and it was left open overnight. The water filled the basin and began to flow into the overflow drain. The overflow drain line for tank TW-3 is also connected to the drains in the stack filter pit, the stack and the truck stall. The basin overflow caused water in the drains to back up into the filter pit, the stack base and the truck stall. In 1973, the truck ramp sloped below the 309 building grade. The truck ramp filled with 0.68 meters (1.5 feet) of water. The problem was first discovered by an employee who observed water leaking out from under the roll-up door in the truck stall. Since the truck ramp extends outside the building, contamination was found both inside and outside the 309 Building.
UPR-300-5 is associated with the 309 Fuel Storage Basin overflow drain line, the TW-3 Storage Tank, the stack base, the filter vault, truck stall, and the truck ramp.

Waste Type: Storage Tank

Waste Description: The waste was low-level radioactive water. The primary isotope was cesium-137. Surveys of the truck ramp outside of the building and of the truck stall floor within the storage basin area prior to initial decontamination revealed direct radiation levels to 20 millirad per hour and smearable contamination of 30 millirad per hour, respectively. The smearable contamination within the truck stall and on the floor in the storage basin area was initially reduced by flushing with water to levels up to 7,000 counts per minute (wet), 25,000 counts per minute (dry), and 4,000 counts per minute (wet), 10,000 counts per minute (dry), respectively. Further decontamination efforts reduced these levels to 7,000 counts per minute (dry) and 1,000 counts per minute (dry), respectively. Air concentrations remained normal following the incident. No detectable radioactive stack emissions were revealed by the continuous exhaust air monitoring equipment or the air sampling system in the stack pit.

Code: UPR-300-10  Classification: Accepted
Names: UPR-300-10; Contamination Under 325 Building; UN-300-10  Reclassification: None
Type: Unplanned Release  Start Date: 1/1/1977
Status: Inactive  End Date: 1/1/1977
Description: The site was an unplanned release to the soil beneath the northwest corner of the 325 Building.
Location: UPR-300-10 occurred in the radioactive waste sewer line that served the 325-B Hot Cells, between the west basement wall of Room 32 and the north foundation wall of Room 202 of Building 325.
Release Description: Leak testing of the radioactive liquid waste sewer identified a leak between the west basement wall of Room 32 in the 325 Building and the north foundation wall of Room 202.
Related Sites/ Structures: UPR-300-10 was associated with the radioactive liquid waste sewer that served the 325-B Hot Cells.

Process Description: The 325 Radiochemistry Building was built to safely house and handle multi-curie level chemical development work with high activity substances. The High-Level Radiochemistry addition, with its three larger hot cells, housed several pioneering "isotope campaigns". A number of new techniques developed in the 325 Building separated or fractionized specific isotopes from high-level waste by ion exchange, carrier precipitation, solvent extraction, and various combinations of these and other methods. In addition, studies that were part of a Nuclear Waste Vitrification Project took place in the Hot Cells from 1977 to 1980.

Waste Type: Storage Tank

Waste Description: UPR-300-10 included waste from dissolution of highly radioactive samples including irradiated reactor fuels.

UPR-300-11 included waste from dissolution of highly radioactive samples including irradiated reactor fuels.

Code: UPR-300-11  Classification: Accepted
Names: UPR-300-11; UN-300-11; Underground Radioactive Liquid Line Leak near 340 Facility  Reclassification: Consolidated (10/16/2014)
Type: Unplanned Release  Start Date: 10/31/1977
Status: Inactive  End Date: 10/31/1977

Hanford Site Waste Management Units Report
February 2015
Description: The site was a release to the soil that involved a 1.22 meter (4 foot) diameter column of gravel-covered soil in the 340 Complex yard, located immediately south of the 340 Vault. The release occurred around and below a leaking flanged-tee that connected the Retired Radioactive Liquid Waste Sewer (RRLWS) to the 340 Vault. UPR-300-1, UPR-300-2, and UPR-300-11 sites are adjacent to the 340 facility. Demolition of the facility and remediation of the soil waste site includes the areas of these unplanned release sites. It is not practical to distinguish these sites from the larger site. The UPR sites have been reclassified to Consolidated.

Location: UPR-300-11 occurred in the soil on the southeast side of the 340 Building, southwest of the 340 Vault.

Release Description: On October 31, 1977, during a project to install a new double-contained system to replace the old Radioactive Liquid Waste System piping (Project V-659), contamination was found in the soil beneath leaking flanges on a tee section of the RRLWS south of the 340 vault. When sheets of lead shielding were found draped over the old line, a shovel-full of soil was removed from beneath the shielding and counted. Subsequent excavation around the flanged tee revealed contamination caused by effluent leaking from between the flanges. The leak contaminated a column of soil approximately 1.22 meters (4 feet) in diameter and 5.5 meters (18 feet) long. The contamination was first identified approximately 2 meters (7 feet) below the top of the 340 vault. The highest dose rate (5 rads per hour) was measured under the lead sheet draped over the waste line. Smears of the area showed that alpha contamination was also present. At a depth of approximately 7.6 meters (25 feet), contamination spread laterally in an interface between the undisturbed soil and backfill.

Related Sites/Structures: UPR-300-11 is associated with a flanged "tee" connecting the east and west legs of the Retired Radioactive Liquid Waste Sewer (RRLWS) to the 340 Facility. Analysis of the contamination below the "tee" suggested the effluent was derived from 325-A building processes.

Process Description: While in service, the Retired Radioactive Liquid Waste Sewer (RRLWS) system transferred liquid waste from laboratories and facilities in the 300 Area to the 340 Complex for sampling and disposal.

Waste Type: Storage Tank

Waste Description: Soil samples collected near the broken pipe were analyzed and yielded concentrations of 0.2 strontium-90, 0.24 europium-155, 0.09 cerium-144, 0.0017 plutonium-239 and 240, and 0.014 americium-241 and plutonium-238 (all microcuries per cubic centimeter). Approximately 1 curie of contamination was left in place.

This Site Was Consolidated With:

Code: 340 COMPLEX

Names: 340 COMPLEX; 340 Radioactive Liquid Waste Handling Facility; 340 Vault

UPR-300-12 was a release to the soil that involved contamination beneath the floor on the east side of the 325-A Building. The site was an unplanned release to the soil under the floor on the east side of the 325-A Building. The waste migrated through cracks in the floor to the soil beneath the building.
On January 8, 1979, a Pacific Northwest Laboratory (PNL) supervisor located in the 325-A building notified the Westinghouse 340 facility supervisor that approximately 15,140 liters (4,000 gallons) of contaminated liquid needed to be transferred from tank WT-1. Shortly before 1600 hours, the transfer began utilizing a steam jet pump. The jet pump had ran all night and was still operating the next morning. The liquid level on tank WT-1 located indicated decrease approximately 15,140 liters (4,000 gallons) had been transferred. However, the 340 facility reported they had not received the liquid waste. An investigation of the Radioactive Liquid Waste System line-up revealed that an isolation valve on the discharge line, outside the building, was shut, thus precluding discharge of the water to the storage and retention tanks at the 340 Building. The valve was opened and a rush of water was heard. However, the 340 facility storage tank revealed only a negligible amount of water. The 325-A Building was examined for the presence of waste water. Water was noticed on the floor of Room 50-A. No other unexplained volumes of water could be found in 325-A Building. The discharge stop valve for 325-A Building was opened and residual water in the combined drain line allowed to gravity drain to the 340 Building waste storage complex. Tank levels were rechecked and verified that approximately 11,355 liters (3,000 gallons) of low level radioactive water could not be accounted for. A test was initiated in Room 50-A that wetted the floor with 265 liters (70 gallons) clean water. It was estimated that over 189.25 liters (50 gallons) flowed into the confluence of the wall and floor, primarily along the northern and eastern walls. It was the consensus of opinion from all interested parties that the subject water flowed down the drain line, through the sump pump discharge line, into the sump and thence to the floor where it exited through existing cracks to the soil. The floor of Room 50-A in the 325 Building was core drilled to obtain a sample of the earth below the floor. The earth was analyzed to determine if radionuclides present in the soil matched the material that was transferred from the 325-A Building on January 8 and 9, 1979.

The 325 Radiochemistry Building was built to safely house and handle multi-curie level chemical development work with high activity substances. The High-Level Radiochemistry addition, with its three larger hot cells, housed several pioneering "isotope campaigns". A number of new techniques developed in the 325 Building separated or fractionized specific isotopes from high-level waste by ion exchange, carrier precipitation, solvent extraction, and various combinations of these and other methods. In addition, studies that were part of a Nuclear Waste Vitrification Project took place in the Hot Cells from 1977 to 1980.

The site received radioactive rinse water overflow containing nitrate ions, promethium-147, fission products, and transuranic nuclides. The total activity in the rinse water was estimated to be 70 Curies, of which 95% was promethium-147. The rinse water contained nitrate ions, promethium-147, fission products, and transuranic radionuclides. Nitrate ions, but no radionuclides, were detected in samples taken from a nearby groundwater monitoring well. PNL (Occurrence Report #79-2) reports that coring through the cement floor of Room 50-A and sampling of the soils below was completed on January 26, 1979.

### Related Sites/Structures
- UPR-300-12 was associated with the WT-1 Tank, 325 Sump Tank, 325 Overflow Tank, Room 50-A in the 325-A Building and the 340 Complex.

### Process
**Description:**

The 325 Radiochemistry Building was built to safely house and handle multi-curie level chemical development work with high activity substances. The High-Level Radiochemistry addition, with its three larger hot cells, housed several pioneering "isotope campaigns". A number of new techniques developed in the 325 Building separated or fractionized specific isotopes from high-level waste by ion exchange, carrier precipitation, solvent extraction, and various combinations of these and other methods. ### Waste Type
**Description:**

Storage Tank

### Code: UPR-300-17

**Classification:** Accepted

**Reclassification:** Final Closed Out (2/18/2014)

**Start Date:** 1/1/1979

**End Date:** 1/1/1979

**Status:** Inactive

**Description:** The release site has been remediated and Interim Closed Out. It was the asphalt area at the southeast corner of Building 333. The site was not marked or labeled in the field, and its
Location: The site was within a "Radiologically Controlled Area" that surrounded the 333 Building on its north, south and east sides. The asphalt and concrete at the southeast corner of 333 were painted gray and labeled "Fixed Contamination Area." The unpainted asphalt east of the "Fixed Contamination Area" was old and cracked. There was no clear indication where the asphalt was replaced in 1979.

Location: UPR-300-17 was confined to the asphalt area at the southeast corner of Building 333.

Release Description: The site was adjacent to the 618-1 Burial Ground.

Release Description: The release occurred on September 2, 1979, when a garbage can containing oily rags and other waste material caught fire. Rain caused metal shavings, which were believed to be uranium, in the can to ignite. The can was inside a plastic-lined wooden burial box, which also caught on fire. Smoke from the fire contaminated a propane tank located about 3.0 meters (10 feet) away to 500 counts per minute, a forklift about the same distance away to 700 counts per minute, and a 15.2 meter (50 foot) piece of fire hose to 1500 counts per minute. The ground about 0.6 meters (2 feet) from the wooden burial box was contaminated to 15,000 counts per minute for approximately 1.2 meters (4 feet). Contamination was limited to the ground around the wooden burial box, with a radius of approximately 3 meters (10 feet). The propane bottle and forklift were decontaminated and released. The ground and burial box were covered with plastic. According to site personnel, the asphalt in the contaminated area was removed and the area was patched with new asphalt. The effectiveness of the cleanup was not documented.

Release Description: The release occurred on September 2, 1979, when a garbage can containing oily rags and other waste material caught fire. Rain caused metal shavings, which were believed to be uranium, in the can to ignite. The can was inside a plastic-lined wooden burial box, which also caught on fire. Smoke from the fire contaminated a propane tank located about 3.0 meters (10 feet) away to 500 counts per minute, a forklift about the same distance away to 700 counts per minute, and a 15.2 meter (50 foot) piece of fire hose to 1500 counts per minute. The ground about 0.6 meters (2 feet) from the wooden burial box was contaminated to 15,000 counts per minute for approximately 1.2 meters (4 feet). Contamination was limited to the ground around the wooden burial box, with a radius of approximately 3 meters (10 feet). The propane bottle and forklift were decontaminated and released. The ground and burial box were covered with plastic. According to site personnel, the asphalt in the contaminated area was removed and the area was patched with new asphalt. The effectiveness of the cleanup was not documented.

Waste Type: Storage Tank

Waste Description: The waste consisted oily rags and other waste material, including what was believed to be uranium shavings.

Closure Info: Interim

Remediation of the waste site was performed from May 5 through May 11, 2009. Approximately 445 metric tons (490 US short tons) of concrete, asphalt and soil were removed. The soil within the waste site footprint was excavated to a depth of 1 meter (3 ft) below ground surface, and the resulting 195 bank cubic meters (255 bank cubic yards) of soil was disposed at the Environmental Restoration Disposal Facility.

On July 27, 2009, radiological field screening for beta and gamma activity was conducted following the site remedial action to confirm that waste site excavation was complete.

A large portion of the site was documented as having been painted gray, but it is unknown how much of the painted area has been replaced or has worn away over time. Areas within and outside of the formerly painted area were either simply loose gravel or unpainted asphalt, and the boundary of the waste site on the north and west sides of the site were extended to the edges of the 333 Building and 3716 Building. The excavation was performed to remove the fixed contamination area composed of painted or unpainted asphalt and concrete. Also, the excavation for the 618-1 waste site remediation extended into and below the eastern portion of the WIDS boundary for the UPR-300-17 waste site. The area excavated as part of the 618-1 waste site is therefore excluded from the UPR-300-17 waste site remediation scope and will be closed out as part of the 618-1 waste site scope and was closed out as part of the 618-1 waste site scope CVP-2010-00001.

Final

This group of sites [303-M SA, 303-M UOF, UPR-300-17, UPR-300-46, 333 ESHWSA] are listed in the 300-FF-2 Record of Decision. Institutional Controls to maintain industrial land use are required.
The Unplanned Release site has been Interim Closed Out. In 2014, the site was reclassified to Final Closed Out. The contamination resulted from multiple unplanned release events. The 313 building was demolished in 2004 and the foundation/slab was left in place. UPR-300-38 consisted of the contaminated soil beneath the 313 Building, as well as the foundation. The 313 building foundation was removed in 2011. WIDS sites 313 URO and UPR-300-44 were consolidated with UPR-300-38.

The soil contamination is beneath the southern half of the 313 Building. The 313 Building is located at the north end of the main 300 Area (within the security fence). It is located north of Ginko Street, east of the 303K, 305, and 314 Buildings, and west of the 3712 and 3720 Buildings.

Unplanned release site UPR-300-38 represents the area of soil contamination beneath the southern half of the 313 Building. Because of a general failure of the process sewer line beneath the building, any discharges into the process sewer may have contributed to the contamination.

In the early 1970s, during floor repairs in the 313 Building, liquid was observed flowing over the acid brickwork installed beneath the concrete floor. The liquid was collected and processed through the uranium recovery operation. Some of the subfloor was removed and replaced. According to site personnel, the pipe trench (which runs east to west) and the filter press were lined with stainless steel after the spill. The sump in this trench which leads to the process sewer has been grouted.

The contamination is associated with releases from the 313 Uranium Recovery Operations (WIDS Site 313 URO) and the 300 Area Waste Acid Treatment System (300 WATS). WIDS sites 313 URO and UPR-300-44 were Consolidated into UPR-300-38.

Materials released to the soil beneath the building may have included uranium-bearing acid (nitric and sulfuric acid with uranium in solution), neutralized acid waste (typically sodium fluoride, sodium nitrate, sodium dichromate, and sodium sulfate in solution with precipitates of uranium, chromium, copper and zirconium), etch acids (nitric, hydrofluoric, sulfuric, and chromic acids), tetrachloroethene (perchloroethylene), sodium hydroxide solutions, and contaminated water.

The UPR-300-38 waste site consisted of contaminated soil beneath the 313 Building, as well as the foundation. The contamination resulted from multiple unplanned release events. The 313 ESSP (East Side Storage Pad) waste site was the footprint of a large concrete pad adjacent to the southeastern side of the former 313 Building, with an asphalt ramp that connected the pad to Ginko Street. The 300-270 waste site was the area of a release of whitish storm water that came from a pipe under the loading dock on the east side of the former 313 Building. The pipe drained the roof of the former 313 Building.

Remediation of the UPR-300-38 waste site was performed from January 10, 2010, through June 2, 2011. The soil within the northern portion of the waste site footprint was excavated to an
approximate average depth of 1 meter (3.3 ft) below ground surface (bgs). The southern area of the waste site was excavated to an approximate average depth of 2 meters (6.6 ft) bgs, with limited areas of deeper soil contamination to 5 meters (16.4 ft) bgs. The resulting 15,204 bank cubic meters (BCM) (19,887 bank cubic yards [BCY]) of soil was disposed at the Environmental Restoration Disposal Facility (ERDF).

Remediation of a large portion of the 313 ESSP waste site was performed by the excavation of concrete, asphalt, and underlying soil during the remediation of the UPR-300-38 waste site and the adjacent area near the footprint of the former 303-F Building. This work was performed on July 8, 2011. The soil within the waste site footprint was excavated to a depth of 1 meter (3.3 ft) bgs, and the resulting 153 BCM (205 BCY) of soil was disposed at ERDF. Approximately 98 BCM (128 BCY) was associated with the UPR-300-38 excavation; the remainder (55 BCM [72 BCY]) was associated with the 313 ESSP excavation near the footprint of the former 303-F Building. An additional 38 BCM (50 BCY) was removed from the northeast corner and the southern edge of the 313 ESSP waste site on August 26, 2011, resulting in a total of 191 BCM of debris and soil removed from the 313 ESSP waste site.

Remediation of the 300-270 waste site was performed May 23, 2011. The soil within the waste site footprint was excavated to a depth of 0.5 meter (1.6 ft) bgs, and the resulting 40 BCM (52 BCY) of soil was disposed at ERDF.

A total of 15,435 bank cubic meters (20,194 bank cubic yards) of soil and debris from the remediation of all three waste sites was disposed at the Environmental Restoration Disposal Facility.

Final

The UPR-300-38, Soil Contamination Beneath the 313 Building; 313 ESSP, 313 East Side Storage Pad; and 300-270, Unplanned Release at 313 Building waste sites were either within or immediately adjacent to the footprint of the demolished 313 Building. The UPR-300-38 waste site consisted of contaminated soil beneath the 313 Building, as well as the foundation. The contamination resulted from multiple unplanned release events. The 313 ESSP waste site was the footprint of a large concrete pad adjacent to the southeastern side of the former 313 Building, with an asphalt ramp that connected the pad to Ginko Street. The 300-270 waste site was the area of a release of whitish storm water that came from a pipe under the loading dock on the east side of the former 313 Building. The pipe drained the roof of the former 313 Building. Remediation of the UPR-300-38 waste site was performed from January 2010 through June 2011. Remediation of a large portion of the 313 ESSP waste site occurred July 8 and August 26, 2011 and included excavation of concrete, asphalt, and underlying soil. Remediation of the 300-270 waste site was performed May 23, 2011. The maximum depth of the remediation at the UPR-300-38 waste site was 5 meters (16.4 ft) below ground surface. The 313 ESSP and 300-270 waste sites were remediated to 1 meters (3.3 ft) bgs.

The 300-270, 313 ESSP, and UPR-300-38 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Site-specific RESRAD modeling predicts that the radionuclide verification focused sampling results meet the excess cancer risk and allowable radiation dose and are protective of groundwater and the Columbia River under an industrial land use scenario. The remaining verification sampling results show that the site meets the CUL’s for direct exposure and groundwater protection and river protection and support an industrial land use scenario. Contamination at these waste sites did not extend into the deep zone soils. Because the remediation of the waste sites did not meet residential land use cleanup levels, the waste sites require institutional controls to maintain industrial land use. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-270, 313 ESSP, and UPR-300-38 waste sites to Final Closed Out.
UPR-300-39

Description: The waste site has been remediated and Interim Closed Out. The waste site was the soil adjacent to the caustic storage tanks in the 311 Tank Farm. The location and extent of the release was not visibly discernible in the field. The ground around the two tanks was covered by a concrete containment, that was surrounded by more concrete and gravel. The concrete containment was not marked or labeled in any way to warn about excavating in the area. In February 2006, the 311 Tank Farm and concrete containment was demolished, including the two sodium hydroxide tanks that had been labeled "Empty."

Location: UPR-300-39 occurred in the soil adjacent to the caustic storage tanks in the 311 Tank Farm, which is located between the 303-F and 303-G Buildings.

Release Description: An unplanned release occurred in the 311 Tank Farm when one of two 37,850 liter (10,000 gallon) sodium hydroxide tanks leaked. A 50 percent sodium hydroxide solution contaminated soil around the tanks.

Related Sites/Structures: UPR-300-39 was associated with the caustic storage tanks in the 311 Tank Farm.

Process Description: The 311 Building and Tank Farm were constructed to distill methanol for re-use. They operated until 1971 when the last single-pass reactor closed at the Hanford Site. The 311 Building and 311 Tank Farm wastes consisted of chemical spills and leaks (primarily methanol, trichloroethylene and perchloroethylene).

Waste Type: Storage Tank

Waste Description: The waste consisted of caustic solution containing 50 percent sodium hydroxide solution.

Closure Info: Interim

Remediation of the 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste sites was performed from May 24, 2010, through July 20, 2010. The soil within the waste site footprints was excavated to a depth of 1 meter (3.3 ft) below ground surface, and the resulted in 911 bank cubic meters (1,192 bank cubic yards) of soil being disposed at the Environmental Restoration Disposal Facility. On March 8, 2011, radiological field screening for beta and gamma activity was conducted in the 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste site areas. The radiological field screening surveys did not indicate any significant residual radiological activity.

Final

The 300-40, Corrosion of Vitrified Clay Process Sewer Pipe, UPR-300-40, Acid Release at the 303-F Pipe Trench, UPR-300-39, Sodium Hydroxide Leak at 311 Tank Farm, and UPR-300-45, 303-F Building Uranium-Bearing Acid Spill were located in close proximity. The southern section of the 300-40 waste site consists of the area around the footprint of the demolished 303-F Building and 311 Tank Farm. The northern section of the 300-40 waste site is within the footprint of the demolished 3712 Building. The UPR-300-40 waste site is associated with the drain pipe connections between the 303-F Building and the 300 Area process sewer. The waste consisted of uranium-bearing acid waste containing nitric and sulfuric acid with uranium in
solution and chromic acids with copper and zinc in solution. The UPR-300-39 waste site is the soil adjacent to the caustic storage tanks in the 311 Tank Farm. The UPR-300-45 waste site is the soil beneath the former uranium-bearing acid transfer pipeline, adjacent to the 303-F Building. The uranium-bearing acid transfer pipeline ran through the pipe trench from the 333 Building to the valve box at the southeast corner of the 313 Building outside the Uranium Recovery Room. The leak contained uranium-bearing waste acids identified as nitric acid and sulfuric acid with uranium in solution. Remediation occurred in 2010 to a depth of 3 feet.

The 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that concentrations of COCs meet the CULs for direct exposure and groundwater protection and river protection and support a residential land use scenario. Contamination at the 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste sites did not extend into the deep zone (below 4.6 meters [15 ft]). Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not required. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste sites to Final Closed Out.

Remediation of the 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste sites was performed from May 24, 2010, through July 20, 2010. The soil within the waste site footprints was excavated to a depth of 1 meter (3.3 ft) below ground surface, and the resulted in 911 bank cubic meters (1,192 bank cubic yards) of soil being disposed at the Environmental Restoration Disposal Facility. On March 8, 2011, radiological field screening for beta and gamma activity was conducted in the 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste site areas. The radiological field screening surveys did not indicate any significant residual radiological activity.

Final

The 300-40, Corrosion of Vitrified Clay Process Sewer Pipe, UPR-300-40, Acid Release at the 303-F Pipe Trench, UPR-300-39, Sodium Hydroxide Leak at 311 Tank Farm, and UPR-300-45, 303-F Building Uranium-Bearing Acid Spill were located in close proximity. The southern section of the 300-40 waste site consists of the area around the footprint of the demolished 303-F Building and 311 Tank Farm. The northern section of the 300-40 waste site is within the footprint of the demolished 3712 Building. The UPR-300-40 waste site is associated with the drain pipe connections between the 303-F Building and the 303 Area process sewer. The waste consisted of uranium-bearing acid waste containing nitric and sulfuric acid with uranium in solution and chromic acids with copper and zinc in solution. The UPR-300-39 waste site is the soil adjacent to the caustic storage tanks in the 311 Tank Farm. The UPR-300-45 waste site is the soil beneath the former uranium-bearing acid transfer pipeline, adjacent to the 303-F Building. The uranium-bearing acid transfer pipeline ran through the pipe trench from the 333 Building to the valve box at the southeast corner of the 313 Building outside the Uranium Recovery Room. The leak contained uranium-bearing waste acids identified as nitric acid and sulfuric acid with uranium in solution. Remediation occurred in 2010 to a depth of 3 feet.

The 300-40, UPR-300-40, UPR-300-39, and UPR-300-45 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). <tr>
<td>Description:</td>
<td>The site was Closed Out in 1999. It was considered to be Final Closed Out in 2014. The Unplanned Release involved an acid spill to asphalt and soil in the 340 Complex yard. The spilled material was neutralized, absorbed and packed into drums in 1986.</td>
</tr>
<tr>
<td>Location:</td>
<td>UPR-300-41 occurred approximately 4.6 meters (15 feet) west of the 340 Building. Facility personnel do not know the exact location of the spill.</td>
</tr>
<tr>
<td>Release</td>
<td>Three drums, allegedly containing nitric acid, were received from Battelle for use in a charcoal filter efficiency test on April 17, 1986. On June 3, 1986, one of the 55 gallon plastic drums was</td>
</tr>
</tbody>
</table>
found to have failed. Approximately 113.6 liters (30 gallons) of liquid had contaminated part of an asphalt pad and an area of soil next to the pad.

The drum was labeled "Sulfuric Acid." The initial clean up involved using sodium bicarbonate and water to neutralize the acid. The spill area did not respond to the clean up method so a sample of the spilled liquid was analyzed. The results indicated the spilled material was actually phosphoric acid, with high concentrations of chromium, manganese, iron, and nickel in solution. The drum had been labeled incorrectly.

Related Sites/Structures: UPR-300-41 was associated with an asphalt pad west of the 340 Building.

Waste Type: Storage Tank
Waste Description: A detailed analysis on a sample taken from the leaking drum showed the released liquid consisted of phosphoric acid containing 14,000 parts per million chromium, 1,900 parts per million manganese, 1,700 parts per million iron, and 400 parts per million nickel.

Closure Info: Interim

The WIDS Reclassification Form (99-011) states the spilled material was neutralized, absorbed and packed into drums in 1986.

When the original neutralization process did not respond as expected, it was determined the drum was labeled incorrectly. Litmus paper indicated a pH of 6. A sample was collected and determined the drum contents was phosphoric acid containing chromium, manganese, iron and nickel.

Contaminated soils were excavated to a maximum depth of 4 inches. The soil was placed in drums for disposal. The asphalt pad was scrubbed with detergent. Cleanup was judged to be complete when the concentration of chromium in soil samples was less than 5 parts per million.

Final

This group of sites [311 MT1, 311 MT2, 313 MT, UPR-300-41, 600-46] is listed in the 300-FF-2 Record of Decision.

Code: UPR-300-42
Names: UPR-300-42; 300 Area Powerhouse Fuel Oil Spill; UN-300-42
Type: Unplanned Release
Status: Inactive
Description: The waste site has been remediated and Interim Closed Out with the 300-6 waste site remediation. In 2014, the site was reclassified to Final No Action. The group of sites were evaluated and Interim Closed out in a single document and on a single reclassification form (form 2011-107) This release was not visible on the surface. The release was an overflow of Number 6 fuel oil onto the ground adjacent to the Number 2 Day Tank, an underground storage tank. The surface area around the day tanks was paved with asphalt.

Because the unplanned release extended below the powerhouse structure, remediation of UPR-300-42 was deferred until the 384 powerhouse was demolished. During the demolition of the 384 building below-grade structures in 2009-2010, shallow dark, stained soil was encountered near the northwest corner of the building near the approximate location of the 300-223 day tanks and UPR-300-42 waste site. The Post Demolition Summary Report for the 384 and 3503
Buildings (CCN-152459) stated that the UPR-300-42 waste site was removed with the building.

Location: The release occurred adjacent to the Number 2 Day Tank on the north side of the 384 Powerhouse.

Release Description: Due to an automatic shutoff failure, approximately 750 to 1135 liters (200 to 300 gallons) of number 6 fuel oil overflowed from the Number 2 Day Tank and spilled onto the ground.

Related Sites/Structures: UPR-300-42 was associated with the Number 2 Day Tank (WIDS Site 300-223) and the 384 Powerhouse.

Waste Type: Equipment

Waste Description: The release consisted of approximately 750 to 1135 liters (200 to 300 gallons) of #6 fuel oil.

Closure Info: Interim

The 300-6 waste site (fuel oil bunkers) was expected to be excavated to groundwater, a depth of approximately 15.8 meters (52 ft) below ground surface (bgs), as necessary to remediate contaminated soil. Remediation of the waste site was performed from August 2 to December 8, 2010. The western portion of the 300-6 waste site excavation did reach the groundwater, and a pool of water remains in the floor of the excavation. The excavation was approximately 15 meters (49.5 ft) deep in the 300-6 west borehole location (when measured to the surface of the pool of water) and approximately 11.5 meters (37.7 ft) deep in the 300-6 east borehole location.

The 300-6 and associated waste sites' excavation resulted in approximately 34,770 bank cubic meters (45,477 bank cubic yards) of material removed for disposal at the Environmental Restoration Disposal Facility (ERDF).

Debris (piping and concrete) and soil from the remediation of the 300-6 and associated waste sites were direct loaded to ERDF. No overburden soil stockpiles were associated with the waste sites as a result of remediation, and no anomalies were noted.

The 300-123 UIC was identified as a WIDS waste site. The french drain was removed as part of the layback to remove the contaminated soil at the 300-6 waste site. The french drain consisted of soil and rock that extended to approximately 1.4 meters (4.5 ft) bgs. The existing floor of the 300-6 waste site excavation is approximately 11.3 m (37 ft) bgs.

The 300-65, 300-66, 300-122, and 300-124 UICs were located within the footprint of the 300-6 excavation layback and also removed during the 300-6 excavation. The 3715, 303E and 303J building slabs were removed during the 300-6 waste site excavation because they were located in the excavation layback as well.

The 300-268 site was located within the 300-6 layback area. It was excavated to a depth of 3.0 meters (9.8 ft).

During excavation of the 300-6 waste site, it was verified that the eastern half of the 300-273 waste site pipeline had been previously removed. In addition, as the project conducted test pits along the western half of the 300-273 waste site pipeline right-of-way on November 3, 2010, no pipeline structure was encountered at the elevations presented in the as-built drawings for the pipeline (USAEC 1974). Also in November 2010, the project excavated two test pits along the former 384 Powerhouse foundation within the UPR-300-42 waste site. No below-grade structure was noted, and no visible soil staining was observed, as was expected since the site was reportedly removed in 2009.

During excavation of the 300-6 waste site, it was verified that the eastern half of the 300-273 waste site pipeline had been previously removed. In addition, as the project conducted test pits...
along the western half of the 300-273 waste site pipeline right-of-way on November 3, 2010, no pipeline structure was encountered at the elevations presented in the as-built drawings for the pipeline. Also in November 2010, the project excavated two test pits along the former 384 powerhouse foundation within the UPR-300-42 waste site. No below-grade structure was noted, and no visible soil staining was observed, as was expected since the site was reportedly removed in 2009 with the demolition of the 384 powerhouse structure.

Final

The 300 Area Fuel Oil bunkers and associated waste sites were remediated in 2010. The excavation extended to groundwater at a depth of 52 feet. The 300-6, 300-123, 300-268, 300-273, and UPR-300-42 waste sites were remediated and have been evaluated in accordance with the 300 Area Final Action ROD (EPA 2013) and the 300 Area RDR/RAWP (DOE-RL 2014). Verification sampling results show that the site meets the CUL’s for direct exposure and groundwater protection and support a residential land use scenario. Contamination that extended into the deep zone (greater than 4.6 meters [15 ft] bgs) has been removed; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. In accordance with this evaluation, the verification sampling results support a reclassification of the 300-6, 300-123, 300-268, 300-273, and UPR-300-42 waste sites to Final Closed Out.

<tr>
<td>Description:</td>
<td>In January 2010, the UPR-300-46 waste site was remediated by excavating to remove contaminated soil and debris. All debris and excavation materials were disposed into the Environmental Restoration Disposal Facility. The release site was a layer of radioactively contaminated soil found during a pipe trench excavation. There is currently no visual evidence of the release. The area is not marked or posted. The gravel east of the telephone pole along the north perimeter fence appears to be</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
slightly newer than other gravel in the vicinity.

**Location:** The release site was an area of soil inside the 333 building fence. It occurred east of a telephone pole at the north end of the 333 facility property.

**Release Description:** On June 21, 1989, radioactively contaminated soil was discovered while excavating a pipe trench north of the 333 Building. The contamination appeared to be confined to a narrow band of soil approximately 2.5 to 5 centimeters (1 to 2 inches) thick.

**Related Sites/Structures:** UPR-300-46 was associated with the 333 Building and a french drain known as Miscellaneous Stream #455 (See WIDS Site 300-109).

**Waste Type:** Process Effluent

**Waste Description:** The contaminated soil was analyzed, and it was determined that the soil did not contain any significant quantities of hazardous chemicals. The truck load of contaminated soil was disposed of as low-level waste. The contamination was likely caused by a spill of Uranyl Nitrate.

**Closure Info:** Interim

Remediation of the UPR-300-46 waste site was performed from April 28 through June 4, 2009. The soil within the waste site footprint was excavated to a depth of 1 meter (3 ft) below ground surface (bgs), and the resulting 75 bank cubic meters (BCM) (100 bank cubic yards [BCY]) of soil was disposed at the Environmental Restoration Disposal Facility (ERDF). Remediation of the 300-109 waste site was performed from April 28 through April 29, 2009. The soil and asphalt within the waste site footprint were excavated to an average depth of 2.6 meters (8.5 ft) bgs, with a maximum depth of 3.7 meters (12 ft) below ground surface at the location of the drain. The resulting 325 BCM (425 BCY) of soil was disposed at ERDF. The french drain and associated vitrified clay pipe was found and removed during the remediation. The PVC pipe noted in documentation from the 1990's was not found during remediation. A radiological survey was done to confirm the excavations were complete.

This report demonstrates that the 300-109, 333 Building Stormwater Runoff and UPR-300-46, Contamination North of 333 Building sites have met the rural-residential scenario RAOs established in the RDR/RAWP and the ROD. The evaluation shows that the sites have been successfully remediated and that there are no residual hazardous/dangerous materials present above the RAOs in the soil. Therefore, the 300-109 and UPR-300-46 waste sites are protective of human health, groundwater, and the Columbia River.

**Final**

This group of sites [303-M SA, 303-M UOF, UPR-300-17, UPR-300-46, 333 ESHWSA] are listed in the 300-FF-2 Record of Decision. Institutional Controls to maintain industrial land use are required.

</tbody>
</table>
drain elbow.

**Release Description:** On October 23, 1991, during the confirmation of the 325 Building sewer system configuration, a potential problem with one of the drain lines was discovered. As a precaution, residual material at the bottom of the sump was analyzed. This analysis showed the presence of mercury (700 parts per million) in the sample. The presence of mercury in the sump was believed to be a result of prior, not current, building operations. Further analysis of the sewer line discovered an elbow in a feeder line to the main line had deteriorated and allowed liquids to leak to soil under the basement floor. Soil samples were taken and analyzed.

**Related Sites/Structures:** The site is associated with the Process Sewer.

**Waste Type:** Storage Tank

**Waste Description:** The site received radioactive liquid from a leak in the process sewer drain pipe. The site was discovered during dye testing of drains during development of the Facility Effluent Monitoring Plan development for the 325 Building. The contamination may have resulted from routine releases and accumulated in the soil under the crack. Samples of the soil under the drain were analyzed for gross radioactivity and for hazardous metals by TCLP. Radioactivity up to 1700 disintegrations per minute alpha was detected. The TCLP results were below regulatory limits.

**Names:** UPR-600-22; WPPSS Windrow Site; 600-21

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The site consists of a series of small parallel berms, which are approximately 0.6 meters (2 feet), 0.9 meters (3 feet) wide and 91 meters (100 yards) long. The berms are arranged to form a triangle approximately 137 meters (150 yards) by 91 meters (100 yards) long. Perimeter berms are approximately 1.2 meters (4 feet) tall.

**Location:** The site is located west of the Washington Public Power Supply System (WPPSS) Plant #2, adjacent to the north fence of the 618-11 Burial Ground.

**Release Description:** The area was contaminated prior to 1972 with particulate fallout from burial activities in the 618-11 Burial Grounds. UPR-600-9 occurred on April 14, 1967 and indicates a fan-shaped area (approximately 230 meters [250 yards] long and 91 meters [100 yards] wide) was contaminated during a routine cask unloading operation. The contaminated area outside the fence was turned over with bulldozer to bury the contamination.

**Related Sites/Structures:** The site is associated with UPR-600-9 and 618-11.

**Waste Type:** Storage Tank

**Waste Description:** The area was contaminated prior to 1972 with particulate fallout from burial activities in the 618-11 Burial Grounds. The contaminated area was covered by scraping the affected ground into windrows. On October 24, 1972, a backhoe was used to cut across each windrow at a spacing of every 15 meters (50 feet) to a depth of 15 centimeters (6 inches) below ground level. Radiological surveys were made of all soils removed and of the walls of each cut. No beta, gamma, or alpha radioactivity was detected above the normal background of 100 counts/minute.

## Reclassification: Deleted From NPL (9/30/1996) 1100-3; Antifreeze and Degreaser Pit; Antifreeze Pit; UPR-1100-3

### Names:
- 1100-3
- Antifreeze and Degreaser Pit
- Antifreeze Pit
- UPR-1100-3

### Type:
- Depression/Pit (nonspecific)

### Status:
- Start Date: 1/1/1979
- End Date: 1/1/1985
- Inactive

### Description:
The site was originally a gravel pit used as a source of backfill material. This contaminated soils have been cleaned up under the 1100 Area Record of Decision. The site currently appears as a shallow roughly circular depression.

### Location:
The unit is located north of 1171 Building and west of the Hanford Rail Line inside Gravel Pit #3 (Site Code 1100-15).

### Related Sites/Structures:
The waste is related to Hanford construction activities and 1171 Building Operations. The site is associated with Hanford Gravel Pit #3.

### Process Description:
The site was used to dispose of waste construction material. Prior to use as a disposal site, the unit was a sand and gravel pit known as Pit #3 (Site Code 1100-15).

### Waste Type:
- Chemicals

### Waste Description:
Ethylene glycol, degreasing solvents and wash water from engine cleaning may have been disposed of at this site although it is not documented.

## Reclassification: Deleted From NPL (9/30/1996) 1100-4; 1171 Building Spills; Antifreeze Tank Site; UN-1100-4; UPR-1100-4

### Names:
- 1100-4
- 1171 Building Spills
- Antifreeze Tank Site
- UN-1100-4
- UPR-1100-4

### Type:
- Storage Tank

### Status:
- Start Date: 1/1/1976
- End Date: 1/1/1986
- Inactive

### Description:
This site was cleaned up under the 1100 Area Record of Decision. This site is the former location of a steel underground storage tank.

### Location:
The unit was located below grade under the northern section of the 1171 Building.

### Related Sites/Structures:
The was associated with the 1171 Building vehicle maintenance activities.

### Process Description:
The unit temporarily stored waste antifreeze from vehicle maintenance activities. Because there were no risks identified with this site, no further action is required.

### Waste Type:
- Chemicals

### Waste Description:
The unit stored waste antifreeze until removal in 1986. Recent investigations have found metals contamination and slight ethylene glycol contamination.

## Reclassification: Deleted From NPL (9/30/1996) 1100-11; Ephemeral Pool

### Names:
- 1100-11
- Ephemeral Pool

### Type:
- Pond

### Classification:
- Accepted

### Description:
This site was cleaned up under the 1100 Area Record of Decision. This site is the former location of a steel underground storage tank.

### Location:
The unit was located below grade under the northern section of the 1171 Building.

### Related Sites/Structures:
The was associated with the 1171 Building vehicle maintenance activities.

### Process Description:
The unit temporarily stored waste antifreeze from vehicle maintenance activities. Because there were no risks identified with this site, no further action is required.

### Waste Type:
- Chemicals

### Waste Description:
The unit stored waste antifreeze until removal in 1986. Recent investigations have found metals contamination and slight ethylene glycol contamination.
**Status:** Inactive  
**End Date:** 1/1/1995  
**Description:** The site has been regraded to a smooth, uniform surface. The Ephemeral Pool site was a long, narrow depression designed to act as a drainage collection point for precipitation runoff flowing from the 1171 parking area. The north and south boundaries of the site were not distinct because the depression gradually rose toward both the north and south to near the elevation of the surrounding land. Settlement and/or poor grading of the depression floor resulted in the formation of a series of linked pools after rainfall events that temporarily held a portion of the collected moisture within the drainage way until it evaporated or infiltrated into the ground. A pervious gravel lining encouraged infiltration of the collected runoff into the vadose zone beneath this site.  
**Location:** The Ephemeral Pool was located west of the 1171 parking area, near the U.S. Government Railroad lines.  
**Related Sites/Structures:** The site is associated with the 1171 parking area.  
**Waste Type:** Barrels/Drums/Buckets/Cans  
**Waste Description:** The site was designed to receive stormwater runoff from the adjacent 1171 Building parking area.

|            |                |                                                                      |                                        |               |            |          | Waste Type: Water  
**Waste Description:** During the remedial investigation of the site, a small amount of medical waste was discovered. It consisted of a milky white substance, an eye dropper bottle with clear liquid and another bottle with clear liquid. A single plastic intravenous dispenser bag was also found. Because of the unknown hazards associated with this waste, it was reburied in the landfill.  
**Waste Type:** Water  

---

*Hanford Site Waste Management Units Report*

February 2015
Waste Description: Asbestos was found to be distributed throughout the landfill.

Waste Type: Water

Waste Description: Various types of construction debris were found at the site.

Waste Type: Water

Waste Description: Automotive debris was found in all areas of the landfill. Stainless steel lathe shavings were found in the central portion of the landfill. Miscellaneous trash including paint containers was also found at the site.

Waste Type: Water

Waste Description: Hydraulic oil contaminated with polychlorinated biphenyls was disposed at the site.

Closure Info: Remedial actions began January 3, 1995 at the site. Fourteen characterization boreholes were drilled. Sixty three surface and subsurface soil samples were collected during Phase I and twenty one soil samples were collected during Phase II Remedial Investigations. Geophysical and soil gas sampling was also done. Eight exploration trenches were excavated. Tires found in an open trench at the site were radiologically surveyed and removed for recycling. Approximately 1,230 cubic meters (1,608 cubic yards) of polychlorinated biphenyl (PCB) contaminated soil was removed from the site and disposed in Arlington, Oregon. A 25 acre soil cap was placed over the landfill. The soil cap was revegetated.

Five groundwater monitoring wells were installed in August 1995, down gradient from the landfill.

---

Code: UPR-1100-5
Names: UPR-1100-5; 1171 Parking Lot; UN-1100-5
Type: Unplanned Release
Status: Inactive
Start Date: 1/1/1962
End Date: 1/1/1962
Description: The site of the release was a transport truck in the 1171 Building parking lot.
Location: The release occurred in the parking lot northwest of 1171 Building.
Release Description: A missing O-ring resulted in zirconium and plutonium oxide contaminated water being released from a transport truck carrying liquid waste from Idaho. The truck was decontaminated. Although additional corrective action may have been provided, there are no documents describing the cleanup of the parking lot.
Related Sites/Structures: The release was related to a transport truck from Idaho.
Waste Type: Process Effluent
Waste Description: The chemical release consisted of water in which metal specimens were immersed. One metal capsule ruptured contaminating the water with zirconium and plutonium oxides.

Classification: Accepted
Reclassification: Deleted From NPL (9/30/1996)

---

Code: UPR-1100-6
Names: UPR-1100-6; Discolored Soil Site; UN-1100-6
Classification: Accepted
Reclassification: Deleted From NPL (9/30/1996)
Type: Depression/Pit (nonspecific)

Status: Inactive

Start Date: 
End Date: 1/1/1995

Description: The site was a patch of oily, dark-stained soil within an elongated east-west oriented depression. This site was remediated in 1995 under the 1100-EM-1 Record of Decision.

Location: The site was located northwest of the 1171 Building, in a depression west of the Hanford Rail Line and southeast of an irrigation canal.

Release Description: The source of the soil discoloration is conjectured to be the isolate, unauthorized disposal of one or more containers of liquid material to the ground surface. No records exist that explain the nature or origin of the material found at the site.

Related Sites/Structures: adjacent to Gravel Pit #1

Process Description: The site was used for the isolated, unauthorized disposal of liquid waste.

Waste Type: Storage Tank

Waste Description: The site consists of dark-colored, oily residue, and soil. The material includes metal, organic, and pesticide contaminants. Bis(2-ethylhexyl)phthalate (BEHP) and chlordane were identified. BEHP is a probable human carcinogen.

Closure Info: Fifteen soil samples were collected during the Phase I, 1100 Area Investigation. Contaminants identified included lead, potassium, zinc, alpha-chlordane, gamma-chlordane, 4,4"-DDE, bis(2-ethylhexyl) phthalate (BEHP), heptachlor, 3-hexanone, di-n-octylphthalate and 1,1,1-trichloroethane. In Phase II, fourteen soil gas probes were installed to depths ranging from 0.46 meters (1.5 feet) to 1.22 meters (4 feet). No contaminants were identified in the soil gas samples. The remedial action chosen was to excavate 90 cubic yards of contaminated soil.

The soil was removed on February 14, 1995 and transported to a permitted, offsite incinerator (Aragonite, Utah). After incineration, the residuals were disposed of in that facility's ash disposal landfill.
**1100-EM-2**

**Code:** 700 WST  
**Names:** 700 WST; 703-1; 700 Area Underground Waste Solvent Tank; 700 Area Waste Solvent Tank  
**Type:** Storage Tank  
**Status:** Inactive  
**Start Date:** 1/1/1989  
**End Date:** 1/1/1989  
**Classification:** Accepted  
**Reclassification:** Deleted From NPL (9/30/1996)  

**Description:** The waste site was an underground steel storage tank that was removed and examined. The tank was empty. There was a thick crust of soil over much of the tank bottom that prevented a detailed observation of the tank. There were no obvious holes. The waste site was Deleted from the NPL.

**Location:** This site was located east of the 703 Building approximately 30.5 centimeters (12 inches) from the foundation. The long axis of the tank was north-south. The top of the tank was approximately 45.7 centimeters (18 inches) below grade.

**Waste Type:** Stormwater Runoff  
**Waste Description:** The unit contained combustible solution of aliphatic hydrocarbons with 162 parts per million of 1,1,1-trichloroethane.

**Closure Info:** In 1989, the tank was excavated (but still in place), there was an odor of solvents. The soil around the tank was stained dark in places. Readings of the excavation with an HNU model F1 101 10.2 Electron Volt lamp (photo ionization organic vapor detector) showed breathing zone of 3 parts per million, varying from 0-4 parts per million with occasional spikes greater than 7 parts per million. The narrow space beneath the tank read greater than 20 parts per million. HNU readings less than 2.5 centimeters (1 inch) from the soil surface seemed to indicate greater contamination near the south end of the tank impression (after pulling the tank).

Soil was removed from the south end of the tank impression using a backhoe and non-decontaminated shovels.

During the excavation, surface contamination was reported above the tank. Contaminated surface soil was disposed of in five 208 liter (55 gallon) drums by Operations Support Services (OSS) during excavation. Drum contents were sampled analyzed. The drums and the tank were removed from the site by OSS personnel.

**Code:** 1100 BSUHR  
**Names:** 1100 BSUHR; 1100 Area Bus Shop Underground Hoist Rams  
**Type:** Storage Tank  
**Status:** Inactive  
**Start Date:** 1/1/1953  
**End Date:**  
**Classification:** Accepted  
**Reclassification:** Deleted From NPL (9/30/1996)  

**Description:** This site was cleaned up under the 1100 Area Record of Decision. The 1100 BSUHR Site consists of four single manifold, triple tank hoists. Each is related to the 1171 Building Maintenance activities.

**Location:** The units are located within the 1171 Building Bus Shops.

**Related Sites/Structures:** The site is associated with the 1171 Building Maintenance activities.
### Process Description:
The storage tanks hold hydraulic oil for the operation of the hoists.

### Waste Type:
Stormwater Runoff

### Waste Description:
The units contain non-PCB hydraulic oil.

**Description:** The site consists of a concrete pad that was used to store waste containers.

**Location:** The hazardous waste staging area was located at the northeast corner of the 1208 Building Shop in the 3000 Area.

**Related Sites/Structures:** The hazardous waste staging area was associated with the 1208 Building Paint Shop.

**Process Description:** The unit was used to stage hazardous waste for periods less than 90 days.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** Typical wastes contained in the staging area included paints and solvents. The unit received approximately 300 gallons (1,140 liters) per year.

**Description:** This site is an open area surrounded by a fence. Access was controlled by a single locked gate. This site was used for the storage of raw and structural materials. The Simulated High-Level Waste Treatment and Storage (SHLWST) sites were located within this site. The SHLWST was a permitted Treatment, Storage, and Disposal (TSD) unit that was clean closed.

**Location:** This site is located just southwest of the intersection of Stone Street and "W" Avenue.
### Related Sites/Structures:
This site was associated with the Simulated High-Level Waste Slurry Treatment and Storage (SHLWST).

### Waste Type:
Stormwater Runoff

### Waste Description:
This area was used for storage of raw materials and equipment. Raw materials included grout used in the Simulated High-Level Waste Slurry Treatment/Storage.

### Description:
The release site was a sink used only for nonradioactive work in Room 1623 of the Physical Science Laboratory Building. A sign was installed by the sink and the whole middle island was designated plainly as a cold region. The whole middle island was marked with floor tape and a bench top tape to plainly segregate the area from the radioactive area.

### Location:
UPR-3000-1 originated in the sink in Room 1623 of the Physical Science Laboratory Building. The Physical Science Laboratory Building lies west of the Math Building, south of the Engineering Development Laboratory, and northeast of the intersection of Battelle Boulevard and Stevens Drive in the 3000 Area.

### Release Description:
A technician disposed of 1,650 milliliters of waste cesium-134 solution into a cold drain that empties into the Richland City sewer system.

<td>Description:</td>
<td>The area was evaluated, Deleted from the NPL and reclassified in 1996. This site consisted of a former U. S. Army Nike Missile Base. The base is split into two parts: the radar site is on top of Rattlesnake Mountain and the missile launch area is at the foot of Rattlesnake Mountain on the southeast slope. Some of these facilities were subsequently used by Battelle Northwest. The following buildings are found at the site: 6652C (Space Science Laboratory), 6652CSHED (Storage Building), 6652D (Pumphouse), 6651DOME1 (Observatory), 6652DOME2 (Small Observatory), 6652E (Garden Building), 6652G (ALE Field Storage), 6652H (ALE Laboratory I), 6652I (ALE Headquarters), 6652J (ALE Laboratory II), 6652K, 6652L (Underground Missile Bunkers), 6652LP (Rattlesnake Mountain Lower Pumphouse), 6652M (Fallout Laboratory), 6652O (Missile Assembly and Test Building), 6652P (Generator Building), 6652R (Paint Shed/ Flammable Storage Block Shed), and 6652UP (Rattlesnake Mountain Upper Pumphouse).</td>
<td></td>
<td></td>

</tbody>
</table>
In 2010, footprint reduction activities were done on the Fitzner/Eberhardt Arid Lands Ecology Reserve (ALE). Structures on the Upper ALE included research facilities, storage buildings, water storage tanks and distribution piping, and electric and communications wires and cables both aboveground and below ground. The slabs were removed, and utilities were disconnected and excavated to 0.9 meters (3 ft) below grade. Septic tanks and drain fields were properly closed (per WAC code) and left in place.

Removal of excess buildings at the Upper ALE eliminated approximately 750 square meters (8,100 sq. ft) of existing facilities, along with excess power and phone lines, and a quantity of miscellaneous debris. When considering the removal of roads, parking areas, utilities, and other use areas that supported building operations, the developed footprint at the top of the ridge was reduced from approximately 43,432 square meters (467,500 sq. ft.) to approximately 3,716 square meters (40,000 sq. ft.). In addition, the height of the communication towers was reduced from a total of 192 vertical meters (630 ft) to 91 vertical meters (300 ft). Miscellaneous debris collected on the Upper ALE is listed with demolition debris. The two waste streams were consolidated for disposal.

Upper ALE structures removed included 623A, 6631, 6632, 6633, 6635, 6636, 6637, 6652C, 6652CSHED, 6652G, 6652T and 6652U.

Lower ALE structures removed included 6652G, 6652H, 6652J, 6652M, 6652R and 6652S.

Septic tanks and drain fields were closed and left in place.

Location: The site is located at the summit of Rattlesnake Mountain and the toe of the southeast slope of Rattlesnake Mountain.

Related Sites/Structures: Site Codes 600-112, 600-113, 600-114, and 600-115 are septic tanks associated with this site. Septic tanks and drain fields were closed and left in place. Sites 600-270 Horseshoe Landfill and 600-271 Nike Missile Base Landfill have also been deleted from the NPL.

The following buildings were associated with the missile base: 6652C (Space Science Laboratory), 6652CSHED (Storage Building), 6652D (Pumphouse), 6651DOME1 (Observatory), 6652DOME2 (Small Observatory), 6652E (Garden Building), 6652G (ALE Field Storage), 6652H (ALE Laboratory I), 6652I (ALE Headquarters), 6652J (ALE Laboratory II), 6652K, 6652L (Underground Missile Bunkers), 6652LP (Rattlesnake Mountain Lower Pumphouse), 6652M (Fallout Laboratory), 6652O (Missile Assembly and Test Building), 6652P (Generator Building), 6652R (Paint Shed/Flammable Storage Block Shed), and 6652UP (Rattlesnake Mountain Upper Pumphouse).

The following buildings were used by PNNL and are recorded as being contaminated as of 1998 (source: 1998 Vulnerability & Legacy Report - ALE Buildings - not available): 6652C, Space Science Laboratory on top of Rattlesnake Mt., including 6652D, the Fire System Pumphouse (lead-based paint, PCBs in light fixture ballasts, mercury switches, and asbestos insulation are suspected based on the age of the facility) 6652C-SHED, also on top of Rattlesnake Mt., includes both an upper pumphouse (6652-UP) and Lower Pumphouse (6652-LP) (The shed has asbestos siding and shingles). 6652E, the Garden Building (Sealed neutron probes are stored in the building as of 11/6/1998 for field tests).

6652DOME1 This is the observatory on Rattlesnake Mt. (A slight potential exists for lead-based paint and mercury switches). This facility is still (8/2001) operating and under the control of Alliance for the Advancement of Science through Astronomy (AASTA).

6652G, the ALE Field Storage building (The building has asbestos tiles, siding, and insulation,
The site is a former NIKE missile base consisting of structures which supported missile launch, control, and maintenance functions, as well as living quarters for base personnel and storage buildings for hazardous substances used in the maintenance of the physical plant and missile operations. As of July 1999, all base facilities had been abandoned with the exception of 6652L, the underground missile bunkers, which were actively being used for an experiment according to a sign outside the door. The large observatory (Dome 1) is also still operating (as of 8/2001) and under the control of a non-profit organization, the Alliance for the Advancement of Science through Astronomy.

6652H and 6652I (Connected buildings; Labs 202, 204, and 206 previously contained radioactively contaminated equipment and ductwork, including HEPA filters these were removed in August 2000. Also reported at the site in the Vulnerability and Legacy report are PCBs, which may be in transformers and ballasts, lead-based paint may have been used for the building, asbestos tile and insulation are present, and mercury may be in switches and thermostats).

6652J (Lead-based paint and lead sheets in the vent lines are possible, mercury is expected in the thermostats, and floor tiles are asbestos).

6652L, the Nike missile bunkers (PCBs are expected in light ballasts, lead is expected in the paint, lead batteries, and in the form of 20 tons of lead bricks, mercury is suspected in light switches, freons are expected in the refrigerant system, and asbestos is in the tiles, insulation, and siding).

6652M, the Fallout laboratory (There is potential for lead-based paint and lead around the vent pipes on the roof).

**Process Description:**

The site contains PCB's from transformers, asbestos in insulation, tiles, and siding, mercury in switches, and lead-based paint and bricks in various buildings.

**Closure Info:**

The area was evaluated, Deleted from the NPL and reclassified in 1996. Structures were removed in 2010.

Prior to intrusive investigations at the two landfills, Horseshoe and Nike Base, geophysical surveys were conducted by Golder to identify areas where wastes were present. Eleven anomalous areas within the 2.8 hectare (6.9 acre) Horseshoe Landfill site and nine anomalous areas within the 1.9 hectare (4.6 acre) Nike Base Landfill were identified. (See Sitecodes 600-270 and 600-271).

In 1994, Geophysical investigations were done to identify underground storage tanks (USTs) in the area. Two 7600 liter (2000 gallon) underground fuel storage tanks were identified at buildings 6652-G and 6652-H. These two tanks were removed. The soil beneath the tanks was sampled and found to be clean. 4.6 cubic meters (6 cubic yards) of petroleum contaminated soil was found inside another underground fuel storage tank at 6652-G. This soil was taken to a landfarm in to 100 Area. Other UST's were identified at 6652-H, 6652-I and 6652-J. One abandoned fuel oil UST, with an unknown volume, was found south of 6652-H. One 22,800 liter (6000 gallon) underground diesel fuel tank was identified near the observatory dome, at 6652-C. This tank was closed in place in 1994.
In 2010, footprint reduction activities were done on the Fitzner/Eberhardt Arid Lands Ecology Reserve (ALE). Structures on the Upper ALE included research facilities, storage buildings, water storage tanks and distribution piping, and electric and communications wires and cables both above ground and below ground. The slabs were removed, and utilities were disconnected and excavated to 0.9 meters (3ft) below grade. Septic tanks and drain fields were closed and left in place. Septic tanks were cleaned and closed in accordance with WAC 246-272A-0300, "On-Site Sewage Systems, Abandonment," as part of the building removal process on the Upper ALE and Lower ALE, including the tank at Building 646 at Rattlesnake Springs.

Removal of excess buildings at the Upper ALE eliminated approximately 750 square meters (8,100 sq. ft) of existing facilities, along with excess power and phone lines, and a quantity of miscellaneous debris. When considering the removal of roads, parking areas, utilities, and other use areas that supported building operations, the developed footprint at the top of the ridge was reduced from approximately 43,432 square meters (467,500 sq. ft.) to approximately 3,716 square meters (40,000 sq. ft.). In addition, the height of the communication towers was reduced from a total of 192 vertical meters (630 ft) to 91 vertical meters (300 ft). Miscellaneous debris collected on the Upper ALE is listed with demolition debris. The two waste streams were consolidated for disposal.

Upper ALE structures removed included 623A, 6631, 6632, 6633, 6635, 6636, 6637, 6652C, 6652CSHED, 6652G, 6652T and 6652U.

Structures on Lower ALE that were not in use by US Fish and Wildlife Services (6652-E, -K, -O, -PH) or to support ongoing gravitational studies (6652-L) were demolished as part of the footprint reduction activities. In addition, Hodges Well, located along the 106 Road to the ridgeline, was removed, along with the power lines and poles that supplied electricity to the well. Building slabs were removed, and utilities were disconnected and excavated to 0.9 meters (3 ft) below grade. Septic tanks and drain fields were closed (properly abandoned) and left in place.

Lower ALE structures removed included 6652G, 6652H, 6652I, 6652J, 6652M, 6652R and 6652S.

Approximately 3,300 square meters (35,500 sq. ft.) of facilities were demolished and removed from the Lower ALE. Considering parking areas, roads, and other developed sites, approximately 74,000 square meters (800,000 sq. ft.) of disturbed land will be restored by planting native vegetation. Approximately 2,464,564 kilograms (5,422,040 lb) of building rubble was generated from the demolition of structures at the Lower ALE. In addition to the removal of structures, numerous debris items totaling 178,372 kilograms (329,418 lb) were removed in the vicinity of the Lower ALE.

Code: 216-A-16  Classification: Accepted
Names: 216-A-16; 216-A-16 Dry Well  Reclassification: None
Type: French Drain  Start Date: 1/1/1956
Status: Inactive  End Date: 3/1/1969
Description: The unit is composed of bell-end concrete pipe, 1.8 meters (6 feet) long, placed vertically 3.4 meters (11 feet) below grade. The unit is rock-filled with a 1.9-centimeter (3/4-inch) carbon-steel cover. A 5-centimeter (2-inch) steel vent riser extends 0.9 meters (3 feet) from the top. There is a carbon steel inlet pipe, approximately 0.6 meters (2 feet) long coming from the 216-A-17 French Drain.
Location: The french drain is located in the southeast corner of the 241-A Tank Farm, inside the tank farm fence.
Process Description: The site received the floor drainage and the 296-A-11 Stack drainage from the 241-A-431 Building.
Waste Type: Oil
Waste Description: The site received the floor drainage and the 296-A-11 Stack drainage from the 241-A-431 Building. The waste is low in salt, neutral to basic, and contains less than 10 curies total beta activity.

Type: French Drain  Start Date: 1/1/1956
Status: Inactive  End Date: 1/1/1969
Description: The unit is composed of bell-end concrete pipe, 1.8 meters (6 feet) long, placed vertically 3.3 meters (11 feet) below grade. The unit is rock-filled with a carbon steel cover. The side slope of the excavation is assumed to have been 1:1.
Location: The french drain is in the southeast corner of the 241-A Tank Farm, inside the tank farm fence.
Waste Type: Construction Debris
Waste Description: The site received the floor drainage and the 296-A-11 Stack drainage from the 241-A-431 Building. The waste is low in salt, neutral to basic, and contains less than 1 curie total beta activity.

Code: 216-A-23A  Classification: Accepted

Hanford Site Waste Management Units Report
February 2015
### French Drain

**Names:** 216-A-23A; 216-A-23-A French Drain  
**Reclassification:** None

**Type:** French Drain  
**Start Date:** 9/1/1957

**Status:** Inactive  
**End Date:** 3/1/1969

**Description:** The unit is a 1.07-meter (3.5-foot) diameter, 1.8-meter (6-foot) long bell-end concrete pipe, placed vertically 1.98 meters (6.5 feet) below grade. The concrete pipe is filled with 0.9 meters (3 feet) of rock and has a carbon steel cover. A 5.1-centimeter (2-inch) carbon steel vent riser extends from the top to 0.9 meters (3 feet) above grade. A Schedule 80 steel inlet pipe enters approximately 2.7 meters (9 feet) below grade.

**Location:** This waste site is located in the southeast corner of the 241-A Tank Farm, just south of the 241-A-431 Fan House building.

**Related Sites/Structures:** The french drain is associated with the 241-A-431 Building. The 216-A-23-A French Drain is connected to the 216-A-23-B French Drain, located 3 meters (10 feet) to the west, by an underground overflow pipe.

**Process Description:** The site received the deentrainer tank condensate and the back flush waste from the 241-A-431 Building.

**Waste Type:** Equipment

**Waste Description:** The site received the deentrainer tank condensate and the back flush waste from the 241-A-431 Building. The waste is low in salt, neutral to basic and contains less than 50 curies total beta activity. The total amount discharged by this waste stream, 6,000 liters (1,580 gallons), applies to both A-23A and A-23B.

---

### 216-A-23B

**Names:** 216-A-23B; 216-A-23-B French Drain  
**Reclassification:** None

**Type:** French Drain  
**Start Date:** 1/1/1957

**Status:** Inactive  
**End Date:** 1/1/1969

**Description:** The unit is a 1.07-meter (3.5-foot) diameter, 1.8-meter (6-foot) long bell-end concrete pipe, placed vertically 1.98 meters (6.5 feet) below grade. The unit is filled with 0.9 meters (3 feet) of rock and has a carbon steel cover. The side slope is assumed to be 1:1.

**Location:** This site is located in the southeast corner of the 241-A Tank Farm, just south of the 241-A-431 Fan House.

**Related Sites/Structures:** The french drain is associated with the 241-A-431 Building. The 216-A-23-B French Drain is connected to the 216-A-23-A French Drain by an underground overflow pipe.

**Process Description:** The site received the deentrainer tank condensate and the back flush waste from the 241-A-431 Building.

**Waste Type:** Vegetation

**Waste Description:** The site received the deentrainer tank condensate and the back flush waste from the 241-A-431 Building. The waste is low in salt, neutral to basic and contains less than 5 curies total beta activity. Total waste stream discharge was 6,000 liters (1,580 gallons) to the 216-A-23A and 216-A-23B French Drains.

---

### 241-A-A

**Names:** 241-A-A; 241-A-A Diversion Box; 241-A-A  
**Reclassification:** None

**Type:** French Drain  
**Start Date:** 1/1/1957

**Status:** Inactive  
**End Date:** 1/1/1969

**Description:** The unit is a 1.07-meter (3.5-foot) diameter, 1.8-meter (6-foot) long bell-end concrete pipe, placed vertically 1.98 meters (6.5 feet) below grade. The unit is filled with 0.9 meters (3 feet) of rock and has a carbon steel cover. The side slope is assumed to be 1:1.

**Location:** This waste site is located in the southeast corner of the 241-A Tank Farm, just south of the 241-A-431 Fan House.

**Related Sites/Structures:** The french drain is associated with the 241-A-431 Building. The 216-A-23-B French Drain is connected to the 216-A-23-A French Drain by an underground overflow pipe.

**Process Description:** The site received the deentrainer tank condensate and the back flush waste from the 241-A-431 Building.

**Waste Type:** Vegetation

**Waste Description:** The site received the deentrainer tank condensate and the back flush waste from the 241-A-431 Building. The waste is low in salt, neutral to basic and contains less than 5 curies total beta activity. Total waste stream discharge was 6,000 liters (1,580 gallons) to the 216-A-23A and 216-A-23B French Drains.

### Names

### Type

- Single-Shell Tank

### Status

- Inactive

### Description

The unit is carbon-steel lined, with a reinforced concrete shell, dome, and base. The dome is located below grade for shielding. This is a third-generation tank with an increased operating depth and a flat (instead of dished) bottom.

### Location

The 241-A-104 tank is located in the western portion of the 241-A Tank Farm.

### Process Description

The tank is used for the storage of mixed waste generated at Hanford.

### Waste Type

Sanitary Sewage

### Waste Description

The tank contains non-complexed waste.

---

## Tank 241-A-105

**Waste Description:**

### Description

The unit is carbon-steel lined, with a reinforced concrete shell, dome, and base. The dome is located below grade for shielding. This is a third-generation tank with an increased operating depth and a flat (instead of dished) bottom.
Location: The 241-A-106 tank is located in the eastern portion of the 241-A Tank Farm, north of than 241-A-103.

Process Description: The tank is used for the storage of mixed waste generated at Hanford.

Waste Type: Equipment

Waste Description: Tank 241-A-106 received deentrained waste and condensate waste from the boiling waste tanks in the A Tank Farm from 1957 to 1960. The waste is classified as concentrated phosphate.

---

Code: 241-A-152
Names: 241-A-152; 241-A-152 Diversion Box
Type: Diversion Box
Status: Inactive

Description: This diversion box is a reinforced concrete structure containing four stainless steel transfer pipes and adequate space to allow for jumper replacement activities. The major portion of the diversion box is below grade with concrete cover blocks and lifting hooks.

Location: The unit is located inside the 241-A Tank Farm fence, east of the 241-A-106 Tank.

Process Description: This unit routed waste from 241-A-151 Diversion Box to 241-CR-151 Diversion Box through a pipe encasement containing four stainless steel lines.

Waste Type: Steam Condensate

Waste Description: The diversion box contains lead shielding.

---

Code: 241-A-153
Type: Diversion Box
Status: Inactive

Description: This diversion box is a reinforced concrete structure sized to accommodate the pipes and provide space for jumper replacement. The 241-A-153 is one type of diversion box, known as a transfer box. It connects one common pipe to several others, one at a time, uses only one jumper and has the several nozzles arranged in a circle about the common nozzle.

Location: The 241-A-153 Diversion Box is located inside the 241-A Tank Farm fence, southwest of tank 241-A-104.
Process Description: This unit routes waste from the 241-A Tank Farm to the 244-AR Vault.

Waste Type: Sanitary Sewage

Waste Description: This unit contains lead shielding.

Waste Type: Sanitary Sewage

Waste Description: This unit contains PUREX high level waste, and PUREX organic wash waste. Lead shielding may also be contained inside the diversion box.

Code: 241-A-302B
Type: Catch Tank
Status: Inactive
Description: The east slope of the 241-A Tank Farm has been sprayed with shotcrete. The shotcrete surrounds the area where the 241-A-302B Catch Tank is located. A riser and electrical box are visible. A staircase has been installed to provide access to the tank surface. The underground tank is positioned horizontally. The tank is marked and radiologically posted.

Location: The 241-A-302B catch tank is buried outside the tank farm perimeter fence, east of 241-A Tank Farm, adjacent to Canton Ave.

Related Sites/Structures: The unit is associated with 241-A Tank Farm and 241-A-152 Diversion Box and the 200-E-182-PL pipeline. The drain line to this catch tank is V062.

Process Description: The tank received liquid effluents from the 241-A-151 Diversion Box, located south of PUREX, and the 241-A-152 diversion box, that is located inside the tank farm perimeter fence.

Waste Type: Steam Condensate

Waste Description: This unit was used for transfer of waste solutions from processing and decontamination operations to the tank farms. Volumes varied according to specific plant operation. The tank was isolated in 1985 and stabilized (pumped) in 1990. The volume of waste reported to be remaining in the tank is not consistent in all documents. The Miscellaneous Underground Radioactive Tanks report (1992) states there is 8581 liters (2270 gallons) of supernate and 3137 liters (830 gallons) of sludge. The Waste Tank Summary Report for April 1996 states there is a total of 18,685 liters (4943 gallons) of waste remaining in the tank.

Code: 241-A-350
Type: Catch Tank
Status: Inactive
Description: The unit is an underground reinforced concrete pump pit, with a cover block. The pump pit
drains any leaks from the pump through the pump pit floor drain to an 800-gallon (3000-liter) stainless steel tank below.

Location: The unit is located inside the 241-A Tank Farm fence, southeast of tank 241-A-106.

Waste Type: Steam Condensate

Waste Description: This unit contains aging PUREX high-level waste, PUREX acid concentrator waste, organic wash waste, and 241-A-207 Retention Basin solution.

---

Code: 241-A-417
Type: Catch Tank
Status: Inactive
Description: This unit is an underground cylindrical concrete vault lined with an all welded steel liner. Two overflow lines near the top of the vault prevent overflow of the tank. Above the tank are two rectangular pits, a pump pit and a valve pit. The floor of both pits slope to drains that empty to the tank.

Location: The tank is located inside the 241-A Tank Farm fence, east of the 241-A-702 Building.

Release Description: On March 25, 1980, a routine pressure test of the underground F-100 condensate return pipeline from the AX-501 Valve Pit to the 241-A-417 condensate catch tank failed. An April 3, 1980 investigation found a leak at the flange connection. An excavation at the pipeline leak was done. Two barrels of contaminated soil, reading 10,000 counts per minute, was taken to a burial ground. A new gasket was installed.

Related Sites/Structures: The unit is associated with 241-A Tank Farm, 241-AX Tank Farm, and the 216-A-24 Crib.

Process Description: This unit collects condensate from the 241-A-401 Condenser House, 241-A-702, and from 241-AZ-154. Condensate may be pumped back to the 241-AX Tank Farms or overflow to the 216-A-24 Crib.

Waste Type: Steam Condensate

Waste Description: This unit collects condensate for the 241-A-702 process condensate, the 241-A-401 process condensate, and the 241-AZ-154 steam condensate.

---

Code: 241-A-431
Type: Process Unit/Plant
Status: Inactive
Description: The unit is a concrete structure, with the lower portion below grade. The unit is divided into
two sections. One section houses the ventilation equipment. The other section houses the de-
entrainment equipment. The building is 8 meters (25 feet) high, with the lower 4.9 meters (16
feet) below grade.

Location: The unit is located southeast of the 241-A-103 Tank, inside the 241-A Tank Farm fence.

Related Sites/ Structures: The building is associated with the 241-A Tank Farm, 216-A-16, 216-A-17, 216-A-23-A and

Process Description: This structure is a tank farm ventilation building that provided off gas de-entrainment for the
241-A Tank Farm and also received the 296-A-11 Stack drainage.

Waste Type: Equipment

Waste Description: The unit contains radioactively contaminated equipment and concrete. It provided off-gas de-
entrainment for the 241-A Tank Farm and also received the 296-A-11 Stack drainage.

---

Code: 241-A-501 Classification: Accepted
Type: Valve Pit
Status: Inactive
Location: The valve pit is located inside 241-A Tank Farm, west of 241-A-152 diversion box and east of

Related Sites/ Structures: The structure is associated with the 216-A-8 crib.

Process Description: The 241-A-501 valve pit received raw water and cooling water from the PUREX facility, via
the 241-A201 storage tank. The cooling water ran out of the valve pit to the E-411 (EP-241-A-
161) and E-412 (EP-241-A-162) contact condensers. The output from the contact condensers
went to the 241-A-401 condenser building.

---

Code: 241-A-702-WS-1 Classification: Accepted
Names: 241-A-702-WS-1; 702-A Drain Lines
Type: French Drain
Status: Inactive
Location: The unit is located inside the 241-A Tank Farm fence, west of the 241-A-702 Ventilation
Building.

Related Sites/ Structures: The unit is associated with the 241-AY and 241-AZ Tank Farm and the 241-A-702 Ventilation
Building.

Process Description: The drain is used in association with the 241-A-702 ventilation system. Process steam was
used in steam heaters during normal and reduced operating conditions to raise the temperature
of vent gases from the 241-AY and 241-AZ Tanks to prevent wetting of filters. The drain was used in conjunction with a steam trap for the system.
Waste Type: Steam Condensate
Waste Description: The unit received steam condensate from the 241-A-702 Ventilation Building.

Code: 241-AX-A  
Classification: Accepted  
Reclassification: None  
Names: 241-AX-A; 241-AX-A Diversion Box; 241-AX-A Structural Valve Pit; 241-AX-A Valve Pit  
Type: Valve Pit  
Start Date: 1/1/1965  
End Date:  
Status: Inactive  
Description: The unit is an underground reinforced concrete structure with 1 foot (0.31 meter) thick walls and floor.  
Location: The 241-AX-A is located inside the 241-AX Tank Farm, southwest of tank 241-AX-104.  
Related Sites/Structures: This unit is associated with 241-AY-102 and 241-AX Tank Farm. The unit is interconnected with the 241-AX-B Valve Pit, the 241-A-A Pit, the 241-A-B Pit, and the 242-A Evaporator.  
Process Description: 241-AX-A direct slurry into tanks or supernate out of tanks by manipulation of the correct valve.  
Waste Type: Soil  
Waste Description: The unit transports waste solutions from processing and decontamination operations. Quantities are variable according to specific plant operation.

Code: 241-AX-B  
Classification: Accepted  
Reclassification: None  
Names: 241-AX-B; 241-AX-B Diversion Box; 241-AX-B Structural Valve Pit; 241-AX-B Valve Pit  
Type: Valve Pit  
Start Date: 1/1/1965  
End Date:  
Status: Inactive  
Description: The unit is an underground reinforced concrete structure with 1 foot (.31 meters) thick walls and floor.  
Location: The 241-AX-B is located inside the 241-AX Tank Farm, southwest of tank 241-AX-104.  
Related Sites/Structures: The unit is associated with the 241-AY-102 and the 241-AX Tank Farm. The unit is interconnected with the 241-AX-A Valve Pit, the 241-A-A Pit, the 241-A-B Pit, and the 242-A Evaporator.  
Process Description: 241-AX-B directed slurry into tanks or supernate out of tanks by manipulation of the correct valve.  
Waste Type: Process Effluent  
Waste Description: The unit transports waste solutions from processing and decontamination operations. Quantities are variable according to specific plant operation.

Code: 241-AX-IX  
Classification: Accepted  
Reclassification: None  
Names: 241-AX-IX; IMUST; 241-AX Ion Exchanger  

Type: Storage Tank  Start Date: 1/1/1967
Status: Inactive  End Date: 1/1/1976
Description: The ion exchange system consists of an above ground filter and ion exchange column. The ion exchange column is enclosed in a shielded structure. The ion exchange column sits on top of a 2.4 meter (8 foot) concrete structure.
Location: The 241-AX-IX is located in the southern portion of the 241-AX Tank Farm. It is northeast of the 241-A-417 condensate hold up tank, between the 241-A and 241-AX tank farms.
Related Sites/Structures: The system is associated with the 216-A-8 crib.

Process Description: The 241-AX-IX is an ion exchanger comprised of the exchange column and underground piping. The resin column is located inside a shielded structure that is open at the top. It was installed in 1967 and operated from 1973 to 1976 to remove cesium from the 702-A tank vapor condensate, collected in the 241-A-417 tank. Condensate was pumped from 241-A-417 through the filter and into the top of the ion exchange column. The condensate would gravity flow through the column and normally be discharged to the 218-A-8 crib.

Waste Type: Stormwater Runoff

Code: 241-AX-101  Classification: Accepted
Names: 241-AX-101; 241-AX-TK-101  Reclassification: None
Type: Single-Shell Tank  Start Date: 1/1/1965
Status: Inactive  End Date: 1/1/1980
Description: The unit is carbon-steel lined, with a reinforced concrete shell, dome, and base. This is a third-generation tank having a flat bottom, and an additional grid of drain slots beneath the steel liner bottom. The dome is below grade for shielding.
Location: The 241-AX-101 tank is located in the northeast corner of the 241-AX Tank Farm.
Process Description: The 241-AX tanks received high level self boiling waste from PUREX operations.
Waste Type: Soil
Waste Description: Double shell slurry feed is waste concentrated just before reacting the sodium aluminate saturation boundary in the evaporator without exceeding the receiver tank composition limit.

Code: 241-AX-102  Classification: Accepted
Names: 241-AX-102; 241-AX-TK-102  Reclassification: None
Type: Single-Shell Tank  Start Date: 1/1/1966
Status: Inactive  End Date: 1/1/1980
Description: The unit is carbon-steel lined, with a reinforced concrete shell, dome, and base. The dome is below grade for shielding. This is a third-generation tank having a flat bottom, and an additional grid of drain slots beneath the steel liner bottom.
| Location: | The 241-AX-102 tank is located in the southeast corner of the 241-AX Tank Farm. |
| Process Description: | 241-AX tanks received high-level self boiling waste from PUREX operations. |
| Waste Type: | Soil |
| Waste Description: | This tank received concentrated complexant which is a concentrate product from the evaporation of dilute complexed waste. |

| Code: 241-AX-103 | Classification: Accepted |
| Names: 241-AX-103; 241-AX-TK-103 | Reclassification: None |
| Type: Single-Shell Tank | Start Date: 1/1/1965 |
| Status: Inactive | End Date: 1/1/1980 |
| Description: | The unit is carbon-steel lined, with a reinforced concrete shell, dome, and base. This is a third-generation tank having a flat bottom, and an additional grid of drain slots beneath the steel liner bottom. The dome is below grade for shielding. |
| Location: | The 241-AX-103 tank is located in the northwest corner of the 241-AX Tank Farm. |
| Process Description: | 241-AX tanks received high-level, self-boiling waste from PUREX operations. |
| Waste Type: | Misc. Trash and Debris |
| Waste Description: | This tank received concentrated complexant which is concentrated product form the evaporation of dilute complexed waste. |

| Code: 241-AX-104 | Classification: Accepted |
| Names: 241-AX-104; 241-AX-TK-104 | Reclassification: None |
| Type: Single-Shell Tank | Start Date: 1/1/1966 |
| Status: Inactive | End Date: 1/1/1976 |
| Description: | The unit is carbon-steel lined, with a reinforced concrete shell, dome, and base. This is a third-generation tank having a flat bottom, and an additional grid of drain slots beneath the steel liner bottom. |
| Location: | The 241-AX-104 tank is located in the southwestern portion of the 241-AX Tank Farm. |
| Process Description: | 241-AX tanks received high level self boiling waste from PUREX operations. |
| Waste Type: | Demolition and Inert Waste |
| Waste Description: | This tank received non-complexed waste which is a general waste term applied to all Hanford Site non-complexed liquors non-identified as complexed. |

| Code: 241-AX-152DS | Classification: Accepted |
| Names: 241-AX-152DS; 241-AX-152-DS Diverter Station; Line V713; 241-AX-152 Diverter Station | Reclassification: None |
### Diversion Box

**Type:** Diversion Box  
**Status:** Inactive  
**Start Date:** 1/1/1965  
**End Date:** 1/1/2001  
**Description:** The unit is a reinforced concrete structure with the top at ground level. There are two diverter tanks in a common cell with a stainless steel liner on the floor that extends approximately 1 foot (0.31 meters) up the cell wall. There is also a pump pit that does not have a stainless steel liner. The cell and pump pit drain to a catch tank below.  
**Location:** The 241-AX-152 Diverter Station is located in the western portion of the 241-AX Tank Farm.  
**Related Sites/Structures:** The unit is associated with the 241-AX, 241-AZ, and 241-AY tank farms and the 241-AX-152 Catch Tank. The drain line is V713.  
**Process Description:** Diverter station 241-AX-152DS is used to transfer mixed waste solutions from processing and decontamination operations.  
**Waste Type:** Equipment  
**Waste Description:** This unit transports waste solutions from processing and decontamination operations. Volumes are variable according to specific plant operation.

---

### Isolation Jumper Pit

**Type:** Diversion Box  
**Status:** Inactive  
**Start Date:**  
**End Date:**  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 241-AX-153; 241-AX-153 Isolation Jumper Pit  
**Description:** The site is an underground cement structure with cement cover blocks.  
**Location:** The 241-AX-153 Jumper Pit is located west of 241-AX-103 tank and east of the 241-AX-152 diverter Station, inside the 241-AX Tank Farm.  
**Process Description:** The isolation jumper pit had three transfer lines going into it - a three inch line, number 4026 (from 241-AX-152 Diverter station), three inch line number 4026 (a construction pipe that has been isolated - welded cap) and a three inch line number 4021 (line bypasses the 241-AX-152 Diverter Station). Line 4021 was isolatable from the 241-AX-152 diverter station because of this isolation jumper pit.

---

### Valve Pit

**Type:** Valve Pit  
**Status:** Inactive  
**Start Date:**  
**End Date:**  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 241-AX-501; 241-AX-501 Condensate Valve Pit; 241-AX-501 Valve Pit  
**Description:** The unit is a reinforced concrete structure that contains a valve that routes the tank farm condensate to the 241-A-417 Pump Pit.  
**Location:** This unit is located inside the north end of the 241-A Tank Farm, northwest of 241-A-417.
DOE/RL-88-30
Rev. 24

**Related Sites/Structures:**
The unit interconnects AX Tank Farm to the 241-A-417 Pump Pit and Tank.

**Process Description:**
The valve routes and receives tank farm condensate.

**Waste Type:** Water

**Waste Description:**
The unit receives and routes tank farm condensate.

**Description:**
The pit is an underground cement structure with cement cover blocks. The valve pit has been isolated and weather sealed.

**Location:**
The valve pit is located inside the 241-AX Tank Farm fence, east of tank 241-AY-101 and west of 241-AX-103.

**Related Sites/Structures:**
The site is associated with 241-A-417.

**Process Description:**
The 241-AY-501 valve pit was used to distribute condensate from the 702-A ventilation system to the 241-AX, 241-AY and 241-AZ tank farms. The condensate collected in the 241-A-417 tank.

</tr>
<tr>
<td>Location:</td>
<td>This site is defined as the fenced area containing the 241-A, AN, AX, AY, and AZ Tank Farms. It is inside 200 East Area, west of Canton Ave.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Release Description:</td>
<td>The exact extent (horizontal and vertical) of the soil contaminated by unplanned releases that occurred within this farm complex over the years are not known. Some of the single shell tanks have leaked to the soil below the tank farm. Other releases spread contamination to the surface soil surrounding the tanks. Document HW-53449 states that in 1957 the pipeline to the 433 de-entrainment tank were replaced because the lines had failed and leaked. Does rates varied from 2 millirem per hour to 2 rad per hour during the activity. Several hundred gallons of condensed vapors from the 241-A waste storage tanks were pumped out of a stub on the west side of the 417-A jumper pit 11 in 1964. Construction forces were preparing to make the final weld in a line to tie tank 105-A into the 151-AX diverter station. The line was observed to shake and liquid spill out on to the ground in the excavation as a result of a pressurization event in tank A-105. Radiation readings of 400 rads/hr @ 1 foot was observed on January 28, 1965. On March 25, 1980, a routine pressure test of the underground F-100 condensate return pipeline from the AX-501 Valve Pit to the 241-A-417 condensate catch tank failed. An April 3, 1980 investigation found a leak at the flange connection. An excavation at the pipeline leak was done. Two barrels of contaminated soil, reading 10,000 counts per minute, was taken to a burial ground. A new gasket was installed. On January 29, 1968, hot water and a pressurized line from a fire truck was used to try to unplug the 241-AX-102 to 241-C-102 pipeline. Liquid was noticed coming up near the 241-AX-103 tank, so the flushing operation was discontinued.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>Previously individually defined unplanned releases that were identified in WIDS located inside the A Tank Farm Complex are UPR-200-E-47, UPR-200-E-48, UPR-200-E-115, UPR-200-E-119, UPR-200-E-125, and UPR-200-E-126. Some of these sites are listed in TPA Appendix B as TSD-associated sites, but all are to be addressed with the closeout of the tank farm TSD. As such, site 200-E-131 is also a TSD-associated site.</td>

_Hanford Site Waste Management Units Report_  
February 2015  
Hanford Site Waste Management Units Report  
February 2015
Status: Inactive
End Date:
Description: The waste site is four underground, 15 centimeter (6 inch) diameter carbon steel pipelines buried in the same soil trench. The lines split into a “Y” east of the 241-A Tank Farm fence. Lines 802 and 806 divert to 241-AY-152 Diversion Box. Lines 801 and 805 divert to the 241-A-153 Diversion Box.
Location: The pipelines extend from the 244-AR Vault building to the 241-A Tank Farm. The lines cross under Buffalo Ave.
Related Sites/Structures: The transfer line is associated with 244-AR Vault, 241-A-153 and 241-AH-152.

---

Code: 2607-EC
Classification: Accepted
Names: 2607-EC
Reclassification: None
Type: Septic Tank
Start Date: 1/1/1963
End Date:
Description: This unit includes a septic tank and dry well.
Location: HNF-SD-LL-SP-001 shows the location of the septic tank in the northeast corner of 241-A tank farm, near the fence.
Related Sites/Structures: HNF-6612 says the septic tank is associated with 241-AR-271.
Waste Type: Process Effluent
Waste Description: Sanitary wastewater and sewage. In 1995, the estimated rate of waste generation is 0.45 cu m/d.

---

Code: 2607-ED
Classification: Accepted
Names: 2607-ED
Reclassification: None
Type: Septic Tank
Start Date: 1/1/1980
End Date:
Description: The 2607-ED Septic Tank receives sanitary wastewater and sewage from the 2707-AX Building and drains to the drain field. The drain field has a capacity of 257 gallons (973 liters) per day.
Location: This unit lies south of the 241-AX-102 tank, inside the tank farm fence.
Related Sites/Structures: The 2607-ED Septic Tank is associated with the 2707-AX Building and lies within the AX Tank Farm.
Process Description: The 2607-ED Septic Tank and associated drain field are designed to accept sanitary sewer effluent from the 2707-AX Building.
Waste Type: Storage Tank
Waste Description: The 2607-ED Septic Tank receives sanitary wastewater and sewage from the 2707-AX Building at an estimated rate of 10 cubic feet (0.28 cubic meters) per day.

| Description:  | The unit is comprised of a carbon steel liner within a reinforced concrete shell, 9 meters (30 feet) high, with a capacity of 2,017,405 liters (533,000 gallons). The bottom is 11.3 meters (37 feet) below grade, and the dome is located below grade for shielding purposes. This type was built to the original single-shell design, having a dished bottom and a 5.2 meters (17 feet) operating depth. The tank is passively ventilated. | The unit is comprised of a carbon steel liner within a reinforced concrete shell, 9 meters (30 feet) high, with a capacity of 2,017,405 liters (533,000 gallons). This type was built to the original single-shell design, having a dished bottom and a 5.2 meters (17 feet) operating depth. The tank is passively ventilated. |

| Location:     | The tank is located about 914 meters (3,000 feet) north northeast of the 221-B building. | Tank 241-B-102 is located on the north side of the 200 East Area about 914 meters (3,000 feet) north northeast of the 221-B building. |

| Waste Type    | Storage Tank            | Storage Tank            |

| Waste Description: | Initially tank B-101 received metal waste in 1945. The tank received and transferred waste via cascade lines from 1945 until 1963. During 1953, B-101 processed feed for U Plant. From 1953 until 1963, the tank contained supernatant containing evaporator bottoms waste from 241-B tanks. During 1957, in-farm scavenged feed was sent to the 244-CR Vault. From 1960 until 1970, B-101 received wastewater. Also, it was found that during 1960 wastewater leaked into the pipe encasement which drained to B-101. During 1963 the tank received PUREX coating waste. B-101 received B Plant high-level waste (Cell 23) from 1969 until 1970. From 1970 until 1973, the tank received B Plant, Cell 23 evaporator bottoms. The tank also received bismuth phosphate metal waste and waste in route to in-tank solidification. Presently, the waste material is classified as non-complexed and has a total waste volume of 427,705 liters (113,000 gallons). Sludge comprises the total 427,705 liters (113,000 gallons). There is no saltcake or pumpable liquid and 6,000 gallons of drainable interstitial liquid remaining. An analysis was conducted on a B-101 sludge sample in February 1976. The sample was found to have a consistency of soft mud and was dark brown. A heat generation rate based on strontium-89, strontium-90, and cesium-137 was calculated to be 0.0201 watts/liter of sludge. The resulting solids remaining in this tank (based on core samples) contain an estimated 4 million Curies of strontium (92,000 BTU/h). The curie content listed is not decayed to a consistent date; therefore, a cumulative total is inappropriate. | Initially tank B-101 received metal waste in 1945. Hanford Site Waste Management Units Report
February 2015
Release Description: While pumping supernatant from tank 241-B-102 to tank 241-B-101, tank farm personnel noticed soil discoloration around the 241-B-102 heel pit indicating a leak in the transfer line. Surface soil contamination with readings of 10 R/hr were recorded. The contaminated ground area was immediately covered with asphalt to reduce radionuclide migration. This UPR is reported as UPR-200-E-108.

Waste Type: Storage Tank

Waste Description: Tank 241-B-102 went into service in 1945 by receiving metal waste produced by the bismuth phosphate process. The tank was sluiced in 1953 to remove the metal waste for uranium recovery then filled with a transfer from tank 241-B-105 (the active receiver tank for the 242-B Evaporator). Most of the contents of the tank were sent to tank 241-C-112 in 1957 for ferrocyanide scavenging of the supernate. Later that year the tank received water. The tank stood idle until 1963, when it began to receive cladding waste supernate from other tanks. The tank received a supernatant transfer from 241-B-101 in 1969 and was receiving high level waste from B Plant. Most of this supernate was transferred out of the tank in 1970. The tank received ion-exchange waste (B Plant) which was later transferred in a large supernate transfer in 1971. The tank also received low level waste from B Plant (1972), water waste transfer and pumpable liquids from other single-shell tanks (B-105, 107, and 110) that were being taken out of service (1972-1976). During this time tank 241-B-102 was also transferring supernate to tanks 241-B-103, 241-B-106, and 241-SX-106. The tank also received cladding removal waste supernate from the Plutonium-Uranium Extraction (PUREX) process and supernate from the fission product recovery process at B Plant. The tank also received ion exchange waste and evaporator bottoms from 241-B, -BX, and -C tank farms. Presently, the waste material is classified as non-complexed and has a total waste volume of 121,120 liters (32,000 gallons). Sludge comprises 68,130 liters (18,000 gallons) of the tank contents, saltcake 37,850 liters (10,000 gallons) and there is 15,140 liters (4,000 gallons) of drainable supernatant liquid remaining. The waste level is very low 17.8 centimeters (~7 inches).

Code: 241-B-103         Classification: Accepted
Names: 241-B-103; 241-B-TK-103     Reclassification: None
Type: Single-Shell Tank         Start Date: 1/1/1945
Status: Inactive               End Date: 1/1/1977

Description: The unit is a single-shell tank constructed of .3 meter (1 foot) thick reinforced concrete with a 6.4 millimeters (0.25 inch) mild carbon steel liner (ASTM A 283 Grade C) on the bottom and sides and a .38 meter (1.25 foot) thick domed concrete top. The top of the steel liner is 5.5 meters (18 feet) above the bottom of the tank (at the side wall). The tank has a dished bottom, with a maximum depth of 30 centimeters (12 inches) below the side wall of the tank and a 4 foot 1.2 meters (4 feet) radius knuckle. The tank has a 5.2 meters (17 feet) operating depth. The tank is set on a reinforced concrete foundation 11.3 meters (37 feet) below grade. A three-ply cotton fabric waterproofing was applied over the foundation and steel tank. Four coats of primer paint were sprayed on all exposed interior tank surfaces. The tank ceiling dome was covered with three applications of magnesium zincfluorosilicate wash. Lead flashing was used to protect the joint where the steel liner met the concrete dome. Asbestos gaskets were used to seal the manholes in the tank dome. The tank was waterproofed on the sides and top with tar and gunnite. Tank capacity is 2,017,405 liters (533,000 gallons). The tank was covered with approximately 2.2 meters (7.25 feet) of overburden for shielding purposes. Tank 241-B-103 is the third and final tank in a "cascade" connecting to tanks 241-B-101 and 241-B-102. The cascade overflow height is approximately 4.86 meters (192 inches) from the tank bottom (at the sidewall) and .61 meters (2 feet) below the top of the steel liner. The tank is passively ventilated.

Location: Tank 241-B-103 is located on the north side of the 200 East Area about 3,000 feet (914 m)
north northeast of the 221-B building.

Release Description: A leak of 30,280 liters (8,000 gallons) occurred prior to or during 1978. The leak estimate of 30,280 liters (8,000 gallons) is an average total from 19 tanks.

Waste Type: Storage Tank

Waste Description: Tank 241-B-103 went into service in 1945 by receiving waste cascaded from tank 241-B-102 until it was declared full in 1946. The tank was sluiced in 1953 for uranium recovery. From 1954 until 1963 the tank received supernate, evaporator bottoms waste and unknown waste from an unknown source. The tank also received bismuth phosphate metal waste; PUREX coating waste; and supernatant containing ion exchange waste, N Reactor waste, organic wash waste; PNNL waste, REDOX high-level waste, coating waste, evaporator bottoms, B Plant low-level waste, decontamination waste, tributyl phosphate waste, and laboratory waste from 241-B, -BX, and -C tank farms. Additional sources of waste are first and second cycle waste from B Plant and in-tank solidification (ITS-1 & ITS-2) evaporator bottoms. Presently, the waste material is classified as non-complexed and has a total waste volume of 59,000 gallons (223,315 L). Sludge is reported to comprise 59,000 gallons (223,315 L) of the tank contents with no saltcake, drainable, or pumpable liquid remaining. However, the Tank Layer Model (Agnew et al. 1994), estimates that the tank contains mostly saltcake 56,000 gallons (211,960 L), with a small amount of metal waste 3,000 gallons (11,355 L). The waste level in the tank is (~14 inches) 35 cm.

| Description:  | The single-shell tank is constructed of 0.3 meters (1 foot) thick reinforced concrete with a 6.4 millimeter (0.25 inch) mild carbon steel liner (ASTM A 283 Grade C) on the bottom sides and a .38 meter (1.25 foot) thick domed concrete top. The top of the steel liner is 5.5 meters (18 feet) above the bottom of the tank (at the side wall). The tank has a dished bottom, with a maximum depth of 30 centimeters (12 inches) below the side wall of the tank and at 1.2 meters (4 foot) radius knuckle. The tank has a 5.2 meters (17 foot) operating depth. The tank is set on a reinforced concrete foundation 11.3 meters (37 feet) below grade. A three-ply cotton fabric waterproofing was applied over the foundation and steel tank. Four coats of primer paint were sprayed on all exposed interior tank surfaces. The tank ceiling dome was covered with three applications of magnesium zincfluorosilicate wash. Lead flashing was used to protect the joint where the steel liner met the concrete dome. Asbestos gaskets were used to seal the manholes in the tank dome. The tank was waterproofed on the sides and top with tar and gunnite. Tank capacity is 2,017,405 liters (533,000 gallons). The tank was covered with approximately 2.2 meters (7.25 feet) of overburden for shielding purposes. The tank is passively ventilated. |
| Location:     | Tank 241-B-104 is located on the north side of the 200 East Area about 914 meters (3,000 feet) north northeast of the 221-B building. |
| Waste Type:   | Equipment        |
| Waste Description: Tank 241-B-104 is equipped to cascade to tank 241-B-105 and is first in the three-tank cascade flow series. The tank received bismuth phosphate first and second-cycle waste; evaporator bottoms, and supernatant containing evaporator bottoms from the 241-B tanks. Presently, the waste material is classified as non-complexed and has a total waste volume of 371,000 gallons (1,404,235 L). Sludge is reported to comprise 301,000 gallons (1,139,285 L) and saltcake 69,000 (261,165 L). There is 40,000 gallons (151,400 L) pumpable liquid remaining and 47,000 gallons (177,895 L) of drainable liquid remaining. Drainable liquid includes 46,000
gallons (174,110 L) interstitial and 1,000 gallons (3,785 L) of supernatant liquid. The volume of waste converts to a waste level of almost 11 feet (3.4 m). More sample material is needed for full characterization of the waste.

**Location:** Tank 241-B-105 is located on the north side of the 200 East Area about 3,000 feet (914 m) north northeast of the 221-B building.

**Release Description:** A leak of 30,280 liters (8,000 gallons) occurred prior to or during 1978. The leak estimate of 30,280 liters (8,000 gallons) is an average total from 19 tanks. Tank B-105 was categorized "questionable integrity" due to the unexplained high level of activity in Dry Wells 20-05-06 and 20-06-06.

**Waste Type:** Process Effluent

**Waste Description:** Tank 241-B-105 is equipped to receive waste via cascade from tank B-104 and cascade to tank 241-B-106 and is second in the three-tank cascade flow series. The tank received bismuth phosphate first and second-cycle waste and flush water containing evaporator bottoms from the 241-B tanks. Presently, the waste material is classified as non-complexed and has a total waste volume of 306,000 gallons (1,158,210 L). Sludge is reported to comprise 40,000 gallons (151,400 L) and saltcake 266,000 (1,006,810 L). There is 23,000 gallons (87,055 L) of drainable liquid remaining and no pumpable liquid remaining. The volume of waste converts to a waste level of almost 9 feet (2.7 m). No samples have been taken from tank 241-B-105.
maximum depth of 30 centimeters (12 inches) below the side wall of the tank and a 1.2 meter (4 foot) radius knuckle. The tank has at 5.2 meters (17 foot) operating depth. The tank is set on a reinforced concrete foundation 11.3 meters (37 feet) below grade. A three-ply cotton fabric waterproofing was applied over the foundation and steel tank. Four coats of primer paint were sprayed on all exposed interior tank surfaces. The tank ceiling dome was covered with three applications of magnesium zincfluorosilicate wash. ### Tank 241-B-108

**Code:** 241-B-108  
**Type:** Single-Shell Tank  
**Status:** Inactive  
**Classification:** Accepted  
**Reclassification:** None  
**Start Date:** 1/1/1945  
**End Date:** 1/1/1977  
**Description:**

The single-shell tank is constructed of 0.3 meter (1 foot) thick reinforced concrete with a 6.4 millimeters (0.25 inch) mild carbon steel liner (ASTM A 283 Grade C) on the bottom and sides and a .38 meter (1.25 foot) thick domed concrete top. The top of the steel liner is 5.5 meters (18 feet) above the bottom of the tank (at the side wall). The tank has a dished bottom, with a maximum depth of 30 centimeters (12 inches) below the side wall of the tank and a 1.2 meters (4 feet) radius knuckle. The tank has a 5.2 meter (17 feet) operating depth. The tank is set on a reinforced concrete foundation 11.3 meters (37 feet) below grade. A three-ply cotton fabric waterproofing was applied over the foundation and steel tank. Four coats of primer paint were sprayed on all exposed interior tank surfaces. The tank ceiling dome was covered with three applications of magnesium zincfluorosilicate wash. Lead flashing was used to protect the joint where the steel liner met the concrete dome. Asbestos gaskets were used to seal the manholes in the tank dome. The tank was waterproofed on the sides and top with tar and gunnite. Tank capacity is 2,017,405 liters (533,000 gallons). The tank was covered with approximately 2.2 meters (7.25 feet) of overburden for shielding purposes.

**Location:**
Tank 241-B-108 is located on the north side of the 200 East Area about 914 meters (3,000 feet) north northeast of the 221-B building.

**Waste Type:** Process Effluent

**Waste Description:**

241-B-108 tank received PUREX coating waste; bismuth phosphate first-cycle waste, and supernatant containing evaporator bottoms and ion exchange waste from the 241-B and -BY tank farms. The tank also received non-complexed waste and 242-B evaporator saltcake waste. Presently, the waste material is classified as non-complexed and has a total waste volume of 94,000 gallons (355,790 L). Sludge is reported to comprise the 94,000 gallons (355,790 L). There is 4,000 gallons (15,140 L) of drainable interstitial liquid remaining and no pumpable liquid remaining. The volume of waste converts to approximately 2.5 feet (.8 m) in the tank. There have been no samples taken of the tank waste.
millimeter (0.25 inch) mild carbon steel liner (ASTM A 283 Grade C) on the bottom and sides and a .38 meter (1.25 foot) thick domed concrete top. The top of the steel liner is 5.5 meters (18 feet) above the bottom of the tank (at the side wall). The tank has a dished bottom, with a maximum depth of 30 centimeters (12 inches) below the side wall of the tank and a 1.2 meters (4 foot) radius knuckle. The tank has a 5.2 meters (17 foot) operating depth. The tank is set on a reinforced concrete foundation 11.3 meters (37 feet) below grade. A three-ply cotton fabric waterproofing was applied over the foundation and steel tank. Four coats of primer paint were sprayed on all exposed interior tank surfaces. The tank ceiling dome was covered with three applications of magnesium zincfluorosilicate wash. Lead flashing was used to protect the joint where the steel liner met the concrete dome. Asbestos gaskets were used to seal the manholes in the tank dome. The tank was waterproofed on the sides and top with tar and gunnite. Tank capacity is 2,017,405 liters (533,000 gallons). The tank was covered with approximately 2.2 meters (7.25 feet) of overburden for shielding purposes. At present, the tank farm is enclosed by a 1.8 meter (6-foot) high chain link fence. The tanks are marked by yellow riser pipes and the ground surface is covered with gravel.

Location: Tank 241-B-109 is located on the north side of the 200 East Area about 914 meters (3,000 feet) north northeast of the 221-B building.

Waste Type: Process Effluent

Waste Description: 241-B-109 tank received PUREX coating waste; bismuth phosphate first-cycle waste, and supernatant containing evaporator bottoms, and ion exchange waste. The tank also received coating waste from the 241-B, -BY, and -S tank farms, non-complexed waste, waste water, 224-U waste, and 242-B evaporator saltcake waste. Presently, the waste material is classified as non-complexed and has a total waste volume of 127,000 gallons (480,822 L). There is disparity between sources for tank inventories. One source lists sludge for the total waste volume at 8,000 gallons (30,280 L) of drainable interstitial liquid. Another source reports the waste comprises 30,000 gallons (113,550 L) of unknown waste; 13,000 gallons (49,205 L) of sludge; and 84,000 gallons (317,940 L) of saltcake. The volume of waste converts to approximately 3.5 feet (1.1 m) in the tank. There have been no samples taken of the tank waste.
Location: Tank 241-B-110 is located on the north side of the 200 East Area about 914 meters (3,000 feet) north northeast of the 221-B building.

Release Description: An unplanned release occurred in 1969 when approximately 31,416 liters (8,300 gallons) of waste containing about 4,300 Ci of cesium-137 leaked from tank 241-B-110 contaminating the soil surrounding the tank. The leak volume estimate is based solely on observed liquid level decreases in this tank and is considered to be the most accurate method for estimating leak volumes. This UPR is recorded as UPR-200-E-128.

Waste Type: Storage Tank

Waste Description: 241-B-110 tank received Bismuth phosphate first-cycle waste; bismuth phosphate second-cycle wastes; fission product waste; B Plant high-level waste (waste fractionization); B Plant waste from cells 5 and 6; B Plant flushes; and ion exchange waste; B Plant low-level waste; evaporator bottoms; non-complexed waste; decontamination waste; PUREX high-level waste; in-tank solidification waste; cesium recovery waste; and waste water. The waste material is classified as non-complexed and presently has a total waste volume of 931,001 liters (246,000 gallons). Sludge comprises the total except for 3,785 liters (1,000 gallons) of supernatant liquid. There is 64,345 liters (17,000 gallons) of pumpable liquid remaining. Level adjustments in 1982 and 1985 brought waste level measurements in the tank to current readings. The volume of waste converts to approximately 2.2 meters (7 feet) in the tank. While characterization of the solid contents has been performed, complete analysis of the upper layer must take place to more fully characterize this portion of the waste.

Reclassification:

Code: 241-B-111
Names: 241-B-111; 241-B-TK-111
Type: Single-Shell Tank
Status: Inactive

Description: The single-shell tank is constructed of 0.3 meters (1 foot) thick reinforced concrete with a 6.4 millimeter (0.25 inch) mild carbon steel liner (ASTM A 283 Grade C) on the bottom and sides and a .38 meter (1.25 foot) thick domed concrete top. The top of the steel liner is 5.5 meters (18 feet) above the bottom of the tank (at the side wall). The tank has a dished bottom, with a maximum depth of 30 centimeters (12 inches) below the side wall of the tank and a 1.2 meter (4 foot) radius knuckle. The tank has a 5.2 meter (17 foot) operating depth. The tank is set on a reinforced concrete foundation 11.3 meter (37 feet) below grade. A three-ply cotton fabric waterproofing was applied over the foundation and steel tank. Four coats of primer paint were sprayed on all exposed interior tank surfaces. The tank ceiling dome was covered with three applications of magnesium zincfluorosilicate wash. Lead flashing was used to protect the joint where the steel liner met the concrete dome. Asbestos gaskets were used to seal the manholes in the tank dome. The tank was waterproofed on the sides and top with tar and gunnite. Tank capacity is 2,017,405 liters (533,000 gallons). The tank was covered with approximately 2.2 meters (7.25 feet) of overburden for shielding purposes. At present, the tank farm is enclosed by a 1.8 meters (6-foot) high chain link fence. The tanks are marked by yellow riser pipes and the ground surface is covered with gravel.

Location: Tank 241-B-111 is located on the north side of the 200 East Area about 914 meters (3,000 feet) north northeast of the 221-B building.

Release Description: A leak of 8,000 gallons (30,280 L) occurred prior to or during 1978. The leak estimate of 30,280 liters (8,000 gallons) is an average total from 19 tanks. Tank B-111 was categorized "questionable integrity" due to the unexplained activity in Dry Wells 20-11-09 and 20-12-06.

Waste Type: Storage Tank
Waste Description: 241-B-111 tank received bismuth phosphate first-cycle waste; bismuth phosphate second-cycle wastes; ion exchange waste (waste fractionization); fission product waste; B Plant waste from cells 5 and 6; evaporator bottoms; non-complexed waste; decontamination waste; PUREX high-level waste; cesium recovery waste; and waste water. The waste material is classified as non-complexed and presently has a total waste volume of 237,000 gallons (897,045 L) comprised of sludge. There is 60,560 liters (16,000 gallons) of pumpable liquid and 83,270 liters (22,000 gallons) of drainable liquid remaining. The volume of waste converts to approximately 2.2 meters (7 feet) in the tank. More sample material is needed for full characterization of tank waste.

Reclassification: 241-B-112; 241-B-TK-112

Single-Shell Tank

Names: 241-B-112; 241-B-TK-112

Type: Single-Shell Tank

Status: Inactive

Start Date: 1/1/1946

End Date: 1/1/1977

Waste Description: The single-shell tank is constructed of 1 foot (.3 m) thick reinforced concrete with a 0.25 inch (6.4 mm) mild carbon steel liner (ASTM A 283 Grade C) on the bottom and sides and a 1.25 foot (.38 m) thick domed concrete top. The top of the steel liner is 18 feet (5.5 m) above the bottom of the tank (at the side wall). The tank has a dished bottom with a maximum depth of 12 inches (30 cm) below the side wall of the tank and a 4 foot (1.2 m) radius knuckle. The tank has a 17 foot (5.2 m) operating depth. The tank is set on a reinforced concrete foundation 37 feet (11.3 m) below grade. A three-ply cotton fabric waterproofing was applied over the foundation and steel tank. Four coats of primer paint were sprayed on all exposed interior tank surfaces. The tank ceiling dome was covered with three applications of magnesium zincfluorosilicate wash. Lead flashing was used to protect the joint where the steel liner met the concrete dome. Asbestos gaskets were used to seal the manholes in the tank dome. The tank was waterproofed on the sides and top with tar and gunnite. Tank capacity is 533,000 gallons (2,017,405 L). The tank was covered with approximately 7.25 feet (2.2 m) of overburden for shielding purposes. At present, the tank farm is enclosed by a 6-foot (1.8 m) high chain link fence. The tanks are marked by yellow riser pipes and the ground surface is covered with gravel.

Location: Tank 241-B-112 is located on the north side of the 200 East Area about 3,000 feet (914 m) north northeast of the 221-B building.

Release Description: A leak of 2,000 gallons (7,570 L) occurred prior to or during 1978. Tank B-112 was categorized "questionable integrity" due to the unexplained activity in Dry Wells 20-12-03 and 20-12-06.

Waste Type: Storage Tank

Waste Description: 241-B-112 tank received bismuth phosphate second-cycle wastes; B Plant low-level waste; fission product waste; ion exchange waste; evaporator bottoms from the 241-B and -BX tanks; non-complexed waste; first cycle waste; decontamination waste; and waste water. The waste material is classified as non-complexed and presently has a total waste volume of 33,000 gallons (124,905 L) comprised of 30,000 gallons (113,550 L) sludge and 3,000 gallons (11,355 L) of drainable supernatant liquid. Another source indicates that the 30,000 gallons (11,355 L) of sludge is composed of 14,000 gallons (52,990 L) of sludge and 16,000 gallons (60,560 L) of salt cake. The volume of waste converts to approximately 1 foot (.3 m) in the tank. Based on analytical results from the 1995 Auger sampling event, the waste in the tank does not appear to present any immediate safety concerns.

**Description:**
241-B-151 Diversion Box is an underground structure constructed of reinforced concrete with a height of approximately 15 feet (4.6 m). Only an approximate 1 foot (.3 m) of this diversion box appears above grade. The outer dimensions are approximately 20 feet (6.1 m) by 9 feet (2.7 m). Wall thickness ranges from about 2 feet (.61 m) for the lower half to a three step progressively thinner thickness to accommodate the three layers of tapered concrete blocks that make up the cover. The cover is made up in sections consisting of fifteen pre-formed concrete blocks. The layers of concrete blocks are arranged in three stacked rows, the bottom row having the shortest length and the top row having the longest length. The tapered ends aid in locating the blocks into place and each block overlaps with the one above and/or below it. Each block is about 20 inches (51 cm) high and range in length from around 6.8 to 8 feet (2 to 2.4 m).

**Location:**
The 241-B-151 Diversion Box is located inside 241-B Tank Farm, approximately 66.6 meters (219 feet) south of tank 241-B-110.

**Release Description:**
UPR-200-E-4, UPR-200-E-73.

**Related Sites/Structures:**
241-B-151 Diversion Box is associated with the 241-B-152, 241-B-153 diversion boxes, 241-B Tank Farm, 241-BX Tank Farm and the 241-B-301B catch tank.

**Process Description:**
241-B-151 Diversion Box transferred waste solutions from processing and decontamination operations to the 241-B and 241-BX Tank Farms.

**Waste Type:**
Storage Tank

**Waste Description:**
This unit was used for transfer of liquid waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. It is estimated that approximately 50 pounds (23 kilograms) of waste lead is also stored in each diversion box.

---

### 241-B-152 Diversion Box

**Description:**
241-B-152 Diversion Box is an underground structure constructed of reinforced concrete with a height of approximately 4.6 meters (15 feet). Approximate 0.3 meters (1 foot) is above grade. The outer dimensions are approximately 8.5 meters (28 feet) by 2.7 meters (9 feet). Wall thickness is progressively thinner to accommodate for three layers of tapered concrete cover blocks. The layers of concrete blocks are arranged in three stacked rows, the bottom row having the shortest length and the top row having the longest length.

**Location:**
The 241-B-152 Diversion Box is located inside the 241-B Tank Farm, approximately 61 meters (200 feet) southwest of tank 241-B-110.

**Release Description:**
UPR-200-E-74 and UPR-200-E-38 occurred at this diversion box.

**Related Sites/Structures:**
Process Description: 241-B-152 Diversion Box transferred waste solutions from processing and decontamination operations to the 241-B and 241-BX Tank Farms.

Waste Type: Storage Tank

Waste Description: This unit was used for transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. It is estimated that approximately 50 pounds (23 kilograms) of waste lead is stored in each diversion box.

Related Sites/Structures: 241-B-153 Diversion Box is associated with the 241-B Tank Farm, 241-B-151 and 241-B-152 diversion boxes and the 241-B-301 Catch Tank.

Process Description: The 241-B-153 Diversion Box transferred waste solutions from processing and decontamination operations to the 241-B and 241-BX Tank Farms.

Waste Type: Storage Tank

Waste Description: This unit was used for transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.
fence.

Related Sites/Structures: The smaller 241-B-201, 202, 203 and 204 tanks operated independently from the large capacity cascading tanks in 241-B Tank Farm. The tank overflow cascaded to the 216-B-7A crib. In 1946, it was determined that discharging 224-B waste into the 216-B-5 reverse well was a mistake. The waste stream was rerouted to the 241-B-201 tank in 1946. 224-B waste had an average plutonium concentration of 99 micrograms per liter and an average beta concentration of 26 microcuries per liter. 221-B 5-6 tank waste was temporarily combined with the 224-B waste in 1947. 241-B-201 was removed from service in 1948 when it filled with sludge. The influent line was redirected to the 241-B-204 tank and the 241-B-202, 203 and 204 tanks were tied together in a cascade series (with 241-B-202 the last tank in the cascade). Some references indicate the tank was reactivated in 1952 for Uranium Recovery waste that originated in 221-U Plant.

Waste Type: Storage Tank

Waste Description: 224-B building wastes and 221-B metal waste, non-complexed waste, and waste water. The waste material is classified as non-complexed and presently has a total waste volume of 109,765 liters (9,000 gallons) comprised of 105,980 liter (28,000 gallons) sludge, 3,785 liters (1,000 gallons) of supernatant, 15,140 liters (4,000 gallons) drainable liquid, and no pumpable liquid remaining. The volume of waste, in 1996, converts to approximately 3.8 meters (12.5 feet) depth in the tank.

| Code: 241-B-202 | Classification: Accepted |
| Names: 241-B-202; 241-B-TK-202 | Reclassification: None |
| Type: Single-Shell Tank | Start Date: 1/1/1951 |
| Status: Inactive | End Date: 1/1/1977 |

Description: The single-shell tank is the smallest of the tank farm designs with a 6.1 meter (20 foot) diameter, a 7.5 meter (24.9 foot) operating depth, and a 208,175 liters (55,000 gallon) capacity. The tank is constructed of reinforced concrete with a 6.4 millimeter (0.25 inch) steel liner on the bottom and sides and a .48 meter (1.58 foot) thick domed concrete top. The tank is set on a concrete foundation 11.5 meters (37.9 feet) below grade. The tank was covered with approximately 3.3 meters (11 feet) of overburden for shielding purposes. At present, the tank farm is enclosed by a 1.8 meters (6-foot) high chain link fence. The tanks are marked by yellow riser pipes and the ground surface is covered with gravel.

Location: Tank 241-B-202 is located on the north side of the 200 East Area about 914 meters (3,000 feet) north northeast of the 221-B building.

Waste Type: Storage Tank

Waste Description: Wastes consist of: 224 building wastes (lanthanum fluoride), metal waste, non-complexed waste, and B Plant high-level waste. The waste material is classified as non-complexed and presently has a total waste volume of 102,195 liters (27,000 gallons) comprised of 102,195 liters (27,000 gallons) sludge. There is 11,355 liters (3,000 gallons) of drainable liquid remaining. The volume of waste converts to approximately 3.7 meters (12 feet) depth in the tank.

| Code: 241-B-203 | Classification: Accepted |
### Single-Shell Tank

**Names:** 241-B-203; 241-B-TK-203  
**Type:** Single-Shell Tank  
**Status:** Inactive  
**Start Date:** 1/1/1951  
**End Date:** 1/1/1977

**Description:** The single-shell tank is the smallest of the tank farm designs with a 20 foot (6.1 m) diameter, a 24.9 foot (7.5 m) operating depth, and a 55,000 gallon (208,175 L) capacity. The tank is constructed of reinforced concrete with a 0.25 inch (6.4 mm) steel liner on the bottom and sides and a 1.58 foot (.48 m) thick domed concrete top. The tank is set on a concrete foundation 37.9 feet (11.5 m) below grade. The tank was covered with approximately 11 feet (3.3 m) of overburden for shielding purposes. At present, the tank farm is enclosed by a 6-foot (1.8 m) high chain link fence. The tanks are marked by yellow riser pipes and the ground surface is covered with gravel.

**Location:** Tank 241-B-203 is located on the north side of the 200 East Area about 3,000 feet (914 m) north northeast of the 221-B building.

**Release Description:** Between 1951 and 1977, unplanned release (UPR) occurred when about 300 gallons (1,136 L) of lanthanum fluoride escaped from tank 241-B-203 and contaminated the soil surrounding and beneath the tank. This UPR is recorded as UPR-200-E-130. The leak volume estimate is based solely on observed liquid level decreases in this tank and is considered to be the most accurate method for estimating leak volumes. Operating Limit Deviation Report (OLDR) No. 82-08 was issued in May 1982 because the liquid level exceeded the decrease criterion. Environmental Protection Deviation Report 83-02 was issued in November 1983 because of evidence of liquid level decreases, settling of solids around the tank perimeter, and liner corrosion.

**Waste Type:** Storage Tank  
**Waste Description:** Wastes consist of: 224 building wastes (lanthanum fluoride), metal waste, and non-complexed waste. The waste material is classified as non-complexed and presently has a total waste volume of 51,000 gallons (193,035 L) comprised of 50,000 gallons (189,250 L) sludge. There is 6,000 gallons (22,710 L) of drainable liquid remaining. The volume of waste converts to approximately just over 21 feet (6.4 m) depth in the tank.

### Single-Shell Tank

**Names:** 241-B-204; 241-B-TK-204  
**Type:** Single-Shell Tank  
**Status:** Inactive  
**Start Date:** 1/1/1951  
**End Date:** 1/1/1977

**Description:** The single-shell tank is the smallest of the tank farm designs with a 6.1 meters (20 foot) diameter, a 7.5 meters (24.9 foot) operating depth, and a 208,175 liters (55,000 gallon) capacity. The tank is constructed of reinforced concrete with a 6.4 millimeter (0.25 inch) steel liner on the bottom and sides and a 0.48 meters (1.58 foot) thick domed concrete top. The tank is set on a concrete foundation 11.5 meters (37.9 feet) below grade. The tank was covered with approximately 3.3 meters (11 feet) of overburden for shielding purposes. At present, the tank farm is enclosed by a 1.8 meter (6-foot) high chain link fence. The tanks are marked by yellow riser pipes and the ground surface is covered with gravel.

**Location:** Tank 241-B-204 is located on the north side of the 200 East Area about 914 meters (3,000 feet) north northeast of the 221-B building.

**Release Description:** Approximately 1,514 liters (400 gallons) leaked from tank 241-B-204 before or during 1984. The leak volume estimate is based solely on observed liquid level decreases in this tank and is considered to be the most accurate method for estimating leak volumes. Environmental Protection Deviation Report 83-02 was issued in November 1983 because of evidence of liquid level decreases, settling of solids around the tank perimeter, and liner corrosion.
level decreases, settling of solids around the tank perimeter, and liner corrosion.

**Waste Type:** Storage Tank

**Waste Description:** Wastes consist of: 224 building wastes (lanthanum fluoride), metal waste, B Plant flushes, and non-complexed waste. The waste material is classified as non-complexed and presently has a total waste volume of 189,250 liters (50,000 gallons) comprised of 185,465 liters (49,000 gallons) sludge. There is 22,710 liters (6,000 gallons) of drainable liquid remaining. The volume of waste converts to approximately 6.4 meters (21 feet) depth in the tank. Reported Date: May 31, 1996

**Names:** 241-B-301; 241-B-301B; 241-B-301-B Catch Tank; Drain Lines V238 and V312; IMUST; Inactive Miscellaneous Underground Storage Tank

**Type:** Catch Tank

**Status:** Inactive

**Start Date:** 1/1/1945  **End Date:** 1/1/1984

**Description:** The site is an underground tank, located within the 241-B Tank Farm chin link fence. The tank is surrounded by a steel chain and marked with radiological and IMUST signs. Four yellow risers are visible at the surface.

**Location:** The 241-B-301 Catch Tank is located on the west side of the 241-B Tank Farm, inside the tank farm fence. It is south of 12th Street and west of Baltimore Ave..

**Related Sites/Structures:** The 241-B-301 Catch Tank is connected to the 241-B-151, 241-B-152, 241-B-153, 241-B-154, 241-B-252, 242-B-151 diversion boxes in the 241-B Tank Farm. Lines V312, V238 and V238 are the drain lines from the diversion boxes.
**Process Description:** The 241-B-301 Catch Tank was designed to collect waste leaks from the 241-B diversion boxes that occurred during transfers.

**Waste Type:** Storage Tank

**Waste Description:** In 1993, the tank was estimated to contain 2230 liters (590 gallons) of supernate and 81648 liters (21,600 gallons) of sludge. Analytical data for tank liquid show moderately basic pH with extremely low levels of fissile materials. Cesium levels are also very low. The radionuclide analyses have been adjusted for 17.4 year radioactive decay (October 1974 to April 1992). From preliminary observations, supernate in this tank would not be designated as dangerous waste or prove a criticality hazard.

They are located south of the 241-B-101 tank.</td>
<td></td>
</tr>
</tbody>
</table>
Location: Diversion Box 241-BR-152 is located in the southeastern portion of the 241-BY Tank Farm, inside the tank farm fence.

Related Sites/Structures: Diversion Box 241-BR-152 interconnects with the following: 241-BXR-151 Diversion Box, the 241-B Tank Farm, and building 242-B (242-B Evaporator). The transfer line to 241-B Tank Farm is discussed in sitecode 200-E-197-PL.

Process Description: Diversion boxes and receiving vaults drain to catch tanks or single-shell tanks. Diversion Box 241-BR-152 is constructed of reinforced concrete with walls approximately 3.7 meters (12 feet) high and ranging from .3-.6 m (1-2 feet) thick. The outer dimensions are approximately 12.2 meters (40 feet) by 11 meters (36 feet). The concrete cover is about .3 meters (1 foot) above grade and is made up in sections consisting of thirty interlocking pre-formed concrete blocks. The concrete blocks range in thickness from .37 meters (1.2 feet) to .82 meters (2.7 feet) and are equipped with lifting bails made from approximate 3.43 centimeters (1.35 inch) diameter steel bar. Cranes were used to lift the blocks. The blocks were sealed with a combination of hot sealing compound and a flexcell bituminous fiber expansion joint.

Waste Type: Equipment

Waste Description: This unit was used for transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. It is estimated that approximately 50 pounds (23 kilograms) of lead shielding may stored in each diversion box.

Code: 241-BX-101
Names: 241-BX-101; 241-BX-TK-101
Type: Single-Shell Tank
Status: Inactive
Start Date: 1/1/1948
End Date: 1/1/1975

Description: The 22.9 meter (75 foot) diameter single-shell tank is constructed of 0.3 meters (1 foot) thick reinforced concrete with a 1 centimeter (0.375 inch) mild carbon steel liner (ASTM A 283 Grade C) on the bottom and sides and a 0.38 m (1.25 foot) thick domed concrete top. The top of the steel liner is 5.5 meters (18 feet) above the bottom of the tank (at the side wall). The tank has a dished bottom, with a maximum depth of 30 centimeter (12 inches) below the side wall of the tank and a 1.2 meter (4 foot) radius knuckle. The tank has a 16 foot 4.9 meters (4 foot) operating depth. The tank is set on a reinforced concrete foundation about 11.3 meters (37 feet) below grade. A three-ply cotton fabric waterproofing was applied over the foundation and steel tank. Four coats of primer paint were sprayed on all exposed interior tank surfaces. The tank ceiling dome was covered with three applications of magnesium zincfluorosilicate wash. Lead flashing was used to protect the joint where the steel liner met the concrete dome. Asbestos gaskets were used to seal the manholes in the tank dome. The tank was waterproofed on the sides and top with tar and gunnite. Tank capacity is 2,017,405 liters (533,000 gallons). The tank was covered with approximately 2.2 meters (7.25 feet) of overburden for shielding purposes. At present, the tank farm is surrounded by a chain link fence, topped with three strands of barbed wire. The ground surface is covered with gravel and no vegetation is seen.

Location: Tank 241-BX-101 is located on the north side of the 200 East Area about 850 meters (2,800 feet) north of the 221-B (B Plant) building.

Release Description: A leak of 30,280 liters (8,000 gallons) occurred prior to or during 1972. The leak volume estimate is an average of approximately 30,280 liters (8,000 gallons) for 19 tanks.

Waste Type: Water

Waste Description: 241-B-101 tank received bismuth phosphate metal waste; evaporator bottoms; B Plant low-level waste, ion exchange waste (waste fractionization), and supernatant containing B Plant low-
level waste; PUREX organic wash waste, cladding waste, coating waste, #1 acid and concentrator waste, ion exchange waste; REDOX ion exchange waste from 241-BY, -BX, -B, and -C tanks; tributyl phosphate waste; inorganic wash waste; coating waste; uranium recovery waste; complex waste; double-shell slurry feed; evaporator feed; organic wash waste; metal waste; non-complexed waste; waste water; in-tank solidification saltcake; cesium recovery waste. The unit received an inadvertent transfer of ~ 6,813 liters (1,800 gallons) of ARC-359 organic ion exchange resin in early 1972. The waste material is classified as non-complexed and presently has a total waste volume of 162,755 liters (43,000 gallons) comprised of 158,970 liters (42,000 gallons) sludge and 3,785 liters (1,000 gallons) of drainable supernatant liquid. The volume of waste converts to approximately .3 meters (1 foot) in the tank.

<td>Waste Description:</td>
<td>241-BX-102 tank received bismuth phosphate metal waste; diatomaceous earth; supernatant containing tributyl phosphate waste; metal waste; PUREX coating waste; B Plant low level waste; evaporator bottoms from 241-BX, -BY, -B, and -C tanks; organic wash waste; metal waste; non-complexed waste. The waste material is classified as non-complexed and presently has a total waste volume of 363,360 liters (96,000 gallons) comprised of 147,615 liters(39,000 gallons) of unknown waste; 64,345 liters (17,000 gallons) of diatomaceous earth; 151,400 liters (40,000 gallons) of sludge; no pumpable liquid remaining, and 15,140 liters (4,000 gallons) of drainable supernatant liquid. The volume of waste converts to approximately .8 meters (2.5 feet) in the tank.</td>

The 22.9 meters (75 foot) diameter single-shell tank is constructed of 0.3 meters (1 foot) thick reinforced concrete with a 1 centimeter (0.375 inch) mild carbon steel liner (ASTM A 283 Grade C) on the bottom and sides and a 0.38 meter (1.25 foot) thick domed concrete top. The top of the steel liner is 5.5 meters (18 feet) above the bottom of the tank (at the side wall). The tank has a dished bottom, with a maximum depth of 30 centimeters (12 inches) below the side wall of the tank and at 1.2 meters (4 foot) radius knuckle. The tank has a 4.9 meters (16 foot) operating depth. The tank is set on a reinforced concrete foundation about 11.3 meters (37 feet) below grade. A three-ply cotton fabric waterproofing was applied over the foundation and steel tank. Four coats of primer paint were sprayed on all exposed interior tank surfaces. The tank ceiling dome was covered with three applications of magnesium zincfluorosilicate wash. Lead flashing was used to protect the joint where the steel liner met the concrete dome. Asbestos gaskets were used to seal the manholes in the tank dome. The tank was waterproofed on the sides and top with tar and gunnite. Tank capacity is 2,017,405 liters (533,000 gallons). The tank was covered with approximately 2.2 meters (7.25 feet) of overburden for shielding purposes. At present, the tank farm is surrounded by a chain link fence, topped with three strands of barbed wire. The ground surface is covered with gravel and no vegetation is seen.

The contaminated soil in the vicinity of dry wells 21-03-03, 21-03-05, and 21-03-12 is believed to have been caused by tank overflow and spillage a number of years ago. 113,550 to 340,650 liters (30,000 to 90,000 gallons) of waste spilled on the ground between tank BX-102 and BX-103 in 1951.

The waste material is classified as non-complexed and presently has a total waste volume of 257,380 liters (68,000 gallons) comprised of 234,670 liters (62,000 gallons) of sludge and 22,710 liters (6,000 gallons) of drainable supernatant liquid. There is no pumpable liquid remaining. The volume of waste converts to approximately .5 meters (1.7 feet) in the tank.

<td>Waste Description</td>
<td>241-BX-105 tank received bismuth phosphate metal waste; PUREX coating waste; ion exchange waste; evaporator bottoms; supernatant containing metal waste; uranium recovery waste; B Plant low-level waste; concentrated reduction and oxidation (REDOX) waste; complexed and non-complexed waste; double-shell slurry feed from 241-BX, -BY, -C, -S, and -SX tanks; tributyl phosphate waste; evaporator feed; waste water. The waste material is classified as non-complexed and presently has a total waste volume of 193,035 liters (51,000 gallons) comprised of 162,755 liters (43,000 gallons) of sludge; 11,355 liters (3,000 gallons) of saltcake; 18,925 liters (5,000 gallons) of supernatant liquid. There remains 41,635 liters (11,000 gallons) drainable liquid and 15,140 liters (4,000 gallons) of pumpable liquid remaining. The volume of waste converts to approximately 0.3 meters (1 foot) in the tank. (WHC-EP-0182-98). It should be noted that recent FIC gauge level readings taken from riser 1 of the tank indicate a waste depth of 24.8 inches (0.6 m). Core samples recovered from risers 1 and 8 seem to confirm the waste depth and volume indicated by the FIC gauge (WHC-SD-WM-ER-406, Rev. 0B).</td>

</tbody>
</table>
Rev. 24
DOE/RL-88-30

Process Description: 241-BX-302A catch tank was designed to collect waste drainage and spills from the diversion boxes during transfers.

Waste Type: Soil
Waste Description: The total tank volume was estimated in 1984 to be 3,160 liters (835 gallons) of sludge with no supernate. The volume of waste converts to a waste level of about 26 cm (10.25 inches) in the tank. The contents of this tank does not meet the definition of dangerous waste (according to Ecology) and in its present condition, poses no immediate environmental or human safety hazard, either from a criticality risk or leakage of hazardous waste.

---

Code: 244-BX DCRT
Names: 244-BX DCRT; 244-BX Double-Contained Receiver Tank; 244-BX Receiver Vault; 244-BX RT; 244-BX-TK/SMP
Type: Receiver Tank
Status: Inactive
Start Date: 1/1/1983
End Date: 1/1/2005
Classification: Accepted
Reclassification: None

Description: 244-BX Receiver Tank is an underground, double-contained receiver tank (DCRT) constructed of carbon steel with a 117,335 liters (31,000 gallons) design capacity. The tank sets lengthwise in a reinforced concrete, steel-lined vault. The lowest portion of the vault is 8.5 m (28 feet) below grade and houses the tank. The upper portion of the vault is comprised of three sections; the pump pit in the southern section comprises almost half the space. The filter pit is in the middle section and the instrumentation pit is in the northern section of this part of the vault.

Location: 244-BX Receiver Vault is located on the north side of the 200 East Area about 847 meters (2,780 feet) north of the 221-B (B Plant) building and about 22.1 meters (72.6 feet) east of tank 241-BX-101.

Related Sites/Structures: 244-BX Receiver Vault interconnects with the following: 241-B, 241-BX, & 241-BY Tank Farms.

Waste Type: Misc. Trash and Debris
Waste Description: 244-BX Receiver Tank can accept/transport waste from 241-B, 241-BX, & 241-BY Tank Farms. This tank last received waste from the 241-BY-102 and 241-BY-109 Single-Shell Tanks during the 1991 Stabilization Campaign. The tank currently contains 17,636 gallons (66,752 L) of waste. This represents just over one-half of the tank's design capacity.

---

Code: 241-BXR-151
Names: 241-BXR-151; 241-BXR-151 Diversion Box
Type: Diversion Box
Status: Inactive
Start Date: 1/1/1948
End Date: 1/1/1984
Classification: Accepted
Reclassification: None

Description: Diversion Box 241-BXR-151 is an underground structure constructed of concrete. Approximately 0.3 meters (1 foot) of the diversion box concrete cover appears above grade. The outer dimensions are approximately 14.6 meters (48 feet) by 9.4 meters (30.7 feet). The structure is L shaped from the side view with 4 meters (13 feet) of the north side being 5.1 meters (16.7 feet) high and 5.4 m (17.7 feet) of the southern portion being 2.4 meters (7.75 feet) high. The southern portion of the structure is 2.3 meter (7.5 feet) below grade. The concrete cover is made up in sections consisting of twenty nine interlocking pre-formed concrete blocks. The concrete blocks are about 0.9 meters (3 feet) wide and range in thickness from 0.46 meters (1.5 feet) to 0.61 meters (2 feet). Each cover block is equipped with lifting bails made from
steel bar. The blocks were sealed with a combination of hot sealing compound and a flexcell bituminous fiber expansion joint.

**Location:** Diversion Box 241-BXR-151 is located in the southern portion of the 241-BX Tank Farm, south of the 241-BX-107 tank.

**Related Sites/Structures:** The diversion box is associated with the 244-BXR vault.

**Process Description:** Diversion Box 241-BXR-151 connects with the 244-BXR Vault with the 241-BX Tank Farm.

**Waste Type:** Water

**Waste Description:** This unit was used for the transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

---

**Code:** 241-BXR-152

**Names:** 241-BXR-152; 241-BXR-152 Diversion Box

**Type:** Diversion Box

**Status:** Inactive

**Start Date:** 1/1/1948

**End Date:** 1/1/1984

**Description:** 241-BXR-152 is an underground concrete structure. It is co-located in a series of three diversion boxes that are joined together. 241-BXR-152 is the center diversion box. 241-BR-152 Diversion Box is on the eastern end and 241-BYR-152 is on the west end of the diversion box group. Its cover blocks and lifting bails are visible from the surface.

**Location:** Diversion Box 241-BXR-152 is located in the southeastern portion of the 241-BX Tank Farm, inside the tank farm fence. It is south of the 241-BX-101 tank.

**Related Sites/Structures:** Diversion Box 241-BXR-152 is associated with the 241-BX Tank Farm and the 241-BX-302A catch tank.

**Process Description:** Diversion Box 241-BXR-152 is constructed of concrete with a height of approximately 3.4 meters (11.1 feet). Approximately 0.3 meters (1 foot) of the diversion box concrete cover appears above grade. The outer dimensions are approximately 10.7 meters (35 feet) by 11.5 meters (37.8 feet). The structure's cover is in sections consisting of several interlocking pre-formed concrete blocks. Diversion Boxes and receiving vaults drain to catch tanks or single-shell tanks.

**Waste Type:** Chemicals

**Waste Description:** This unit was used to transfer waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. It is estimated that approximately 50 pounds (23 kilograms) of lead shielding may be stored in each diversion box.

---

**Code:** 241-BXR-153

**Names:** 241-BXR-153; 241-BXR-153 Diversion Box; Line 9453

**Type:** Diversion Box

**Status:** Inactive

**Start Date:** 1/1/1948

**End Date:** 1/1/1984

**Description:** The 241-BXR-153 Diversion box is co-located with the 241-BYR-153 Diversion Box. 241-
BXR-153 is on the east side of the 241-BYR-153 Diversion Box. The diversion boxes are underground concrete structures. Their cover blocks and lifting bails are visible from the surface.

**Location:** Diversion Box 241-BXR-153 is located in the southern portion of the 241-BX Tank Farm, inside the tank farm fence. It is south of the 241-BX-104 tank.

**Related Sites/Structures:** Diversion Box 241-BXR-153 is associated with the 241-BX and 241-BY Tank Farms and the 241-B-152 and 241-B-155 diversion boxes. Line 9453 is the drain line.

**Process Description:** Diversion boxes and receiving vaults drain to catch tanks or single-shell tanks. Diversion Box 241-BXR-153 is constructed of concrete with a height of approximately 3.7 meters (12 feet). Approximately 0.3 meters (1 foot) of the diversion box concrete cover appears above grade. The outer dimensions are approximately 11.6 meters (38 feet) by 12 meters (39.3 feet). The structure's cover is in sections consisting of several interlocking pre-formed concrete blocks. The northern section consists of 12 blocks, center section has 11, and the southern section has 8 cover blocks.

**Waste Type:** Process Effluent

**Waste Description:** This unit was used to transfer waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. It is estimated that approximately 50 pounds (23 kilograms) of lead shielding may be stored in each diversion box.
This vault does not pose a criticality hazard from the levels of fissionable isotopes that were found.

Tank 244-BXR-001 is located in an individual cell inside of the 244-BXR Vault. The concrete cell contains a sump with a capacity of 170 liters (45 gallons). Each cell within the vault is separated from the adjacent cell by a 0.6 meter (2 foot) thick concrete wall. The tank is constructed of 0.64 centimeter (1/4 inch) carbon steel and is 6.1 meters (20 feet) in diameter, 6.1 meters (20 feet) tall, and has a nominal capacity of 189,000 liters (50,000 gallons). When in service, the tank was used as a slurry accumulation tank receiving a maximum of 51,930 liters (13,720 gallons) per day of metal waste slurry from tanks in the 241-BX and 241-BY Tank Farms. Tank 244-BXR-001 was isolated in 1985 as part of the 244-BXR Vault isolation. The results for samples taken from the tank and sump in 1984 are available in WHC-SD-EN-ES-040, Rev 0.

Tank 244-BXR-002 is located in an individual cell inside of the 244-BXR Vault. The concrete cell contains a sump with a capacity of 170 liters (45 gallons). Each cell within the vault is separated from the adjacent cell by a 0.6 meter (2 foot) thick concrete wall. The tank is constructed of 0.64 centimeter (1/4 inch) Type 347 stainless steel and is 4.3 meters (14 feet) in diameter, 3.7 meters (12 feet) tall, and has a nominal capacity of 56,800 liters (15,000 gallons). The tank contains in-tank cooling coils. When in service, Tank 244-BXR-002 and Tank 244-BXR-003 were configured and used identically. The tanks were used as a pair in waste
blending operations. Under normal conditions a slurry stream was brought in from tank 244-BXR-001 and mixed with nitric acid. Tank 244-BXR-002 received a maximum of 53,860 liters (14,230 gallons) per day from tank 244-BXR-001 and a maximum of 29,500 liters (7,800 gallons) per day of nitric acid. The blended solution was then pumped to Tank 244-BXR-011. Tank 244-BXR-002 was isolated in 1985 as part of the 244-BXR Vault isolation. The results for samples taken from the tank and sump in 1984 are available in WHC-SD-EN-ES-040, Rev 0. The sump may contain ferrocyanide discharged from the 241-BXR-151 diversion box.

Description: Tank 244-BXR-011 is located in an individual cell inside of the 244-BXR Vault. The cell contains a sump with a capacity of 170 liters (45 gallons). Each cell within the vault is separated from the adjacent cell by a 0.6 meter (2 foot) thick concrete wall. The tank is constructed of 0.64 centimeter (1/4 inch) Type 347 stainless steel and is 6.1 meters (20 feet) in diameter, 6.1 meters (20 feet) tall, and has a nominal capacity of 189,000 liters (50,000 gallons).
gallons). When in service, the tank was used as a pump tank for the Uranium Recovery operations. It received approximately 103,000 liters (27,200 gallons) per day of acid solutions from Tanks 244-BXR-002 and 244-BXR-003. The solutions were pumped from 244-BXR-011 to the 241-ER-151 diverter station and from there to U Plant for uranium recovery. Tank 244-BXR-011 was isolated in 1985 as part of the 244-BXR Vault isolation. The results for a tank solids analysis performed in 1978 are available in WHC-SD-EN-ES-040, Rev. 0. Literature indicates that the wall of the Tank 244-BXR-011 is buckled. Occurrence report 79-70 describes the condition of the tank. The tank failure was due to an overpressure condition on the exterior of the tank from a higher than allowed liquid level in the cell.

### Code: 241-BY-105  
#### Classification: Accepted  
#### Reclassification: None  
#### Type: Single-Shell Tank  
#### Status: Inactive  
#### Description: The unit is a single-shell tank built in 1948-1949. It is comprised of a carbon steel liner within a reinforced concrete shell, 11.3 meters (37 feet) high, with a capacity of 2,869,030 liters (758,000 gallons). The bottom of the unit is 13.7 meters (45 feet) below grade, and the dome is located below grade for shielding purposes. This type was built to the original design, having a dished bottom but with an increased operating depth of 7 meters (23 feet).  
#### Location: The 241-BY Tank Farm is directly north of the 241-BX Tank Farm. The 241-BY-105 tank is located in the central portion of the 241-BY Tank Farm.  
#### Process Description: This tank is an assumed leaker with a leak of approximately 30,280 liters (8,000 gallons) reported in 1984.  
#### Waste Type: Process Effluent  
#### Waste Description: Tank BY-105 received metal waste via cascade (1951), U Plant waste from tanks 241-BY-107 and 241-BY-110 (1954) and U Plant waste intermittently until 1966. The tank received wastewater (1957-1974), coating waste (1962-1967), and was an in-tank solidification bottoms receiver (1967). The tank contained evaporator bottoms waste from the in-tank solidification program (1968-1974). Sixty-three tons of Portland cement was added in 1977. Presently, the waste material is classified as non-complexed and has a total waste volume of 1,903,855 liters (503,000 gallons). Saltcake comprised 1,737,315 liters (459,000 gallons), sludge comprises 166,540 liters (44,000 gallons), and no supernatant. There is no pumpable liquid remaining and 726,720 liters (192,000 gallons) drainable liquid remaining.

**Location:**
The 241-BY Tank Farm is directly north of the 241-BX Tank Farm. The 241-BY-106 tank is located in the northern portion of the 241-BY Tank Farm.

**Release Description:**
Current tank leak volume estimate of 30,280 liters (8,000 gallons) is based on an average of 19 tanks.

**Process Description:**
The tank was used as a settling tank for ferrocyanide scavenged uranium recovery process waste in 1956.

**Waste Type:**
Process Effluent

**Waste Description:**
Bismuth phosphate first-cycle waste (1953), in-plant ferrocyanide waste from 1955-7, wastewater (1957-1974), and supernatant containing coating waste (1961-1970). In 1968 the tank began to receive evaporator bottoms from 241-BY and -C tank farms waste. The tank received in-tank solidification bottoms and recycle waste between 1970 and 1976 and evaporator feed from 1976-7. The tank also received tributyl phosphate waste. Presently, the waste material is classified as non-complexed and has a total waste volume of 2,429,970 liters (642,000 gallons). Saltcake comprises 2,070,395 liters (547,000 gallons), sludge comprises 359,575 liters (95,000 gallons), and no supernatant. There is 616,955 liters (163,000 gallons) pumpable liquid remaining and 757,000 liters (200,000 gallons) drainable liquid remaining. This is an ITS-2 unit.

**Code:** 241-BY-107  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 241-BY-107; 241-BY-TK-107

**Type:** Single-Shell Tank

**Status:** Inactive

**Start Date:** 1/1/1950  
**End Date:** 1/1/1974

**Description:**
The unit is comprised of a carbon steel liner within a reinforced concrete shell, 11.3 meters (37 feet) high, with a capacity of 2,869,030 liters (758,000 gallons). The bottom of the unit is 45 feet below grade, and the dome is located below grade for shielding purposes. This type was built to the original design, having a dished bottom but with an increased operating depth of 7 meters (23 feet).

**Location:**
The 241-BY Tank Farm is directly north of the 241-BX Tank Farm. The 241-BY-107 tank is located in the southern portion of the 241-BY Tank Farm.

**Release Description:**
A leak in the amount of 57,153 liters (15,100 gallons) occurred prior to or during 1984. The leak volume was based on observed liquid level decreases within the tank.

**Waste Type:**
Process Effluent

**Waste Description:**
The tank received tributyl phosphate waste; bismuth phosphate first-cycle waste; and supernatant containing tributyl phosphate waste, coating waste, and evaporator bottoms from 241-C, -BX, and -T (BY) tank farms. Presently, the waste material is classified as non-complexed and has a total waste volume of 1,006,810 liters (266,000 gallons). Saltcake comprises 779,710 liters (206,000 gallons), sludge comprises 227,100 liters (60,000 gallons), there is 94,625 liters (25,000 gallons) of drainable liquid and no pumpable liquid remaining. This is an ITS-2 unit.

**Code:** 241-BY-108  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 241-BY-108; 241-BY-TK-108

**Type:** Single-Shell Tank

**Status:** Inactive

**Start Date:** 1/1/1951  
**End Date:** 1/1/1972

*Hanford Site Waste Management Units Report*  
February 2015  
1566
**Description:** The unit is a single-shell tank built in 1948. It is comprised of a carbon steel liner within a reinforced concrete shell, 11.3 meters (37 feet) high, with a capacity of 2,869,030 liters (758,000 gallons). The bottom of the unit is 13.7 meters (45 feet) below grade, and the dome is located below grade for shielding purposes. This tank type was built to the original design, having a dished bottom but with an increased operating depth of 7 meters (23 feet).

**Location:** The 241-BY Tank Farm is directly north of the 241-BX Tank Farm. The 241-BY-108 tank is located in the central portion of the 241-BY Tank Farm.

**Release Description:** UPR-200-E-135

**Related Sites/Structures:** 241-BY-108 is the second tank in a three-tank cascade series (241-BY-107, 241-BY-108 and 241-BY-109).

**Waste Type:** Process Effluent

**Waste Description:** Initially tank BY-108 received first cycle waste from the tank 241-BY-107 cascade from 1951-1953. The tank received U Plant waste from 1953-1959. The tank received in-plant ferrocyanide waste from 1954-1957. The tank contained U Plant waste and coating waste from 1959-1968. The tank received evaporator bottoms waste from 1968 to 1973. From 1972-1975, the tank received wastewater. Presently, the waste material is classified as non-complexed and has a total waste volume of 862,980 liters (228,000 gallons). Saltcake comprises 280,090 liters (74,000 gallons), sludge comprises 582,890 liters (154,000 gallons), and no supernatant. There is no pumpable liquid remaining and 34,065 liters (9,000 gallons) drainable liquid remaining. This is an ITS-2 unit.

---

**Code:** 241-BY-109  
**Classification:** Accepted

**Names:** 241-BY-109; 241-BY-TK-109  
**Reclassification:** None

**Type:** Single-Shell Tank  
**Start Date:** 1/1/1951  
**End Date:** 1/1/1979

**Description:** The unit is comprised of a carbon steel liner within a reinforced concrete shell, 11.3 meters (37 feet) high, with a capacity of 2,869,030 liters (758,000 gallons). The bottom of the unit is 13.7 meters (45 feet) below grade, and the dome is located below grade for shielding purposes. This type was built to the original design, having a dished bottom but with an increased operating depth of 7 meters (23 feet). It is surrounded by a safety fence within the tank farm.

**Location:** The 241-BY Tank Farm is directly north of the 241-BX Tank Farm. The 241-BY-109 tank is located in the northern portion of the 241-BY Tank Farm.

**Waste Type:** Process Effluent

**Waste Description:** The tank received supernatant containing tributyl phosphate waste; evaporator bottoms; and PUREX organic wash waste from 241-B, -BX, -BY, and -C tank farms. Presently, the waste material is classified as non-complexed and has a total waste volume of 1,601,055 liters (423,000 gallons). Saltcake comprises 1,286,900 liters (340,000 gallons) and sludge comprises 314,155 liters (83,000 gallons). There is 105,980 liters (28,000 gallons) of drainable and 15,140 liters (4,000 gallons) of pumpable liquid remaining.

---

**Code:** 241-BY-110  
**Classification:** Accepted

**Names:** 241-BY-110; 241-BY-TK-110  
**Reclassification:** None

**Type:** Single-Shell Tank  
**Start Date:** 1/1/1951
Status: Inactive  
End Date: 1/1/1977

Description: The unit is a single-shell tank built in 1948. The unit is comprised of carbon steel liner within a reinforced concrete shell, 11.3 meters (37 feet) high, with a capacity of 2,869,030 liters (758,000 gallons). The bottom of the unit is 13.7 meters (45 feet) below grade, and the dome is located below grade for shielding purposes. This type was built to the original design, having a dished bottom but with an increased operating depth of 7 meters (23 feet).

Location: The 241-BY Tank Farm is directly north of the 241-BX Tank Farm. The 241-BY-110 tank is located in the southwestern portion of the 241-BY Tank Farm.

Waste Type: Process Effluent

Waste Description: Initially tank 241-BY-110 received first cycle waste in 1951. The tank received decontamination waste in 1952. The tank contained first cycle supernatant until 1954 when it was pumped to a ditch. The tank received in-plant ferrocyanide waste from 1954-1947. The tank contained U Plant uranium recovery process waste and coating waste from 1957-1958. The tank also received wastewater in 1957. The tank contained coating waste in 1968-1969. From 1969-1976, the tank was used for storage of evaporator bottoms waste. The tank contained concentrated evaporator feed bottoms waste from 1976-1967. Presently, the waste material is classified as non-complexed and has a total waste volume of 1,506,430 liters (398,000 gallons). Saltcake comprises 1,116,575 liters (295,000 gallons), sludge comprises 398,000 liters (103,000 gallons), and no supernatant. There is no pumpable liquid remaining and 34,065 liters (9,000 gallons) drainable liquid remaining.

Code: 241-BY-111  
Classification: Accepted

Names: 241-BY-111; 241-BY-TK-111

Type: Single-Shell Tank

Start Date: 1/1/1952
End Date: 1/1/1977

Description: The unit is comprised of a carbon steel liner within a reinforced concrete shell, 11.3 meters (37 feet) high, with a capacity of 2,869,030 liters (758,000 gallons). The bottom of the unit is 13.7 meters (45 feet) below grade, and the dome is located below grade for shielding purposes. This type was built to the original design, having a dished bottom but with an increased operating depth of 7 meters (23 feet).

Location: The 241-BY Tank Farm is directly north of the 241-BX Tank Farm. The 241-BY-111 tank is located in the western portion of the 241-BY Tank Farm.

Waste Type: Process Effluent

Waste Description: The tank received bismuth phosphate metal waste; tributyl phosphate; PUREX coating waste; organic wash waste; and supernatant containing evaporator bottoms, tributyl phosphate waste, and organic wash waste from 241-BY and -C tanks. Presently, the waste material is classified as non-complexed and has a total waste volume of 1,737,315 liters (459,000 gallons). Saltcake comprises 1,657,830 liters (438,000 gallons), sludge comprises 79,485 liters (21,000 gallons), there is no drainable liquid or pumpable liquid remaining. Net total of liquids pumped from this tank is 1,185,462 liters (313,200 gallons).

Code: 241-BY-112  
Classification: Accepted

Names: 241-BY-112; 241-BY-TK-112

Type: Single-Shell Tank

Start Date: 1/1/1951
Status: Inactive  End Date: 1/1/1976

Description: The unit is comprised of a carbon steel liner within a reinforced concrete shell, 11.3 meters (37 feet) high, with a capacity of 2,869,030 liters (758,000 gallons). The bottom of the unit is 13.7 meters (45 feet) below grade, and the dome is located below grade for shielding purposes. This type was built to the original design, having a dished bottom but with an increased operating depth of 7 meters (23 feet).

Location: The 241-BY Tank Farm is directly north of the 241-BX Tank Farm. The 241-BY-112 tank is located in the northwestern portion of the 241-BY Tank Farm.

Waste Type: Process Effluent

Waste Description: The tank received bismuth phosphate metal waste; tributyl phosphate; supernatant containing tributyl phosphate; coating waste, and evaporator bottoms from 241-B, -BX, -BY, and -C tanks. Presently, the waste material is classified as non-complexed and has a total waste volume of 1,010,435 liters (291,000 gallons). Saltcake comprises 1,082,510 liters (286,000 gallons), sludge comprises 18,925 liters (5,000 gallons), there is no pumpable liquid remaining and 8,000 gallons (30,280 L) of drainable liquid remaining.

Code: 241-BY-ITS1  Classification: Accepted
Names: 241-BY-ITS1; In-Tank Solidification System; ITS-1  Reclassification: None
Type: Storage Tank  Start Date: 1/1/1965
Status: Inactive  End Date: 1/1/1974

Description: The system includes three vessels; the IX column, IX feed tank and the scrub solution circulation tank. Although portions of the equipment and ducting have been removed, the bulk of the off-gas equipment remains. It is enclosed in a locked chain link fence posted with a High Radiation Area sign. The facility is constructed primarily above-ground with some underground components.

Location: The ITS-1 system is located on the east side of the 241-BY tank farm. It is inside the tank farm fenced boundary.

Related Sites/Structures: The system is associated with tanks 241-BY-101 and 241-BY-102 and pipeline 200-E-265-PL. 241-BY-ITS2 is discussed in sitecodes 200-E-59 and 200-E-60.

Process Description: The purpose of the In Tank Solidification System was to concentrate the waste in the underground storage tanks. Evaporation was achieved by sparging hot air into the tank waste solutions. The 241-BY tank farm is the only tank farm to include the operation of the in-tank solidification (ITS) system. The ITS 1 system was installed for tanks 241-BY-101 and 241-BY-102. Hot air was used to evaporate tank waste. The process condensate was drained to the 216-BY-201 flush tank and then disposed to cribs located north of 241-BY Tank Farm. Most of the components of the system have been removed. The remaining components include the de-entrainer, condenser, exhauster and ion exchanger containing zeolite resin. ITS-1 was later converted to a cooler for the ITS-2 system.

Code: 241-BYR-09A  Classification: Accepted
Names: 241-BYR-09A; 241-BY-109 Valve Pit  Reclassification: None
Type: Valve Pit  Start Date: 1/1/1951
Status: Inactive  End Date:
**Description:** The valve pit is an underground, concrete structure extending approximately 6.1 meters (20 feet) below ground surface.

**Location:** The valve pit is located inside the 241-BY Tank Farm, on the northwest side of the 241-BY-109 tank.

**Process Description:** The valve pit contained a pipe valve. The valve handle extended above the ground surface. It was installed as part of the uranium recovery operation project.

---

**Code:** 241-BYR-152  
**Classification:** Accepted  

**Names:** 241-BYR-152; 241-BYR-152 Diversion Box  

**Type:** Diversion Box  

**Status:** Inactive  

**Start Date:** 1/1/1950  
**End Date:** 1/1/1984  

**Description:** 241-BYR-152 is co-located in a series of three diversion boxes that are joined together. 241-BXR-152 is the center diversion box. 241-BR-152 Diversion Box is on the east end and 241-BYR-152 is on the west end of the diversion box group. The diversion boxes are underground cement structures. Their cover blocks and lifting bails are visible from the surface.

**Location:** Diversion Box 241-BYR-152 is located in the southeastern portion of the 241-BX Tank Farm, inside the tank farm fence. It is south of the 241-BX-101 tank.

**Related Sites/Structures:** Diversion Box 241-BYR-152 is associated with the 241-BX Tank Farm and 241-BY Tank Farms and the 241-BXR-152 Diversion Box.

**Process Description:** Diversion Box 241-BYR-152 is constructed of concrete with a height of approximately 3.7 meters (12 feet). Approximately 0.3 meters (1 foot) of the diversion box concrete cover appears above grade. The outer dimensions are approximately 11 meters (36.1 feet) by 11.5 meters (37.8 feet). The structure's cover is in sections consisting of several interlocking pre-formed concrete blocks. Diversion boxes and receiving vaults drain to catch tanks or single-shell tanks.

**Waste Type:** Process Effluent  

**Waste Description:** This unit was used for the transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

---

**Code:** 241-BYR-153  
**Classification:** Accepted  

**Names:** 241-BYR-153; 241-BYR-153 Diversion Box  

**Type:** Diversion Box  

**Status:** Inactive  

**Start Date:** 1/1/1950  
**End Date:** 1/1/1984  

**Description:** The diversion boxes are underground concrete structures. Their cover blocks and lifting bails are visible from the surface. The 241-BYR-153 Diversion box is co-located with the 241-BXR-153 Diversion Box. 241-BYR-153 is on the west side of the 241-BXR-153 Diversion Box.

**Location:** Diversion Box 241-BYR-153 is located in the southern portion of the 241-BX Tank Farm, inside the tank farm fence. It is south of the 241-BX-104 tank.

**Related Sites/Structures:** Diversion Box 241-BYR-153 is associated with the 241-BX and 241-BY Tank Farms.
Process Description: Diversion boxes and receiving vaults drain to catch tanks or single-shell tanks. Diversion Box 241-BYR-153 is constructed of concrete with a height of approximately 3.7 meters (12 feet). Approximately 0.3 meters (1 foot) of the diversion box concrete cover appears above grade. The outer dimensions are approximately 11.3 meters (37 feet) by 10.5 meters (34.5 feet). The structure's cover is in sections consisting of several interlocking pre-formed concrete blocks. The northern section consists of 10 blocks, center section has 11, and the southern section has 8 cover blocks.

Waste Type: Process Effluent

Waste Description: This unit was used for transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

Hanford Site Waste Management Units Report
February 2015

Page 1571
**Location:** The In Tank Solidification (ITS 2) system tank is located inside the 241-BY Tank Farm. The tank is inside the 241-BY-112 Tank Sluice Pit in the northwest portion of the tank farm.

**Related Sites/Structures:** The tank is associated with tanks 241-BY-111 and 241-BY-112, and the ITS-2 System (In-Tank Solidification), sitecode 200-E-60 Heater Flush Tank and Sitecode 241-BY-ITS1. The system is associated with pipeline 200-E-265-PL.

**Process Description:** The 241-BY tank farm is the only tank farm to include the operation of the in-tank solidification (ITS) system. ITS-2 was first installed in tanks 241-BY-111 and 241-BY-112. It was later extended to the remaining 241-BY tanks. The tank received condensate from the heated in-ground waste tank for return to the 241-BY-112 tank. The ITS-2 system used electric immersion heaters.

The most notable difference between the BY tank farm and the other SST facilities is the placement and operation of the in-tank solidification (ITS) system in the tank farm. ITS-1, which used heated air circulated through tank waste, was installed for tanks BY-101 and BY-102. This system began operation in 1965. ITS-2, using an in-tank heater, was installed first in tanks BY-111 and BY-112 and began operation in 1968. ITS-2 was extended to the remaining BY tanks by 1971 and ITS-1 was converted to a cooler for ITS-2. The ITS Process was superseded by salt-well pumping and was shut down in 1974.

**Waste Type:** Steam Condensate

**Waste Description:** The abandoned tank is considered to be the waste. The current contents of the tank is not known.

Description: The site is the soil inside and adjacent to the chain link fence that surrounds the 241-B Tank Farm. Various radiological postings and warning signs are attached to the chain link fence. The interior of the tank farm complex is covered with gravel. Many risers and monitoring devises for the underground structures are visible on the surface. The individual unplanned releases associated with the 241-B Tank Farm are not separately marked or posted. Occasionally, radioactive contamination is found adjacent to the outside of the tank farm fence, resulting in a contamination zone extension around the tank farm perimeter. These areas will also be considered tank farm soil. A posted Contamination Area, marked with steel posts and chain, currently extends east and south outside the 241-B Tank Farm fence. The posted area size and shape varies with additional radiological surveys.

Location: The site is located east of Baltimore Ave. and south of 12th Street in 200 East Area.

Release Description: The exact extent (horizontal and vertical) of the soil contaminated by unplanned releases that occurred within this farm over the years are not known. Some of the single shell tanks have leaked to the soil below the tank farm. Other releases spread contamination to the surface soil surrounding the tanks.

Related Sites/Structures: Unplanned Releases UPR-200-E-4, UPR-200-E-6, UPR-200-E-38, UPR-200-E-73, UPR-200-E-74, UPR-200-E-75, UPR-200-E-76, UPR-200-E-108, UPR-200-E-109, UPR-200-E-127, UPR-200-E-128, UPR-200-E-129, and UPR-200-E-130 are associated with the 241-B Tank Farm. Two of these sites are listed in TPA Appendix B as TSD-associated sites (UPR-200-E-76 and UPR-200-E-109). All are to be addressed with the closeout of the tank farm TSD. As such, site 200-E-120 is also a TSD-associated site.

Hanford Site Waste Management Units Report
February 2015
Description: The site is the soil inside and adjacent to the chain link fence that surrounds the 241-BX/BY Tank Farms. Various radiological postings and warning signs are attached to the chain link fence. The interior of the tank farm complex is covered with gravel. Many risers and monitoring devises for the underground structures are visible on the surface. The individual unplanned releases associated with the 241-BX/BY Tank Farms are not separately marked or posted. Occasionally, radioactive contamination is found adjacent to the outside of the tank farm fence, resulting in a contamination zone extension around the tank farm perimeter. These areas will also be considered tank farm soil. A steep slope is located adjacent to the north and northeast sides of the 241-BY Tank Farm. The contaminated slope has been stabilized with cobble and gravel. The slope is considered part of the tank farm perimeter.

Location: The 241-BX/BY Tank Farm complex is located south of 12th Street and west of Baltimore Ave., inside 200 East Area.

Release Description: The exact extent (horizontal and vertical) of the soil contaminated by unplanned releases that occurred within this farm complex over the years are not known. Some of the single shell tanks have leaked to the soil below the tank farm. Other releases spread contamination to the surface soil surrounding the tanks.

Related Sites/Structures: Previously reported unplanned releases that were identified in WIDS and located inside the 241-BX/BY Tank Farm Complex are UPR-200-E-5, UPR-200-E-135, UPR-200-E-134, UPR-200-E-133, UPR-200-E-132, UPR-200-E-131, UPR-200-E-116, UPR-200-E-110, and UPR-200-E-105. Site UPR-200-E-105 is listed in TPA Appendix B as a TSD-associated site. All the sites are to be addressed with the closeout of the tank farm TSD. As such, site 200-E-132 is also a TSD-associated site.

Waste Type: Chemicals

Waste Description: Liquid releases occurred from underground leaks in tanks and transfer lines. Airborne contamination spreads occurred from activities conducted in valve pits and diversion boxes. Both types of releases contributed to the contamination in the soil.

Code: 200-E-197-PL

Names: 200-E-197-PL; Encased Pipelines Between 241-BR-152 Diversion Box and 241-B Tank Farm; Lines 9002, 9006, 9010, 9014, 9017, 9020, 9031, 9032, 9035, 9037, 9038, 9041, 9044 and 9047

Type: Encased Tank Farm Pipeline

Status: Inactive

Description: The waste site is an underground concrete transfer line encasement. Fourteen 10 centimeter (6 inch) diameter, carbon steel lines are located within the same concrete encasement. They are placed with seven lines on the bottom of the encasement and seven lines above those lines within the concrete encasement.

Location: The pipeline extends from 241-BR-152 Diversion Box, inside 241-BX Tank Farm to the 241-B-101, 241-B-102 and 241-B-103 tanks inside 241-B Tank Farm.

Related Sites/Structures: The waste lines are associated with 241-BR-152 diversion Box, 241-B-101, 241-B-102 and 241-B-103 single shell tanks.

Classification: Accepted

Reclassification: None

Code: 200-E-208-PL

Names: 200-E-208-PL; Lines V304 and V305 from 241-BY Tank Farm to 241-B-252 Diversion Box

Type: Encased Tank Farm Pipeline

Status: Inactive

Description: The waste site is an underground concrete transfer line encasement. Fourteen 10 centimeter (6 inch) diameter, carbon steel lines are located within the same concrete encasement. They are placed with seven lines on the bottom of the encasement and seven lines above those lines within the concrete encasement.

Location: The pipeline extends from 241-BR-152 Diversion Box, inside 241-BX Tank Farm to the 241-B-101, 241-B-102 and 241-B-103 tanks inside 241-B Tank Farm.

Related Sites/Structures: The waste lines are associated with 241-BR-152 diversion Box, 241-B-101, 241-B-102 and 241-B-103 single shell tanks.

Classification: Accepted

Reclassification: None

Hanford Site Waste Management Units Report
February 2015
| Type: | Direct Buried Tank Farm Pipeline | Start Date: |
| Status: | Inactive | End Date: |
| Description: | The waste site is two underground, 10 centimeter (4 inch) diameter, carbon steel lines buried in the same soil trench. |
| Location: | The lines extend out of the north side of the 241-BY Tank Farm, turn south on the west side of Baltimore Ave. and cross under Baltimore Ave. to connect to the 241-B-252 Diversion Box, located inside the 241-B Tank Farm. |
| Related Sites/Structures: | The lines are associated with tanks 241-BY-109 and 241-BY-111 and 241-B-252 Diversion Box. |

| Code: | 200-E-216-PL | Classification: | Accepted |
| Type: | Direct Buried Tank Farm Pipeline | Start Date: |
| Status: | Inactive | End Date: |
| Description: | The waste site is seven stainless steel lines that are buried in the same soil trench. All of the lines are 9 centimeter (3.5 inch) diameter lines. |
| Location: | The transfer lines are located southeast of 241-BX Tank Farm. The lines exit the southeast corner of 241-BX Tank Farm and cross under Baltimore Ave. to connect to the diversion boxes inside 241-B Tank Farm. The lines branch off, forming a "V". Lines V251, V252, V253 and V242 go to the 241-B-152 Diversion Box. Lines V235, V236 and V237 go to the 241-B-151 Diversion Box (see subsites). |
| Related Sites/Structures: | The transfer lines are associated with the 241-BX-153 Diversion Box, located inside 241-BX Tank Farm and 241-B-151 and 241-B-152 Diversion Boxes, located inside 241-B Tank Farm. |
| This Site has the Following SubSites: | |
| Code: | 200-E-216-PL:1 | |
| Names: | 200-E-216-PL:1; Portion of Soil Trench Containing All Seven Lines (V235, V23, V237, V251, V252, V253 and V242) | |
| Code: | 200-E-216-PL:2 | |
| Names: | 200-E-216-PL:2; Northern Portion of Soil Trench Containing Lines V235, V236 and V237 | |
| Code: | 200-E-216-PL:3 | |
| Names: | 200-E-216-PL:3; Southern Portion of Soil Trench Containing Lines V251, V252, V253 and V242 | |

| Code: | 200-E-216-PL:1 | Classification: | Accepted |
| Names: | 200-E-216-PL:1; Portion of Soil Trench Containing All Seven Lines (V235, V23, V237, V251, V252, V253 and V242) | Reclassification: | None |
| Type: | Direct Buried Tank Farm Pipeline | Start Date: |
| Status: | Inactive | End Date: |
**Description:** Subsite 1 is the portion of the group of lines exiting the 241-BX Tank Farm where all seven lines are in the same soil trench.

**The SubSite is Part Of:**
Code: 200-E-216-PL

**The SubSite is Part Of:**
Code: 200-E-216-PL
WMA C

Code: 216-C-8  
Classification: Accepted  
Reclassification: None

Names: 216-C-8; 216-C-8 Crib; 216-C-8 French Drain; 271-CR Crib

Type: French Drain  
Start Date: 6/1/1962

Status: Inactive  
End Date: 6/1/1965

Description: In June 2001, the crib location was no longer marked or posted. The area had been recently covered with gravel during road construction in the vicinity of 7th Street and Buffalo Ave. In 2006, a single post and sign marked the crib location. The pipeline that fed 216-C-8 is WIDS sitecode 200-E-290-PL.

Location: The site is located southeast of the 241-C Tank Farm, outside the tank farm perimeter fence.

Related Sites/Structures: The site is associated with the 271-CR building and pipeline 200-E-290-PL.

Process Description: The site received radioactively contaminated ion exchange waste from the 271-CR Building.

Waste Type: Process Effluent

Waste Description: The site received the ion exchange waste from the 271-CR Building. The waste volume is unknown. The site contains less than 10 curies total beta.

Code: 241-C-101  
Classification: Accepted  
Reclassification: None

Names: 241-C-101; 241-C-TK-101

Type: Single-Shell Tank  
Start Date: 1/1/1946

Status: Inactive  
End Date: 1/1/1970

Description: The tank is an underground, steel tank with a cylindrical reinforced-concrete wall that rests on a reinforced-concrete cylindrical footing. The footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished-shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A steel liner lines the bottom and sidewall of the tank.

Location: The 241-C-101 tank in the eastern portion of the 241-C Tank Farm.

Related Sites/Structures: Four monitoring drywells are identified for this tank. Additionally this tank is equipped with pumps, thermocouples and other ancillary equipment. This tank cascades to 241-C-102. Nine risers are associated with the tank.

Process Description: The 241-C-101 tank received bismuth phosphate metal waste, tributyl phosphate process waste, and PUREX process coating waste from tank 241-C-106, which had high levels of strontium in the waste. From 1952 to 1955 the tank was sluiced to recover uranium that had been discharged as waste.

Waste Type: Process Effluent

Waste Description: This tank contains bismuth phosphate metal waste, tributyl phosphate waste, and PUREX coating waste. Document WHC-SD-WM-ER-349 references the most complete estimated inventory for this tank. Because this tank was the first tank in a cascading series, most of the solids precipitated out of the solutions into this tank.
Code: 241-C-102  Classification: Accepted
Names: 241-C-102; 241-C-TK-102  Reclassification: None
Type: Single-Shell Tank  Start Date: 1/1/1946
Status: Inactive  End Date: 1/1/1976

Description: The tank is an underground steel tank with a cylindrical reinforced-concrete wall that rests on a reinforced-concrete cylindrical footing. The footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished-shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A steel liner lines the bottom and sidewall of the tank.

Location: The 241-C-102 tank is located in the eastern portion of the 241-C tank Farm.

Related Sites/Structures: Structures associated with this tank includes, saltwater pump system, tank monitoring instrumentation, and waste cascade tanks (241-C-103) and piping.

Process Description: Tank 241-C-102 is the second tank in the 241-C-101, 241-C-102, and 241-C-103 cascade line. These tanks received 221-B Building bismuth phosphate process waste. Later, this tank received small amounts from Semiworks (201-C) and the Critical Mass Laboratory, as well as Uranium Recovery and PUREX process wastes.

Waste Type: Chemicals
Waste Description: This tank received bismuth phosphate metal waste, tributyl phosphate waste, PUREX coating waste, high-level waste, PUREX organic wash waste, supernatant containing organic wash wastes and coating wastes from the 241-A, -AX, and -C Tanks.

Code: 241-C-103  Classification: Accepted
Names: 241-C-103; 241-C-TK-103  Reclassification: None
Type: Single-Shell Tank  Start Date: 1/1/1946
Status: Inactive  End Date: 1/1/1979

Description: The tank is an underground steel tank with a cylindrical reinforced-concrete wall that rests on a reinforced-concrete cylindrical footing. The footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished-shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A steel liner lines the bottom and sidewall of the tank.

Location: The 241-C-103 tank is located in the northeastern corner of 241-C Tank Farm.

Release Description: In 2008, the Hanford C-Farm Leak Assessment Report (RPP-ENV-33418) was issued. It documented failed pipelines and unplanned releases associated with C Farm activities. In 1965, a liquid level rise in the 241-C-103 cesium feed tank was apparently caused by a failed line in the encasement between the 241-CR-152 diversion box and 241-C-102. This permitted coating waste from the Purex Plant to leak into the encasement and drain to Tanks 241-C-101, 241-C-102 and 241-C-103 via the tank pump pits. Coating waste was routed through a spare line to 241-C-102 and no further leaks were detected. The coating waste solution accumulated in 241-C-103 did not significantly affect cesium loading capability as a cask was loaded normally following the incident.

Related Sites/Structures: Structures associated with this tank include 5 drywells, tank monitoring instrumentation, tank risers, the three other tanks in this waste cascading series, and associated piping.
Process Description: Tank 241-C-103 is the third tank in the 241-C-101, 241-C-102, 241-C-103 cascade line. These tanks largely received waste from the B Plant bismuth phosphate process. Additional waste was received from the semi-works and the critical mass laboratory. Later waste received by the tank was generated by PUREX and U Plant.

Waste Type: Process Effluent

Waste Description: This tank has waste from the following process: PUREX coating waste, tributyl phosphate waste, coating waste, PUREX high-level waste, B Plant high-level waste, B Plant waste fractionization low-level waste, PUREX sludge supernatant, PUREX low-level waste, waste fractionization PUREX sludge, PUREX organic wash waste, laboratory waste, decontamination waste, REDOX ion exchange waste, REDOX high-level waste, noncomplexed waste, waste fractionization ion exchange waste, N Reactor waste, PNL waste, and evaporator bottoms from 241-A -B, -BX, and -C tank farms. This unit was used as the receiver for operating P-10 saltwell systems within the 241-C Tank Farm. An additional source of waste is PUREX and insoluble strontium-rich sluicing solids from the operation of 244-CR Vault.

Code: 241-C-103 VP
Names: 241-C-103 VP; 241-C Valve Pit; 241-C-103 Valve Pit
Type: Valve Pit
Status: Inactive
Description: The waste site is an underground corrugated metal structure.
Location: The valve pit is located inside 241-C tank farm, on the southwest side of the 241-C-103 tank.
Process Description: The valve pit was installed as part of the C Farm tank waste interim stabilization salt well system.

Code: 241-C-104
Names: 241-C-104; 241-C-TK-104
Type: Single-Shell Tank
Status: Inactive
Description: The underground tank is constructed with a cylindrical reinforced-concrete wall that rests on a reinforced-concrete cylindrical footing. The footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished-shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A steel liner lines the bottom and sidewall of the tank.
Location: Tank 241-C-104 is located in the southern row of tanks, inside the 241-C Tank Farm.
Related Sites/Structures: Tank 241-C-104 is the first tank in the 241-C-104, 241-C-105, and 241-C-106 cascade line. Other associated structures include ventilation, monitoring drywells, instrumentation, and piping.
Process Description: This tank was sluiced during the 1952 to 1955 uranium recovery sluicing operation. During 1954, this tank was used as a tank-to-tank sluicing receiver. This waste was later sent to the 244-CR process vault. The tank began receiving bismuth phosphate metal waste in 1946.
Waste Type: Steam Condensate
**Waste Description:** Waste is comprised of unknown waste, sludge, and pumpable liquid. This tank received bismuth phosphate metal waste starting in 1946, strontium-leached sluicing solids in 1977, and fissile material (including uranium-223) from PUREX thorium campaigns.

**Code:** 241-C-105  
**Classification:** Accepted

**Names:** 241-C-105; 241-C-TK-105  
**Reclassification:** None

**Type:** Single-Shell Tank  
**Start Date:** 1/1/1946

**Status:** Inactive  
**End Date:** 1/1/1979

**Description:** The underground tank is constructed with a cylindrical reinforced-concrete wall that rests on a reinforced-concrete cylindrical footing. The footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished-shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A steel liner lines the bottom and sidewall of the tank.

**Location:** Tank 241-C-105 is located near the center of the 241-C Tank Farm.

**Related Sites/Structures:**
- The tank is associated with Radiation monitoring wells, 8 active; Operating exhauster; Temperature element, read manually; Liquid level gage, and automatic on CASS.
- Process Description: As part of the 241-C-104, 241-C-105, 241-C-106 cascade line, this tank received bismuth phosphate metal waste from 1947 until 1953. This tank was used as a receiver for PUREX sludge supernate enroute to B Plant for cesium ion exchange processing. This tank was sluiced during 1952 and 1953 for the uranium recovery program.

**Waste Type:** Process Effluent

**Waste Description:** This tank was used as a receiver tank for PUREX sludge supernate enroute to B Plant. It received bismuth phosphate metal waste from 1947 to 1953. The tank contains unknown waste, sludge, and pumpable liquid.

**Code:** 241-C-106  
**Classification:** Accepted

**Names:** 241-C-106; 241-C-TK-106  
**Reclassification:** None

**Type:** Single-Shell Tank  
**Start Date:** 1/1/1947

**Status:** Inactive  
**End Date:** 1/1/1979

**Description:** The underground tank is constructed with a cylindrical reinforced-concrete wall that rests on a reinforced-concrete cylindrical footing. This footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A partial spherical shell dome rests on the cylindrical wall. A steel liner lines the bottom and sidewall of the tank. The operating depth for this tank is 5.2 meters (17 feet).

**Location:** The tank is located in the northeastern portion of the 241-C Tank Farm.

**Related Sites/Structures:**
- Associated structures for 241-C-106 include monitoring equipment, cascade piping and tanks, ventilation and drywells.
- Process Description: This tank is the last tank in the 241-C-104, 241-C-105 and 241-C-106 cascade. One of the first generation tanks, this unit was designed to receive non-boiling waste. Tank 241-C-106 received bismuth phosphate metal waste in 1947. The tank was sluiced from 1952 to 1955 for uranium recovery efforts.
Waste Type: Process Effluent
Waste Description: This tank received bismuth phosphate metal waste, and PUREX process fission product waste, which included large amounts of strontium. The tank was sluiced in 1952-1955 for the uranium recovery project. The waste contains process supernate, unknown waste products, sludge, and pumpable liquid.

Code: 241-C-107
Names: 241-C-107; 241-C-TK-107
Type: Single-Shell Tank
Status: Inactive
Description: The underground tank is constructed with a cylindrical reinforced-concrete wall that rests on a reinforced-concrete cylindrical footing. This footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A partial spherical shell dome rests on the cylindrical wall. A steel liner lines the bottom and sidewall of the tank. The operating depth for this tank is 5.2 meters (17 feet).
Location: The 241-C-107 tank is located in the northwestern portion of the 241-C Tank Farm.
Related Sites/Structures: Structures associated with this tank include other tanks in the cascade, piping and pumps, instrumentation, and ventilation.
Process Description: This is the first tank in the 241-C-107, 241-C-108, 241-C-109 cascade line, designed to receive non-boiling waste. Tank 241-C-107 received first cycle waste and process decontamination wastes from B Plant. This tank also received insoluble, strontium-leached sluicing solids.
Waste Type: Process Effluent
Waste Description: This tank received Bismuth Phosphate first cycle waste beginning in 1946. The tank received insoluble strontium leached, sluicing solids in 1977. This unit is a low-heat load, passively ventilated tank.

Code: 241-C-108
Names: 241-C-108; 241-C-TK-108
Type: Single-Shell Tank
Status: Inactive
Description: The underground tank is constructed with a cylindrical reinforced-concrete wall that rests on a reinforced-concrete cylindrical footing. This footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A partial spherical shell dome rests on the cylindrical wall. A steel liner lines the bottom and sidewall of the tank. The operating depth for this tank is 5.2 meters (17 feet).
Location: Tank 241-C-108 is located near the center of the 241-C Tank Farm.
Related Sites/Structures: Structures associated with this tank include cascade piping, tanks 241-C-107, and 241-C-109, dry wells, instrumentation, and ventilation.
Process Description: Tank 241-C-108 was designed as the second tank of the 241-C-107, 241-C-108, 241-C-109 cascade series. It received non-boiling, cascade overflow from tank 241-C-107.
received by this tank include first cycle waste, and process decontamination waste from B Plant. The tank also acted as a primary settling tank for "In-Farm" waste scavenging for the Uranium Recovery process.

**Waste Type:** Process Effluent  
**Waste Description:** Tank 241-C-108 received cascade overflow from tank 241-C-107 in 1947. This tank was also used as a primary settling tank for "in farm" scavenging for the Uranium Recovery process. This tank is on the ferrocyanide watch list. Waste is composed entirely of sludge, with no pumpable liquid.

Location: Tank 241-C-110 is located in the southwestern portion of 241-C Tank Farm.

Release Description: This tank is an assumed leaker, with a loss of 2,000 gallons (7,600 liters).

Related Sites/Structures: Associated structures with this tank include four dry wells, instrumentation the two other tanks in the cascade series, piping, and ventilation.

Process Description: This tank is the first tank in the 241-C-110, 241-C-111, 241-C-112 cascade line. It was designed to receive non-boiling waste. The tank received bismuth phosphate first cycle waste from 1946 to 1967. Tanks 241-C-108, 241-C-109, 241-C-110, 241-C-111, and 241-C-112 were also used as primary settling tanks for "In-Farm" scavenging for the Uranium Recovery process.

This footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A partial spherical shell dome rests on the cylindrical wall. A steel liner lines the bottom and sidewall of the tank. The operating depth for this tank is 5.2 meters (17 feet).

Location: The 241-C-111 tank is located on the western side of the 241-C Tank Farm.

Related Sites/Structures: Associated with this tank include five dry wells, instrumentation, the two other tanks in the cascade series, piping, and ventilation.

Process Description: This tank is the second tank in the 241-C-110, 241-C-111, 241-C-112 cascade line. It was designed to receive non-boiling waste. The tank received bismuth phosphate first cycle waste beginning in 1946. Tanks 241-C-108, 241-C-109, 241-C-110, 241-C-111, and 241-C-112 were also used as primary settling tanks for "In-Farm" scavenging for the Uranium Recovery process.

Waste Type: Steam Condensate

Waste Description: Tank 241-C-111 is the second tank in the 241-C-110, -111, and -112 cascade line. This tank received bismuth phosphate first cycle waste and B Plant decontamination waste. Additionally, this tank was used as a primary settling tank for "In-Farm Scavenged Uranium". There is no pumpable liquid remaining in the tank.

Description: The underground tank is constructed with a cylindrical reinforced-concrete wall that rests on a reinforced-concrete cylindrical footing. This footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A partial spherical shell dome rests on the cylindrical wall. A steel liner lines the bottom and sidewall of the tank. The operating depth for this tank is 5.2 meters (17 feet).

Location: The 241-C-111 tank is located on the western side of the 241-C Tank Farm.

Related Sites/Structures: Associated with this tank include five dry wells, instrumentation, the two other tanks in the cascade series, piping, and ventilation.

Process Description: This tank is the second tank in the 241-C-110, 241-C-111, 241-C-112 cascade line. It was designed to receive non-boiling waste. The tank received bismuth phosphate first cycle waste beginning in 1946. Tanks 241-C-108, 241-C-109, 241-C-110, 241-C-111, and 241-C-112 were also used as primary settling tanks for "In-Farm" scavenging for the Uranium Recovery process.

Waste Type: Steam Condensate

Waste Description: Tank 241-C-111 is the second tank in the 241-C-110, -111, and -112 cascade line. This tank received bismuth phosphate first cycle waste and B Plant decontamination waste. Additionally, this tank was used as a primary settling tank for "In-Farm Scavenged Uranium". There is no pumpable liquid remaining in the tank.
**Description:** The underground tank is constructed with a cylindrical reinforced-concrete wall that rests on a reinforced-concrete cylindrical footing. This footing gradually tapers to a reinforced-concrete basemat foundation. The basemat foundation is dished shaped and lined with a layer of grout and a layer of asphaltic waterproofing membrane. A partial spherical dome rests on the cylindrical wall. A steel liner lines the bottom and sidewall of the tank. The operating depth for this tank is 5.2 meters (17 feet).

**Location:** The 241-C-112 tank is located in the northwestern portion of 241-C Tank Farm.

**Related Sites/Structures:** Associated structures include four dry wells, instrumentation, the two other tanks in the cascade series, piping, and ventilation.

**Process Description:** This tank is the third tank in the 241-C-110, -111, -112 cascade line, and was designed to receive non boiling waste. The tank received bismuth phosphate first cycle waste starting in 1976. Tanks -108, -109, -110, and -112 were also used as primary settling tanks for "In-Farm Scavenged Uranium".

**Waste Type:** Steam Condensate

**Waste Description:** Tank 241-C-112 is the third tank in the 241-C-110, 241-C-111, and 241-C-112 cascade line. This tank received bismuth phosphate first cycle waste and process decontamination waste from B Plant. Additionally, this tank was used as a primary settling tank for "In-Farm" scavenging for the Uranium Recovery process.

**Code:** 241-C-151

**Classification:** Accepted

**Names:** 241-C-151; 241-C-151 Diversion Box

**Type:** Diversion Box

**Start Date:** 1/1/1946

**End Date:** 1/1/1985

**Description:** The diversion box is an underground, reinforced concrete structure. Surface features include concrete coverblocks with lifting bails.

**Location:** The 241-C-151 Diversion Box is located in the southwestern portion of the 241-C Tank Farm.

**Related Sites/Structures:** This diversion box is associated with the 241-C Tank Farm and the soil described in sitecode 200-E-133. It is connected to the 241-C-152 and 241-C-153 diversion boxes.

**Process Description:** Diversion boxes and receiving vaults drain to catch tanks. They are designed to contain leaks and spills from waste transfers and drainage during jumper operations within the unit.

**Waste Type:** Process Effluent

**Waste Description:** This unit was used to transfer waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operations. Chemical residues may be present. Radiological contamination is estimated to be high in alpha, beta, and gamma.

**Waste Type:** Process Effluent

**Waste Description:** This unit was used to transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operations. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box. Radiological contamination is estimated to be high in alpha, beta, and gamma.

---

**Code:** 241-C-152

**Classification:** Accepted

**Names:** 241-C-152; 241-C-152 Diversion Box

**Reclassification:** None
Type: Diversion Box
Status: Inactive

Description: This diversion box is a reinforced concrete structure.

Location: The 241-C-152 Diversion Box is located in the southwestern portion of the 241-C Tank Farm, west of the 241-C-151 Diversion Box.

Related Sites/Structures: The 241-C-152 diversion box is associated with 241-C-301 Catch Tank. This unit interconnects the 241-B-154, and 241-B-153 diversion boxes with the 241-C Tank Farm.

Process Description: Diversion boxes and receiving vaults drain to catch tanks. They are designed to contain leaks or spills from waste transfers and drainage during jumper operations within the unit.

Waste Type: Process Effluent
Waste Description: This unit was used to transfer waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operations. Radiological contamination is estimated to be extremely high.

Waste Type: Process Effluent
Waste Description: It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

---

Code: 241-C-153
Classification: Accepted

Names: 241-C-153; 241-C-153 Diversion Box
Reclassification: None
Type: Diversion Box
Status: Inactive

Description: The diversion box is an underground, reinforced concrete structure. Surface features include concrete cover blocks and lifting bails.

Location: The 241-C-153 Diversion Box is located in the southwestern portion of the 241-C Tank Farm, south of the 241-C-110 tank.

Related Sites/Structures: The diversion box is associated with the 241-C-301 Catch Tank and 241-C-Tank Farm. This unit interconnects the 241-C-151 and 241-C-152 diversion boxes.

Process Description: Diversion boxes and receiving vaults drain to catch tanks. They are designed to contain leaks or spills resulting from waste transfers during jumper operations within the unit.

Waste Type: Process Effluent
Waste Description: This unit was used to transfer waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. Diversion box contamination is estimated to be high in alpha, beta, and gamma. Chemical residues may be present.

Waste Type: Process Effluent
Waste Description: The diversion box transferred liquid waste from the processing plants to the tank farms. The Part A Permit assumed that 50 pounds (23 kilograms) of lead shielding bricks may also be stored in this diversion box.

**Location:**
The 241-C-201 tank is located on the north side of the 241-C Tank Farm, inside the tank farm fence.

**Related Sites/Structures:**
Structures associated with this tank include: ventilation, piping, instrumentation, and the 241-C-202, 241-C-203 and 241-C-204 tanks.

**Process Description:**
This tank was sluiced during the uranium recovery process. No pumpable liquid remains in the tank.

**Waste Description:**
Tank 241-C-201 began to operate in 1947 by receiving bismuth phosphate metal waste. This tank was sluiced during the uranium recovery process. No pumpable liquid remains in the tank.

---

**Code:** 241-C-203  
**Classification:** Accepted  
**Names:** 241-C-203  
**Reclassification:** None  
**Type:** Single-Shell Tank  
**Start Date:** 1/1/1947  
**End Date:** 1/1/1977  
**Status:** Inactive  
**Description:** The underground tank is a vertically configured, reinforced-concrete cylinder, with a slab roof. It is lined with steel. The tank rests on a footing which is integral to the tank base.  
**Location:** Tank 241-C-202 is located on the north side of the 241-C Tank Farm, inside the tank farm fence.  
**Related Sites/Structures:** Structures associated with this tank include: ventilation, piping, instrumentation, and the other 200-series tanks.  
**Process Description:** This tank is a 200-series single-shell tank, designed to receive non-boiling waste. Tanks 241-C-201, 241-C-202, 241-C-203, and 241-C-204 have tie lines between each tank to equalize the waste volumes in each tank. This tank received metal waste, and is plumbed to the 241-C-252 diversion box.  
**Waste Type:** Process Effluent  
**Waste Description:** Tank 241-C-202 began to operate in 1947 by receiving metal waste. Tanks 241-C-201, -202, -203, and -204 were used to settle waste while supernatant was sent to a crib. This tank was sluiced for uranium recovery. No pumpable liquid remains in the tank. Metal waste in the tank was removed in 1954 and the tank received waste from hot semi-works in 1955 and 1956. Most of the hot semi-works waste was removed in 1970. Waste retrieval completed in August 2005 with the retrieval of 1,032 gallons of waste, resulting in an ending volume in the tank of 147 gallons. Retrieval was accomplished using a vacuum retrieval system. Waste was transported to 241-AN-106 through a hose-in-hose transfer line.
Names: 241-C-203; 241-C-TK-203

Hanford Site Waste Management Units Report
February 2015 1587
Description: The diversion box is an underground, reinforced concrete structure. Surface features include concrete cover blocks and lifting bails.

Location: The diversion box is located in the northwest portion of the 241-C Tank Farm, west of tank 241-C-204.

Related Sites/Structures: Diversion box 241-C-252 is associated with the 241-C-301 Catch Tank and the 241-C Tank Farm. The unit interconnects diversion box 241-C-151 and the 241-C Tank Farm.

Process Description: Diversion boxes and receiving vaults drain to catch tanks. They are designed to contain leaks and spills from waste transfers and drainage during jumper operations within the unit.

Waste Type: Steam Condensate

Waste Description: It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

Waste Type: Steam Condensate

Waste Description: This unit was used to transfer waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operations. Radiological contamination is expected to be high in alpha, beta, and gamma. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

Code: 241-C-301

Classification: Accepted

Reclassification: None

Names: 241-C-301; 241-C-301C; 241-C-301-C Catch Tank; IMUST; Inactive Miscellaneous Underground Storage Tank; Lines V114 and V155

Type: Catch Tank

Start Date: 1/1/1946

End Date: 1/1/1985

Description: The 241-C-301 Catch tank is an underground tank. It is surrounded with post and chain and marked with Inactive Miscellaneous Underground Storage Tank (IMUST) signs.

Location: The 241-C-301 catch tank is located in the northwest portion of the 241-C Tank Farm, northwest of the 241-C-112 tank.

Related Sites/Structures: This tank is associated with 241-C-151, 241-C-152, 241-C-153, 241-C-252 diversion boxes and 241-C Tank Farm. Line V114 and V155 are the drain lines from the diversion boxes.

Process Description: Tank 241-C-301C received drainage from diversion boxes 241-C-151, 241-C-152, 241-C-153, and 241-C-252. These diversion boxes received wasted transfers from and the C Farm, B Plant, and PUREX. Incidental wastes were received from the Hot Semiworks operations. Catch tanks are components of tank farms that collect spills and/or leaks during waste transfers between processing facilities and tank farms. Catch tanks also received any water from rainfall, snowmelt, or dust that entered the diversion boxes (the diversion boxes were later weather proofed.) The tanks were coal coated for corrosion protection, and later underwent two cathodic protection upgrades. The catch tank was constructed with 15.2 centimeter (6 inch) thick walls, coated with Amercoat to obtain a non-porous surface.

Waste Type: Water

Waste Description: The 241-C-151, 241-C-152, 241-C-153 and 241-C-252 diversion boxes drained waste solutions from leaks or spills that occurred during waste transfer operations. The wastes received in the catch tank include waste from B Plant, PUREX and Hot Semiworks operations. In 1994, the
tank contained 5586 liters (1470 gallons) of liquid supernate and 34,260 liters (9016 gallons) of sludge. The tank may also have received ferrocyanide waste.

**Description:** The site is a single story building located inside the 241-C Tank Farm. The upper portion of the building is constructed of prefabricated metal. The bottom 2.9 meters (9.5 feet) of the building is constructed of concrete walls and foundations, approximately 0.3 meters (1 foot) thick. This part of the structure is covered with earth. The main building sections include the loadout room, which is 9.8 by 4.3 by 6.1 meters (32 by 14 by 20 feet). The operating room, which is 4.3 by 3.7 by 6.1 meters (14 by 12 by 20 feet). A valve pit, measuring 2.4 by 2.1 by 2.4 meters (8 by 7 by 8 feet) is located in the southwest portion of the building. A rollup door that allowed truck access to the High Bay portion of the building. The High Bay occupies approximately half of the building and has a 5 ton capacity crane bridge.

There are two dry wells associated with this building (H-2-4566). One drywell is located inside the tank farm fence, near the north wall of 801-C. The other dry well is located approximately 23 meters (75 feet) north of the 801-C building, outside the tank farm fence, that is fed by two stainless steel pipelines.

**Location:** The Cesium Loadout Facility is located in the northeastern portion of the 241-C Tank Farm.

**Related Sites/Structures:** The 241-C-801 Facility is associated with the 241-C-102 and 241-C-103 tanks and two drywells.

**Process Description:** Two tank farm underground storage tanks are associated with this facility. The 241-C-103 tank was used for cesium feed storage. Waste from this tank was pumped into the 801-C Loadout facility into a truck mounted demineralizer. The demineralizer removed the cesium from the liquid waste and retained it inside the shielded container. The cesium depleted waste was transferred to the 241-C-102 tank. The truck containing the cesium was transported offsite. The 241-C Valve pit was installed in the upper level of the 241-C-801, Cesium Loadout Facility, which received cesium-rich waste from tank 241-C-103. The waste was pumped through an ion exchanger before being transferred to tank 241-C-102. The Cesium Loadout Facility was declared inactive and isolated in September 2002.

**Waste Type:** Water

**Waste Description:** The unit is a radioactively contaminated structure. Contamination levels are estimated at 30 curies beta. There may be residual chemicals and radioactive material in processing equipment and piping. There are no storage tanks inside this building. The drywell located north of the building, outside the fence, is posted with Contamination Area signs.

**Type:** Diversion Box

**Start Date:** 1/1/1946

**End Date:** 1/1/1985

**Description:**
The diversion box is an underground, reinforced concrete structure. Surface features include...
Location: The 241-CR-153 Diversion Box is located in the southern portion of the 241-C Tank Farm, northwest of the 244-CR Vault. It is attached to the 241-CR-152 Diversion Box.

Related Sites/Structures: This unit adjoins the 241-C-152 diversion box. Line 8307 is the diversion Box drain line.

Process Description: This diversion box is designed to contain leaks from transfers and drainage from operations within the unit. This unit acts as secondary containment for transfer line jumper connections.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: It was estimated that approximately 50 pounds (23 kilograms) of waste lead was stored in this unit.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: This unit was used for transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation.

Code: 244-CR VAULT

Names: 244-CR VAULT; Line 8765; 244-CR Vault

Type: Receiving Vault

Status: Inactive

Start Date: 1/1/1946

End Date: 1/1/1988

Description: This vault is an underground, reinforced concrete structure. It is a two-level, multi-cell structure (cells 1, 2, 3 and 11). The lower cell contains the process vessels. Upper cells contain piping and equipment. The structure is constructed with concrete cover blocks which, when removed, allow access to the upper cells. The lower cells contain four process vessels: TK-CR-001, TK-CR-011, TK-CR-002, and TK-CR-003 (see subsites).

Location: This unit is located in the southern portion of the 241-C Tank Farm, southeast of the 241-CR-151 Diversion Box.

Release Description: In 2008, the Hanford C-Farm Leak Assessment Report (RPP-ENV-33418) was issued. It documented failed pipelines and unplanned releases associated with C Farm activities. On February 18, 1965, the 244-CR Vault was found flooded up to approximately the level of the tank tops. Immediate steps were taken to reduce the liquid level by jetting the solution to the 011 Tank. Partial cause of the flooding is attributed to a failure in the coating waste line which enters the 241-CR-151 diversion box. Drainage from this diversion box collects in the 002-CR vault sump. Water from a sampler flush line and drainage from rain and snow contributed to the liquid level in the vault. To date, the 001, 002, and 003 sumps have been emptied, and the 011 sump is being emptied, to the 011 Tank. This liquid is being pumped from the 011 Tank to Tank 103-A in the 241-A Tank Farm. In May 1966, a leak in the PUREX coating waste route (via 241-CR-152 diversion box) was detected by an abnormal liquid level increase of the 002-CR vault sump. The leaking flexible jumper in the 241-CR-152 diversion box was replaced. Diversion box 241-CR-152 and 244-CR Vault sump are concrete structures with painted surfaces. It is uncertain whether leaked waste was contained inside diversion box 241-CR-152 and 244-CR Vault sump.

Related Sites/Structures: The associated structures include the 241-C Tank Farm and the Hot Semiworks operations. Line 8765 is the drain line from 241-CR-151 to the 244-CR sump.

Process Description: The receiver was used for interim storage and processing operations of 241-C Tank Farm. It had the capacity to add chemicals, mix solutions and cool the tank contents. Waste was also
received from the Hot Semiworks Facility. The 244-CR-003 Tank in the 244-CR Vault is used for the interim storage of salt well waste from 241-C Tank Farm.

Waste Type: Process Effluent
Waste Description: The unit contained the following wastes: metal waste, first cycle waste, B Plant decontamination waste, PUREX fission product waste, uranium recovery sluicing waste, coating waste, radioactive condensates, sink wastes, REDOX spent solvent waste, other REDOX waste, PUREX organic wash waste, PUREX acid process waste, PUREX spent solvent waste, strontium recovery waste, and critical mass laboratory waste.

Description: 244-CR-001 is a 189,250 liter (50,000 gallon) tank located in a 6.7 meter (22 foot) by 7.9 meter (26 foot) by 8.8 meter (29 foot) cell (cell 1) within the 244-CR Vault. The concrete cell has a 170 liter (45 gallon) capacity sump. The 244-CR Vault and associated tanks and cells were used as the uranium sludge recovery and distribution vault for the 241-C Tank Farm. CR Vault was also used for the interim storage and transfer of waste from B-Plant, PUREX and Hot Semi-Works. Tank 244-CR-001 was the slurry accumulator, receiving waste from the C Farm tanks. The slurry was processed with nitric acid. In 2002, the tank was estimated to contain 7,570 liters (2,000 gallons) of waste solids from the Uranium Recovery Program. In 2005, the tank contained 5,197 liters (1,375 gallons) of liquid and sludge. Cell #1 contained 291 liters (77 gallons) of liquid.

Description: 244-CR-011 is a 189,250 liter (50,000 gallon) tank located in a 6.7 meter (22 foot) by 7.9 meter (26 foot) by 8.8 meter (29 foot) cell (cell 11) within the 244-CR Vault. The concrete cell has a 170 liter (45 gallon) capacity sump. The 244-CR Vault and associated tanks and cells were used as the uranium sludge recovery and distribution vault for the 241-C Tank Farm. CR Vault was also used for the interim storage and transfer of waste from B-Plant, PUREX and Hot Semi-Works. Initially, tank 244-CR-011 acted as a process pump tank for the transfer of processed waste from the CR Vault to the diversion station for transfer to the Uranium Recovery facility or other operations. In 2002, the tank was estimated to contain 132,475 liters (35,000 gallons) of supernate and rainwater. In 2005, 15,082 liters (3,990 gallons) of sludge was reported. No liquid volume was remaining in the tank. Cell 11 contained 27,639 liters (7,312 gallons) of liquid and sludge.

<tbody>
<tr>
<td>Contamination Migration</td>
<td>Inactive</td>
<td>The site is the soil inside and adjacent to the chain link fence that surrounds the 241-C Tank Farm. Various radiological postings and warning signs are attached to the chain link fence. The interior of the tank farm complex is covered with gravel. Many risers and monitoring devises for the underground structures are visible on the surface. The individual unplanned releases associated with the 241-C Tank Farms are not separately marked or posted. Occasionally, radioactive contamination is found adjacent to the outside of the tank farm fence, resulting in a contamination zone extension around the tank farm perimeter. These areas are also part of this site. The 241-C Tank Farm is located at the intersection of 7th Street and Buffalo Ave. in 200 East Area. The exact extent (horizontal and vertical) of the soil contaminated by unplanned releases that occurred within this farm complex over the years are not known. Some of the single shell tanks have leaked to the soil below the tank farm. Other releases spread contamination to the surface soil surrounding the tanks. In 2008, the Hanford C-Farm Leak Assessment Report (RPP-ENV-33418) was issued. It documented failed pipelines and unplanned releases associated with activities inside the 241-C Tank Farm. Some of the releases included the underground process line (V172) from the 252-C diversion box to 241-C-112 tank in C Tank Farm failure.</td>
</tr>
</tbody>
</table>
failed pipeline, inside C tank farm, was isolated. Jumpers were fabricated and installed to establish a new process route. Line V112, adjacent to diversion box 241-C-151, was identified as a leaker. The date and amount of waste leaker from this pipeline is unknown. In August 1974, Occurrence Report 74-120 states that pipeline V-103, located inside 241-C farm, leaked and caused high levels of contamination between tanks 241-C-104 and 241-C-105. High readings were noted in dry well 30-03-02. A liquid level rise in Tank 103-C, the cesium feed tank, was apparently caused by a failed line in the encasement between the 152-CR diversion box and Tank 102-C which permitted coating waste from the Purex Plant to leak into the encasement and drain to Tanks 101-C, 102-C, and 103-C via the tank pump pits. Coating waste has been routed through a spare line to Tank 102-C and no further leaks have been detected. The coating waste solution accumulated in Tank 103-C did not significantly affect cesium loading capability as a cask was loaded normally following the incident.

Related Sites/Structures: The site is associated with UPR-200-E-16, UPR-200-E-27, UPR-200-E-68, UPR-200-E-81, UPR-200-E-82, UPR-200-E-107, UPR-200-E-118, UPR-200-E-136, and UPR-200-E-137. Most of these sites are listed in TPA Appendix B as TSD-associated sites, and are to be addressed with the closeout of the tank farm TSD. As such, site 200-E-133 is also a TSD-associated site.

Waste Type: Process Effluent
Waste Description: Liquid releases occurred from underground leaks in tanks and transfer lines. Airborne contamination spreads occurred from activities conducted in valve pits and diversion boxes. Both types of releases contributed to the contamination in the soil.

Names: 2607-EG
Type: Septic Tank
Start Date: 1/1/1951
End Date: None

Description: There were two, 2607-EG septic tanks. The first tank failed and was replaced in 1972. A large diameter, vertical concrete pipe extends above the ground surface. It received sanitary wastewater and sewage from the 271-CR Building. The associated drain field had a capacity of 619 gallons (2,350 liters) per day.

Location: This septic tanks are located southeast of the 241-C Tank Farm fence and east of the 271-CR Building.

Related Sites/Structures: The 2607-EG Septic Tank is associated with the 241-C Tank Farm and the 271-CR Building.

Process Description: The 2607-EG Septic Tanks and associated drain fields were designed to accept sanitary sewer effluent from the 271-CR Building.

Waste Type: Steam Condensate
Waste Description: The current flow rates to Septic Tank 2607-EG are unknown. However, the 2607-EG septic system received sanitary sewer effluent from the 271-CR Building at a rate of 6 cubic feet (0.2 cubic meters) per day in 1987.

Names: UPR-200-E-72; Radioactive Contamination from Uncovered Buried Waste; UN-200-E-72
Type: Unplanned Release
### Status: Inactive

**End Date:**

**Description:** A WIDS sign has been placed at the approximate location of the site.

**Location:** The site is located south of the 241-C Tank Farm, near the 216-C-8 Crib.

**Release Description:** In 1985, radiological surveys were being performed outside the 241-C Tank Farm fence following a contamination incident at 241-C-151. A contaminated area was found south of 241-C Tank Farm that indicated the burial of previously undocumented contaminated material. The area contained specks of contamination reading up to 7 rad per hour. The source of the contamination is assumed to be the buried material.

**Waste Type:** Abandoned Chemicals

**Waste Description:** The contamination consisted of beta/gamma particulates with dose rates up to 7 rad per hour on the uncovered material and the surrounding area.

### Code: UPR-200-E-91

**Classification:** Accepted

**Reclassification:** None

**Type:** Unplanned Release

**Status:** Inactive

**Start Date:**

**End Date:**

**Description:** This site was a large area of contaminated soil, located north and east of the 241-C Tank Farm. In 1981, the contaminated soil was removed from this area and taken to another location (UPR-200-E-56). The radiological posting was removed in 1981. This release site is no longer marked or posted.

**Location:** UPR-200-E-91 was located adjacent to the northeast corner of the 241-C Tank Farm.

**Release Description:** The release occurred over time, due to radioactive particles migrating out of the adjacent 241-C Tank Farm. At one time, water from an equipment decontamination station, located inside the tank farm, seeped downhill into this area. Vapor emissions and windblown particulates from the contaminated surfaces of the tank farm contributed to the buildup of ground contamination at the site.

**Related Sites/Structures:** UPR-200-E-91 was associated with the 241-C Tank Farm. The contaminated soil was removed to UPR-200-E-56. A smaller radiologically posted area is located in the vicinity of where this unplanned release had been. See WIDS site code 200-E-115.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The release consisted of wind blown radiologically contaminated soil from tank farm activities and water run off from an equipment decontamination located inside 241-C tank farm. The contaminated soil was removed. The area outside the tank farm fence was revegetated with perennial wheatgrass and cheatgrass in 1981.
WMA S/SX

**Code:** 216-S-3  
**Classification:** Accepted

**Names:** 216-S-3; 216-S-3 Crib; 216-S-5  
**Reclassification:** None

**Type:** Crib  
**Start Date:** 1/1/1953

**Status:** Inactive  
**End Date:** 1/1/1956

**Description:** The unit consists of two open bottomed crib boxes 3.1 meters (10 feet) by 3.1 meters (10 feet) made of timbers. The two crib boxes are connected in series 15 meters (50 feet) apart, with overflow from one box into the other via a pipe. These boxes are set into a gravel layer in the bottom of a trench. The trench was the backfilled. Each box contains two flanged riser pipes extending from the top of the box.

**Location:** The unit was located outside the 241-S Tank Farm east fence. In 1996, the eastern tank farm fence line was expanded. The crib is now inside the tank farm fence.

**Related Sites/Structures:** The crib is associated with the condensers on the 241-S-101 and 241-S-104 tanks located inside the 241-S Tank Farm. The site is also associated with the 216-S-15 Pond.

**Process Description:** The unit received condensate from the riser condensers on the 241-S-101 and 241-S-104 Tanks.

**Waste Type:** Process Effluent

**Waste Description:** The site received condensate from condensers on the 241-S-101 and 241-S-104 Tanks in the 241-S Tank Farm. The waste is low in salt and is neutral to basic. The inorganics at the site consist of nitrate, sodium, sodium dichromate, sodium hydroxide, sodium aluminate, and ammonium nitrate. The Reduction Oxidation (REDOX) Radiation Monitoring Report for September 1953 states that the condensate diverted to this crib was sampled. The analysis indicated 95% of the activity was due to zirconium-niobium.

---

**Code:** 216-S-15  
**Classification:** Accepted

**Names:** 216-S-15; 216-S-2; 241-S-110 Pond; UN-216-W-3; 110-S Tank Overflow Pond  
**Reclassification:** None

**Type:** Pond  
**Start Date:** 1/1/1951

**Status:** Inactive  
**End Date:** 1/1/1952

**Description:** This site consists of a pond that was deactivated by removing the above-ground piping and backfilling it with clean soil.

**Location:** This site is located at the northeast corner of the 216-S-3 Crib. The site was located outside the east 241-S Tank Farm fence. In 1996, the eastern tank farm fence line was expanded. The site is now inside the tank farm fence.

**Related Sites/Structures:** The site is associated with the 241-S-110 tank.

**Process Description:** The site provided surface liquid disposal for the 241-S-110 Tank condenser spray cooling water.

**Waste Type:** Storage Tank

**Waste Description:** The site received condenser spray cooling water from the 241-S-110 Tank. The waste was low in salt, neutral to basic, and contained nitrates.
This unit is a rectangular concrete structure used to divert waste flow to the proper destination. Valve handles extend through and above a concrete cover block on the 241-S-A Valve Pit.

Location:
The 241-S-A Valve Pit is located in the 241-S Tank Farm, between Tanks 241-S-102 and 241-S-101.

Related Sites/Structures:
Structures associated with the 241-S-A Valve Pit include: a flush pit, a leak detector, valve handles, and the 241-S-102 Tank.

Process Description:
The 241-S-A Valve Pit is used to direct waste flow.

Waste Type: Storage Tank

Waste Description:
The unit transports waste solutions from processing and decontamination operations. Quantities of waste are variable according to specific plant operations. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

This unit is a rectangular concrete structure used to divert waste flow to the proper destination. Valve handles extend through and above a concrete cover block on the 241-S-B Valve Pit.

Location:
The 241-S-B Valve Pit is located in the 241-S Tank Farm, south of Tanks 241-S-102 and 241-S-101.

Related Sites/Structures:
Structures associated with the 241-S-B Valve Pit include: a flush pit, a leak detector, valve handles, and the 241-S-102 Tank.

Process Description:
The 241-S-B Valve Pit is used to direct waste flow.

Waste Type: Process Effluent

Waste Description:
The unit transports waste solutions from processing and decontamination operations. Quantities of waste are variable according to specific plant operations. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

Hanford Site Waste Management Units Report
February 2015

1600
### Tank 241-S-103

**Description:** This unit is a second generation single-shell storage tank. Tank 241-S-103 is the third tank of a three-tank cascade series. This tank is a reinforced concrete, cylindrical structure with a single steel liner lying across the tank bottom and up the tank wall. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-S-103 is located within 241-S Tank Farm Facility. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

**Related Sites/Structures:** Structures associated with Tank 241-S-103 include passive ventilation, a liquid observation well, drywells, temperature and surface level measurement instruments.

**Process Description:** Waste sources for Tank 241-S-103 include the REDOX facility and 241-S, 241-SX, 241-SY, and 241-U Tank Farms.

**Waste Type:** Storage Tank

**Waste Description:** Waste transferred to Tank 241-S-103 included REDOX high-level waste, REDOX coating waste, evaporator bottoms, noncomplexed waste, partial neutralization feed, and double-shell slurry feed from 241-S, 241-SX, 241-SY, and 241-U Tank Farms.

### Tank 241-S-104

**Description:** This unit is a second generation single-shell storage tank. Tank 241-S-104 is the first tank of a three-tank cascade series. This tank is a reinforced concrete, cylindrical structure with a single steel liner lying across the tank bottom and up the tank wall. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-S-104 is located within 241-S Tank Farm Facility. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

**Related Sites/Structures:** Structures associated with Tank 241-S-104 include passive ventilation, drywells, temperature and surface level measurement instruments.

**Process Description:** Tank 241-S-104 received waste from the REDOX facility and the 241-S Tank Farm.

**Waste Type:** Storage Tank

**Waste Description:** Waste transferred to Tank 241-S-104 included REDOX high-level and coating waste, and waste from 241-S Tank Farm.

### Tank 241-S-105

**Description:** This unit is a second generation single-shell storage tank. Tank 241-S-105 is the second tank of a three-tank cascade series. This tank is a reinforced concrete, cylindrical structure with a single steel liner lying across the tank bottom and up the tank wall. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-S-105 is located within 241-S Tank Farm Facility. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

**Related Sites/Structures:** Structures associated with Tank 241-S-105 include passive ventilation, drywells, temperature and surface level measurement instruments.

**Process Description:** Tank 241-S-105 received waste from the REDOX facility and the 241-S Tank Farm.

**Waste Type:** Storage Tank

**Waste Description:** Waste transferred to Tank 241-S-105 included REDOX high-level and coating waste, and waste from 241-S Tank Farm.

Location: Tank 241-S-105 is located within 241-S Tank Farm Facility. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

Related Sites/Structures: Structures associated with Tank 241-S-105 include passive ventilation, a liquid observation well, five drywells, temperature and surface level measurement instruments.

Process Description: Tank 241-S-105 received waste from the REDOX facility.

Waste Type: Process Effluent

Waste Description: REDOX coating and high-level waste were transferred to Tank 241-S-105.

---

**Code:** 241-S-106

**Description:** This unit is a second generation single-shell storage tank. Tank 241-S-112 is the third tank of a three-tank cascade series. This tank is a reinforced concrete, cylindrical structure with a single steel liner lying across the tank bottom and up the tank wall. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-S-112 is located within 241-S Tank Farm Facility. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

**Related Sites/Structures:** Structures associated with Tank 241-S-112 include passive ventilation, a hydrogen monitoring system, a liquid observation well, five drywells, temperature and surface level measurement instruments.

**Process Description:** Waste sources for Tank 241-S-112 include the REDOX facility and 241-S Tank Farm.

**Waste Type:** Chemicals

**Waste Description:** Waste transferred to Tank 241-S-112 included REDOX high-level waste and evaporator bottoms from 241-S Tank Farm. The tank contained 614,000 gallons (82,075 cubic feet) of waste, primarily salt cake. A retrieval campaign was completed in May 2005, retrieving 583,000 gallons (77931 cubic feet) of waste. As of May 2005, 31,000 gallons (4,144 cubic feet) of waste remained in the tank.

---

**Code:** 241-S-151  
**Names:** 241-S-151; 241-S-151 Diversion Box  
**Type:** Diversion Box  
**Status:** Inactive  
**Classification:** Accepted

**Description:** This unit is constructed of reinforced concrete and is rectangular in shape.

**Location:** This unit is located inside the 241-S, SX, SY fence, northeast of 241-SX-101 and west of the 241-S-302 catch tank.

**Related Sites/Structures:** The unit interconnects 240-S-151 Diversion Box, 241-SX-151 Diversion Box, 241-SY Tank Farm, and 241-S Tank Farm (see transfer line sitecodes 200-W-97-PL, 200-W-99-PL and 200-W-100-PL). The 241-S-302A Catch Tank is associated with the 241-S-151 Diversion Box.

**Process Description:** This unit was used for the transfer of waste solutions from processing and decontamination operations.

**Waste Type:** Chemicals

**Waste Description:** The unit transports waste solutions from processing and decontamination operations. Quantities are variable according to specific plant operations. Lead shielding may also be contained inside the diversion box.
Reclassification: 241-S-152; 241-S-152 Diversion Box

Description: This unit is constructed of reinforced concrete and is rectangular in shape. The 241-S-152 Diversion Box has been weather covered.

Location: The 241-S-152 Diversion Box is located east of the 242-S Evaporator Building.

Related Sites/Structures: The 241-S-152 Diversion Box is associated with the 241-S Tank Farm. The drain line is DR324.

Process Description: This unit was used for the transfer of waste solutions from processing and decontamination operations.

Waste Type: Process Effluent

Waste Description: Equipment associated with the diversion box includes transfer piping and nozzles. Waste lead is also stored in the diversion box.

Waste Type: Process Effluent

Waste Description: This unit was used for transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operations. Lead shielding may also be contained inside the diversion box.

Code: 241-S-302A

Reclassification: None

Names: 241-S-302A; 241-S-302-A Catch Tank; IMUST; Inactive Miscellaneous Underground Storage Tank; Lines V542, V763, V764, and DR324

Description: This unit is a cylindrical, steel tank. The catch tank is buried underground for radiation shielding. The tank is surrounded with posts and chain and labeled with IMUST signs.

Location: The 241-S-302A Catch Tank is located east of the 241-S and the 241-SX Tank Farms, inside the tank farm fence. It is north of the 241-S-151 diversion box.

Related Sites/Structures: The 241-S-302A Catch Tank is associated with the 241-S-151 and the 241-SX-151 Diversion Boxes. Drain lines V542, V763, V764 and DR324 are associated with the diversion boxes.

Process Description: The tank was installed to receive spills, leakage, line flushes, and drainage associated with waste transfers through the 241-S-151 and 241-SX-151 Diversion Boxes.

Waste Type: Process Effluent

Waste Description: The tank collected leaking and excess process waste that passed through the 241-S-151 and 241-SX-152 Diversion Boxes. Wastes characteristic of the 241-S, 241-SX and 241-U Tank Farms as well as the 222-S Laboratory are expected to be present in the catch tank.
### 241-S-304 Catch Tank

**Names:** 241-S-304; 241-S-304 Catch Tank  
**Reclassification:** None

**Type:** Catch Tank  
**Start Date:** 1/1/1991

**Status:** Inactive  
**End Date:** 1/1/2005

**Description:** The catch tank is below ground surface, inside a concrete pump pit with concrete cover blocks. The pump pit measures 3 meters by 3 meters (10 foot by 10 foot) and is 1.75 meters (5.75 feet) deep. The catch tank is constructed of carbon steel.

**Location:** The 241-S-304 Catch Tank is located east of 241-SX Tank Farm and northeast of the 241-S-151 Diversion Box. It is inside the fenced boundary of the 241-S, SX and SY Tank Farm complex.

**Related Sites/Structures:** The tank is associated with the 241-S-151 Diversion Box.

**Process Description:** The 241-S-304 catch tank received precipitation drainage and drainage from the 241-S-151 Diversion Box. This tank was placed into service in 1991 to replace the 241-S-302A catch tank.

**Waste Type:** Equipment

**Waste Description:** The catch tank receives precipitation drainage and 241-S-151 Diversion Box drainage.

### 244-S Receiver Tank

**Code:** 244-S DCRT  
**Classification:** Accepted

**Names:** 244-S DCRT; 244-S Double-Contained Receiver Tank; 244-S Receiver Tank; 244-S RT; 244-S-TK/SMP; Lines 5350 and 5351; 244-S Catch Station  
**Reclassification:** None

**Type:** Receiver Tank  
**Start Date:** 1/1/1987

**Status:** Inactive  
**End Date:** 1/1/2005

**Description:** The 244-S Receiver Tank is constructed of carbon steel. It sets vertically inside a reinforced concrete, steel lined vault with 0.31 meters (1 foot) thick walls and a 1.4 meters (4.5 foot) thick base. The tank vault is separated from a pump pit above by a 30 centimeter (12 inch) thick concrete slab.

**Location:** The 244-S Receiver Tank is located inside the S, SX, SY Tank Farm fence, south of the 241-SY-103 Tank.

**Related Sites/Structures:** This unit is associated with Diversion Boxes 241-S-151 and 241-UX-154. The 244-S Receiver Tank is also associated with 222-S, Plutonium Finishing Plant, U Plant, and T Plant Facilities.

**Process Description:** The 244-S Receiver Tank served as an interim storage area for liquid radioactive mixed waste.

**Waste Type:** Chemicals

**Waste Description:** The unit stores and transports radioactive mixed waste solutions from processing and decontamination operations. Quantities are variable according to specific plant operations.

### 241-SX-A

**Code:** 241-SX-A  
**Classification:** Accepted

**Names:** 241-SX-A; 241-SX-A Diversion Box; 241-SX-A Valve Pit  
**Reclassification:** None

---

*Hanford Site Waste Management Units Report*  
February 2015
Type: Valve Pit  
Status: Inactive  
Description: This unit is a rectangular concrete structure used to divert waste flow to the proper destination. It has been covered with foam. Valve handles extended through and above the concrete cover block.  
Location: The 241-SX-A Valve Pit is located southeast of Tank 241-SX-102 and northeast of Tank 241-SX-105.  
Related Sites/Structures: Structures associated with the 241-SX-A Valve Pit include: a flush pit, a leak detector, valve handles, and Tank 241-SX-102.  
Process Description: The 241-SX-A Valve Pit is used to direct waste flow.  
Waste Type: Process Effluent  
Waste Description: The unit is used to transport radioactive waste solutions from processing and decontamination operations. Quantities are variable according to specific plant operation. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

Code: 241-SX-B  
Names: 241-SX-B; 241-SX-B Diversion Box; 241-SX-B Valve Pit  
Type: Valve Pit  
Status: Inactive  
Description: This unit is a rectangular concrete structure used to divert waste flow to the proper destination. The structure has been covered with foam. Valve handles extended through and above the concrete cover block.  
Location: The 241-SX-B Valve Pit is located southeast of Tank 241-SX-101 and northwest of Tank 241-SX-104.  
Related Sites/Structures: Structures associated with the 241-SX-B Valve Pit include: a flush pit, a leak detector, valve handles, and Tank 241-SX-102.  
Process Description: The 241-SX-B Valve Pit is used to direct waste flow.  
Waste Type: Process Effluent  
Waste Description: The unit is used to transport radioactive waste solutions from processing and decontamination operations. Quantities are variable according to specific plant operation. It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.

Code: 241-SX-101  
Names: 241-SX-101; 241-SX-TK-101  
Type: Single-Shell Tank  
Status: Inactive  
Description: This unit is a third generation single-shell tank designed for self-boiling waste. Tank 241-SX-
101 is the first tank of a three tank cascade series. This tank is a reinforced concrete, cylindrical structure with a steel liner. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-SX-101 is located in the 241-SX Tank Farm. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

**Related Sites/Structures:** Structures associated with Tank 241-SX-101 include: drywells, a liquid observation well, a hydrogen monitor, temperature and surface level measurement instruments. This tank is actively vented through Tank 241-SX-109 which is connected to the 241-SX Sludge Cooler.

**Process Description:** Waste sources for Tank 241-SX-101 include the REDOX facility, and 241-BX, 241-S, 241-SX, and 241-U Tank Farms.

**Waste Type:** Asbestos (non-friable)

**Waste Description:** Waste transferred to Tank 241-SX-101 included: REDOX high-level waste and ion exchange waste, evaporator bottoms, partial neutralization feed, and complexed waste from 241-S, 241-BX, 241-SX, and 241-U Tank Farms.

---

**Code:** 241-SX-102  
**Classification:** Accepted  
**Names:** 241-SX-102; 241-SX-TK-102  
**Reclassification:** None  
**Type:** Single-Shell Tank  
**Start Date:** 1/1/1954  
**Status:** Inactive  
**End Date:** 1/1/1980  
**Description:** This unit is a third generation single-shell tank designed for self-boiling waste. Tank 241-SX-102 is the second tank of a three tank cascade series. This tank is a reinforced concrete, cylindrical structure with a steel liner. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-SX-102 is located in the 241-SX Tank Farm. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

**Related Sites/Structures:** Structures associated with Tank 241-SX-102 include: drywells, a liquid observation well, a hydrogen monitor, temperature and surface level measurement instruments. This tank is actively vented through Tank 241-SX-109 which is connected to the 241-SX Sludge Cooler.

**Process Description:** Waste sources for Tank 241-SX-102 include the REDOX facility, and the 241-BX, 241-TX, 241-SX, and 241-U Tank Farms.

**Waste Type:** Process Effluent

**Waste Description:** Waste transferred to 241-SX-102 included: REDOX high-level waste, carbonate waste, concrete, REDOX high-level waste, ion exchange waste, evaporator bottoms, and partial neutralization feed from 241-BX, 241-SX, 241-TX, and 241-S Tank Farms.

---

**Code:** 241-SX-103  
**Classification:** Accepted  
**Names:** 241-SX-103; 241-SX-TK-103  
**Reclassification:** None  
**Type:** Single-Shell Tank  
**Start Date:** 1/1/1954  
**Status:** Inactive  
**End Date:** 1/1/1980  
**Description:** This unit is a third generation single-shell tank designed for self-boiling waste. Tank 241-SX-103 is the third tank of a three tank cascade series. This tank is a reinforced concrete, cylindrical structure with a steel liner. The tank is buried underground to provide radiation shielding.
### Tank 241-SX-103

**Location:** Tank 241-SX-103 is located in the 241-SX Tank Farm. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

**Related Sites/Structures:** Structures associated with Tank 241-SX-103 include: drywells, a liquid observation well, a hydrogen monitor, temperature and surface level measurement instruments. This tank is actively vented through Tank 241-SX-109 which is connected to the 241-SX Sludge Cooler.

**Process Description:** Waste sources for Tank 241-SX-103 include the REDOX facility, and the 241-BX, 241-S, and 241-SX Tank Farms.

**Waste Type:** Barrels/Drums/Buckets/Cans

**Waste Description:** Waste transferred to Tank 241-SX-103 included: REDOX high-level waste, concrete, coating waste, evaporator bottoms, organic wash waste, and partial neutralization feed from 241-BX, 241-SX, and 241-S Tank Farms.

### Tank 241-SX-104

**Location:** Tank 241-SX-104 is located in the 241-SX Tank Farm. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

**Related Sites/Structures:** Structures associated with Tank 241-SX-104 include: drywells, a liquid observation well, a hydrogen monitor, temperature and surface level measurement instruments. This tank is actively vented through Tank 241-SX-109 which is connected to the 241-SX Sludge Cooler.

**Process Description:** Waste sources for Tank 241-SX-104 include the REDOX facility, the 241-S, and the 241-SX Tank Farms.

**Waste Type:** Process Effluent

**Waste Description:** Waste transferred to Tank 241-SX-104 included: REDOX high-level waste and ion exchange waste, double-shell slurry feed, and evaporator bottoms from the 241-S and the 241-SX Tank Farms.

241-SX-106; 241-SX-TK-106

Single-Shell Tank

Inactive

Start Date: 1/1/1954
End Date: 1/1/1980

This unit is a third generation single-shell tank designed for self-boiling waste. Tank 241-SX-106 is the third tank of a three tank cascade series. This tank is a reinforced concrete, cylindrical structure with a steel liner. The tank is buried underground to provide radiation shielding.

Location: Tank 241-SX-106 is located in the 241-SX Tank Farm. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

Related Sites/Structures: Structures associated with Tank 241-SX-106 include drywells, a liquid observation well, a hydrogen monitor, temperature and surface level measurement instruments. This tank is actively vented through Tank 241-SX-109 which is connected to the 241-SX Sludge Cooler.

Waste Type: Process Effluent

Code: 241-SX-107

Classification: Accepted

Recycling: None

Start Date: 1/1/1956
End Date: 1/1/1964

This unit is a third generation single-shell tank designed for self-boiling waste. Tank 241-SX-107 is the first tank of a three tank cascade series. This tank is a reinforced concrete, cylindrical structure with a steel liner. The tank is buried underground to provide radiation shielding.

Location: Tank 241-SX-107 is located in the 241-SX Tank Farm. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

Related Sites/Structures: Structures associated with Tank 241-SX-107 include: lateral wells, drywells, a liquid observation well, a hydrogen monitor, temperature and surface level measurement instruments. This tank is actively vented through Tank 241-SX-109 which is connected to the 241-SX Sludge Cooler.
Process Description: Waste sources for Tank 241-SX-107 include the REDOX facility, 100 F Area, and the 241-SX Tank Farm.

Waste Type: Process Effluent

Waste Description: Waste transferred to Tank 241-SX-107 included: coating waste and REDOX high-level waste. The unit contains 41 small bottles of neutralized waste from 100 F Area, each containing less than 1 gram (0.04 ounce) Plutonium 239.

Type: Single-Shell Tank

Status: Inactive

Description: This unit is a third generation single-shell tank designed for self-boiling waste. Tank 241-SX-108 is the first tank of a three tank cascade series. This tank is a reinforced concrete, cylindrical structure with a steel liner. The tank is buried underground to provide radiation shielding.

Location: Tank 241-SX-108 is located in the 241-SX Tank Farm. This facility is located on Thirteenth Street, northwest of the REDOX Plant.

Related Sites/Structures: Structures associated with Tank 241-SX-108 include: lateral wells, drywells, temperature and surface level measurement instruments. This tank is actively vented through the 241-SX Sludge Cooler.

Process Description: Waste sources for Tank 241-SX-108 include the REDOX facility, and the 241-SX Tank Farm.

Waste Type: Chemicals

Waste Description: Waste transferred to Tank 241-SX-108 included: REDOX high-level waste, concrete, and supernatant containing REDOX high-level waste from the 241-SX Tank Farm.

Reclassification: 241-SX-109; 241-SX-TK-109

### Notes:
- **Type:** Catch Tank
- **Start Date:** 1/1/1954
- **End Date:** 1/1/1983

### Description:
The 241-SX-302 Catch Tank is an underground, horizontal, cylindrical steel tank. Three yellow risers are visible on the surface. It is surrounded with post and chain and marked with radiological and IMUST signs.

### Location:
The 241-SX-302 Catch Tank is located east of the 241-SX-101 Tank, inside the tank farm fence.

### Related Sites/Structures:
The 241-SX-302 Catch Tank is associated with drain line V595, the 241-SX-151 Diversion Box and the 241-SX-152 Diversion Box.

### Process Description:
Drainage and leaks from the 241-SX-151 Diversion Box and the 241-SX-152 Diversion Boxes collected and were stored in the 241-SX-302 Catch Tank.

### Waste Type:
Process Effluent

### Waste Description:
This tank collected excess and leaking waste that transferred through the 241-SX-151 and 241-SX-152 Diversion Boxes. In 1993, the tank was estimated to contain 1152 liters (305 gallons) of liquid supernate and 3969 liters (1050 gallons) of sludge.

</tr>
</thead>
</table>

### Notes:
- **Type:** Process Unit/Plant
- **Start Date:** 1/1/1954
- **End Date:** 1/1/1975

### Description:
This unit is constructed of reinforced concrete with walls varying in thickness from 0.31 to 0.77 meters (1 to 2.5 feet) thick for shielding purposes.

### Location:
The 241-SX-401 Condenser Building is located west of Tank 241-SX-106, inside the 241-SX Tank Farm.

### Related Sites/Structures:
A dry well is associated with the condenser building, 216-S-21 crib and pipeline 200-W-160-PL.

### Process Description:
This building processed condensation from the 241-SX Tank Farm off gases.

### Waste Type:
Process Effluent

### Waste Description:
The unit contains radioactively contaminated equipment and concrete. The quantity of waste has not been determined. Radiation levels are high.

### Single-Shell Tank 241-T-103

**Type:** Single-Shell Tank  
**Status:** Inactive  
**Start Date:** 1/1/1945  
**End Date:** 1/1/1974  

**Description:** This unit is a first generation, underground single-shell storage tank. Tank 241-T-103 is the third and final tank of a cascade that also includes tanks 241-T-101 and 241-T-102. The tank is a cylindrical, dome roofed, concrete reinforced structure with a steel liner lying across the tank bottom and up the concrete wall. This unit is below grade for shielding purposes.

**Location:** Tank 241-T-103 is located in the center portion of the 241-T Tank Farm. The 241-T Farm is located north of the intersection of 23rd Street and Camden Avenue.

**Process Description:** Waste sources for Tank 241-T-103 include waste cascaded from Tanks 241-T-101 and 241-T-102, waste from Tank 241-C-102 and waste from the T Plant operations.

**Waste Type:** Water  
**Waste Description:** Waste in Tank 241-T-103 include bismuth phosphate metal waste, low level coating and supernate from the B Plant, REDOX ion exchange, REDOX high level waste, and evaporation bottoms.

---

### Single-Shell Tank 241-T-104

**Type:** Single-Shell Tank  
**Status:** Inactive  
**Start Date:** 1/1/1946  
**End Date:** 1/1/1974  

**Code:** 241-T-104  
**Classification:** Accepted  
**Reclassification:** None  

**Description:** This unit is a first generation, underground single-shell storage tank. Tank 241-T-104 is the first tank of the second cascade of tanks receiving waste in the T Farm. Tank 241-T-105 and 106 are the second and third tanks in the series.

**Location:** Tank 241-T-104 is located in the eastern portion of the 241-T Tank Farm, north of the intersection of 23rd Street and Camden Avenue.

**Related Sites/Structures:** Structures associated with 241-T-104 include a temperature element, a liquid observation well, drywells, passive ventilation, and a surface level measurement device.

**Process Description:** Tank 241-T-104 received first cycle decontamination waste.

**Waste Type:** Misc. Trash and Debris  
**Waste Description:** Tank 241-T-104 received bismuth phosphate first cycle waste.

---

### Single-Shell Tank 241-T-105

**Type:** Single-Shell Tank  
**Status:** Inactive  
**Start Date:** 1/1/1946  
**End Date:** 1/1/1976  

**Code:** 241-T-105  
**Classification:** Accepted  
**Reclassification:** None  

**Description:** This unit is a first generation, underground single-shell tank. Tank 241-T-105 is the second tank of the second cascade of tanks receiving waste in the 241-T Farm. The tank is cylindrical,
dome-roofed, and concrete-reinforced with a steel liner lying across the tank bottom and up the concrete wall. This unit is below grade for shielding purposes.

**Location:** Tank 241-T-105 is located in the center portion of the 241-T Tank Farm, which is located north of the intersection of 23rd Street and Camden Avenue.

**Related Sites/Structures:** Structures associated with 241-T-105 include drywells, passive ventilation, and a surface level measurement device.

**Process Description:** Waste sources for 241-T-105 include decontamination waste coating and ion exchange waste.

---

**Code:** 241-T-106

**Names:** 241-T-106; 241-T-TK-106

**Type:** Single-Shell Tank

**Status:** Inactive

**Description:** This unit is a first generation, underground single-shell tank. Tank 241-T-106 is the third tank of the second cascade of tanks receiving waste in the 241-T-Farm. The tank is cylindrical, dome-roofed, and concrete-reinforced with a steel liner lying across the tank bottom and up the concrete well. This unit is below grade for shielding purposes.

**Location:** Tank 241-T-106 is located in the western portion of the 241-T Tank Farm, which is located north of the intersection of 23rd Street and Camden Avenue.

**Release Description:** See UPR-200-W-148.

**Related Sites/Structures:** Structures associated with 241-T-106 include dry wells, passive ventilation, temperature monitoring device, and surface level measurement devices.

**Process Description:** The waste source for 241-T-106 is second cycle decontamination cascade overflow waste from Tank 241-T-105.

---

**Code:** 241-T-107

**Names:** 241-T-107; 241-T-TK-107

**Type:** Single-Shell Tank

**Status:** Inactive

**Description:** This unit is a first generation, underground single-shell tank. Tank 241-T-107 is the first tank of the third cascade of tanks receiving waste in the T-Farm. The tank is cylindrical, dome-roofed, and concrete-reinforced with a steel liner lying across the tank bottom and up the concrete well. This unit is below grade for shielding purposes.

**Location:** Tank 241-T-107 is located in the eastern portion of the 241-T Tank Farm, which is located north of the intersection of 23rd Street and Camden Avenue.

**Related Sites/Structures:** Structures associated with 241-T-107 include dry wells, passive ventilation, temperature measurement device, and surface level measurement devices.

**Process Description:** Waste sources for Tank 241-T-107 include B Plant ion exchange waste from Tank 241-BX-104, coating waste from Tank 241-C-102, tributyl phosphate waste and first cycle decontamination waste.

**Type:** Single-Shell Tank

**Status:** Inactive

**Start Date:** 1/1/1945  
**End Date:** 1/1/1974

**Description:**

- Tank 241-T-108 is the second tank of the third cascade of tanks receiving waste in the T-Farm. The tank is cylindrical, dome-roofed, and concrete-reinforced with a steel liner lying across the tank bottom and up the concrete well. This unit is below grade for shielding purposes.

- Tank 241-T-108 is located in the center of the 241-T Tank Farm, which is located north of the intersection of 23rd Street and Camden Avenue.

- Tank 241-T-109 is the third tank of the third cascade of tanks receiving waste in the T-Farm. The tank is cylindrical, dome-roofed, and concrete-reinforced with a steel liner lying across the tank bottom and up the concrete wall. This unit is below grade for shielding purposes.

- Tank 241-T-109 is located in the western portion of the 241-T Tank Farm, which is located north of the intersection of 23rd Street and Camden Avenue.

- Waste sources for Tank 241-T-109 include saltcake from 241-T Evaporator that was added from Tank 241-TX-117, tributyl phosphate process waste, and first cycle decontamination cascade overflow waste from Tank 241-T-108.

- Tank 241-T-110 is the first tank of the fourth cascade of tanks receiving waste in the T-Farm. The tank is cylindrical, dome-roofed, and concrete-reinforced with a steel liner lying across the tank bottom and up the concrete wall. This unit is below grade for shielding purposes.
Location: Tank 241-T-110 is located in the southeastern portion of the 241-T Tank Farm, which is located north of the intersection of 23rd Street and Camden Avenue.

Related Sites/Structures: Structures associated with 241-T-110 include drywells, passive ventilation, liquid observation well, and a surface level measurement device.

Process Description: Waste sources for Tank 241-T-110 include 224-U waste and second cycle decontamination waste.

---

Code: 241-T-111

End Date: 1/1/1976

Description: This unit is a first generation, underground single-shell tank. Tank 241-T-112 is the third tank of the fourth cascade of tanks receiving waste in the T Farm. The tank is cylindrical, dome-roofed, and concrete-reinforced with a steel liner lying across the tank bottom and up the concrete wall. This unit is below grade for shielding purposes.

Location: Tank 241-T-112 is located in the southwestern portion of the 241-T Tank Farm, which is located north of the intersection of 23rd Street and Camden Avenue.

Related Sites/Structures: Structures associated with 241-T-112 include drywells, passive ventilation, temperature and surface level measurement devices.

Process Description: Waste sources for Tank 241-T-112 include second cycle decontamination waste, decontamination waste, and laboratory waste.

---

Code: 241-T-151
Names: 241-T-151; 241-T-151 Diversion Box
Type: Diversion Box
Classification: Accepted
Reclassification: None
Start Date: 1/1/1944
### Status: Inactive
### End Date: 1/1/1980
#### Description:
The diversion box is a rectangular reinforced concrete structure. Most of the structure is below ground. A few inches of the structure that extends above ground is covered with a gray weather coating. The tank farm fence is posted with various radiological postings.

#### Location:
The 241-T-151 Diversion Box is located near the southeast corner of 241-T Tank Farm, inside the tank farm fence.

#### Related Sites/Structures:
The 241-T-151 Diversion Box is associated with the 241-T-153 and 241-U-151 Diversion Box, the 241-T-301 Catch Tank, and the 241-T Tank Farm.

#### Process Description:
The 241-T-151 Diversion Box was used to direct liquid waste to other tank farm locations in 200 East and West Areas via jumper connections and underground transfer lines.

*Hanford Site Waste Management Units Report*

February 2015
Names: 241-T-201; 241-T-TK-201  
Reclassification: None

Type: Single-Shell Tank  
Start Date: 1/1/1952

Status: Inactive  
End Date: 1/1/1976

Description: This unit is an underground, concrete-reinforced vertical single-shell tank. Tank 241-T-201 has a steel liner and rests upon a concrete base slab. This unit is below grade for shielding purposes.

Location: Tank 241-T-201 is located in the western portion of the 241-T Tank Farm.

Related Sites/Structures: The tank is associated with the 216-T-32 crib and the 241-T-252 Diversion Box. Equipment associated with 241-T-201 includes passive ventilation, temperature, and surface level measurement devices.

Process Description: Some documents state the waste in 241-T-201 is from the 224-U Building. However, WHC-SD-WM-ER-351 states the 241-T-201 was full of "224" waste when initial level readings were taken in 1952, but does not specify if the waste was from 224-T or 224-U. ARH-2155 and RHO-CD-673 both state that the 216-T-32 Crib received 224-T waste via the 241-T-201 tank.

---

Names: 241-T-202; 241-T-TK-202  
Reclassification: None

Type: Single-Shell Tank  
Start Date: 1/1/1952

Status: Inactive  
End Date: 1/1/1976

Description: This unit is an underground, concrete-reinforced vertical single-shell tank. Tank 241-T-202 has a steel liner and rests upon a concrete base slab. This unit is below grade for shielding purposes.

Location: Tank 241-T-202 is located in the western portion of the 241-T Tank Farm.

Related Sites/Structures: Structures associated with 241-T-202 include the 241-T-252 Diversion Box, passive ventilation, temperature, and surface level measurement devices.

Process Description: Some documents state the waste in 241-T-201 is from the 224-U Building. However, WHC-SD-WM-ER-351 states the 241-T-201 was full of "224" waste when initial level readings were taken in 1952, but does not specify if the waste was from 224-T or 224-U. ARH-2155 and RHO-CD-673 both say that the 216-T-32 Crib received 224-T waste via the 241-T-201 tank.

**Names:** 200-W-52; 216-T-7 Crib; 241-T-3 Crib
**Type:** Crib
**Status:** Inactive

**Description:** The crib is located inside the 241-T Tank Farm fence. The fence is posted with Radiological Buffer Area/Underground Radioactive Material signs. The tank farm has a gravel surface. The crib is not separately identified.

**Location:** The crib is located inside the 241-T Tank Farm fence, east of the 216-T-7 Tile Field.

**Related Sites/Structures:** The crib is associated with the 216-T-7 Tile Field, the 241-T Tank Farm, 221-T and 224-T.

**Process Description:** The site consists of one wooden crib box with inlet and outlet piping and a riser pipe. The box is set into a gravel layer in the bottom of a pit with sloping sides. It is connected to a tile field that is located west of the crib. The 216-T-7 crib received second cycle supernate from 221-T, 224-T waste and tank 5-6 waste after it cascaded through the 241-T-110, 241-T-111 and 241-T-112 tanks. The 216-T-7 Tile Field received overflow from the crib.

**Names:** 200-W-93; Contaminated Soil at 241-T Tank Farm
**Type:** Unplanned Release
**Status:** Inactive

**Description:** The site is the soil inside and adjacent to the chain link fence that surrounds the 241-T Tank Farm. Various radiological postings and warning signs are attached to the chain link fence. The interior of the tank farm complex is covered with gravel. Many risers and monitoring devices for the underground structures are visible on the surface. The 216-T-7 and 216-T-32 Cribs are located inside the tank farm fence and are marked with "Crib" signs. The 216-T-7 Tile Field is partially inside the tank farm, but most of it extends westward, beyond the fence line. The individual unplanned releases associated with the 241-T Tank Farm are not separately marked or posted. Occasionally, radioactive contamination is found adjacent to the outside of the tank farm fence, resulting in a contamination zone extension around the tank farm perimeter. These areas will also be considered tank farm soil. A posted Underground Radioactive Material area currently extends outside the 241-T Tank Farm fence on the west side.

**Location:** The site is located west of 221-T, at the intersection of 23rd Street and Camden Ave., in 200 West Area.
### Waste Type:
- Equipment

### Waste Description:
- Liquid releases occurred from underground leaks in tanks and transfer lines. Airborne contamination spreads occurred from activities conducted in valve pits and diversion boxes. Both types of releases contributed to the contamination in the soil.

### Release Description:
The exact extent (horizontal and vertical) of the soil contaminated by unplanned releases that occurred within this farm over the years are not known. Some of the single shell tanks have leaked to the soil below the tank farm. Other releases spread contamination to the surface soil surrounding the tanks.

### Related Sites/Structures:
- Unplanned Releases UPR-200-W-7, UPR-200-W-147 and UPR-200-W-148 are associated with the 241-T Tank Farm. The 216-T-7 and 216-T-32 Cribs are located inside the tank farm fence.
WMA TX/TY

Code: 242-T
Classification: Accepted

Names: 242-T; 242-T Evaporator Facility; 241-T Evaporator
Reclassification: None

Type: Evaporator
Start Date: 1/1/1950
End Date: 1/1/1986

Status: Inactive

Description: The 242-T is a reinforced concrete and structural steel building. The facility consists of the 242-T building with the control room in the southeast portion, 242-TB and the 242-TA vault. The evaporator portion of 242-T contains a feed cell, an evaporator vessel, a cyclone separator, a catch tank and two preheater tanks. The condensate portion contains the off-gas vessels, two condensate catch tanks and a sample gallery. The 242-TA Vault is a concrete lined pit with a ground level steel cover. A 15,120 liter (4000 gallon) receiver tank is inside the vault. This tank received Z Plant waste.

Location: The building is adjacent to the east side of the 241-TX/TY Tank Farm fence.

Related Sites/Structures: The 242-T is associated with the 241-TX/TY tanks and the 200-W-166-PL and 200-W-167-PL pipelines.

Process Description: The 242-T Evaporator Facility was originally constructed to increase storage capacity in the existing underground tank farm tanks through a batch evaporation, waste concentration process. From 1950 to 1955 and 1965 through 1976, 242-T operated as a tank waste evaporator. The evaporation operation of non-boiling tank farm waste was discontinued in 1976. From 1976 to 1980, the 242-T Evaporator was used to neutralize Z Plant salt acid waste. This process ended in 1980, with the completion of the 244-TX Double-Shell Receiver Tank. From 1980 to 1985 the control area of the facility was utilized to support the saltwell pumping program.

Waste Type: Soil

Waste Description: During the 1950's, the facility concentrated separation process, first cycle decontamination waste from the tank farms. First cycle waste typically contained 10% of the original fission products and 1% plutonium in solution with nitrates, phosphates and sulfates. From the 1960's to the late 1970's, it received single-shell supernatant waste, complexed radioactive waste, and dilute miscellaneous radioactive waste. From 1976 to 1980, the evaporator was used to neutralize Z Plant waste. During its active life, the facility received and processed 127,204,560 liters (33,652,000 gallons) of waste.

Code: 242-T-135
Classification: Accepted

Names: 242-T-135; IMUST; Inactive Miscellaneous Underground Storage Tank
Reclassification: None

Type: Storage Tank
Start Date:
End Date:

Status: Inactive

Description: The unit is a tank partially below grade, constructed of stainless steel. An agitator and a hopper are installed on top of the tank. The tank is surrounded with steel posts and chain, located behind a steel radiation shield wall. The area surrounding the tank is posted with Contamination Area and IMUST signs.

Location: The tank is located adjacent to the east wall of the 242-T Catch Tank Room and north of the 242-T Control Room. The 242-T buildings are located adjacent to the 241-TX Tank Farm, outside the fence.
**Process Description:** The tank was installed to hold decontamination solutions from the 242-T Evaporator. The solutions were charged through a hopper on the top of the tank and removed through the top using a jet.

**Waste Type:** Soil

**Waste Description:** The contents of the tank are not known. The tank mission was storage of 242-T decontamination solutions. The content of the tank would include 242-T decontamination solutions.

---

**Code:** 242-T-151  
**Names:** 242-T-151; 242-T-151 Diversion Box. Line V830  
**Type:** Diversion Box  
**Status:** Inactive  
**Description:** This unit is constructed of reinforced concrete and is rectangular in shape. This unit is located southeast of the 241-TX-116 Tank, inside the 241-TX Tank Farm. The 242-T-151 Diversion Box is associated with the 241-TX Tank Farm, 241-T-153 Diversion Box, and 242-T Evaporator. The drain line for this diversion box is V830. This unit was used for the transfer of waste solutions from processing and decontamination operations. Equipment associated with the diversion box includes transfer piping and nozzles. This unit was used for the transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operations.

**Waste Type:** Soil  
**Waste Description:** It is estimated that approximately 23 kilograms (50 pounds) of lead shielding may be stored in each diversion box.
IMUST signs.

**Location:** The unit is located inside the 241-TX Tank Farm, adjacent to the southwest corner of the 242-T Building.

**Related Sites/Structures:** The tank is associated with the 241-Z facility.

**Process Description:** The Z Waste Receiver Tank received high salt waste from tank D-5 in the 241-Z building. The Z Waste Receiver Tank waste was sent to the Blend Tank TK-B1 inside the 242-T building. Off-gasses from the tank are sent to the vessel vent system in the 242-TB building.

**Waste Type:** Water

**Waste Description:** The waste reportedly contains 0.007 grams per gallon of Plutonium; 4.756 molar concentration of nitrate ion; 0.15 molar concentration of Sodium ion; 0.842 molar concentration of trivalent Aluminum; 0.648 molar concentration of free Hydrogen atoms; 0.454 molar concentration of divalent Aluminum Fluoride; 0.180 molar concentration of bivalent Magnesium; 0.087 molar concentration of trivalent Iron; 0.059 molar concentration of Potassium ion; 0.013 molar concentration of Sulphate ion; and 0.0005 molar concentration of divalent Uranium Oxide.

**Code:** 241-TX-101

**Status:** Inactive

**Start Date:** 1/1/1949  
**End Date:** 1/1/1980

**Description:** This unit is a second-generation underground single-shell storage tank. Tank 241-TX-101 is the first tank of a four-tank cascade series. This cylindrical tank is concrete-reinforced with a single steel liner lying across the tank bottom and up the tank wall. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-TX-101 is located in the southeastern portion of the 241-TX Tank Farm.

**Related Sites/Structures:** Structures associated with Tank 241-TX-101 include passive ventilation, drywells, temperature and surface level measurement instruments.

**Process Description:** Waste sources for Tank 241-TX-101 included the REDOX Facility, PUREX, and B-Plant.

**Waste Type:** Sludge

**Waste Description:** Waste transferred to this unit includes bismuth phosphate metal waste, REDOX waste, coating waste, tributyl phosphate, and waste fractionization ion exchange waste. Other waste includes high level and low level waste from B-Plant, non-complexed waste, PUREX low-level waste, organic wash waste, partial neutralization feed waste, and evaporator bottoms. The unit also received decontamination waste from 241-C, -BX, -SX, -TX Tank Farms.

**Code:** 241-TX-102

**Type:** Single-Shell Tank  
**Status:** Inactive  

**Description:** This unit is a second-generation, underground single-shell storage tank. Tank 241-TX-115 is the third tank of a three-tank cascade series. This cylindrical tank is concrete-reinforced with a single steel liner lying across the tank bottom and up the tank wall. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-TX-115 is located in the western portion of the 241-TX Tank Farm.
Related Sites/Structures: Structures associated with Tank 241-TX-115 include passive ventilation, a liquid observation well, drywells, temperature and surface level measurement instruments.

Code: 241-TX-116 Classification: Accepted
Names: 241-TX-116; 241-TX-TK-116 Reclassification: None
Type: Single-Shell Tank Start Date: 1/1/1952
Status: Inactive End Date: 1/1/1976

Description: This unit is a second-generation, underground single-shell storage tank. Tank 241-TX-116 is the first tank of a three-tank cascade series. This cylindrical tank is concrete-reinforced with a single steel liner lying across the tank bottom and up the tank wall. The tank is buried underground to provide radiation shielding.

Location: Tank 241-TX-116 is located in the northeastern portion of the 241-TX Tank Farm.

Related Sites/Structures: Structures associated with Tank 241-TX-116 include passive ventilation, drywells, temperature and surface level measurement instruments.

Process Description: Waste sources for Tank 241-TX-116 included the 241-TX Tanks.

Code: 241-TX-117 Classification: Accepted
Names: 241-TX-117; 241-TX-TK-117 Reclassification: None
Type: Single-Shell Tank Start Date: 1/1/1952
Status: Inactive End Date: 1/1/1976

Description: This unit is a second-generation, underground single-shell storage tank. Tank 241-TX-117 is the second tank of a three-tank cascade series. This cylindrical tank is concrete-reinforced with a single steel liner lying across the tank bottom and up the tank wall. The tank is buried underground to provide radiation shielding.

Location: Tank 241-TX-117 is located in the northern portion of the 241-TX Tank Farm.

Related Sites/Structures: Structures associated with Tank 241-TX-117 include passive ventilation, drywells, temperature and surface level measurement instruments.

Process Description: Waste sources for Tank 241-TX-117 included the 242-T Evaporator and 241-TX Tanks.

Code: 241-TX-118 Classification: Accepted
Names: 241-TX-118; 241-TX-TK-118 Reclassification: None
Type: Single-Shell Tank Start Date: 1/1/1952
Status: Inactive End Date: 1/1/1980

Description: This unit is a second-generation, underground single-shell storage tank. Tank 241-TX-118 is the third tank of a three-tank cascade series. This cylindrical tank is concrete-reinforced with a
single steel liner lying across the tank bottom and up the tank wall. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-TX-118 is located northwestern portion of the 241-TX Tank Farm.

**Related Sites/Structures:** Structures associated with Tank 241-TX-118 include passive ventilation, a liquid observation well, drywells, temperature and surface level measurement instruments.

---

**Code:** 241-TX-153  
**Classification:** Accepted  
**Names:** 241-TX-153; 241-TX-153 Diversion Box  
**Reclassification:** None  
**Type:** Diversion Box  
**Start Date:** 1/1/1949  
**End Date:** 1/1/1980  
**Description:** The diversion box is a rectangular reinforced concrete structure. Most of the structure is below ground. A few inches of the structure that extends above ground is covered with a gray weather coating. The tank farm fence is posted with various radiological postings.

**Location:** This unit is located inside the 241-TX Tank Farm, southeast of the 241-TX-101 Tank.

**Related Sites/Structures:** The 241-TX-153 Diversion Box is associated with the 241-TX-155 Diversion Box and the 241-TX Tank Farm, the 241-TX-302A and 241-TX-302B Catch Tanks and UPR-200-W-126. The pipeline from the diversion box to the 216-T-19 crib is sitecode 200-W-213-PL.

**Process Description:** This unit is used to transfer of solutions from processing and decontamination operations to various tank farm facilities via underground transfer lines.

---

**Code:** 241-TX-302A  
**Classification:** Accepted  
**Names:** 241-TX-302A; 241-TX-302-A Catch Tank; IMUST; Inactive Miscellaneous Underground Storage Tank; Lines V627 and V628  
**Reclassification:** None  
**Type:** Catch Tank  
**Start Date:** 1/1/1949  
**End Date:** 1/1/1982  
**Description:** This unit is an underground, horizontal cylindrical tank made of steel. The tank farm surface has been covered with gravel. The tank is surrounded with posts and chain and labeled with IMUST signs.

**Location:** This tank is located southwest of the 241-TX-153 Diversion Box, inside the 241-TX Tank Farm.

**Related Sites/Structures:** This unit is associated with the 241-TX-153 Diversion Box and the 241-TX-302X Catch Tank. Lines V627 and V628 are the drain lines from the 241-TX-153 diversion Box.

**Process Description:** The 241-TX-302A Catch Tank received drainage from Diversion Box 241-TX-153 and associated encasements.

---

**Code:** 241-TX-302XB  
**Classification:** Accepted  
**Names:** 241-TX-302XB; IMUST; Inactive Miscellaneous Underground Storage Tank; 241-TX-302B Catch  
**Reclassification:** None

Hanford Site Waste Management Units Report
February 2015
**Code:** 241-TXR-152  
**Classification:** Accepted  
**Names:** 241-TXR-152; 241-TXR-152 Diversion Box; Line 7053  
**Reclassification:** None  
**Type:** Diversion Box  
**Status:** Inactive  
**Start Date:** 1/1/1949  
**End Date:** 1/1/1980  
**Description:** This unit is constructed of reinforced concrete and is rectangular in shape. The 241-TXR-152 has been weather covered.  
**Location:** This unit is located east of Tank 241-TX-105, inside the 241-TX Tank Farm.  
**Related Sites/Structures:** The 241-TXR-152 Diversion Box is associated with the 241-TXR-151 Diversion Box and the 241-TX Tank Farm and drains to the 241-TX-101 Tank through line 7053.  
**Process Description:** This unit was used for the transfer of waste solutions from processing and decontamination operations.

**Code:** 241-TXR-153  
**Classification:** Accepted  
**Names:** 241-TXR-153; 241-TXR-153 Diversion Box; Line 7253  
**Reclassification:** None  
**Type:** Diversion Box  
**Status:** Inactive  
**Start Date:** 1/1/1949  
**End Date:** 1/1/1980  
**Description:** This unit is constructed of reinforced concrete and is rectangular in shape. The 241-TXR-153 has been weather covered.  
**Location:** This unit is located east of Tank 241-TX-105, inside the 241-TX Tank Farm.  
**Related Sites/Structures:** The 241-TXR-153 Diversion Box is associated with the 241-TXR-151 Diversion Box and the 241-TX Tank Farm and drains to the 241-TX-105 Tank through line 7253.  
**Process Description:** This unit was used for the transfer of waste solutions from processing and decontamination operations.

**Code:** 244-TXR VAULT  
**Classification:** Accepted  
**Names:** 244-TXR VAULT; 244-TXR Vault (Tanks TXR-001, -002, -003); IMUST; Inactive Miscellaneous Underground Storage Tank; 241-TXR-244; 244-TXR  
**Reclassification:** None  
**Type:** Receiving Vault  
**Status:** Inactive  
**Start Date:** 1/1/1950  
**End Date:** 1/1/1957  
**Description:** The 244-TXR Vault is a rectangular, reinforced concrete pit. The vault is surrounded with post and chain and marked with IMUST signs. The vault houses three steel storage tanks (244-TK-TXR-1, -TXR-2, and TXR-3; see "Subsite" sections). The 244-TK-TXR-1 Tank has a 50,000 gallon (189,000 liter) capacity and the 244-TK-TXR-2 and TXR-3 each have a 15,000 gallon (56,800 liters) capacity. The vault is buried to a depth that places the upper surface of its lid about 12 inches (30.5 centimeters) above grade.
Location: The vault is located within the tank farm fence, south of the 241-TX Tank Farm and west of Camden Avenue.

Related Sites/Structures: The 244-TK-TXR-1, TXR-2, and TXR-3 Tanks are housed in the 244-TXR Vault. The vault is connected to the 241-TXR-151, 241-TR-152, and 241-TR-153 Diversion Boxes.

Process Description: The vault and associated tanks were used for processing was from 241-T and 241-TX tank farms and to transfer the processed waste to U Plant for uranium recovery.

This Site has the Following SubSites:
- **Code:** 244-TXR VAULT:1
  - **Names:** 244-TXR VAULT:1; 244-TXR-001
  - **Classification:** Accepted
  - **Reclassification:** None
  - **Start Date:**
  - **End Date:**
  - **Type:** Receiving Vault
  - **Status:** Inactive
  - **Description:** Tank 244-TXR-0001 is located in a concrete cell, inside the 244-TXR Vault. The cell is 6.7 meters (22 feet) by 7.9 meters (26 feet) by 8.8 meters (28.8 feet). The tank is 6.1 meters (20 feet) tall and 6.1 meters (20 feet) in diameter. The tank has a 189,000 liter (50,000 gallon) capacity. The tank was used as a slurry accumulator for bismuth phosphate waste from tanks in T and TX farms. The tank is isolated and stabilized. Samples were collected and analyzed in 1984 from both the tank and the sump. Results included 1.05 micro curies/liter Total Alpha, 4,510 micro curies/liter Total Beta, and 4,490 micro curies/liter cesium-137 GEA. 0.108 N02 and 0.442 N03 were noted without units. Hanford Occurrence Report 79-68 indicates this tank is of questionable integrity.

- **The SubSite is Part Of:**
  - **Code:** 244-TXR VAULT
  - **Names:** 244-TXR VAULT; 244-TXR Vault (Tanks TXR-001, -002, -003); IMUST; Inactive Miscellaneous Underground Storage Tank; 241-TXR-244; 244-TXR

- **Code:** 244-TXR VAULT:2
  - **Names:** 244-TXR VAULT:2; 244-TXR-002
  - **Classification:** Accepted
  - **Reclassification:** None
  - **Start Date:**
  - **End Date:**
  - **Type:** Receiving Vault
  - **Status:** Inactive
  - **Description:** Tank 244-TXR-0002 is located in a concrete cell, inside the 244-TXR Vault. The cell is 4.9 meters (16 feet) by 6.1 meters (20 feet) by 5.8 meters (19 feet). The tank is 3.7 meters (12 feet) tall and 4.3 meters (14 feet) in diameter. It has a 56,775 liter (15,000 gallon) capacity. The tank was used to acidify material for the uranium recovery process. Slurry was transferred from tank 001 and nitric acid was added prior to being pumped to U-Plant. The tank is isolated and stabilized. The tank contains 11,147 liters (2945 gallons) of sludge and no supernate. Samples were collected and analyzed in 1975 from the tank and had a dose rate of 1.5 R/hr. Results
included 0.72 microcuries/liter Pu, 100 microcuries/liter Cs-134, 22,000 microcuries/liter Cs-
-137 and 10 microcuries/liter Sr-90. There was also 630 mg/L Al, 19,400 mg/L Na, 82,500
mg/L NO3 and 110 mg/L Cl.

The SubSite is Part Of:
Code: 244-TXR VAULT

Underground Storage Tank; 241-TXR-244; 244-TXR

Code: 244-TXR VAULT:3
Names: 244-TXR VAULT:3; 244-TXR-003
Type: Receiving Vault
Status: Inactive
Description: Tank 244-TXR-003 is located in a concrete cell, inside the 244-TXR Vault. The cell is 4.9
meters (16 feet) by 6.1 meters (20 feet) by 5.8 meters (19 feet). The tank is 3.7 meters (12 feet)
tall and 4.3 meters (14 feet) in diameter. It has a 56,775 liter (15,000 gallon) capacity. The tank
was used to acidify material for the uranium recovery process. Slurry was transferred from tank
001 and nitric acid was added prior to being pumped to U-Plant. The tank is isolated and
stabilized. The tank contains 26,450 liters (6460 gallons) of sludge and no supernate. No
sample information is mentioned.

The SubSite is Part Of:
Code: 244-TXR VAULT
Names: 244-TXR VAULT; 244-TXR Vault (Tanks TXR-001, -002, -003); IMUST; Inactive Miscellaneous
Underground Storage Tank; 241-TXR-244; 244-TXR

Code: 241-TY-101
Type: Single-Shell Tank
Status: Inactive
Description: This unit is a second-generation, underground single-shell storage tank. Tank 241-TY-101 is
the first tank of a two-tank cascade series. This tank is concrete-reinforced, cylindrical, and
dome-roofed with a steel liner lying across the tank bottom and up the tank wall. The tank is
buried underground to provide radiation shielding.
Location: Tank 241-TY-101 is located in the northeastern portion of the 241-TY Tank Farm.
Related Sites/ Structures: Structures associated with Tank 241-TY-101 include passive ventilation, drywells, temperature
and surface level measurement devices.
Process Description: Waste sources for Tank 241-TY-101 include the 242-T Evaporator and T-Plant.
Waste Type: Not Specified
Waste Description: Waste transferred to Tank 241-TY-101 included bismuth phosphate first-cycle waste, tributyl
phosphate waste, and evaporator bottoms from 241-TY, -TX, and -SX Tank Farms.

This unit is constructed of reinforced concrete and is rectangular in shape.

**Location:** This unit is located in the southeast corner of the 241-TY Tank Farm.

**Related Sites/Structures:** The 241-TY-153 Diversion Box is associated with the 241-TY Tank Farm, the 241-TY-302A Catch Tank, and the 241-TX-153 and 241-TX-155 Diversion Boxes. The drain line is V651.

**Process Description:** This unit was used for the transfer of waste solutions from processing and decontamination operations.

**Waste Type:** Not Specified

**Waste Description:** This unit was used for transfer of waste solution from processing and decontamination operations. Lead shielding may also be contained inside the diversion box.

**Waste Type:** Not Specified

**Waste Description:** Waste lead is stored in the diversion box.

**Waste Type:** Not Specified

**Waste Description:** Equipment associated with the diversion box includes transfer piping and nozzles.

This unit is a horizontal, cylindrical tank made of steel. The tank is surrounded with post and chain and marked with IMUST signs. The tank is buried underground to provide radiation shielding.

**Location:** This unit is located in the southeast corner of the 241-TY Tank Farm.
Related Sites/Structures: The 241-TY-302A Catch Tank is associated with the 241-TY Tank Farm. The drain line is line V651.

Process Description: The catch tank received drainage from Diversion Box 241-TY-153.

Waste Type: Not Specified

Waste Description: This tank collected overflow waste solutions from processing and decontamination operations that passed through the 241-TY-153 Diversion Box. Volumes were variable according to specific plant operation. The volume is unknown and not monitored.

Code: 241-TY-302B
Name: 241-TY-302B; 241-TY-302-B Catch Tank; IMUST; Inactive Miscellaneous Underground Storage Tank
Type: Catch Tank
Status: Inactive
Start Date: 1/1/1953
End Date: 1/1/1981
Description: This unit is a horizontal, cylindrical tank made of steel. The tank is surrounded with post and chain and marked with IMUST signs. The tank is buried underground to provide radiation shielding.

Location: This unit is located in the northeast corner of the 241-TY Tank Farm.

Related Sites/Structures: The 241-TY-302B Catch Tank is associated with the 241-TY-153 Diversion Box.

Process Description: This catch tank received drainage from a concrete encasement originally at Diversion Box 241-TY-153.

Waste Type: Not Specified

Waste Description: This unit accepted overflow waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation.

Classification: Accepted
Reclassification: None

Code: 200-W-94
Names: 200-W-94; Contaminated Soil at 241-TX/TY Tank Farm
Type: Unplanned Release
Status: Inactive
Start Date:
End Date:
Description: The site is the soil inside and adjacent to the chain link fence that surrounds the 241-TX/TY Tank Farm complex. Various radiological postings and warning signs are attached to the chain link fence. The interior of the tank farm complex is covered with gravel. Many risers and monitoring devices for the underground structures are visible on the surface. The individual unplanned releases associated with the 241-TX/TY Tank Farms are not separately marked or posted. Occasionally, radioactive contamination is found adjacent to the outside of the tank farm fence, resulting in a contamination zone extension around the tank farm perimeter. These areas will also be considered tank farm soil. A portion of the 242-T Evaporator building is located inside the tank farm fence.

Location: The site is located south of 23rd Street and west of Camden Ave., in 200 West Area.
Release Description: The exact extent (horizontal and vertical) of the soil contaminated by unplanned releases that occurred within this farm over the years are not known. Some of the single shell tanks have leaked to the soil below the tank farm. Other releases spread contamination to the surface soil surrounding the tanks.

Waste Type: Steam Condensate

Waste Description: Liquid releases occurred from underground leaks in tanks and transfer lines. Airborne contamination spreads occurred from activities conducted in valve pits and diversion boxes. Both types of releases contributed to the contamination in the soil.

---

Code: 2607-WT
Names: 2607-WT; 241-T-601 Control Bldg. Tile Field
Type: Septic Tank
Status: Inactive

Classification: Accepted
Reclassification: None
Start Date: 1/1/1952
End Date:

Description: The 2607-WT Septic Tank is surrounded by a chain link fence and is marked with Miscellaneous Inactive Storage Facility (MISF) signs and two WIDS waste site signs. This septic tank is connected to a sanitary tile field.

Location: The septic system is located west of the 242-T Evaporator inside the tank farm fence. It is between the 241-TX an the 241-TY Tank Farms.

Related Sites/Structures: The 2607-WT Septic Tank is associated with a drain field and the 242-T Evaporator Control Building. The replacement for this abandoned system is sitecode 200-W-232.

Process Description: The 2607-WT Septic Tank and associated drain field were designed to accept sanitary sewer effluent from the connected structures.

---

Code: 2607-WTX
Names: 2607-WTX
Type: Septic Tank
Status: Inactive

Classification: Accepted
Reclassification: None
Start Date: 1/1/1950
End Date:

Description: The 2607-WTX Septic Tank and associated sanitary tile field are surrounded with post and chain and a sign that reads "MISF". The acronym stands for Miscellaneous Inactive Storage Facility.

Location: The septic tank and tile field is located on the south side (outside) of the 241-TX Tank Farm.

Related Sites/Structures: The 2607-WTX Septic Tank is associated with the 241-TX Tank Farm and the former 241-TXR Control House.

Process Description: The 2607-WTX Septic Tank and drain field were designed to accept and treat sanitary sewer effluent from the associated structure.

### 241-U-101 Single-Shell Tank

**Names:** 241-U-101; 241-U-TK-101

**Reclassification:** None

**Type:** Single-Shell Tank

**Start Date:** 1/1/1946

**Status:** Inactive

**End Date:** 1/1/1959

**Description:** This unit is a first-generation, underground single-shell storage tank. Tank 241-U-101 is the

---

*Hanford Site Waste Management Units Report*

February 2015
first tank of a three-tank cascade series. This tank is concrete-reinforced, cylindrical, dome-roofed with a single steel liner lying across the tank wall. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-U-101 is located northeastern portion of the 241-U Tank Farm.

**Related Sites/Structures:** Structures associated with Tank 241-U-101 include passive ventilation, two drywells, temperature and surface level measurement instruments.

**Process Description:** Waste sources for Tank 241-U-101 included the T-Plant and REDOX Facilities.

**Waste Type:** Not Specified

**Waste Description:** Waste transferred to Tank 241-U-101 included metal waste from T-Plant. Waste was received from various storage tanks for processing in the 242-T Evaporator. Tank 241-U-101 received a variety of solid waste items. These included experimental fuel elements, shroud tubes, and samarium balls. The total fissile material contents of the waste was 54.01 ounces (1,530 grams) of 4.5 percent enriched uranium and 0.21 ounces (6 grams) of plutonium.

---

**Code:** 241-U-102 **Classification:** Accepted

**Names:** 241-U-102; 241-U-TK-102 **Reclassification:** None

**Type:** Single-Shell Tank **Start Date:** 1/1/1946

**Status:** Inactive **End Date:** 1/1/1976

**Description:** This unit is a first-generation, underground single-shell storage tank. Tank 241-U-102 is the second tank of a three-tank cascade series. This tank is concrete-reinforced, cylindrical, dome-roofed with a single steel liner lying across the tank wall. The tank is buried underground to provide radiation shielding.

**Location:** Tank 241-U-102 is located in the northern portion of the 241-U Tank Farm.

**Related Sites/Structures:** Structures associated with Tank 241-U-102 include passive ventilation, six drywells, temperature and surface level measurement instruments.

**Process Description:** Waste sources for Tank 241-U-102 included the T-Plant and REDOX Facilities.

**Waste Type:** Not Specified

**Waste Description:** Waste transferred to Tank 241-U-102 included metal waste from T-Plant. Waste was also received from various storage tanks for processing in the 242-T Evaporator.

**Start Date:** 1/1/1946  
**End Date:** 1/1/1981  
**Description:** The tank farm is surrounded with a locked chain link fence. The tank farm has been covered with a layer of gravel. The 241-U-153 Diversion Box structure is mostly below ground. It is a reinforced concrete structure with 3 inch (8 centimeter) Hanford style nozzles.  
**Location:** The 241-U-153 Diversion Box is located in the southeast corner of the 241-U Tank Farm. It is east of the 241-U-110 tank.  
**Related Sites/ Structures:** This unit is associated with the 241-U-151, 241-U-152, 241-UR-152, 241-U-153 Diversion Boxes, 200-W-181-PL, 200-W-184-PL, 200-E-185-PL and the 241-U Tank Farm.  
**Process Description:** This unit was used for the transfer of waste solutions from processing and decontamination operations.  
**Waste Type:** Not Specified  
**Waste Description:** Equipment associated with the diversion box includes transfer piping and nozzles.

---

**Code:** 241-U-201  
**Classification:** Accepted  
**Reclassification:** None  
**Names:** 241-U-201; 241-U-TK-201  
**Type:** Single-Shell Tank  
**Status:** Inactive  
**Start Date:** 1/1/1956  
**End Date:** 1/1/1977  
**Description:** This tank is made of reinforced-concrete and is lined with a steel cylinder. The structure has a concrete base slab and is buried underground to provide radiation shielding.  
**Location:** Tank 241-U-201 is located inside the 241-U Tank Farm, west of tank 241-U-109.
**Related Sites/Structures:** 241-U-201 is associated with 241-U-202, 241-U-203, 241-U-204 and 241-U-252. It has passive ventilation and temperature and surface level measurement instruments.

**Process Description:** Waste sources for Tank 241-U-201 included the REDOX Facility and 241-U Tanks.

**Waste Type:** Soil

**Waste Description:** Waste transferred to Tank 241-U-201 included supernatant containing REDOX high-level waste from the 241-U Tank Farm.

Hanford Site Waste Management Units Report
February 2015
### 241-UR-151 Diversion Box

**Status:** Inactive  
**End Date:** 1/1/1980  
**Description:** The diversion box and surrounding area has been covered with shotcrete. This unit is constructed of reinforced concrete and is rectangular in shape.  
**Location:** The 241-UR-151 Diversion Box is located in the northern portion of the 241-U Tank Farm, inside the tank farm fence.  
**Related Sites/Structures:** The 241-UR-151 Diversion Box is associated with the 241-UR-152, 241-UR-153, 241-UR-154, and 241-U-151 Diversion Boxes. The unit is also associated to the 221-U Canyon Building and various 200 West Area Operations Facilities. The drain lines are 5764 and 5765.  
**Process Description:** This unit is the master diversion box for the 241-U Tank Farm. The diversion box was used to transfer waste solution to and from the tank farm.

### 241-UR-152 Diversion Box

**Status:** Inactive  
**Start Date:** 1/1/1949  
**End Date:** 1/1/1980  
**Description:** This unit is an underground reinforced concrete structure. All nozzles are 4 inch (10 centimeters) REDOX style.  
**Location:** This unit is located east of Tank 241-U-101, inside the 241-U Tank Farm.  
**Related Sites/Structures:** The 241-UR-152 Diversion Box is associated with the 241-UR-151 Diversion Box and the 241-U-101, 241-U-102, and 241-U-103 cascade series. The drain line to 241-U-102 is line 5053.  
**Process Description:** This unit was used for the transfer of waste solutions from processing and decontamination operations.

| Code: 244-UR VAULT | **Classification:** Accepted |
| Names: 244-UR VAULT; 244-UR Vault (Tanks -001 Through -004); IMUST; Inactive Miscellaneous Underground Storage Tank; Lines 5764 and 5765 | **Reclassification:** None |
| Type: Receiving Vault | **Start Date:** 1/1/1952 |
| Status: Inactive | **End Date:** 1/1/1975 |
| **Description:** The 241-U Tank Farm is posted as a Contamination Area. The vault was covered with pumped concrete in 1992. The vault is surrounded with post and chain and marked with IMUST signs. The 244-UR Vault is an underground concrete structure divided vertically into four sections (process vaults). Each section houses a tank and a sump. The sections are divided horizontally to provide pump pits above the tanks. The pump pits contain pumps and piping that were used during liquid transfers. The walls, floors, horizontal divisions, and roofs (ground level) are constructed of reinforced concrete. The sumps are located in the sections occupied by Tanks 244-UR-001, 244-UR-002, 244-UR-003 and 244-UR-004. Tank 244-UR-001 is a slurry accumulator tank. Tanks 244-UR-002 and 244-UR-003 are identical blend tanks. Tank 244-UR-004 is a process tank. There are also above ground service facilities that include four instrument shelters, an inlet filter enclosure, and six risers used to measure liquid levels in tanks and sumps. Conditioned inlet air to the vault was supplied through an above grade supply system located just north of the vault. Exhaust air from the vault was passed through an underground filter chamber, then to an above grade exhaust fan and discharge stack. The 244-UR Vault was used until 1956 and was taken out of regular service in 1957. Apparently, the vault tanks were not used after this time and the entire vault was interim stabilized in 1985. Presumably, some wastes (sludges and liquids) were left in the tanks of the 244-UR Vault at the close of active vault use in the 1950's as records from the 1970's and early 1980's report varying amounts of wastes in the tanks and tank pits/sumps. Intrusion of water (precipitation) from the ground surface above the vault contributed to the varying amounts of liquid found in the tank pits during this period. SD-WM-TI-356 lists liquid level readings (and the reasons for increases and decreases in the liquid level readings) in the tanks and sumps over the period from 1974 through 1985. The records associated with the tank isolation project (B-231) of the mid 1980's provide the most reliable current estimates of tank and tank pit waste volumes. These estimates are provided for each of the tanks (see subsites section). Project B-231 isolated the 244-UR Vault as a single system. Four above grade instrument and electrical enclosures were removed. The underground conduit trenches existing between each enclosure and the companion vault compartment were sealed by casting a concrete slab over the enclosure footing. Grade level raw water nozzles that connected to the vault internal piping were cut and capped. Grade level...|
steam distribution piping and control valving were removed. Process steam lines that connected to the vault internal piping were cut and capped. Encased process pipelines interconnect the 244-UR Vault with the 241-UR-151 Diversion Box. Closure of these lines was not required as both diversion boxes were already isolated. Process air lines were cut and blind flanges were installed onto both sides of each branch line isolated. The evaporative cooling unit was abandoned in place and the ducting cut, then sealed with a concrete plug. The above grade ventilation fans, above grade ducting, and discharge stack were previously removed. The fan inlet plenum was built into the fan base structure and was plugged by filling the plenum with sand and casting a fiberglass weather cover over the fan inlet ducts. The grade level vault cover blocks were sealed by a fiberglass weather cover. WHC-EP-0560 states that liquid level readings for 1979 indicate the 244-UR-001 and 244-UR-003 had been pumped down to "minimum level", whereas 244-UR-002 was still listed as "active" ("Auxiliary Tanks, Sumps, and Vaults Solid and Liquid Volumes", J. E. Mirabella, 1978). Tank 244-UR-004 was also pumped to a minimum heal.

Location: This site is located at the north end of the 241-U Tank Farm.

Related Sites/Structures: The unit is associated with 241-U Tank Farm and transfer lines. The drain lines to the sump are lines 5764 and 5765.

Process Description: The 244-UR Vault was constructed in 1951 for use in conjunction with uranium recovery processing conducted in U Plant (221-U). The function of the vault included reception of uranium-bearing waste slurries from Tanks 241-U-101, 241-U-102, 241-U-103, and 241-U-107 in the 241-U Tank Farm, which at that time contained neutralized metal waste generated by the original bismuth phosphate process. The vault was used for subsequent blending, pH adjustment (acidification) and conditioning of this waste as feed material for the tributyl phosphate uranium extraction process in the U Plant Canyon.

Hanford Site Waste Management Units Report
February 2015
from Tank 244-UR-001 to other tanks in the vault for further conditioning (see subsites 244-UR-002 and 244-UR-003). Limited analytical data on the contents of Tank 244-UR-001 are available from a 1977 Atlantic Richfield Hanford Company (ARHCO) employee memorandum, "Isolation Criteria for 'Auxiliary' Tanks", C. M. Walker (Memorandum not in Waste Information Data System [WIDS] files). The values listed below have been taken from WHC-SD-EN-ES-040, Rev. 0. - pH 7.5, radiation level 25 millirads/hour, specific gravity 1.0 - cesium-137 476 microcuries/liter (1,800 microcuries/gallon) - uranium 0.528 milligrams/liter (2 milligrams/gallon) - total beta 845 microcuries/liter (3,200 microcuries/gallon) - total alpha 0.032 microcuries/liter (0.12 microcuries/gallon). Limited information on the contents of the 244-UR-001 Sump were reported in the same memorandum listed above. The values listed below have been taken from WHC-SD-EN-ES-040, Rev. 0. - pH 8.6, radiation level 30 millirads/hour - cesium-137 673 microcuries/liter (1,700 microcuries/gallon) - total beta 845 microcuries/liter (3,200 microcuries/gallon) - total alpha 0.0145 microcuries/liter (0.055 microcuries/gallon) WHC-SD-EN-ES-040, Rev.0 has listed the following safety issues: - Hydrogen Buildup: Low risk since the total waste volume in the tank and sump is limited to about 18,925 liters (5,000 gallons). - Ferrocyanide: No risk since little or no ferrocyanides are present and the tank contains mostly water. - Organic Salts: Tributyl phosphate containing wastes were present in this tank, so some amount of organic salts is probably present. However, it is expected that this represents a low risk as the wastes are dilute. - Flammability: Low risk as little or no flammable material and no ignition sources are present. - Vapor Emission: Low risk because present waste content is not expected to contain significant amounts of volatile material. - Tank Integrity: No evidence of leaks emerged in the 1970's. Present waste content is not strongly corrosive, yet design life of the tank has been exceeded. Consequently, there is low to moderate risk of tank leakage. - Criticality Safety: Low risk (traces of plutonium only). - Radiological Hazard: High risk because UPR-200-W-24 resulted in contamination of soils surrounding the vault. Background readings in the vault are the 1 to 50 millirem range. - Heat Generation: Low risk (No Data). SD-WM-TI-356 lists liquid level readings and cumulative change history for the tank and sump. The last reading for the tank, on July 15, 1985, was 20.3 centimeters (8.00 inches). The last reading in the sump, on June 27, 1985, was 55.9 centimeters (22.00 inches).

**The SubSite is Part Of:**

**Code:** 244-UR VAULT  
**Names:** 244-UR VAULT; 244-UR Vault (Tanks -001 Through -004); IMUST; Inactive Miscellaneous Underground Storage Tank; Lines 5764 and 5765

Hanford Site Waste Management Units Report  
February 2015
A sample of liquid was obtained from cell 2 of the 244-UR Vault on November 5, 1974
(Sample # T-9505 - laboratory data not available in the Waste Information Data System
[WIDS] files.) The results listed below have been taken from WHC-SD-EN-ES-040, Rev. 0 and

- visual appearance, yellow with no solids
- pH 9.1, radiation level 1 millirad/hour, specific gravity 1.01
- cesium-137 177 microcuries/liter (670 microcuries/gallon)
- aluminum <.0013 molar (< 35 milligrams/liter)
- sodium .0732 molar (1,690 milligrams/liter)
- nitrite .000645 molar (30 milligrams/liter)
- nitrate .0306 molar (1,900 milligrams/liter)
- plutonium < 1.40 micrograms/liter (<5.34 micrograms/gallon)
- phosphate <.00356 molar (340 milligrams/liter)
- iron .0000414 molar (<1 milligram/liter)
- carbonate .0325 molar (2,000 milligrams/liter)
- strontium-89,90 5.68 microcuries/liter (21.5 microcuries/gallon)
- water 99.95%

Although the memorandum indicates that the sample was from Tank 244-UR-002, it is
suspected that the sample is actually from the pit or sump since the June 7, 1977 Atlantic
Richfield Company (ARCO) internal memorandum, "Isolation Criteria for 'Auxiliary' Tanks",
C. M. Walker, 1977, gives limited analytical results for Tank 244-UR-002 and sump contents as
follows.

- total beta 845 microcuries/liter (3,200 microcuries/gallon)
- total alpha 0.032 microcuries/liter (0.12 microcuries/gallon).

Tank

- pH 0.7, radiation level 50 millirads/hour
- specific gravity 1.03
- cesium-137 0.87 microcuries/liter (3.3 microcuries/gallon)
- total beta 1321 microcuries/liter (5,000 microcuries/gallon)
- total alpha 0.37 microcuries/liter (1.4 microcuries/gallon)

Sump

- pH 9.0, radiation level 10 millirads/hour
- cesium-137 47.56 microcuries/liter (180 microcuries/gallon)
- total beta 66.05 microcuries/liter (250 microcuries/gallon)
- total alpha 0.1 microcuries/liter (0.38 microcuries/gallon)

WHC-SD-EN-ES-040, Rev.0 has listed the following safety issues.

- Hydrogen Buildup: Low risk since the total waste volume in the tank and sump is limited to
  about 11,355 liters (3,000 gallons) of dilute liquid waste. Any hydrogen generated should
  readily diffuse out of the tank and vault.
- Ferrocyanide: No risk since little or no ferrocyanides are present and the tank contains mostly
  water.
- Organic Salts: Tributyl phosphate containing wastes were present in this tank, so some
  amount of organic salts is probably present. However, it is expected that this represents a low
  risk as the wastes are dilute.
- Flammability: Low risk as little or no flammable material and no ignition sources are present.
- Vapor Emission: Low risk because present waste content is not expected to contain significant
amounts of volatile material.
- Tank Integrity: No evidence of leaks emerged in the 1970's. Present waste content is not moderately corrosive, and the design life of the tank has been exceeded. Consequently, there is moderate to high risk of tank leakage.
- Criticality Safety: Low risk (traces of plutonium only).
- Radiological Hazard: High risk because UPR-200-W-24 resulted in contamination of soils surrounding the vault. Background readings in the vault are the 1 - 50 millirem range.
- Heat Generation: Low risk (No Data).

SD-WM-TI-356 lists liquid level readings and cumulative change history for the tank and sump. The last reading for the tank, on July 12, 1985, was 71.8 centimeters (28.25 inches). The last reading in the sump, on April 23, 1985, was 55.9 centimeters (15.25 inches).

SD-WM-TI-356 lists liquid level readings and cumulative change history for the tank and sump. The last reading for the tank, on July 15, 1985, was 41.9 centimeters (16.5 inches). The last reading in the sump, on July 15, 1985, was 66.7 centimeters (26.25 inches).

The SubSite is Part Of:
### The 244-UR VAULT:4

**Code:** 244-UR VAULT:4  
**Classification:** Accepted  
**Reclassification:** None  
**Type:** Receiving Vault  
**Start Date:**  
**End Date:**  

**Description:** The 244-UR-004 is a stainless steel process tank measuring 3 meters (10 feet) in diameter and 4.2 meters (14 feet) tall. The tank has a 31,150 liter (8,230 gallon) capacity. The UR-004 was used to store nitric acid and has been reported to be empty. This tank fed nitric acid to the UR-002 and UR-003 tanks, during the Uranium Recovery Process operation in the 1950's. Because it was an acid feed tank, it is not believed to be radiologically contaminated.

### The SubSite is Part Of:

**Code:** 244-UR VAULT  
**Names:** 244-UR VAULT; 244-UR Vault (Tanks -001 Through -004); IMUST; Inactive Miscellaneous Underground Storage Tank; Lines 5764 and 5765

### The 200-W-95

**Code:** 200-W-95  
**Classification:** Accepted  
**Reclassification:** None  
**Type:** Contamination Migration  
**Start Date:**  
**End Date:**  

**Description:** The site is the soil inside and adjacent to the chain link fence that surrounds the 241-U Tank Farm. Various radiological postings and warning signs are attached to the chain link fence. The interior of the tank farm complex is covered with gravel. Many risers and monitoring devices for the underground structures are visible on the surface. The individual unplanned releases associated with the 241-U Tank Farm are not separately marked or posted. Occasionally, radioactive contamination is found adjacent to the outside of the tank farm fence, resulting in a contamination zone extension around the tank farm perimeter. These areas will also be considered tank farm soil. A small area near the west access gate, outside the fence, was excavated to attempt to remove contaminated soil. This area was marked with Contamination Area signs but was covered with clean dirt and downposted to an Underground Radioactive Material area in December 2003.

**Location:** The site is located at the intersection of 16th Street and Camden Ave., in 200 West Area.

**Release Description:** The exact extent (horizontal and vertical) of the soil contaminated by unplanned releases that occurred within this farm over the years are not known. Some of the single shell tanks have leaked to the soil below the tank farm. Other releases spread contamination to the surface soil surrounding the tanks.

**Related Sites/Structures:** Unplanned Releases UPR-200-W-128, UPR-200-W-132, UPR-200-W-154, UPR-200-W-155, UPR-200-W-156, UPR-200-W-157, UPR-200-W-24 and 200-W-91 are associated with the 241-U Tank Farm. These WIDS sitecodes have been consolidated into 200-W-95.

**Waste Type:** Construction Debris
| Waste Description | Liquid releases occurred from underground leaks in tanks and transfer lines. Airborne contamination spreads occurred from activities conducted in valve pits and diversion boxes. Both types of releases contributed to the contamination in the soil. |

### Description

**Spoils Pile/Berm**

The site is a rectangular area 8.5 meters (28 feet) east/west by 13.1 meters (43 feet) north/south and encircled by large stones neatly stacked 0.3 meters (1 foot) high. Inside the area and on the north end is a 4 meter (13 foot) by 4.0 meter (13 foot) area encircled by 0.3 meter (1 foot) soil berm. Two 0.3 meter (1 foot) mounds of soil are in the south portion of the area. The surrounding area appears to have been a plowed field that was cleared of large stones. A long line of similar rocks runs parallel to the perimeter road, between the encircled area and the road. The site is distinguishable from the surrounding area only by the arrangement of large stones and soil. During a site visit on 9/13/94, two metal objects were present nearby, but didn't appear to be necessarily associated with this site. One of the objects looked like an empty, rusty paint can.

**Location:**

The site is in the 100B area, 760 meters (2500 feet) northeast of the 105-B reactor building and 170 meters (550 feet) northwest of 1607-B1. It is due west of the perimeter road.

### Type

**Product Piping**

The site encompasses the clean water upstream pipelines for the 100-B Area, including underground pipelines used to transport raw, fire, export, and sanitary water from the river pumphouse, to the water treatment facilities and to 100-B Area facilities and fire hydrants. Excluded lines are those within buildings, process and septic sewer pipes, pipes that carried water treated with sodium dichromate, and all lines that are downstream from the reactor building, i.e., those lines that carry cooling water from the reactor to the retention basin, trench, and/or the river are excluded.

**Location:**

The location is described as underground lines running from the 181-B Pumphouse to the 183-B Water Treatment Facilities, and from there to other 100-B Area buildings, fire hydrants, and south to the 100-C Area, stopping at a line about half-way between the B and C areas, at about northing 144370 N.

### Related Sites/Structures

- Related structures include the 181-B River Pumphouse, the 182-B Reservoir, 108-B Building, 183-B Basins and Clearwells, 185-B Building, 190-B Building, and 105-B Reactor.
- Associated pipeline sites include 100-B-14 (Septic and Process Sewer Pipelines), 100-B-8 (Effluent Pipelines), and 100-C-5 (100-C Area Water Treatment Facility Pipelines, which connect to these in the 100-B Area).

### Process Description

Reactor cooling water was pumped from the Columbia River, settled and treated to remove minerals, and pumped to the reactor core at a rate of 1.93E+05 liters (51,000 gallons) to 2.69E+05 liters (71,000 gallons) per minute.

<td></td>
<td></td>
<td>The site consists of an approximately 0.08 m (3 in) carbon steel pipe, over 4 m (13 ft) long, with a coupling joint on one end. The pipe appears to be lined with concrete. The other end was severed, possibly with the use of a cutting torch. The pipe is oriented in a northwest to</td>
</tr>
</tbody>
</table>
southeast direction and is not part of an intact system. The southeasterly end of the pipe is partially buried below grade and the presence of vegetation at that end suggests that the pipe has been at this location for an extended period of time. There is no evidence of staining or any additional pipe or piping systems in the area, and is located in an area of other scattered surface debris outside the 100-B/C perimeter fence. The pipe is believed to be surficial debris only.

**Location:** The site is located in 100-B/C Area, south of the 100-B/C perimeter road, and north of the railroad tracks. At approximate Washington State Plane Coordinates E 564732, N 143699, The inner pipe material was sampled on February 18, 2009 (Sample No. J18HX2) and analyzed for asbestos using Polarized Light Microscopy. The results showed that the material did not contain asbestos minerals.

**Waste Type:** Sanitary Sewage

**Waste Description:** The waste is a single segment of pipe.

overall site dimensions are approximately 200 meters by 200 meters (650 feet by 650 feet).

**Location:** The 126-B-1 Ash Pit is located north of the 184-B Powerhouse.

**Related Sites/Structures:** The ash pit is related to the 184-B Powerhouse.

**Process Description:** Coal ash from the 184-B Powerhouse was mixed with raw river water and sluiced in slurry form to the ash pit via a 20 centimeter (8 inch) ashcolite pipe.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The site received coal ash from the 184-B Powerhouse. Coal ash from analogous sites has been analyzed using the EP Toxicity Test in accordance with WAC 173-303, and no hazardous materials were found.

---

**Code:** 126-B-4  
**Classification:** Accepted

**Names:** 126-B-4; 126-B-4 Brine Pit, 184-B Salt Dissolving Pit and Brine Pump House, B Area Brine and Salt Dilution Pits

**Type:** Sump  
**Start Date:** 1/1/1944  
**End Date:** 1/1/1969

**Description:** The salt dissolving pits and brine pump pit were part of a single below-grade concrete structure that provided brine for the 184-D Powerhouse. The structure has been demolished and buried in situ. No evidence of the site remains at the surface. Before the structure was demolished, it was described as being partially backfilled with rubble with approximately 1900 liters (500 gallons) of water in the brine pump pit. The two salt dissolving pits each had inner dimensions of 4.3 meters (14 feet) long by 2.4 meters (8 feet) wide by 2.8 meters (9.25 feet) tall. They had a design high water line 2.4 meters (7.75 feet) from the pit bottom. An overflow slot connecting the two dissolving pits was located 0.3 meters (1 foot) above the high water line. The bottom of each pit was filled with a 12.7 centimeter (5 inch layer) of 1.3 to 2.6 centimeter (1/2 to 1 inch) gravel topped by a 17.8 centimeter (7 inch) layer of 0.3 to 0.6 centimeter (1/8 to 1/4 inch) gravel. The dissolving pits each had a 2.4 meter (8 foot) by 0.9 meter (3 feet) opening at the top for receiving salt. Each pit had a capacity of 23,600 kilograms (52,000 pounds) of salt. The brine pump pit is located adjacent to the two salt dissolving pits. The pit was 3.3 meters (10.67 feet) long by 2.2 meters (7.33 feet) wide by 2.1 meters (7 feet) deep. It held two pumps and associated piping (all brass) for the brine system. The floor of the pump pit sloped toward a 46 by 46 by 46 centimeter (18 by 18 by 18 inch) sump in a corner.

**Location:** The site is located north of 184-B and just south of the railroad tracks.

**Related Sites/Structures:** The site is associated with the 184-B Power House.

**Process Description:** The brine was used to regenerate the zeolite ion exchange demineralizers that were part of the powerhouse water treatment system.

**Waste Type:** Chemicals

**Waste Description:** The structure was demolished and buried in situ.

### Names:
128-B-1; 100 B/C Burning Pit; 100-B Burning Pit

### Type:
Burn Pit

### Status:
Inactive

### Start Date:
1/1/1943

### End Date:
1/1/1968

### Description:
The site has been described as a burn pit. During a field investigation on October 17, 1995, it was noted that the area is covered with cheatgrass and appears undisturbed with no evidence of burning. An elevated area to the south is covered with rabbitbrush, boulders, and appears to be disturbed. The elevated area also shows no evidence of burning.

### Location:
The 128-B-1 burn pit is identified in PNL-6456 as a 30 meters (100 feet) by 30 meters (100 feet) pit at coordinates WCS83S E565942.7, N145244.7 (N71500 W78500). This places it in a low area southeast of 116-C-1 and west of the perimeter road.

### Code:
132-B-2

### Classification:
Accepted

### Names:
132-B-2; 132-B-2 Stack; 116-B Reactor Exhaust Stack

### Type:
Stack

### Status:
Inactive

### Start Date:
1/1/1944

### End Date:
1/1/1968

### Description:
The unit is part of the 105-B Reactor Gas and Exhaust Air System. The unit is still standing and constructed of reinforced concrete with a base diameter of approximately 4.9 meters (16 feet).

### Location:
The unit is located on the south side of 105-B.

### Related Sites/Structures:
Following completion of the confinement project in 1960, the air was diverted via an above-ground aluminum duct and an underground, reinforced concrete duct to the 117-B Filter Building. After flowing through the filters, the air went through a below-grade concrete duct and an above-grade aluminum duct into the exhaust stack.

---

### Code:
1607-B3

### Classification:
Accepted

### Names:
1607-B3; 1607-B3 Sanitary Sewer System; 1607-B3 Septic Tank System; 124-B-3

### Type:
Septic Tank

### Status:
Inactive

### Start Date:
1/1/1944

### End Date:
1/1/1974

### Description:
The site is a Closed Out septic system which includes a septic tank, tile field, and associated piping. It was demolished in place in 1988. The site is no longer visually apparent and appears as a cobble-covered field with natural vegetation growing on its surface.

The 1607-B3 Septic Tank was constructed of reinforced concrete. The tank was 2.9 meters (9.5 feet) long, 1.4 meters (4.5 feet) wide and 3.5 meters (11.42 feet) deep (inner dimensions). The tank had a design capacity of 6,360 liters (1,680 gallons) based on a user capacity of 48 persons, a flow of 132 liters (35 gallons) of sewage per capita per day, and an average detention time of 1 day. The top of the tank was at the ground surface and the tank was accessible.
through three 0.9-meter (3-foot) manholes.

**Location:** The site is located approximately 60 meters (200 feet) north of the 184-B Building.

**Related Sites/Structures:** The site is associated with the 184-B Powerhouse.

**Waste Type:** Asbestos (friable)

**Waste Description:** This unit received an unknown amount of sanitary sewage from 184-B Powerhouse.

**Closure Info:**
The 1607-B3 Septic Tank was demolished and buried in-situ between January and March 1988 as part of the 184-B Powerhouse decommissioning. Prior to demolition, the contents of the tank were sampled. No significant radioactivity was found above background and the Hanford Environmental Health Foundation (HEHF) Laboratory detected no reportable concentrations of heavy metals. The remaining contents were taken to 124-N-10 Sanitary Sewer System for disposal. Holes were punched into the bottom of the tank for drainage. The tank was then partially backfilled with rubble which was compacted in place to minimize subsidence. The area was then leveled to grade with at least 0.9 meters (3 feet) of clean fill. The reclassification is documented on form 2001-015.

analyzed for radiological contaminants. The sample results were lower than detection limits. The tank contents were pumped out and the tank was filled with clean fill material. A letter was sent to notify the Washington State Department of Health of the abandonment. The closure and abandonment are documented on Reclassification Form 2000-121.

### Code: 1607-B6

**Classification:** Accepted  
**Reclassification:** None

#### Names: 1607-B6; 1607-B6 Septic Tank System; 124-B-5; 1607-B5; 1607-B5 Sanitary Sewer System; 1607-B5 Septic Tank System

#### Type: Septic Tank

#### Status: Active

**Start Date:** 1/1/1944  
**End Date:**

**Description:** The site currently appears as a small concrete box with a wooden lid. It is posted with a "Confined Space" warning sign. There is a yellow steel post at each of its four corners. The reinforced concrete septic tank is 8 ft 4 in (2.5 m) deep with a 25-person capacity (35 gal [130 L] per capita) and an average detention period of 24 hr. Its walls are 8 in (20 cm) thick and its floor is 6 in (15 cm) thick. The tile drain field is 4 in (10 cm) vitrified pipe, concrete pipe or drain tile with a minimum of 8 linear ft (2.4 m) per capita. The laterals are open-jointed and spaced 8 ft (2.4 m) apart. This system is active. This system includes the feed pipeline from the 183-B Filter House, the septic tank, and the drain field.

**Location:** This septic system is south of the 182-B Reservoir and Pump House.

**Waste Type:** Steam Condensate

**Waste Description:** This unit receives 35 gal/day (130 L/day) of sanitary sewage from the 182-B Pump Station and cooling water and leakage from pumps located in the 182-B facility. It also received sewage from 183-B Headhouse, which was decommissioned in 1987.

### Code: 100-C-2

**Classification:** Not Accepted  
**Reclassification:** None

#### Names: 100-C-2; Monitoring Station 1614-B-1; Possible Building Foundation and Parking Lot

#### Type: Foundation

#### Status: Inactive

**Start Date:**  
**End Date:**

**Description:** The site is a small square concrete slab and nearby gravel parking area. Northwest of the slab is a gravel road with a gravel area on the other side. A few small pieces of asbestos transite, a few dry-cell batteries, and some steel anchoring cable were noted around the site during a 9/13/94 field investigation by Kathryn J. Moss.

**Location:** The site is located near the southwest corner of the 100BC Area, adjacent to the southwest corner of the patrol road. The site is approximately 170 meters (558 feet) southwest of the 118-B-1 Burial Ground.

#### Type: Valve Pit

#### Status: Active

**Start Date:**  
**End Date:**

*Hanford Site Waste Management Units Report*  
February 2015  
1676
Description: The site is a valve pit located along the export water line. The pit is marked with post and chain. The 1.8 by 1.8 meter (6 by 6 foot) wooden cover is caving into the valve pit. The cover is posted with a "Danger: Cave-In Potential" sign.

Location: The site is located approximately 600 meters (2000 feet) east of the 105-C Reactor Building, between the 100-B Perimeter Road and Route 1 near mile post 9.

Related Sites/Structures: The site is associated with the export water line from 182-B Reservoir to the 200 Areas.

---

Code: 100-C-5
Names: 100-C-5; 100-C Clean Water Pipelines; 100-C Service Water Pipelines
Type: Product Piping
Status: Inactive
Start Date: 1/1/1952
End Date: 1/1/1969
Description: The site encompasses the clean water upstream pipelines for the 100-C Area, including underground pipelines used to transport raw, fire, export, and sanitary water from the river pump house, to the water treatment facilities and to 100-C Area facilities and fire hydrants. Lines within buildings, process and septic sewer pipes, pipes that carried water treated with sodium dichromate, and all lines that are downstream from the reactor building, i.e., those lines that carry cooling water from the reactor to the retention basin, trench, and/or the river are excluded.

Location: The location is described as underground lines running from the 181-C Pump house to the 183-C Water Treatment Facilities, and from there to other 100-C Area buildings, fire hydrants, and north to the 100-B Area, stopping at a line about half-way between the B and C areas, at about northing 144370 N.

Related Sites/Structures: Related structures are the 181-C Pump house, 182-C Reservoir, the 183-C Basins and Clearwells, the 190-C Buildings, and the 105-C Reactor Building. Other pipeline sites in the 100-B/C Area include 100-C-9, the 100-C Area Process and Sanitary (Septic) Sewer Underground Pipelines; 100-C-6, the Effluent Pipelines; and 100-B-7, the 100-B Area Water Treatment Facilities Pipelines.

Process Description: Reactor cooling water was pumped from the Columbia River, settled and treated to remove minerals, and pumped to the reactor core at a rate of 1.93E+05 liters (51,000 gallons) to 2.69E+05 liters (71,000 gallons) per minute.

Waste Type: Process Effluent
Waste Description: Only uncontaminated piping remains.

---

Code: 100-C-8
Names: 100-C-8; 105C Hydraulic Oil Release
Type: Unplanned Release
Status: Inactive
Start Date: 1/1/1998
End Date: 1/1/1998
Description: The site is not marked or posted, no visible evidence of the spill remains because the concrete rubble that it was spilled on has been removed.

Location: The spill was located below the Rod Control Room of the 105-C Reactor Building, in a pile of
Rev. 24

DOE/RL-88-30

concrete rubble approximately 7 feet deep. This rubble was contained within the basement directly below the old (now demolished) Outer Rod Room.

**Release Description:** On Monday, August 24, 1998, at approximately 0900 hours, the CAT 375 excavator broke a main hydraulic line while dismantling a concrete pad at 105-C. The excavator was taken out of service for repair. The exact quantity was not known at the time of the hose failure and was believed to be below the DOE reportable threshold of 160 liters (42 gallons). A large area was sprayed due to the hydraulic system being under pressure. On Wednesday, August 26, 1998, the 105-C Task Lead was notified the excavator hydraulic line was repaired and the replacement fluid equaled 182 liters (48 gallons). It is assumed that the entire hydraulic system was full to capacity prior to the hose failure and that the amount released was the exact amount of product that was put back into the reservoir [182 liters (48 gallons)].

**Waste Type:** Construction Debris

**Waste Description:** Unocal Unax AW46 Hydraulic Oil, unregulated product.

---

**Code:** 100-C-10

**Classification:** Not Accepted

**Names:** 100-C-10; Yellow Stained Soil Northwest of 183-C Headhouse

**Type:** Unplanned Release

**Status:** Inactive

**Description:** The discovery of stained soil has been determined to be inclusive of 100-C-7:1 and classified as a Not Accepted waste site. An area of yellow stained was discovered in the layback of the western end of the 100-C-7:1 waste site while excavating in May 2011. Soil samples of the discolored soil were collected on May 19, 2011 and analyzed for metals and hexavalent chromium analysis. The sample having the highest result (197 mg/kg) of hexavalent chromium was J1JCD9.

**Location:** The stained soil waste site is located west of the intersection of Burnett Road and Belle Street. The stained area was visible approximately 65 meters (213 ft) west of the 183-C sedimentation basins, north of the Head House.

**Related Sites/Structures:** This site is associated with 100-C-7:1.

---

**Code:** 124-C-4

**Classification:** Not Accepted

**Names:** 124-C-4; Sanitary Waste Site

**Type:** Sanitary Sewer

**Status:** Inactive

**Description:** This site was assigned by Bill Hayward based on the information from BHI D&D in the 1995 RARA Summary Report. D&D could not identify the site location nor could the BHI historian. The site is thought to be either 1607-B10 or 1607-B11 as they are the only remaining septic systems in the 100B Area that have a 124 alias assigned to them. If a determination can be made that it is one of above referenced septic systems, the 124-C-4 will be added to the site as an alias. This site reference (as a separate site) will then be removed from the database.

large, vegetation covered field. There are no features that clearly identify the site.

**Location:**
The site is located southeast of the 105-DR Reactor, outside of the 100D perimeter fence and north of Route 2 North.

**Waste Type:** Equipment

**Waste Description:**
The site likely contains burned construction debris.

---

**Code:** 100-D-26

**Classification:** Not Accepted

**Names:**
100-D-26; Borrow Pit; Potential Burial Trenches

**Reclassification:** None

**Type:** Depression/Pit (nonspecific)

**Start Date:**

**End Date:**

**Status:** Inactive

**Description:**
The site is a borrow pit used as a source of clean fill. On July 10, 1997 a field investigation was performed by T. F. Johnson. The site appeared as a depression approximately 330 feet (100 meters) in diameter that was created from excavations with heavy equipment. Four distinct trenches were observed within the depression. All four trenches were covered with blown in tumbleweeds. A few tumbleweeds were removed for inspection and no waste or discolored soil was observed. An empty 208 liter (55 gallon) steel drum was located at the end of one trench and an empty 0.95 liter (1 quart) oil can was also observed near the site.

**Location:**
The site is located approximately 250 meters (820 feet) east of the northeast corner of the patrol road that surrounds 100-D Area.

**Waste Type:** Equipment

**Waste Description:**
An empty steel 55 gallon drum and an empty 1 quart oil can were observed at the site.

---

**Code:** 100-D-33

**Classification:** Accepted

**Names:**
100-D-33; Minor Construction Burial Ground #4 East Trench

**Reclassification:** Rejected (3/20/2008)

**Type:** Burial Ground

**Start Date:** 1/1/1954

**End Date:**

**Status:** Inactive

**Description:**
The site appeared as a vegetation-free, cobble-covered field. The trench was estimated to have been approximately 30 meters (100 feet) long by 15 meters (50 feet) wide. A Ground Penetrating Radar scan, done in 2004, did not identify any trench-like features.

**Location:**
The site was located east/southeast of the 105-D Reactor, just south of the rail spur to the fuels transfer bay and east of 100-D-35. The site was outside the security fence for the 105-D Reactor Building.

**Related Sites/Structures:**
Co-located with 100-D-35, Minor Construction Burial Ground #4 East Trench.

**Process Description:**
The site was thought to have been used for disposal of low-level construction wastes from reactor modifications.

**Waste Type:** Misc. Trash and Debris
**Waste Description:** The site received low-level construction wastes from the reactors. Potential contaminates include: Co-60, Ni-63.

Description: During a 1999 walkdown, no evidence of the burial ground was observed. The area appeared as a vegetation covered field.

Location: The site was thought to be located 210 meters (700 feet) east of the 105-D Reactor Building and 23 meters (75 feet) south of railroad tracks that serviced the 105-D Reactor Building.

Related Sites/Structures: Co-located with 100-D-40, Minor Construction Burial Ground #5 Hole.

Process Description: This burial ground has been described as receiving irradiated reactor parts, dummies, thimbles, rods, gun barrels, and other contaminated solid wastes. During the March 31, 1999 site visit, no evidence of the trench was visible. A Ground Penetrating Radar scan, done in 2004, did not identify any trench like features.

Waste Type: Sludge

Waste Description: The waste is miscellaneous construction related solid wastes from the 100-D Reactors. Potential contaminants include: Co-60, Ni-63.

Code: 100-D-53

Classification: Accepted

Type: Process Unit/Plant

Start Date: 1/1/1960

Status: Inactive

End Date:

Description: The site has been remediated and Interim Closed Out for CERCLA. It has two entries in the WIDS database. Sitecode 122-DR-1:4 documented the RCRA component closure of this site.

The ventilation exhaust filter building housed blowers and particulate filters used to treat the ventilation exhausted from the 105-DR Reactor Building. Included in this site were the 117-DR Building, the intake ventilation duct from the 105-DR Reactor Building, and the exhaust ventilation duct to the 116-DR Reactor Exhaust Stack. The building and below-grade duct work were made of reinforced concrete 0.3 to 0.6 meters (1 to 2 feet) thick. Above grade ducts were constructed of 10 gauge black steel. The building was approximately 20.7 meters (68 feet) long, 11.9 meters (39 feet) wide, and 10.4 meters (34 feet) high with 2.4 meters (8 feet) above grade. A soil berm was built up around the building from grade level to the top of the structure.

Location: The site was located south of the 105-DR Reactor (118-DR-2), near the 116-DR Stack (132-DR-2).

Related Sites/Structures: The site was associated with the 105-DR Reactor (118-DR-2), the 116-DR Stack (132-DR-2), the 119-DR Sample Building, 122-DR-1:4 and the 117-DR Seal Pit Crib (116-DR-8).

Process Description: Before filter buildings were used, unfiltered ventilation was exhausted directly from the reactor to the atmosphere. The reactor confinement system diverted the exhaust just before the stack and routed it to the filter building where it passed through a series of filters. The filtered exhaust was then routed back to the ventilation exhaust stack where it was discharged to the atmosphere. Sealwells within the filter building provided the ability to direct the exhaust into one or both of the filter cells. The building was divided into two large filter cells with a smaller operating area between them. The filter cells each could hold six filter frames (two wide and three deep). The filter frames were designed to hold twenty-four filters that were 0.6 meters (2 feet) square by 0.3 meters (1 foot) thick. There are spaces between the frames to allow access for filter maintenance. The operating area between the two cells was divided into two levels. The upper level, called the access gallery had ten doors that led from it. Four doors opened into each of the filter cells and the other two doors provided access to the intake and exhaust ducts.
The operating gallery was located below the access gallery. A sump was located at each end of the operating gallery to collect incidental drainage from above. A large open area extended the full length of the structure above the access gallery and the filter cells. It ranged in height between 2.5 and 2.4 meters (8.1 and 7.8 feet), due to the structure's sloping roof. The space provided access to the cement cover blocks that were positioned over each of the filter frames.

**Waste Type:** Chemical Release

**Waste Description:** The site contained radiologically contaminated surfaces and contamination from 105-DR Reactor ventilation exhaust. Hazardous residue from the Large Sodium Fire Facility is accounted for within that site (122-DR-1).

**Closure Info:** Note - The 105-DR reactor operated between 1950 and 1964 for plutonium production. In 1973, the exhaust system portions of the 105-DR reactor were reactivated and re-purposed to support the Large Sodium Fire Facility (LSFF). The LSFF (sitecode 122-DR-1) was a RCRA TSD. Most of the components of the reactor exhaust system have two entries in the WIDS database, one representing the CERCLA (radioactive) contaminants and the other representing the RCRA hazardous chemical contaminants.

The portions of the LSFF TSD that are included in this remedial activity are the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the underground exhaust tunnel (122-DR-1:2), the 119-DR Exhaust sample building (100-D-64), two dry wells (100-D-23 and 100-D-54) and the 116-DR Exhaust Stack (132-DR-2/122-DR-1:5) Four of the seven 122-DR-1 subsites (122-DR-1:1, 122-DR-1:3, 122-DR-1:6 and 122-DR-1:7) were closed out under the 105-DR Large Sodium Fire Facility RCRA Closure Plan (LSFF Closure Plan) are not discussed in the CVP-2003-00018 Cleanup Verification Package.

The remedial objective for the structures was to remove each structure to a minimum of 0.9 meters (3 feet) below surface grade. In July 2003, remedial/removal action activities removed the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the downstream (post-filter) tunnel and the additional 0.9 meters (3 ft) of the 116-DR Reactor Exhaust Stack (132-DR-2/122-DR-1:5). The aboveground portion of the 132-DR stack had been demolished in 1999.

Large Sodium Fire Facility (LSFF) subsite 122-D-1:2 (underground tunnel between the 105-DR Building) and the 117-DR Exhaust Filter Building were entirely removed. The 315 and 316 exhaust plenums, (aka upper and lower exhaust tunnels) are also associated with the 122-D-1:2 subsite. The upper exhaust tunnel and approximately the top 0.9 meters (3 ft) of the lower exhaust tunnel were removed. The 119-DR Exhaust Stack Sampling Building and two stack sampling building dry wells (100-D-23 and 100-D-64) were also demolished and excavated as part of the remedial/removal action activities in July 2003.

At the completion of the remedial action, the total excavation was approximately 1,010 square meters (10,872 square feet) in area with an approximate depth of 5 meters (16.4 feet). Approximately 14,011 metric tons (15,412 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

**Code:** 100-D-55

**Classification:** Not Accepted

**Names:** 100-D-55; Gravel Pit #21; Pit 21

**Reclassification:** None

**Type:** Depression/Pit (nonspecific)

**Start Date:**

**Status:** Active

**End Date:**

**Description:** The site is a large excavation containing another waste site, 100-D-15, which is debris in the east end of the pit. The debris is marked with post and chain and labeled as a separate waste site. The remainder of the pit is available to use as clean fill material (Gravel Pit #21). There is
no other waste material in the pit. The soil is sandy.

Location: The gravel pit is located south of the 100-D Area perimeter road.

Related Sites/Structures: The pit is associated with the dumping area known as Site Code 100-D-15.

Waste Type: Soil

Waste Description: There is an area of discarded debris located in the east end of this gravel pit. The debris is a separate waste site known as 100-D-15. In 1994, Kaiser Hanford removed sediments from the 182-D basins and deposited them inside this gravel pit, partially over top of the previously discarded debris. The sediment was determined to be "clean dredge soil" as defined in Washington Administrative Code 173-304-100. The total content of the discarded debris is unknown.

Reclassification: 100-D-57; Earth Crib Near 107-DR

Inactive

Names: 100-D-57; Earth Crib Near 107-DR

Type: Crib

Status: Inactive

Description: This site is a duplicate of 100-D-4, which has been excavated and closed out. Site 100-D-57 was initially identified from Drawing H-1-8630-DR, which shows an "Earth Crib" at an unrecognizable, but short, distance off the southeast side of the 116-DR-9 Retention Basin. Through examination of Ground Penetrating Radar results, other documents, and excavations of the 116-DR-9, 100-D-4, and 100-D-49 sites, which effectively removed all soil and subsurface structures in this area, it has been determined that this site, 100-D-57, was created in error.

Location: The crib is located 30 meters (100 feet) east of the southeast corner of the 116-DR-9 Retention Basin.

Reclassification: 100-D-58; 100-DR Area On-Site Sewage System for MO-980 & 4-Closet Restroom Facility; 100-DR OSS

Inactive

Names: 100-D-58; 100-DR Area On-Site Sewage System for MO-980 & 4-Closet Restroom Facility; 100-DR OSS

Type: Septic Tank

Status: Inactive

Description: The septic tank has been properly abandoned and Closed Out per Washington State Code requirements. The septic tank is surrounded by yellow steel posts and the drain field is surrounded with light duty chain and steel fence posts. The drainfield area is covered with tumbleweeds. The septic tank is a 5,680 liter (1,500 gallon), two compartment tank with a 5,680 liter (1500 gallon) pump chamber. The tank can be accessed through 0.765 meter (30 inch) diameter ribbed PVC risers that extend to grade and are covered by fiberglass lids that are bolted in place. The risers are centered over 0.609 meter (24 inch) diameter openings through the concrete lid.

Location: The site is located approximately 183 meters, (600 feet) north northwest of the 105-DR Reactor Building and 76 meters, (250 feet) southwest of the 105-D Reactor Building.

Related Sites/Structures: The site received sanitary sewage from MO-980 and the restroom trailer. There are no radiation zones or known contamination areas in or near MO-980 or the restroom trailer.
Process Description: The septic tank separated the settleable solids and floating effluent scum from the clear liquid. The effluent was passed from the septic tank to the pump chamber through a "Bio-Tube" effluent filter. The filter was located at the outlet end of the septic tank. The filter was accessed through one of the 0.203 meter (30 inch) PVC risers. It had a removable filter element which can be easily cleaned. A 0.203 meter (4 inch) diameter PVC pipe carried the effluent from the outlet of the filter to a 5,676 liter (1,500 gallon) pump chamber. The disposal area consisted of buried pressurized PVC pipe distribution system constructed in a gravel-lined trench. The outlet orifices of the system were sized at 4.76 millimeter (3/16 inch) diameter [1.5 millimeters (1/16 inch) larger than the effluent screen] to avoid orifice plugging. The disposal area provided the absorption area for disposal of the clear sewage liquid.

Waste Type: Process Effluent

Closure Info: The requirements for septic tank abandonment for the 100-D-58 sewage system fall under WAC 246-272A-0300. On August 2 and 6, 2012, approximately 1.3 meters (4 feet) of soil was removed to expose the septic tank. The lid was removed and crushed. The tank was filled with sand and gravel. The abandoned tank was backfilled to grade. The electronic components, pump, and float switches associated with the septic system were removed and either disposed or recycled. The drain-field inspection ports, consisting of polyvinyl chloride (PVC) pipes placed vertically in the drainfield, were also removed and disposed. All below-grade PVC piping associated with the sewage system was abandoned in place. The site has been abandoned in accordance with WAC 246-272A-0300 and is Closed Out.

</tbody>
</table>
The waste site has been evaluated and determined to require No Action. The pump house has been demolished to 1 meter (3 feet) below-grade and backfilled. Before demolition the building included a basement, pipe gallery operating floor, suction tunnel and hot well bay, process tunnels, and two valve houses.

The facility was located due south of the 151-D Substation, east of the 183-DR Clearwells and southeast of the 105-DR Reactor.

The associated structures include the 126-DR-1 (183-DR Clearwell Tank Pit), the 118-DR-2 (105-DR Reactor), 100-D-27, (151-D Substation), and the 100-D-28 septic system, piping and tile fields.

The Process Water Pump House provided high volume treated water to 105-DR Reactor for cooling. The facility contained eight electric primary water pumps that pumped treated water from the clearwell tanks to the reactor. The discharge water pipelines were composed of four sets of lines with each line 30.5 cm (12 in) in diameter. These pipelines combined into four 30.5 cm (24 in) discharge pipelines. Two sets of dual 30.5 cm (24 in) pipelines ran from the 190-DR facility to two valve pits. From each valve pit, the dual 30.5 cm (24 in) pipelines routed the process water to the 105-DR Reactor.

Prior to demolition, above-grade wastes included polychlorinated biphenyls (PCBs), asbestos (roofing, siding, pipe trays, and thermal piping insulation), mercury (installed in instrumentation and control systems), lead (lead-based paint and lead washers), and oils/greases. Since the above-grade structure was completely removed during demolition, the only remaining waste was the below-grade structure. The waste in the basement included water, sludge and potentially contaminated concrete.

Prior to demolition, all friable asbestos was removed, including all asbestos containing material and all potential asbestos containing material from ventilation fan housings, pipes, and loose materials that had fallen to the ground. Additionally, biological hazards, i.e., bird droppings, small dead birds, and eggshells were removed.

In the spring of 2005, the above-grade portion of the facility was demolished and the below-grade portion of the facility was demolished to 1 meter (3 feet) below-grade. The debris went to ERDF. The remainder of the concrete facility was left in place. The two valve houses were also demolished.

Approximately, 20 to 25 centimeters (8 to 10 inches) of standing water that had accumulated from runoff of storm water was present in the north and south annex basement areas (B and C Bays). B Bay (a.k.a., main basement sump) contained sludge that had accumulated. The water was removed prior to below-grade demolition. In order to leave the basement in place as clean concrete, sampling results had to show that contaminants in the concrete were below the applicable remedial action goals as defined in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17).

The water tunnels were left in place and are currently being used as bat habitat. All of the piping was removed and recycled.
**Reclassification:** 100-D-79; SCA Area 1; SCA Area 2; 100D Posted Soil Contamination Areas

**Names:**

**Type:** Dumping Area  
**Status:** Inactive  
**Description:** This site consists of two posted radiological soil contamination areas (SCA). Area 1 is an SCA that was found during the 2006 Orphan Site Evaluation (OSE) field investigation. The SCA is posted and is in an area of previously disturbed soils. Area 2 is also an SCA that was identified during the 100-D Orphan Site field investigation in 2006.

**Location:** There are two posted soil contamination areas located north of 105-D. Area 1 is near the north perimeter road and southeast of the 1904-DR outfall. A hand held Global Positioning unit found the center of Area 1 coordinates to be E573663.40, N152389.29. Area 2 is located on the north side of the 126-D-1 (188-D) ash pile. A hand held Global Positioning unit found the center of Area 2 to be at coordinates E573470.92, N152198.90.

**Process Description:** Construction drawing M-1600-D, Sheet 8 indicates that Area 1 was located in was used as a spoil pile area in 1947. No other information is available. No information was available for Area 2.

---

**Reclassification:** 100-D-89; Power Pole and Junction Box Debris Dumping Area  

**Names:**

**Type:** Dumping Area  
**Status:** Inactive  
**Description:** This site consists of two surface debris areas containing abandoned electrical components.

**Location:** This site is located 83 meters (272 feet) north of the 108-D Chemical Facility.

**Process Description:** The 100-D-31 Process Sewer runs below this location.

**Related Sites/Structures:**

**Waste Type:** Soil  
**Waste Description:** No contaminants of potential concern were noted. This electrical box was used as a junction box and should not have contained PCB's.

---

**Reclassification:** 100-D-91; 100-D/DR Electrical Components Debris Dumping Area  

**Names:**

**Type:** Dumping Area  
**Status:** Inactive  
**Description:** The site consists of a flat gravel area where pallets of electrical components once were staged.
**Location:** This site is located 12 m (39 ft) northeast of the 1713-D Store House.

**Related Sites/Structures:** The closest structure was the 1713-D Store House.

**Waste Type:** Soil

**Waste Description:** There are no contaminants of concern.

**Type:** Storage Tank

**Status:** Inactive

**Description:** This waste site consists of an underground concrete utility encasement for freshwater pipelines and the underlying soil located below a rail line. The site was originally reported, in a geophysical investigation, as a potential underground storage tank (UST). A detailed spatial analysis was conducted and determined that the feature was a known piping encasement located below the railroad tracks.

**Location:** This structure is co-located with 100-D-93 and associated with the 183-D Water Treatment facilities, the 100-D-12 Sodium Dichromate Transfer Station (pump station), 100-D-63, 100-D/DR Service Water Pipelines, 100-D/DR Clean Water Pipelines, and 100-D-56, 100-D Area Sodium Dichromate Underground Supply Lines (see subsites).

**Related Sites/Structures:** This structure is co-located with 100-D-93 and associated with the 183-D Water Treatment facilities, the 100-D-12 Sodium Dichromate Transfer Station (pump station), 100-D-63, 100-D/DR Service Water Pipelines, 100-D/DR Clean Water Pipelines, and 100-D-56, 100-D Area Sodium Dichromate Underground Supply Lines (see subsites).

**Process Description:** The encasement protected utilities buried beneath rail road lines and is located approximately 0.91 meter (3 feet) below grade. A 7.6 centimeter (3 inch) sodium dichromate pipeline and a 40.64 centimeter (16 inch) freshwater pipeline was observed inside the encasement.

**Waste Type:** Soil

**Waste Description:** The encasement contains a portion of the 100-D-56 pipeline. WIDS 100-D-56 states "Historical review, geophysical surveys and a site visit in 2005 concluded that the site appeared to contain hazardous constituents (i.e. hexavalent chromium) at levels in exceedance of remedial action goals" Potential Contaminants of Concern: As stated in the Site Comment, the encasement location consists of a portion of the 100-D-56 pipeline. WIDS 100-D-56 states "Historical review, geophysical surveys and a site visit in 2005 concluded that the site appeared to contain hazardous constituents (i.e. hexavalent chromium) at levels in exceedance of remedial action goals".

### Additional Notes

- **Waste Name:** 100-D-93; Potential UST Near Dichromate Station
- **Process Description:** The encasement protected utilities buried beneath rail road lines and is located approximately 0.91 meter (3 feet) below grade. A 7.6 centimeter (3 inch) sodium dichromate pipeline and a 40.64 centimeter (16 inch) freshwater pipeline was observed inside the encasement.

---

_Hanford Site Waste Management Units Report_  
February 2015  
1689
Description: This site consists of an underground concrete utility encasement for freshwater pipelines and the underlying soil located below a rail line. The site was originally reported, during a geophysical investigation, as a potential underground storage tank (UST). A detailed spatial analysis was conducted and determined that the feature was a known piping encasement located below the railroad tracks.

Location: This site is located 10 meters (32 feet) east of the 100-D-12 Sodium Dichromate Transfer Station and 73 meters (239 feet) southeast of the 183-D building. It is approximately 1.54 m (5 ft) below grade.

Related Sites/Structures: This structure is co-located with 100-D-92 and associated with the 183-D Water Treatment facilities, the 100-D-12 Sodium Dichromate Transfer Station (pump station), 100-D-63, 100-D/DR Service Water Pipelines, 100-D/DR Clean Water Pipelines, and 100-D-56, 100-D Area Sodium Dichromate Underground Supply Lines (see subsites).

Process Description: The encasement protected utilities buried beneath rail road lines and is located approximately 0.91 meter (3 feet) below grade. A 7.6 centimeter (3 inch) sodium dichromate pipeline and a 40.64 centimeter (16 inch) freshwater pipeline was observed inside the encasement.

Waste Type: Process Effluent

Waste Description: The encasement contains a portion of the 100-D-56 pipeline. WIDS 100-D-56 states "Historical review, geophysical surveys and a site visit in 2005 concluded that the site appeared to contain hazardous constituents (i.e. hexavalent chromium) at levels in exceedance of remedial action goals."

---

Code: 100-D-95
Names: 100-D-95; 100-D/DR Unnumbered Septic Tanks and Tile Field
Type: Septic Tank
Status: Inactive
Description: The site was suspected to consist of two septic tanks and a tile field. Gravel and rabbit brush were observed on the surface of the site. Based on information gathered during the geophysical investigation, and historical review it was determined that a septic tank and drain field do not exist at the 100-D-95 site. The site was reclassified to Rejected on form 2009-04.
Location: This site is located approximately 150 meters (492 feet) northwest of the 182-D Reservoir. The coordinates are the centroid of the geophysics performed.
Related Sites/Structures: This septic system may have serviced the 1735-D Division Engineers Office, Training Headquarters, Miscellaneous Storage Facility and other temporary construction facilities.
Process Description: During construction of the Hanford Engineer Works, temporary sewer lines and septic tanks were installed for the disposal of sanitary sewage. The "Plot Plan of Temporary Construction Facilities 100-D Area, August 1944" indicated that a septic tank and tile field were proposed at this location to service several temporary buildings.
Waste Type: Soil
Waste Description: Transfer of non-radioactive liquid sanitary sewage waste.

Hanford Site Waste Management Units Report
February 2015

1690
### 120-D-1; 100-D Ponds

**Reclassification:** Closed Out (8/27/1999)

**Type:** Pond

**Start Date:** 1/1/1977

**End Date:** 5/27/1994

**Description:** The waste site was originally a single excavation created in 1977 in the Ash Disposal Basin to receive non-hazardous 183-D sand filter backwash water. It modified in 1979 to form a two-compartment pond, one overflowing to the other. The north pond was a percolation pond and the south pond was a settling pond. From 1979 through 1994, it received corrosive dangerous waste from the regeneration of three ion exchange columns located in the 185-D/189-D building. It was designated as a RCRA TSD unit.

On August 27, 1999, a letter was issued from the State of Washington Department of Ecology that declared the Treatment Storage and Disposal (TSD), RCRA Part A permit portion of this unit to be closed.

**Location:** This site is located within the 100-D Ash Disposal Basin (126-D-1).

**Process Description:** The waste site was originally a single excavation created in 1977 in the Ash Disposal Basin to receive non-hazardous 183-D sand filter backwash water. The 100-D Ponds received corrosive waste from the regeneration of ion exchange columns located in 185-D and 189-D. Successive discharge of acidic waste and caustic waste to the ponds served to neutralize the waste in the ponds. Approximately 45,000 gallons (170,000 liters) per day was treated in the ponds. A fraction of this amount was corrosive dangerous waste. It received the last discharge of dangerous waste in January 1986. It last received a discharge of non-regulated process water in May 1994.

**Waste Type:** Oil

**Waste Description:** This site received nonhazardous 183-D Sandfilter backwash, small quantities of filtered, chlorinated water from hydraulic test loops, and fuel discharge trampoline tests in 1977. The estimated flow rate was 1.7E+05 liters/day (45,000 gallons/day). After 1979, it received corrosive demineralizer recharge effluent from two sources was released at intervals of once every 2 to 3 years for one regenerate source and once every 6 years for the other. Sampling indicates the potential for mercury and polychlorinated biphenyl (PCB) contamination.

**Closure Info:** This was a RCRA TSD unit. On August 27, 1999, a letter was issued from the State of Washington Department of Ecology that declared the Treatment Storage and Disposal (TSD), RCRA Part A permit portion of this unit to be closed.

### 126-D-1

**Classification:** Accepted

**Reclassification:** Rejected (6/25/1998)

**Type:** Coal Ash Pit

**Start Date:** 1/1/1950

**End Date:** 1/1/1960

**Description:** The 126-D-1 site is a large ash disposal area. The site was originally a large excavated basin approximately 60 meters (200 feet) long, 60 meters (200 feet) wide, and 3 meters (10 feet) deep. The extent of the original basin obscured by ash piles.

**Location:** The site is located north of the 184-D Powerhouse.

**Process Description:** Coal ash from the 184-D Powerhouse was mixed with raw river water and sluiced in slurry form to the ash pit via a 20 centimeter (8 inch) ashcolite pipe.
Waste Type: Process Effluent
Waste Description: This site received an unknown amount of coal ash that was sluiced to pits with raw river water from the 184-D Powerhouse. The ash has been determined by testing in accordance with WAC 173-303 to be nonextraction process (EP) toxic.

<td>Description:</td>
<td>The salt dissolving pits and brine pump pit were part of a single below-grade concrete structure that provided brine for the 184-D Powerhouse. The structure has been demolished and buried in situ. No evidence of the site remains at the surface. The two salt dissolving pits each had inner dimensions of 4.3 meters (14 feet) long by 2.4 meters (8 feet) wide by 2.8 meters (9.25 feet) tall. They had a design high water line 2.4 meters (7.75 feet) from the pit bottom. An overflow slot connecting the two dissolving pits was located 0.3 meters (1 foot) above the high water line. The bottom of each pit was filled with a 12.7 centimeter (5 inch) layer of 1.3 to 2.6 centimeter (1/2 to 1 inch) gravel topped by a 17.8 centimeter (7 inch) layer of 0.3 to 0.6 centimeter (1/8 to 1/4 inch) gravel. The dissolving pits each had a 2.4 meter (8 foot) by 0.9 meter (3 feet) opening at the top for receiving salt. Each pit had a capacity of 23,600 kilograms (52,000 pounds) of salt. The brine pump pit is located adjacent to the two salt dissolving pits. The pit was 3.3 meters (10.67 feet) long by 2.2 meters (7.33 feet) wide by 2.1 meters (7 feet) deep. It held two pumps and associated piping (all brass) for the brine system. The floor of the pump pit sloped toward a 46 by 46 by 46 centimeter (18 by 18 by 18 inch) sump in a corner.</td>

<tr>
<td>Location: The stack was located south of the 105-D Reactor Building.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Process Description: The unit was a monolithic structure constructed of reinforced concrete. The maximum wall thickness was 0.46 meters (1.5 feet) at the base. It rested on a double octagon-shaped base that extended 5.3 meters (17.5 feet) below grade. An opening at the base provided access to its interior portion. This opening was fitted with a steel door. The outside rungs had been removed to about 3 meters (10 feet) above grade. Originally exhaust air flowed directly from the 105-D Building to the exhaust stack. Following completion of the confinement project in 1960, the exhaust air was diverted to the 117-D Filter Building, via underground ducts, prior to release through the stack.

Waste Type: Oil
Waste Description: This unit was used to exhaust confinement air that originated from the work areas in the 105-D Reactor Building. The interior of the stack contains an unknown quantity of low-level radioactive materials.

Closure Info: In 1984 when the reactor shut down, the Fuel Storage Basin (FSB) water level was lowered and the basin was cleaned out. Ruptured fuel elements had caused the shielding water to become highly contaminated. The remaining water was processed and released to 116-D-10 pond. Then an asphalt emulsion was applied to the floors and walls of the basin to fix the loose contamination to the basin structure. The hardware remaining in the basin (perfs, buckets, and sludge) were packaged and disposed of as low-level radioactive waste in the 200 Area burial grounds. The 132-D-4 stack was demolished and remediated to a depth of 0.9 meters (3 ft) below grade in 1999.

Removal and disposal activities at the 105-D site began in January 2000. For remediation purposes, the reactor area was divided into several Demolition Zones, the reactor core and the remaining portion of 132-D stack foundation. These areas were surveyed, and contamination was removed in preparation for clean demolition. With the exception of the Fuel Storage Basin walls and floor below 4.6 meters (15 feet), all structures in this zone were removed due to surface contamination being present. Sampling of underlying soils was not required because structures in this zone were not subjected to standing contaminated water and there was no mechanism for residual surface contamination to penetrate into the concrete and the underlying soil. The above and below grade structures were demolished. The demolition debris sent to ERDF. A section of 100 D-48:4 effluent pipeline remains buried under what was room 210. This section of pipeline will be considered separately from Demolition Zone 1 and deferred to the Remedial Action Project.

All known flammable and hazardous material was removed inside and outside of the Safe Storage Enclosure (SSE), with the exception of non-removable lead, generally in the form of lead-based paint inside the SSE. Concentrations of lead in the lead-based paint were determined to be below regulatory limits. After the hazardous materials were removed, the above and below grade structures at the 105-D site were ready for demolition. The above-grade structures were demolished, the overburden around the foundations was excavated, and the below-grade structures were demolished. During the demolition process, the resulting debris was loaded out and shipped to ERDF for disposal. The 105-D site D&D activities included complete removal of above-grade structures outside of the 105-D Reactor core shield walls. A majority of the below-grade structures outside of the 105-D Reactor core shield walls were completely demolished. A portion of the south wall of the valve pit area (demolished to 0.9 meters [3 ft] below grade) and the entire Fuel Storage Basin floor and a portion of the walls (demolished to 4.6 meters [15 ft] below grade) were left in place based on deep zone cleanup criteria. The overburden piles produced during excavation were found to be contaminated. The overburden was deemed unsuitable for use as backfill of the site and was disposed in ERDF. The site was backfilled with clean soil/aggregate, using material from Borrow Pit 21 and graded to match the surrounding terrain. The 105-D D&D activities generated approximately 1,585 bulk containers of low-level contaminated material that were shipped to ERDF, accounting for approximately 21,613 metric tons (23,824 tons).
It was determined in the Sampling and Analysis Plan for Interim Closure of the 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils that the 105-D FSB would not be cored to sample the underlying soils because this Fuel Storage Basin was not known to have leaked (the water level variations were consistent with evaporation). Coring would have been very difficult and potentially unsafe. The soils beneath the 100-C and 105-DR FSBs were found to be clean. The 100-D Reactor Site Technical Baseline Report suggests that all of the FSBs had leaked. However, this statement is not supported by the process history of the 105-D FSB. Sampling of the underlying soils at the 105-C and 105-DR FSBs showed that they had not leaked. The FSB concrete floors from all of the previously decommissioned reactors were found to have various types of contamination that penetrated only a maximum of a few millimeters into the concrete. Sampling showed the contamination had not penetrated through the 0.3 to 0.6 meters (1 to 2 feet) of concrete in the FSB floors.

The north decontamination pad, a section of 100-D-48:4 effluent pipeline, and the FSB side-slope soils remained to be addressed, having been deferred to the Remedial Action Project.

| Code: 1607-D3 | Classification: Accepted |
| Names: 1607-D3; 1607-D3 Sanitary Sewer System; 1607-D3 Septic Tank; 1607-D3 Septic Tank and Associated Drain Field | Reclassification: Closed Out (2/23/2001) |
| Type: Septic Tank | Start Date: 1/1/1944 |
| Status: Inactive | End Date: 1/1/2000 |
| Description: The site is an inactive, abandoned septic system associated with the 151-D Substation. A sign stating "Abandoned Septic Tank per WAC 246-272-1850 DynCorp Environmental" is posted at the site. The tank has been abandoned per WAC 246-272-18501 and as of August 2000 is indistinguishable in a dirt and cobble field. The reinforced concrete tank is 1.8 meters (6 feet) long, 0.9 meters (3 feet wide), and 3 meters (9 feet 10 inches) deep (inner dimensions). The tank had a design capacity of 1325 liters (350 gallons) based on a user capacity of 10 persons, a flow of 132 liters (35 gallons) of sewage per capita per day, and an average detention time of 1 day. The walls are 20 centimeters (8 inches) thick. The floor is 15 centimeters (6 inches) thick. The tile field was constructed of 10 centimeter (4 inch) vitrified or concrete pipe, or drain tile with a minimum of 2.4 meter (8 foot) per capita. The laterals are open jointed and spaced 2.4 meters (8 feet) apart. Prior to decommissioning, the septic tank was surrounded by light posts and chain. | Location: The septic tank and drain field are located east of the 151-D Electrical Substation. |
| Process Description: The site serviced the 151-D Electrical Substation. Waste Type: Chemicals | Waste Description: This unit received sanitary waste from the 151-D Electrical Distribution Substation. The flow rate to this unit was estimated at 3,970 Liters (1,050 gallons) per day. |
| Closure Info: The tank has been abandoned per WAC 246-272-18501. The septage was removed from the tank sometime in the past. In July 2000, the lid was removed from the tank and the void space in the tank was filled with soil. A radiological survey was done on the empty tank and excavated soil. The reclassification is documented on form 2000-122. |
### Description:
The Large Sodium Fire Facility RCRA TSD (T-1.1) has been Closed Out. The facility RCRA closure plan divided the facility into seven areas for sampling and closure purposes. The seven areas became subsites of the 122-DR-1 WIDS site. Some components of the facility also required CERCLA remediation. These components were addressed in a Cleanup Verification Package (CVP-2003-00018). The TSD was Closed Out under RCRA on 7/1/2004, after the CERCLA remediation was completed. A Certification of Closure Acceptance Letter, signed by Ecology, was issued to document completion of the RCRA TSD closure.

Four of the seven 122-DR-1 subsites (122-DR-1:1, 122-DR-1:3, 122-DR-1:6 and 122-DR-1:7) were closed out under the 105-DR Large Sodium Fire Facility RCRA Closure Plan (LSFF Closure Plan) (DOE-RL 1995). The remaining components are discussed in the CVP-2003-00018 Cleanup Verification Package.

### Location:
The 105-DR Large Sodium Fire Facility was located in the supply and exhaust fan wing of the 105-DR Reactor Building.

### Process Description:
The Large Sodium Fire Facility (LSFF) was used to study the fire and safety aspects associated with sodium and other alkali metal fires for application to liquid metal reactors. The LSFF occupied the former supply/exhaust fan room of the 106-DR Reactor Building and used the 105-DR Reactor Building exhaust system, which includes the 117-DR Filter Building, exhaust tunnels, exhaust stack, exhaust stack sampling building, and exhaust stack sampling building drywell. The 105-DR Reactor Building exhaust system began operations in 1960, and ceased operations in 1964 in conjunction with the 105-DR Reactor. The exhaust system was reactivated and re-purposed in 1972 to support the LSFF and continued operation until 1986.

The laboratory tests conducted at the 105-DR Large Sodium Fire Facility (LSFF) can be grouped into the following general types by test purposes: (1) formation of alkali metal aerosols in air, steam, nitrogen, or carbon dioxide atmospheres for the purpose of determining aerosol properties and release ratios, using both pool and spray fires; (2) reaction of an alkali metal with concrete and insulation to study corrosion rates and to determine the reaction products formed; (3) generation of aerosols to be used for testing and measurement of air-cleaning filter and scrubber performance and for evaluating hydrogen ignition characteristics; (4) production of fire and smoke to test alkali metal fire extinguishing methods and equipment, to test protective equipment, and for training in equipment use; (5) testing of purchased lithium-lead alloy reaction rates and aerosol formation in various atmospheres; (6) development tests using cesium and zinc metal to demonstrate aerosol generation techniques; and (7) thermal treatment of sodium residue (sodium waste) generated in other facilities.

### Waste Type:
Asbestos (non-friable)

### Waste Description:
Wastes consisted of sodium, lithium, sodium-potassium alloy, lithium-lead alloy, and their oxidation products.
The RCRA TSD component was clean closed. The facility RCRA closure plan divided the facility into seven areas for sampling and closure purposes. The seven areas became subsites of the 122-DR-1 WIDS site.

Area 1 consists of the exhaust fan room, small fire room, large fire room, sodium handling room, and an office area.

The exhaust fan room is 6.2 meters (20.5) feet wide, 8.2 meters (27 feet) long, and 6.4 meters (21 feet) high. In this room, waste alkali metals from various sources, including residuals from tests, failed equipment, and drum heels, were reacted at atmospheric pressure. The burn pans and equipment were cleaned periodically using water and the rinsate was collected in a sump. The wash water was pumped from the sump to a seal pit where it was neutralized prior to discharge.

The small fire room is 6.2 meters (20.5 feet) wide, 8.2 meters (27 feet) long, and 6.4 meters (21 feet) high. It contains one steel cylindrical pressure vessel with a dished top. The vessel has a volume of approximately 14 cubic meters (500 cubic feet). When in use, the vessel could be purged with nitrogen or argon to maintain a controlled atmosphere. This vessel was the only one used to burn lithium-lead alloy waste.

The large fire room is 6.2 meters (20.5 feet) wide, 8.2 meters (27 feet) long, and 6.4 meters (21 feet) high. It contains the Large Test Cell which is a steel cubicle 110 cubic meters (3,700 cubic feet) in volume. The cell could be purged with nitrogen or argon to maintain a controlled atmosphere.

The sodium handling room contained drum melters and a 3,400 liter (900 gallon) type-304 stainless-steel sodium batch tank which provided sodium to the Large Test Cell. The tank was resupplied from sodium drums that were heated to liquefy the sodium, which was then discharged into the tank with inert gas.
The office area provided space for office work and storage of nondangerous materials. During cleanup activities equipment was removed from the rooms, decontaminated and stockpiled for either recycling or reuse. The interiors of the Large Test Cell and the pressure vessel were decontaminated with a high pressure water blast to remove lead and carbonate contamination. The rooms were washed down using a pressure washer and a mildly acidic solution to remove visible residue. All penetrations into the reactor exhaust tunnels were sealed to isolate the area and prevent recontamination.

A 90-day waste accumulation area was set up at the north end of the office area for use during clean up activities. The accumulation area was enclosed within a wire cage. When the waste was removed, the unit was closed.

**Location:** The 105-DR Large Sodium Fire Facility is located in the supply and exhaust fan wing of the 105-DR Reactor Building.

**The SubSite is Part Of:**

**Code:** 122-DR-1

**Names:** 122-DR-1; LSFF; 100-D-51; 105-DR Large Sodium Fire Facility; 105-DR Sodium Fire Facility

**Type:** Laboratory

**Status:** Inactive

**Description:** This subsite has been remediated and Interim Closed Out for CERCLA. The RCRA LSFF Closure Plan deferred the remaining three LSFF TSD subsites (122-DR-1:2, 122-DR-1:4, and 122-DR-1:5) to the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) process. The facility RCRA closure plan divided the facility into seven areas for sampling and closure purposes. The seven areas became subsites of the 122-DR-1 WIDS site. Prior to RCRA closure, subsites 122-DR-1:2, 122-DR-2:4, and 122-DR-1:5 had been reclassified as Interim Closed Out under CERCLA. The reclassification status for these subsites was changed to Closed Out to be consistent with the reclassification of the main site.

Area 2 consisted of the upper and lower exhaust tunnel, the blower that moved Large Sodium Fire Facility (LSFF) exhaust from the lower to the upper tunnel, the exterior underground tunnel to the 117-DR HEPA Filter Building, and the ducts to the submerged gravel scrubber. Steel barricades at the north end of the tunnels blocked air flow to and from the reactor. The tunnel had low, but measurable radioactivity when sampled in 1987 (see DOE/RL-90-25, Rev 2, Appendix A for sampling information). This area is part of the 105-DR Reactor Building and is also included in its Waste Information Data System (WIDS) site (118-DR-2).

**Closure Info:** Note - The 105-DR reactor operated between 1950 and 1964 for plutonium production. In 1973, the exhaust system portions of the 105-DR reactor were reactivated and re-purposed to support the Large Sodium Fire Facility (LSFF). The LSFF (sitecode 122-DR-1) was a RCRA TSD. Most of the components of the reactor exhaust system have two entries in the WIDS database, one representing the CERCLA (radioactive) contaminants and the other representing the RCRA hazardous chemical contaminants.

The portions of the LSFF TSD that are included in this remedial activity are the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the underground exhaust tunnel (122-DR-1:2), the 119-DR Exhaust sample building (100-D-64), two dry wells (100-D-23 and 100-D-54).
and the 116-DR Exhaust Stack (132-DR-2/122-DR-1:5) Four of the seven 122-DR-1 subsites (122-DR-1:1, 122-DR-1:3, 122-DR-1:6 and 122-DR-1:7) were closed out under the 105-DR Large Sodium Fire Facility RCRA Closure Plan (LSFF Closure Plan) are were not discussed in the CVP-2003-00018 Cleanup Verification Package.

The remedial objective for the structures was to remove each structure to a minimum of 0.9 meters (3 feet) below surface grade. In July 2003, remedial/removal action activities removed the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the downstream (post-filter) tunnel and the additional 0.9 meters (3 ft) of the 116-DR Reactor Exhaust Stack (132-DR-2/122-DR-1:5). The aboveground portion of the 132-DR stack had been demolished in 1999.

Large Sodium Fire Facility (LSFF) subsite 122-D-1:2 (underground tunnel between the 105-DR Building) and the 117-DR Exhaust Filter Building were entirely removed. The 315 and 316 exhaust plenums, (aka upper and lower exhaust tunnels) are also associated with the 122-D-1:2 subsite. The upper exhaust tunnel and approximately the top 0.9 meters (3 ft) of the lower exhaust tunnel were removed. The 119-DR Exhaust Stack Sampling Building and two stack sampling building dry wells (100-D-23 and 100-D-64) were also demolished and excavated as part of the remedial/removal action activities in July 2003.

At the completion of the remedial action, the total excavation was approximately 1,010 square meters (10,872 square feet) in area with an approximate depth of 5 meters (16.4 feet). Approximately 14,011 metric tons (15,412 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

Code: 122-DR-1:3
Names: 122-DR-1:3; Gravel Scrubber; 122-DR-1 Area 3
Type: Laboratory
Status: Inactive
Classification: Accepted
Reclassification: Closed Out (10/1/1996)
Start Date: End Date:

Description: The RCRA TSD component was clean closed. The facility RCRA closure plan divided the facility into seven areas for sampling and closure purposes. The seven areas became subsites of the 122-DR-1 WIDS site.

Area 3 consists of a submerged gravel scrubber and ducts that were installed in 1982 as part of a filter development program. Installation of the gravel scrubber allowed the offgas from tests or burning to bypass the 117-DR HEPA Filter Building. The scrubber water was confirmed to be within pH tolerances (2.0 to 12.5) and discharged to the 116-DR-8 Crib. Two gravel samples numbered B0G9F6 and B0G9F7 were taken from the gravel scrubber. Based on evaluation of the sample data, the gravel did not designate as a Dangerous Waste (see WHC-SD-EN-EV-034, Rev. 1 for sample results). The gravel that had been removed from the unit was made available for reuse. The associated ductwork was removed. The area was clean closed.

Location: The site was located at the south end of the 100 D/DR Exclusion Fence.

Classification: Accepted
Reclassification: Closed Out (7/1/2004)
Start Date:
End Date:

Description: The RCRA TSD component was clean closed. The facility RCRA closure plan divided the facility into seven areas for sampling and closure purposes. The seven areas became subsites of the 122-DR-1 WIDS site. Prior to RCRA closure, subsites 122-DR-1:2, 122-DR-2:4, and 122-DR-1:5 had been reclassified as Interim Closed Out under CERCLA. The reclassification status for these subsites was changed to Closed Out to be consistent with the reclassification of the main site. The CERCLA remediation for this subsite is documented in WIDS sitecode 100-D-53.

Area 4 consisted of the 117-DR HEPA Filter Building and the downstream tunnel to the reactor stack. The filter building housed the exhaust air filters. The building was about 18 meters (59 feet) long, 12 meters (39 feet) wide, and 11 meters (35 feet) high. The Filter Building was connected by underground concrete ductwork to the 116-DR exhaust stack. The filter building contained the HEPA filters, which were installed in four filter frames (24 filters per frame). In 1972, the original HEPA filters from the 105-DR Reactor were replaced before Large Sodium Fire Facility (LSFF) operations began. However, remnant radioactivity from the exhaust tunnels or filter holders had probably been picked up by the new filters. The 117-DR Filter Building was also a separate Waste Information Data System (WIDS) site (100-D-53).

Closure Info: Note - The 105-DR reactor operated between 1950 and 1964 for plutonium production. In 1973, the exhaust system portions of the 105-DR reactor were reactivated and re-purposed to support the Large Sodium Fire Facility (LSFF). The LSFF (sitecode 122-DR-1) was a RCRA TSD. Most of the components of the reactor exhaust system have two entries in the WIDS database, one representing the CERCLA (radioactive) contaminants and the other representing the RCRA hazardous chemical contaminants.

The portions of the LSFF TSD that are included in this remedial activity are the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the underground exhaust tunnel (122-DR-1:2), the 119-DR Exhaust sample building (100-D-64), two dry wells (100-D-23 and 100-D-54) and the 116-DR Exhaust Stack (132-DR-2/122-DR-1:5) Four of the seven 122-DR-1 subsites (122-DR-1:1, 122-DR-1:3, 122-DR-1:6 and 122-DR-1:7) were closed out under the 105-DR Large Sodium Fire Facility RCRA Closure Plan (LSFF Closure Plan) are were not discussed in the CVP-2003-00018 Cleanup Verification Package.

The remedial objective for the structures was to remove each structure to a minimum of 0.9 meters (3 feet) below surface grade. In July 2003, remedial/removal action activities removed the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the downstream (post-filter) tunnel and the additional 0.9 meters (3 ft) of the 116-DR Reactor Exhaust Stack (132-DR-2/122-DR-1:5). The aboveground portion of the 132-DR stack had been demolished in 1999.

Large Sodium Fire Facility (LSFF) subsite 122-D-1:2 (underground tunnel between the 105-DR Building) and the 117-DR Exhaust Filter Building were entirely removed. The 315 and 316 exhaust plenums, (aka upper and lower exhaust tunnels) are also associated with the 122-D-1:2 subsite. The upper exhaust tunnel and approximately the top 0.9 meters (3 ft) of the lower exhaust tunnel were removed. The 119-DR Exhaust Stack Sampling Building and two stack sampling building dry wells (100-D-23 and 100-D-64) were also demolished and excavated as part of the remedial/removal action activities in July 2003.
At the completion of the remedial action, the total excavation was approximately 1,010 square meters (10,872 square feet) in area with an approximate depth of 5 meters (16.4 feet). **Description:** The RCRA TSD component was clean closed. The facility RCRA closure plan divided the facility into seven areas for sampling and closure purposes. The seven areas became subsites of the 122-DR-1 WIDS site. Prior to RCRA closure, subsites 122-DR-1:2, 122-DR-2:4, and 122-DR-1:5 had been reclassified as Interim Closed Out under CERCLA. The reclassification status for these subsites was changed to Closed Out to be consistent with the reclassification of the main site. The CERCLA remediation for this subsite is documented in WIDS sitecode 132-DR-2.

Area 5 consisted of the reactor exhaust stack. Over the life of the Large Sodium Fire Facility (LSFF) there were two routes for exhaust to take before entering the reactor exhaust stack. The first route was through the HEPA filters which had a 99.95 percent efficiency rating. The second route was through the submerged gravel scrubber which had an efficiency rating of approximately 99 percent. It was expected that there were no measurable deposits of residue from LSFF operation within the stack. This subsite (116-DR Reactor Exhaust Stack) is also documented in Waste Information Data System (WIDS) as sitecode (132-DR-2).

**Closure Info:** Note - The 105-DR reactor operated between 1950 and 1964 for plutonium production. In 1973, the exhaust system portions of the 105-DR reactor were reactivated and re-purposed to support the Large Sodium Fire Facility (LSFF). The LSFF (sitecode 122-DR-1) was a RCRA TSD. Most of the components of the reactor exhaust system have two entries in the WIDS database, one representing the CERCLA (radioactive) contaminants and the other representing the RCRA hazardous chemical contaminants.

The portions of the LSFF TSD that are included in this remedial activity are the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the underground exhaust tunnel (122-DR-1:2), the 119-DR Exhaust sample building (100-D-64), two dry wells (100-D-23 and 100-D-54) and the 116-DR Exhaust Stack (132-DR-2/122-DR-1:5) Four of the seven 122-DR-1 subsites (122-DR-1:1, 122-DR-1:3, 122-DR-1:6 and 122-DR-1:7) were closed out under the 105-DR Large Sodium Fire Facility RCRA Closure Plan (LSFF Closure Plan) are were not discussed in the CVP-2003-00018 Cleanup Verification Package.

The remedial objective for the structures was to remove each structure to a minimum of 0.9 meters (3 feet) below surface grade. In July 2003, remedial/removal action activities removed the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the downstream (post-filter) tunnel and the additional 0.9 meters (3 ft) of the 116-DR Reactor Exhaust Stack (132-DR-2/122-DR-1:5). The aboveground portion of the 132-DR stack had been demolished in 1999.

Large Sodium Fire Facility (LSFF) subsite 122-D-1:2 (underground tunnel between the 105-D-
DR Building) and the 117-DR Exhaust Filter Building were entirely removed. The 315 and 316 exhaust plenums, (aka upper and lower exhaust tunnels) are also associated with the 122-D-1:2 subsite. The upper exhaust tunnel and approximately the top 0.9 meters (3 ft) of the lower exhaust tunnel were removed. The 119-DR Exhaust Stack Sampling Building and two stack sampling building dry wells (100-D-23 and 100-D-64) were also demolished and excavated as part of the remedial/removal action activities in July 2003.

At the completion of the remedial action, the total excavation was approximately 1,010 square meters (10,872 square feet) in area with an approximate depth of 5 meters (16.4 feet). Approximately 14,011 metric tons (15,412 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

**Type:** Laboratory  
**Status:** Inactive  
**Description:** The RCRA TSD component was clean closed. The facility RCRA closure plan divided the facility into seven areas for sampling and closure purposes. The seven areas became subsites of the 122-DR-1 WIDS site.  
Area 6 consists of the 116-DR-8 Crib meeting RCRA requirements. The crib was originally used from 1960 to 1964 to percolate low-level waste drainage from the 117-DR Building seal pits. When used for the Large Sodium Fire Facility (LSFF), the 116-DR-8 Crib received only water reported not to have been corrosive (the pH level was less than 12.5). This area is considered closed for the purposes of Washington Administrative Code (WAC) 173-303-610. Any contamination associated with Area 6 will be remediated in accordance with the 100-HR-3 RFI/CMS process.  
The 117-DR Seal Pit Crib is documented in WIDS as two separate sites. The first site, 122-DR-1:6, is part the Large Sodium Fire Facility associated with a RCRA TSD. The RCRA permit has been closed for hazardous/dangerous constituents. The second site, 116-DR-8, represents the radioactive constituents remaining at the site that were addressed under CERCLA.  
**Location:** The unit is located south of the exclusion area fence and directly east of the 118-DR-1 Burial Ground.

**The SubSite is Part Of:**

</tbody>
</table>

**Code:** 122-DR-1:7  
**Classification:** Accepted  
**Reclassification:** Closed Out (10/1/1996)  
**Type:** Laboratory  
**Start Date:**
The RCRA TSD component was clean closed. The facility RCRA closure plan divided the facility into seven areas for sampling and closure purposes. The seven areas became subsites of the 122-DR-1 WIDS site.

Area 7 consists of the area to the north and west of the 117-DR HEPA filter building. The burn pans used in the alkali metal fires were sometimes stored in this area. Six soil samples, three random and three authoritative, were collected for this site. The samples were number B0G979 through B0G984. All samples were well below the Hanford Site background 95% thresholds for both lithium and sodium in soil (see WHC-SD-EN-TI-307 for sample results). The area was clean closed.

Location: Area 7 consists of the area to the north and west of the 117-DR HEPA filter building.

The SubSite is Part Of:
Code: 122-DR-1
Names: 122-DR-1; LSFF; 100-D-51; 105-DR Large Sodium Fire Facility; 105-DR Sodium Fire Facility

Code: 132-DR-2
Names: 132-DR-2; 116-DR Reactor Exhaust Stack
Type: Stack
Status: Inactive

Description: The site has been remediated and Interim Closed Out for CERCLA. The RCRA Large Sodium Fire Facility (LSFF) Closure Plan deferred the remaining three (LSFF) TSD subsites (122-DR-1:2, 122-DR-1:4, and 122-DR-1:5) to the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) process. This waste site represents the CERCLA evaluation for 122-DR-1:5. The stack has been demolished. The unit was a monolithic, reinforced concrete structure with a maximum wall thickness of 0.46 meter (1.5 feet) at the base. It rested on a double octagon-shaped base that extended 5.3 meters (17.5 feet) below grade. An opening at the base provided access to its interior portion. This opening was fitted with a steel door.

132-DR-2 is also included in WIDS as subsite 122-DR-1:5 to document the RCRA component closure. The reclassification status for these subsites was changed to Closed Out to be consistent with the reclassification of the main site.

Location: The unit was located on the south side of the 105-DR Building.

Related Sites/Structures: Originally, 105-DR exhaust air flowed directly from the 105-DR to the exhaust stack. Following completion of the confinement project in 1960, the exhaust air was diverted to the 117-DR Filter Building, via underground ducts, prior to release through the stack.

Process Description: The 116 Reactor Exhaust Stacks were used to exhaust confinement air that originated from the work areas in the 105 Reactor Buildings. This stack was later reactivated to support exhausted emissions from the 105-DR Large Sodium Fire Facility operations.

Waste Type: Chemicals

Waste Description: Until 1964 the unit discharged exhaust air from the 105-DR Building. Since 1972, the unit was used to support operations relating to the 105-DR Large Sodium Fire Facility (122-DR-1). The interior of the unit contains an unknown quantity of low-level radioactive materials.

Closure Info: Note - The 105-DR reactor operated between 1950 and 1964 for plutonium production.
1973, the exhaust system portions of the 105-DR reactor were reactivated and re-purposed to support the Large Sodium Fire Facility (LSFF). The LSFF (sitecode 122-DR-1) was a RCRA TSD. Most of the components of the reactor exhaust system have two entries in the WIDS database, one representing the CERCLA (radioactive) contaminants and the other representing the RCRA hazardous chemical contaminants.

The portions of the LSFF TSD that are included in this remedial activity are the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the underground exhaust tunnel (122-DR-1:2), the 119-DR Exhaust sample building (100-D-64), two dry wells (100-D-23 and 100-D-54) and the 116-DR Exhaust Stack (132-DR-2/122-DR-1:5) Four of the seven 122-DR-1 subsites (122-DR-1:1, 122-DR-1:3, 122-DR-1:6 and 122-DR-1:7) were closed out under the 105-DR Large Sodium Fire Facility RCRA Closure Plan (LSFF Closure Plan) are not discussed in the CVP-2003-00018 Cleanup Verification Package.

The remedial objective for the structures was to remove each structure to a minimum of 0.9 meters (3 feet) below surface grade. In July 2003, remedial/removal action activities removed the 117-DR Exhaust Filter Building (100-D-53/122-DR-1:4), the downstream (post-filter) tunnel and the additional 0.9 meters (3 ft) of the 116-DR Reactor Exhaust Stack (132-DR-2/122-DR-1:5). The aboveground portion of the 132-DR stack had been demolished in 1999.

Large Sodium Fire Facility (LSFF) subsite 122-D-1:2 (underground tunnel between the 105-DR Building) and the 117-DR Exhaust Filter Building were entirely removed. The 315 and 316 exhaust plenums, (aka upper and lower exhaust tunnels) are also associated with the 122-D-1:2 subsite. The upper exhaust tunnel and approximately the top 0.9 meters (3 ft) of the lower exhaust tunnel were removed. The 119-DR Exhaust Stack Sampling Building and two stack sampling building dry wells (100-D-23 and 100-D-64) were also demolished and excavated as part of the remedial/removal action activities in July 2003.

At the completion of the remedial action, the total excavation was approximately 1,010 square meters (10,872 square feet) in area with an approximate depth of 5 meters (16.4 feet). Approximately 14,011 metric tons (15,412 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

**Description:** The site is a depression surrounded by a post and chain barricade with warning signs stating "DANGER, KEEP AWAY." The surface of the depression is grass-covered. The site may be the location of a valve box along the raw water line that went from 190-C to the Pump House for the Radiological Science Laboratory Building and the Grazing Plot. During the April 1999 visit, metal and wooden stakes were observed on the ground and a soil gas probe was visible.

**Location:** The depression is approximately 91 meters (300 feet) southwest of the 100-FR-2 Vent Pipe and 30.5 meters (100 feet) north of the northwest corner of 118-F-1 Burial Ground.

**Related Sites/Structures:** The site was probably related to the 190-C Building, the Radiological Science Laboratory Building and the Grazing Plot.

**Description:** The GPR survey correlates fairly well with drawing SK-1-2847, High Purity Water System for 100F Biology. A raw water line tees from the raw water exiting from 190-C, goes south along the outside edge of the 105-F exclusion area fence, along the railroad track and above the north edge of the 118-F-1 Burial Ground and over to a pump house that supplied water to the
Radiological Science Laboratory Building and Grazing Plot. According to the Technical Baseline Document, WHC-SD-EN-TI-169, the Grazing Plot (10-acres) was used to pasture pregnant animals and animals too young for experiments. The document goes on to state that no contaminants are known to exist at this location.

### Code: 100-F-8

**Classification:** Accepted

**Names:** 100-F-8; French Drains Near 105-F Gate

**Type:** French Drain

**Status:** Inactive

**Description:** The two french drains are constructed of 91 centimeter (36 inch) concrete pipe of unknown length buried to a depth which places their upper surfaces a few inches above grade. An excavation permit was issued in September 2010 for the removal of the two 100-F-8 French drains (DAN-4018-1A). A sample was taken to support development of an ERDF profile for disposal of removed material. The French drains have been excavated and backfilled.

**Location:** The french drains are near the main (north) entrance gate to the 105-F Reactor Building security fence. The first drain is about 22.9 meters (75 feet) south of the gate and the second is in line with the first and about 7.6 meters (25 feet) further south.

**Waste Type:** Demolition and Inert Waste

### Code: 100-F-17

**Classification:** Not Accepted

**Names:** 100-F-17; 108-F Chemical Pump House; Chemical Storage Tanks at 108-F; Chemicals Used at 108-F Building

**Type:** Storage Tank

**Status:** Inactive

**Description:** The Pump House and storage tanks have been removed. The site was a four story steel framed building with concrete block walls, concrete foundation and floors, and a concrete tile roof with a tar and gravel surface. The entire building was in poor condition. The chemical storage tanks that were originally located on the west side of the building have been removed. A loading dock extends from the south end of the east wall. A gas dock is attached to the south end of the building. Abandoned equipment and debris is scattered around the southwest corner of the building.

**Location:** The 108-F building is located approximately 100 meters (330 feet) east of the 105-F Reactor Building.

**Process Description:** The 108-F was originally built to be used as a chemical pump house to hold and pump various chemicals needed in reactor water treatment and reactor purging (internal cleansing). It contained many holding and mixing tanks and pumps, along with storage bins for dry materials, conveyor systems, hoppers, and power shovels. Shortly after the F Reactor began operation, it was determined that such treatment would not be required and cooling water treatment could be performed elsewhere in the systems. The 108-F building was then converted to be used as a biological laboratory where the effects of radiation and contamination on plant and animal life were studied.

**Waste Type:** Oil

Names: 100-F-32; 1717-F Underground Fuel Oil Tanks

Type: Storage Tank

Status: Inactive

Description: The site is three underground fuel oil storage tanks. Each tank had a capacity of 94,625 liters (25,000 gallons). Each tank was 10.7 meters (35 feet) long and 2.4 meters (8 feet) in diameter. Pipelines ran to the 1717-F Building (Combined Shops) though a pump pit immediately east of the tanks.

Location: The three tanks are located approximately 33.5 meters (110 feet) west of 1717-F Building.

Related Sites/Structures: The site was related to 1717-F Building. The site is associated with 100-F-5, 1717-F Building Drywell.

---

Waste Description: Samples collected in April 2001 determined the surface ponds held only uncontaminated animal waste resulting from pen cleaning.

Names: 100-F-40; Animal Farm Surface Impoundment

Type: Surface Impoundment

Status: Inactive

Description: This site has been evaluated and reclassified to Rejected. It is a pair of impoundments and the associated ditches. They are no longer visible in the field. It was discovered on aerial photos from 1965 and consisted of two surface impoundments, one covered with tumbleweeds and the other new and unvegetated. The older impoundment had a slightly meandering ditch coming to the north end from the animal farm buildings. This ditch was dry in the September 1965 photo. A straight ditch, with water in it in the September 1965 photo, runs to the northern side of the northern impoundment, also coming from the same animal farm buildings.

Location: The impoundments are north of the 116-F-9 Trench and east of the animal farm. They are on the west side of, and adjacent to, the 100-F Area perimeter road. The approximate coordinates for the centroid of the impoundments are N147970/E5811115.

Waste Type: Sanitary Sewage

---

Waste Description: The site was divided into four subsites. All four subsites have been reclassified to Rejected. Therefore, the parent site is also Rejected.

Names: 100-F-41; 100-F Clean Water Pipelines; 100-F Service Water Pipelines

Type: Product Piping

Status: Inactive

Description: The site was divided into four subsites. All four subsites have been reclassified to Rejected. Therefore, the parent site is also Rejected.
The site included underground pipelines used to transport raw, fire, export, filtered, and sanitary water from the river pump house, to 100-F Area facilities, including the water treatment facilities and fire hydrants. This site does not include lines within buildings, process or septic sewer lines, chemical transfer pipelines, pipelines that carried water treated with sodium dichromate, or pipelines that were downstream from the reactor building, i.e., those lines that carried cooling water from the reactor to the retention basin, Lewis Canal and/or the river.

A total of four (4) major pipelines and (43) smaller pipelines were identified as being associated with the 100-F-41 Service Water Pipelines site.

**Location:**
The pipes were located across the 100-F Area, from the 181-F intake structure to the water treatment facilities, reactor (fire and potable water, not reactor cooling water), strontium gardens, south to the fire and patrol headquarters near the 1701-F gatehouse, west to join with the export water line from the 100-D Areas, and east to the animal farm area.

**Related Sites/Structures:**
The clean water and fire water pipelines ran to or near virtually all the facilities at the 100-F Area. Pipeline sites in the 100-F Area include 100-F-19, Process Effluent Pipelines; 100-F-26, Water Treatment Pipelines; the 100-F-39 river effluent lines; the 100-F-41 clean water pipelines; the 100-F-29 experimental animal farm pipelines and the 100-F-44 miscellaneous pipelines.

The other pipeline sites at the 100-F Area are 100-F-19 (Reactor Cooling Water Effluent); 100-F-26 (Water Treatment Plant Process Sewers); 100-F-29 (Experimental Animal Farm Process Sewers), and 100-F-39 (River Effluent Pipelines).

**Waste Type:** Not Specified

**Waste Description:** The waste is the old buried pipes from the clean water pipeline system. No Contaminants of Potential Concern (COPC's) are identified for underground water service lines. Asbestos-containing wrapping on underground water lines were determined to be neither a hazardous nor a dangerous material of construction (Unit Managers Meeting Minutes for July 2005).

**Code:** 100-F-41:1
**Names:** 100-F-41:1; North/South 4-Inch Steel Pipeline North of 183-F

**Classification:** Accepted
**Reclassification:** Rejected (2/8/2007)

**Type:** Product Piping
**Status:** Inactive

**Description:** The subsite has been reclassified to Rejected.

The subsite consisted of a north-south oriented, 10 centimeter (4 inch) steel pipeline segment of unknown length. It was approximately 0.6 meters (2 feet) below ground surface. It was
identified during an excavation for confirmatory sampling. The line was broken, when sampling was completed the steel pipe was returned to the test pit prior to backfilling with original material. The pipe had no insulation or wrapping of any kind. No samples were collected of the pipe or pipe interior. Drawing H-1-12436 shows a north-south 10 centimeter (4 inch) diameter Fire & Sanitary Water Line.

**Location:** The pipeline segment was north of the 183-F Filter Building and south of the 182-F Reservoir, and is defined by the following coordinates: N148161 E580436, N148152 E580436, N148152 E580483, and N148112 E580483.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The waste is the buried lines from the clean water pipeline system. These pipelines are not CERCLA hazardous waste.

**The SubSite is Part Of:**

**Code:** 100-F-41

**Names:** 100-F-41; 100-F Clean Water Pipelines; 100-F Service Water Pipelines
Description: The subsite has been reclassified to Rejected.

During excavation at the 100-F-26:9 sanitary sewers for collection of confirmatory samples, a north-south oriented, 10 centimeter (4 inch) pipeline was discovered approximately 1.2 meters (4 feet) below ground surface. It was intact and had no insulation or wrapping.

Construction drawing H-1-14562 showed a 7.6 centimeter (3 inch) sanitary water line trending south to north 3 meters west of the junction box sampling location. No depth was indicated on the drawing. The 1.1 centimeter (3 inch) sanitary water line shown on the construction drawing was within 1 meter of the estimated location of the discovered pipe. No reference to pipe diameter was documented to explain the size discrepancy indicated between logbook and the drawing. The discrepancy in pipeline size between the historic drawing and field observations was attributed to erroneous field measurements or the use of a larger diameter pipeline during construction.

Location: The 100-F-41:3 pipeline was located east of the south corner of the 1704-F building beginning at coordinates N147793/E580672, and continuing to N147793/E580675 and N147783/E580675.

Waste Type: Sanitary Sewage

Waste Description: The waste is the buried lines from the clean water pipeline system. These pipelines are not CERCLA hazardous waste.

The SubSite is Part Of:

Code: 100-F-41
Names: 100-F-41; 100-F Clean Water Pipelines; 100-F Service Water Pipelines

Code: 100-F-41:4
Names: 100-F-41:4; East/West 4-Inch Steel Pipeline at West End of 115-F
Type: Product Piping
Status: Inactive
Classification: Accepted
Reclassification: Rejected (2/8/2007)

Description: The subsite consists of an east-west oriented, 10 centimeter (4 inch) steel pipeline approximately 1 meter (3 feet) below ground surface. The segment was identified during an excavation for confirmatory sampling. The steel pipe appeared to have no insulation or wrapping of any type. No samples were taken from the pipe. The pipe was left intact and the test pit was backfilled with the removed material.

Construction drawing H-1-12367 shows a cast iron (CI) fire and sanitary water line near the location of the discovered pipeline. BHI-01504 indicates a 10 centimeter (4 inch) cast iron service water pipe exits the west side of the 115-F Building.

Location: It is located at the west end of the 115-F Building beginning at N147582/E580314, and continuing to N147582/E580299 and N147643/E580299.

Waste Type: Water

Waste Description: The waste is the buried lines from the clean water pipeline system. These pipelines are not CERCLA hazardous waste.

The SubSite is Part Of:

| Status:    | Inactive                          | End Date:                         |                                                               |
| Description:| The facility was evaluated and determined not to meet the criteria of a waste site. The site was a laboratory that was part of the Experimental Animal Farm. The building has been demolished. It was a rectangular one-story, 302 square meter (3,250 square foot), concrete block building. The building contained an office, laboratories, and indoor and outdoor animal runs. |

During the April 1999 visit, a survey grade GPS was used to locate the site using its mapped coordinates. A wooden stake was found in the ground at those coordinates. No evidence of the

Hanford Site Waste Management Units Report
February 2015

1711
site was found. However, the area had been disturbed by heavy equipment, concrete chunks were visible and vegetation was sparse.

**Location:** The building was located south of the 141-F (132-F-1) sheep barn and east of the 141-C hog barn.

**Related Sites/Structures:** Effluent from the lab site went to the 100-F-31 Septic System, south of the building.

**Process Description:** The laboratory was used for particulate exposure experiments and for a series of studies on the effects of ionizing radiation on dogs. Between 300 and 400 beagles were housed at the nearby dog kennels during the studies. The primary isotopes used for the dog studies were plutonium-239 and radium-226.

</table>
**Description:** The salt dissolving pits and brine pump pit were part of a single below-grade concrete structure that provided brine for the 184-H Powerhouse. No evidence of the structure can be seen today. The salt dissolving pits each had inner dimensions of 4.3 meters (14 feet) long by 2.4 meters (8 feet) wide by 2.8 meters (9.25 feet) tall. They had a design high water line 2.4 meters (7.75 feet) from the pit bottom. An overflow slot that connected the two dissolving pits was located 0.3 meters (1 foot) above the high water line. The bottom of each pit was filled with a 12.7 centimeter (5 inch) layer of 1.3 to 2.6 centimeter (1/2 to 1 inch) gravel topped by a 17.8 centimeter (7 inch) layer of 0.3 to 0.6 centimeter (1/8 to 1/4 inch) gravel. The dissolving pits each had a 2.4 meter (8 feet) by 0.9 meter (3 feet) opening at the top for receiving salt. Each pit had a capacity of 23,600 kilograms (52,000 pounds) of salt. The brine pump pit is located adjacent to the two salt dissolving pits. The pit was 3.3 meters (10.67 feet) long by 2.2 meters (7.33 feet) wide by 2.1 meters (7 feet) deep. It held two pumps and associated piping (all brass) for the brine system. The floor of the pump pit sloped toward a 46 by 46 by 46 centimeters (18 by 18 by 18 inches) sump in a corner. A sump pump discharged to a nearby french drain (100-H-32).

**Location:** The site is located south of 184-H and just north of the railroad tracks.

**Related Sites/Structures:** The site is associated with 184-H Power House and the 100-H-32 French Drain.

**Process Description:** The brine was used to regenerate the zeolite ion exchange demineralizers that were part of the powerhouse water treatment system.

**Waste Type:** Ordnance

**Waste Description:** The site was probably demolished in place. No documentation has been located related to cleanup. It is not known if salt cake was left in the structure.
### Status: Inactive
### End Date:

**Description:**
There are no posted areas related to this site.

**Location:**
Affected areas included 100-H and parts of the 600 Area to the west and south. Figure 4 in HW-54636 shows the particulate density within the 100-H Area. Figure 5 in HW-54636 has a larger scale and shows the particulate density over the greater area.

**Release Description:**
On November 1, 1955, a ruptured slug burned briefly during discharge from the reactor. Approximately 0.8 curie of filterable gross beta contamination, mostly barium and rare earth plus yttrium, was emitted from the 105-H stack. The south one-third portion of the 100-H Area was found contaminated with concentrations as high as 12 particles per 9.3 square meters (100 square feet). The contamination level was 1,000 to 10,000 counts/minutes, with isolated particles as high as 1 100 millirads/hour. One particle, found near the 100-H Gatehouse, had a dose rate of 700 millirads/hour. The contamination was found to have spread south of 100-H Area, covering an area of approximately 18.1 square kilometers (7 square miles).

**Waste Type:** Asbestos (friable)

**Waste Description:**
The waste consisted of airborne radioactive particulates released through the 105-H stack.

**Description:**
There are no posted areas related to this release.

**Location:**
The release contaminated an area extending from around the 100-H water tower over a flight path toward the White Bluffs. Figure 6 in HW-54636 shows the levels of contamination that were detected within the 100-H Area.

**Release Description:**
After isolated cases of personnel and vehicle contamination were detected on May 15, 1956, it was discovered that swallows were making nests out of contaminated mud taken from the 107-H Liquid Waste Disposal Trench. The contaminated mud was being dropped around the 100-H water towers and at scattered locations over the flight path to the White Bluffs across the Columbia River. Concentrations ranged from 0 to 6 particles per 9.3 square meters (100 square feet), with a maximum recorded reading of 150 millirads/hour.

**Related Sites/Structures:**
The release is related to the 107-H Liquid Waste Disposal Trench (116-H-1) and the 100-H Water Towers.

**Waste Type:** Demolition and Inert Waste

**Waste Description:**
The 107-H Liquid Waste Disposal Trench received highly contaminated cooling water from the 107-H Retention Basin. The mud used by the swallows would have contained radioactive contamination from fuel element rupture.

**Names:**
- 100-H-32; 184-H Brine Pit French Drain

**Type:** French Drain

**Status:** Inactive

**Description:** There is no visual evidence of a french drain at this location. It was likely removed with the associated brine pit (100-H-16).

**Location:** The french drain site was located on the northeast corner of the 184-H Brine Pit (100-H-16), west of the 184-H Power House.

**Related Sites/Structures:** This site is associated with the 100-H-16 Brine Pit.

**Process Description:** The site is a french drain that received sump drainage from the 184-H Brine Pit (100-H-16). The drain was constructed of 61-centimeter (24-inch) diameter pipe. The french drain was not visible in the field during investigations for the 100-H Area Technical Baseline Report (BHI-00175). The french drain would have received only brine water.

**Waste Type:** Water

**Waste Description:** The french drain received any water or brine that collected in the 184-H Brine Pit Sump. The liquid would be expected to have contained high concentrations of sodium chloride (salt).

<td>100-H-39</td>
<td>Accepted</td>
<td>Rejected (5/3/2010)</td>
</tr>
</tbody>
</table>

**Names:**
- 100-H-39; Orphan Site H-007; Possible Thimble Pit Locations; Potential Thimble Burial Site

**Type:** Trench

**Start Date:**
inactive

Description: The waste site was reclassified to Rejected because it could not be definitively located. The four potential thimble pit or trench locations were evaluated with geophysical surveys and test pit excavations.

Location: Four potential burial sites were determined from document and photographic research. Location one is at Ground position system (GPS) coordinates E577777, N152214 (north end); E577783, N152175 (south end); E577790, N152196 (east side). The west side is the railroad tracks. Location two is approximate coordinates E577752.8, N152287.5 and E577752.8, N152257.0. Location three is coordinates E577758, N152188. Location four is the north and south centroid coordinates of the trench - E577737.6, N152458.9 and E577737.3, N152433.

Related Sites/ Structures: This potential thimble burial site is associated with 118-H-5, 118-H-6:5 and 100-H-2.

Process Description: Historical documents indicate areas that may have been used to bury thimbles or materials related to the removal of thimbles in 100-H Area.

Waste Type: Process Effluent

Waste Description: Radioactive Thimbles may be buried at these locations. The 100-H-2 waste site is an analogous site. There are two types of radioactive waste associated with Thimbles; neutron activated steel and aluminum material containing cobalt-60 and surface contaminated waste primarily with zinc-65.

Code: 100-H-47
Names: 100-H-47; 1717-H Geophysical Anomaly; Orphan Site H-015; Possible UST
Type: Unplanned Release
Status: Inactive

Description: This waste site is an anomaly found during a geophysical investigation. It is possibly an underground propane tank (shown on drawing SK-1-7326) associated with the demolished 1717-H building.

Location: The underground anomaly is located approximately 6 meters (20 feet) to east of the former site of the 1717-H building. The coordinates of the feature are E578008.5, N152616.5.

Related Sites/ Structures: The (potential) underground tank is associated with the 1717-H building.

Process Description: The 1717-H building was a maintenance shop and hot shop (see sitecode 100-H-4).

Code: 100-H-55
Names: 100-H-55; Cast Iron Pipe
Type: Unplanned Release
Status: Inactive

Description: The site has been evaluated and found to be a valve access can not a pipe. Originally, this feature was reported to be a 20 cm (8 in) diameter cast iron pipe protruding 30 cm (12 in) from the ground at an angle (08082007-038-630). The pipe was discovered during an Orphan Sites
Field Evaluation conducted in August of 2007 (EL-1628 p. 2). Geophysics was conducted in February 2009, and the results indicate that the visible segment of the 20 cm (8 in) diameter cast iron pipe is not part of an intact system (0596705). The pipe extends under the road at a depth of 0.8 m (2.6 ft) and terminates at the edge of the other side of the road.

**Location:** The site is located northwest of the 105-H Reactor and approximately 0.2 miles downstream of river mile post #14. The site is bordered by paved and dirt roads. The site is also located in the vicinity of accepted WIDS site 600-151 (Military Dumping Area) and 600-152 (Military Septic Tanks).

**Process Description:** The process associated with this pipe is unknown. The pipe may have been related to pre-Hanford homestead activities or associated with the former military Base Camp 130 (BC 130).

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The waste consists of the pipe and underlying soil. Since the pipe can not be related to any particular human activity, the contaminants of potential concern are unknown.

---

**Code:** 116-H-6  
**Classification:** Accepted  
**Names:** 116-H-6; 183-H Solar Evaporation Basins  
**Reclassification:** Closed Out (5/13/1997)

**Type:** Retention Basin  
**Start Date:** 1/1/1949  
**End Date:** 1/1/1985

**Status:** Inactive  
**Description:** The four basins used for waste evaporation were completely demolished in the fall of 1996. The RCRA TSD permit was closed in May 1997. The site was backfilled and re-vegetated in the spring of 1997. Sitecode 100-H-33 is the 183-H Solar Evaporation Basins Radionuclide Components. It was evaluated and determined to be reclassified to No Action in 2012. The site was a concrete water storage and treatment basin divided into four sections. Each section was subdivided into a deep subsidence basin and a shallow flocculation basin.

**Location:** The basins were located north of the 105-H Reactor and north of the east 183-H Clearwell (WIDS Site 126-H-2).

**Related Sites/Structures:** Sitecode 100-H-33 is the 183-H Solar Evaporation Basins Radionuclide Components.

**Process Description:** The basins were constructed in 1949 and used for 100-H Area water treatment until the mid-1960's. Most of the water treatment structures, including 12 additional adjoining basins were demolished in 1974. The four remaining basins were inactive until July 1973, when radioactive and dangerous (mixed) waste from the 300 Area fuel fabrication facilities began to be shipped to the basins for storage and treatment. The last shipment of waste to the basins took place on November 8, 1985. As of September 1988, all the remaining sludge materials had been removed from each basin. During 1988 and 1989, Basin Number 1 and 4 were partially decontaminated by wet sandblasting. From June to December 1989, the remaining liquid wastes in Basins Number 2 and 3 had been removed and solidified into 208 liter (55 gallon) drums and transported to the 200 West Area Central Waste Complex, Retrievable Waste Storage Facility.

The water treatment basins received a maximum of approximately 1.5E+06 liters (400,000 gallons) of waste a year. The basins had a tank treatment design capacity of 2,650 liters (700 gallons) per day treated by evaporation and a tank storage design capacity of 8.2E+06 liters (2.2E+06 gallons), a collective value representing all four basins.

**Waste Type:** Chemicals
Waste Description: The facility received routine and nonroutine wastes. The routine wastes consisted of spent acid etch solutions (primarily nitric, sulfuric, hydrofluoric, and chromic acids) generated by the Nuclear Fuel Fabrication process. These acidic solutions were reacted with excess sodium hydroxide before being transported to the 183-H Basins. Metal constituents include copper, silicon, zirconium, nickel, aluminum, chromium, manganese, and uranium, which were in the form of precipitates. Nonroutine wastes consisted of unused chemicals and spent solutions from miscellaneous processes. The waste has been designated an Extremely Hazardous Waste (EHW) because of toxicity, waste code (WT01). The basins also received various nonradioactive waste (listed discarded chemical products), resulting in designation for cyanide (P030), vanadium pentoxide (P120), and formic acid (U123). Additionally, Basin #2 was designated EP Toxic because of the presence of chromium (D007). More detailed descriptions of these wastes and quantities are contained in DOE/RL 88-04, Interim Status Closure/Post-Closure Plan 183-H Solar Evaporation Basins.

Closure Info: The 116-H-6 basins structures were remediated in late 1995 and 1996. All detectable contamination was removed, packaged and disposed. The contaminated surface of the concrete was scabbled and disposed. The remaining concrete was surveyed. The rubble was placed into the adjacent 183-H Clearwells. The residual radioactivity in the rubble was calculated with the RESRAD model. Clean closure of the basin waste site was not achieved due to levels of fluoride and nitrate remaining in the soil below the excavated 6.1 meters (20 feet). The levels were determined to be above the Method B cleanup levels of the Model Toxics Control Act (MTCA), Washington Administrative Code (WAC) 173-340. Therefore, the RCRA unit was closed under the partial closure option, with specified remedial measures provided under post closure care. The modified closure certification was accepted by the State of Washington Department of Ecology on May 13, 1997. The site was backfilled and revegetated in the spring of 1997.

Remedial measures included the placing of a vapor barrier at the bottom of the excavation and replacing the excavated soils with clean, compacted backfill. Post closure groundwater monitoring will continue at the unit under WAC 175-303-645 final status permit, compliance monitoring program. Corrective actions for the contaminated groundwater attributable to 183-H will be coordinated with remedial actions for the 100-HR-3 operable unit pursuant to CERCLA.

The footprint of the basins was released from radiological posting after 0.6 meters (2 feet) of soil was removed. Chemical contaminants were identified and removed to a maximum depth of 6.1 meters (20 feet).

Three boreholes were drilled through the site in 1991. Borehole C7860 (199-H4-84) was drilled in the waste site footprint in February 2011 as part of the Remedial Investigation. Strontium-90, Tc-99 and tritium were detected above background levels.

Reclassification form 99-124 was created to document the TSD closure, with the 1997 Ecology Acceptance of Certification Closeout letter attached.

<tr>
<td>Description:</td>
<td>The 126-H-1 site is a large ash disposal pit and ash pile. The ash pit is approximately 76.2 meters (250 feet) long, 76.2 meters (250 feet) wide and 3.7 meters (12 feet) deep. The pit is divided into two parts by a 2.4 meter (8 foot) berm that runs east to west. The floor of the ash pit is...</td>
</tr>
</tbody>
</table>
pit is evenly covered with ash and cinder. Some light vegetation is evident. An ash pile is located just south of the pit. The pile measures approximately 25 meters (82.0 feet) by 60 meters (196.9 feet).

**Location:** The site is located northwest of the 105-H Reactor and west of the where the 184-H Powerhouse was located.

**Process Description:** Coal ash from the 184-H powerhouse was mixed with raw river water and sluiced in slurry to the ash pit via a 20 centimeter (8 inch) steel pipeline.

**Waste Type:** Equipment

**Waste Description:** Unknown amounts of coal ash were sluiced to the pit with raw river water. Ash from other Hanford ash pits has been analyzed using the EP Toxicity Test in accordance with WAC 173-303, and no hazardous materials were found.

---

**Code:** 100-K-2

**Classification:** Accepted

**Names:** 100-K-2; 118-K-2; 118-K-2 Sludge Burial Ground; Burial Area

**Type:** Burial Ground

**Status:** Inactive

**Description:** The site consists of a suspected sludge burial ground. The size of the trench was unknown. Over time, historical documentation has indicated different locations on several sketch type drawings for the burial ground.

**Location:** The site is located east of the 107-KE Retention Basins, between the 107-KE Retention Basins and the 100-K Perimeter Road.

**Related Sites/Structures:** The site was related to the 107-KE and 107-KW Retention Basins.

**Process Description:** The site is a burial ground that was used to dispose of sludge from the 116-KE-4 (107-KE) and 116-KW-3 (107-KW) Retention Basins.

**Waste Type:** Sanitary Sewage

**Waste Description:** The site is described as having received sludge from the retention basins (107-KE and 107-KW). Although an exact inventory for this sludge trench is not available, it is analogous to the 107-B retention basin sludge trench (116-B-14). Characterization done at the 107-B trench in 1978 found an average concentration of plutonium of 0.7 picocuries per gram and an average beta/gamma concentration of 240 picocuries per gram. The expected radionuclides include europium-155, cobalt-60, cesium-137, strontium-90 and nickel-63. Note: DOE/RL-94-61 Appendix K (Draft A), mistakenly lists the average plutonium concentration for the 107-B Sludge Trench (116-B-14) as 0.7 curies per gram. The original report for this sampling activity lists the value as 0.7 picocuries per gram (see UNI-946, page 2-36).

_Hanford Site Waste Management Units Report_

February 2015
Description: The site was two carbon steel underground (positioned horizontally) ethylene glycol storage tanks. Both tanks were excavated and removed for reuse in June of 1994. All piping was blanked at the foundation of the 165-KW Building and exterior piping from the foundation of the building to the tanks was removed. Process knowledge from the excavation of the glycol tank at the 165-KW (August of 1993) indicated that the piping needed to be removed in order to remove the tanks. There was no evidence in the soil of a leak and the tanks appeared to be intact. One tank contained pure ethylene glycol and the other tank contained a mixture of water and ethylene glycol. The tanks supplied mixed and pure ethylene glycol for injection into process water pipelines to prevent freezing during cold periods. A pair of 10 centimeters (4 inches) fill pipelines led to a street box that contained a 10 centimeters (4 inches) cap. The street box was used for making a connection to railroad tank cars. The street box was just off the edge of a railroad spur.

Today, the site is gravel covered and no evidence of the site remains.

Location: The unit was located directly north of the 165-KE Building, adjacent to the 165-KE Building, and west of the personnel entry door.

Related Sites/Structures: The site was related to the 165-KE Building, the 116-KE-5 (150-KE Heat Recovery Station), and process pipelines.

Waste Type: Equipment

Waste Description: The waste was tanks that contained ethylene glycol.

Description: The site was two carbon steel underground (positioned horizontally) ethylene glycol storage tanks. Both tanks were excavated and removed for reuse on August 16, 1993. All piping was blanked at the foundation of the 165-KW Building and exterior piping from the foundation of the building to the tanks was removed. Process knowledge from the excavation of the glycol tanks at the 165-KW indicated that the piping needed to be removed in order to remove the tanks. There was no evidence in the soil of a leak and the tanks appeared to be intact. One tank contained pure ethylene glycol and the other tank contained a mixture of water and ethylene glycol. The tanks supplied mixed and pure ethylene glycol for injection into process water pipelines to prevent freezing during cold periods. A pair of 10 centimeters (4 inches) fill pipelines led to a street box that contained a 10 centimeters (4 inches) cap. The street box was used for making a connection to railroad tank cars. The street box was just off the edge of a railroad spur.

All piping associated with these tanks utilized welded joints with threaded couplings at the top of each tank. The pipelines related to these tanks were: (1) suction line -- 2.54 centimeters (1 inch) outside diameter by 6.1 meters (20 feet) to the building; (2) -- 10.2 centimeters (4 inches) outside diameter by 6.1 meters (20 feet) to the building (165-KW-E [east] tank only); (3) vent line -- 10.2 centimeters (4 inches) outside diameter by 9.1 meters (30 feet) (including the above ground components); (4) fill connection and street box -- 10.2 centimeters (4 inches) outside diameter by 4.6 meters (15 feet) long (empty during normal operation); (5) cross tie line -- 10.2 centimeters (4 inches) by 3.05 meters (10 feet) long (empty during normal operation).
Today, the site is gravel covered and no evidence of the site remains.

**Location:** The unit was located 3.05 meters (10 feet) north of the 165-KW Building and west of the personnel entry door.

**Related Sites/Structures:** The site was related to 165-KW Building, 116-KW-4 (150-KW Heat Recovery Station) and process pipelines.

**Waste Type:** Soil

**Waste Description:** The waste was tanks that contained Ethylene glycol. The tanks had been rinsed and flushed during the shut down of the 105-KW Reactor and did not contain any fluid.

**Code:** 100-K-9  
**Classification:** Not Accepted  
**Reclassification:** None

**Names:** 100-K-9; 104-K Dry Well; 118-KE-2 French Drain (North)

**Type:** French Drain  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** The site was the northernmost of two french drains at the 118-KE-2 rod storage cave. The drain structure was removed during the 118-KE-2 remediation. The french drain was a 0.6 meters (2 feet) diameter steel pipe with a steel cover. It was gravel filled to grade and surrounded by a yellow wooden barricade. The steel cover was posted with a confined space sign. The adjacent area was covered with gravel and cobbles.

**Location:** The site is located 3.5 meters (11.5 feet) from the northwest side of the 118-KE-2, 105-KE Horizontal Control Rod Storage Cave.

**Related Sites/Structures:** The site is related to the 118-KE-2, 105-KE Horizontal Control Rod Storage Cave (118-KE-2 Thimble Cave) and 100-K-10.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The inlet to this french drain is between the two semi-circular steel pipes. It received stormwater that percolated down through the earth berm covering the caves.

code: 100-K-20
names: 100-K-20; 183-KW Sodium Silicate Storage Tank (West)
type: Foundation
status: Inactive
start date: 1/1/1955
end date: 1/1/1964
description: the site was the western-most of the above-ground vertical tanks that were used to store liquid sodium silicate. Initially, tank trucks supplied the chemical for the tanks. Estimating from procurement and construction drawings for the bauxite tank (Project CAI 105), the sodium silicate tanks were removed in 1964 or 1965. Following removal, the bagged dry powder form of the chemical was used. The grade-level concrete base remained following removal of the tanks. The west tank base (Sodium Silicate Tank #1) is occupied by a bauxite storage tower (silo) and transfer system.

location: the site is the western-most of two sodium silicate storage tanks that were located southeast of the 183-KW Head House and adjacent to the sulfuric acid tanks. The western-most tank was 10.7 meters (35 feet) southeast of the 183-KW Head House.

related sites/structures: the site was related to the 183-KW Head House.

process description: during the seasons of high water turbidity, activated silica solution was fed into the raw water as an aid in coagulation. The silica was activated by sulfuric acid and prepared in two open-top, flat-bottom cylindrical steel mixing tanks. Each tank was 3.5 meters (11.5 feet) in diameter and 3.35 meters (11 feet) high, and was capable of mixing a batch to supply one-half of the plant for three hours at maximum rate. The batch cycle was completely automatic and electrically controlled, with sequence operation initiated by float level. Components (sodium silicate, sulfuric acid and water), of the activated silica were measured by displacement type meters and quantities were controlled by impulse counters. After batching, the activated silica was transferred to one of four steel tanks provided within the building for storing the solution. Each tank was sized to supply one-half of the plant for five hours at maximum flow and maximum parts per million. From the storage tanks the activated silica was pumped through metering orifices before injection into the raw water stream. The quantity of activated silica injected was regulated by a control valve whose operation was calibrated so that the metered quantity was in proportion to raw water flow. HW-24800-103, Vol 2, Page 137 shows the process flow for the sodium silicate system.

waste type: chemicals
waste description: the unit stored sodium silicate. While the tanks were in use, the sodium silicate was purchased and stored in liquid form.

From the storage tanks the activated silica was pumped through metering orifices before injection into the raw water stream. The quantity of activated silica injected was regulated by a control valve whose operation was calibrated so that the metered quantity was in proportion to raw water flow. HW-24800-103, Vol 2, Page 137 shows the process flow for the sodium silicate system.

Waste Type: Chemicals
Waste Description: The unit stored sodium silicate. While the tanks were in use, the sodium silicate was purchased and stored in liquid form.

| Description     | The site was a single bauxite (aluminum oxide) above-ground storage tank (silo). The tank has been removed and disposed at ERDF. This tank is no longer in existence. The addition of the tank was part of a proposal to reduce water treatment costs by approximately $278,000 per year in the 183-KE and KW Buildings. Hanford document, HW-76926, is the engineering study that proposed replacing the existing liquid alum coagulant feed process with one which fed bauxite and sulfuric acid.

The tank was constructed on the site of the former Sodium Silicate #1 Tank. The tank had a capacity of 109,000 kilograms (240,000 pounds). One of the unused solution tanks, 45,400 kilograms (100,000 pounds) in capacity in the 183 Building (KE and KW) was converted to a bauxite feed bin. The feed bin was vented and equipped with a bag filter. The two silos (KE and KW) and the feed bin together provided approximately 33 days storage capacity. Other components of the system are listed below.

A pneumatic conveying system was provided that was equipped with cyclone separators to transfer bauxite from hopper cars or boxcars to the outside silos and from either silo to the feed bin inside the building. The bauxite was transferred intermittently from the silos to the feed bin and did not interfere with any rail car unloading. The system was sized to unload a rail car in a single work shift. Two dry feeders, including one spare, moved bauxite from the feed bin to a slurry mix tank. The spare feeder was included to eliminate the need to prepare slurry manually on a batch basis during maintenance shutdown of the other feeder.

A mix tank, with agitator, for slurring bauxite and water was a component of the system. Two pumps in parallel were used to transfer the slurry to reaction vessels.

Two parallel systems, each consisting of a glass-lined reaction vessel, with glass-lined pipe tie-ins; an eductor which took suction from the reaction vessel, adding dilution water; and a pump, in series with the eductor, discharged through the chlorine injection piping to the raw water headers. Glass-lined pipe was used between the reaction vessel and eductor, and plastic pipe between the eductors and injection piping. Acid was supplied to the reaction vessel, where it was mixed with the bauxite slurry by steam sparging, from an existing head tank by gravity feed. An exhaust system included a water scrubber to remove steam, air, and acid fumes from the reaction vessels.

Location: The unit was located 11.6 meters (38 feet) southeast of the 183-KW Head House and on the northwest portion of the original Sodium Silicate Tank concrete base.
The process description for the site is as follows:

**Process Description:**
The bauxite (hydrous aluminum oxide) in combination with sulfuric acid was used as a coagulant in the water treatment process. Mixing of the chemicals, water and sediment caused a gelatin-like flake (floc) to form. The water with the floc flowed from the Head House to the Sedimentation Basins where the flocs allowed to settle.

**Related Sites/Structures:**
The site was related to the 183-KW, (183.2) Flocculation and Sedimentation Basins and the (183.1) Head House.

**Waste Type:** Misc. Trash and Debris

**Waste Description:**
The tank was used to store dry bauxite (hydrous aluminum oxide or hydroxides with various impurities). The tank appears to have been emptied, although dry powder can be seen through the plexiglass cover indicating that no additional cleanup was performed. Bauxite is not listed in 40 CFR 302.4 as a hazardous substance and is not a CERCLA pollutant. No dangerous wastes or CERCLA hazardous substances, pollutants, or contaminants were stored or disposed of at this site.

**Code:** 100-K-28

**Names:** 100-K-28; 183-KE Bauxite Tank

**Type:** Storage Tank

**Status:** Inactive

**End Date:** 1/1/1972

**Classification:** Not Accepted

**Reclassification:** None

**Start Date:** 1/1/1966

Code: 100-K-39

Names: 100-K-39; 118-K-3 Filter Crib

Type: Crib

Status: Inactive

Description: The site was reported to be a crib. The first reference to a site identified as 118-K-3 Filter Crib was DOE/RL-90-20 (1992). In this document, it states that the site was used to dispose of demineralizer, and research and development waste from the 1706-KE Building. A sketch, Figure 5-1. Proposed Boring Locations at 100-KR-1 Operable Unit High Priority Liquid Waste Facilities, shows a site labeled 118-K-3 Filter Crib between and south of the retention basins. The area where this site is mapped is the identical location of a fenced electrical distribution intertie that connects electrical service between 100K East and 100K West. WHC-SD-EN-TI-239, 100-K Area Technical Baseline Report states that the crib could not be located during field investigations for the report. Further, it says that a fenced, high-voltage power distribution system is located at the site described by DOE/RL-90-20. The document continues with the crib received liquid wastes from the 1705KE/KER Laboratory. Discussions with present and former site employees, and investigations using Hanford Drawings (H-1-20305, H-1-23215, and H-1-24226), indicate that all cribbed wastes from the 1706-KE/KER facilities were disposed in the 116-KE-2 Crib. The initial Waste Information Data System (WIDS) entry for this site was not done until 1994. The information contained on the data entry form (A-6000-501) was based on WHC-SD-SD-TI-239. It was also recommended that the site not be entered as a waste site due to the uncertainty of the site's existence. A field visit by WIDS personnel was performed on August 16, 1994. There was no evidence of a waste site at the prescribed location.

Location: The 118-K-3 Filter Crib was purported to be located between the 116-KW-3 and 116-KE-4 Retention Basins.

Related Sites/Structures: According to DOE/RL-90-20 the site was related to the 1706-KE Building. According to Waste Information Data System (WIDS) 1994 Data Entry Form (A-6000-501) signed by the operable unit manager, the site was related to the 1705KE/KER Laboratory.

Code: 100-K-44

**Code:** 100-K-51  
**Names:** 100-K-51; 105-KE 90-Day Waste Accumulation Area; 100K 90-Day Waste Storage Facility  
**Type:** Storage Pad (<90 day)  
**Status:** Inactive  
**Reclassification:** Rejected (9/14/2000)

**Description:** The site is a white, portable steel building, with no windows, and three doors that are all on one side. The site is being used by the Spent Fuel Division for the 90 day storage of hazardous waste.

**Location:** The site is located approximately 150 meters (492 feet) west southwest of the 105-KE Reactor Building, and northwest of the 1717K Maintenance Building.

**Waste Type:** Soil

### 100-K-52

**Classification:** Not Accepted

**Names:** 100-K-52; 1706-KE Wet Fish Studies Laboratory  
**Type:** Storage  
**Status:** Inactive  
**Start Date:** 1/1/1956  
**End Date:** 1/1/1965

**Description:** The site was a laboratory (used by Pacific Northwest Laboratory) that conducted studies on fish using effluent cooling water. There was a small "wet lab" located inside the 1706-KE Building and three small outdoor ponds. The building and pond structures have been removed and disposed at ERDF. This facility no longer exists.

**Location:** The site was located in the northwest corner of the 1706-KE Building.

**Related Sites/Structures:** The site was related to 100-K-3, 1706-KE Fish Pond Valve Pit and Heat Exchanger Pit and 100-K-4, 1706-KE Wet Fish Studies Laboratory Ponds.

**Process Description:** The laboratory consisted of eight 1.5 meters (5 feet) long by 0.3 meters (1 foot) wide troughs containing a mixture of raw water and heated effluent water. The water was diverted from the heat exchanger pit (Site: 100-K-3) on the 105-KE Reactor discharge pipeline and passed through the troughs. Originally, the laboratory was planned in the event of shutdown of the 105-F Reactor and its laboratory. The laboratory was later used as a store room.

**Waste Type:** Equipment

**Waste Description:** A mixture of raw water and heated effluent water passed through the troughs. The troughs and laboratory equipment have been removed from the building.

**Code:** 100-K-58

</table>
Code: 126-K-1  
Classification: Accepted  
Names: 126-K-1; 100-K Gravel Pit  
Reclassification: Rejected (4/29/2009)  
Type: Inert/Demolition Landfill  
Start Date: 1/1/1975  
Status: Inactive  
End Date:  
Description: The site has been reclassified to rejected. The debris disposed was of an inert/demolition type not regulated under CERCLA. The site status was changed to inactive since the gravel pit is not in use.  
This unit is a gravel borrow pit that resulted from 100-K Area construction. The slope of the southwest corner contains demolition waste. This area is covered with pit run backfill material. The bottom contains one layer approximately 1.5-meter (5-foot) thick of demolition and inert waste covered with approximately 0.3 meters (1 foot) of pit run backfill material. Approximately 80% of this unit is unused.  
Location: The western perimeter of this unit is located approximately 191 meters (625 feet) east of the 100-K Area's east perimeter fence and borders the eastern perimeter of the 118-K-1 Burial Ground.  
Waste Type: Oil  
Waste Description: The unit contains demolition and inert waste from the 100-K Area, the Near Surface Test Facility (NSTF) at Gable Mountain, and the Exploratory Shaft (ES) Site. Waste consists primarily of concrete, wood, steel pipe, structural steel, conduit, and wire.

Code: 130-K-1  
Classification: Not Accepted  
Names: 130-K-1; 1717-K Gasoline Storage Tank  
Reclassification: None  
Type: Storage Tank  
Start Date: 1/1/1955  
Status: Inactive  
End Date: 1/1/1972  
Description: The site was an underground gasoline storage tank oriented with the long axis of the tank in an east-west direction. The tank was excavated in July 1989. A 6.4 centimeters (2.5 inches) pipeline connected the tank to the building. The tank was emptied and rinsed with water when the facilities were deactivated in 1971. The concrete pad over the top of the tanks was removed in July, 1989. This allowed Pacific Northwest Laboratories to return to the tank site and perform Ground Penetrating Radar (GPR) to aid in locating the tank without the interference caused by the rebar in the concrete. The tank was excavated in July 1989. The soil around where the tanks had been located was sampled, the results analyzed, and the site backfilled to match the surrounding grade.  
Location: The site was located approximately 3.7 meters (12 feet) north of the 1717-K, Maintenance and Transportation Service Building and 10.7 meters (35 feet) from the northwest corner of this building.  
Related Sites/Structures: The site was related to the 1717-K, Maintenance and Transportation Service Building.  
Waste Type: Process Effluent  
Waste Description: The unit was used for storage of gasoline (product).
Description: The unit consisted of two steel underground diesel oil storage tanks. The tanks were excavated and removed on April 13, 1993. The tanks were used to supply diesel fuel to three engines located within the 182-K (Emergency Water Pump House). The engines ran emergency pumps used to provide backup cooling water for the 105-KE and 105-KW Reactors.

The tanks were covered by a bermed mound of soil with the top of the mound 1.5 meters (5 feet) above grade level. The top of each tank was 1.2 meters (3.5 feet) above grade and covered by 0.46 meters (1.5 feet) of the soil berm. A 0.7 meters (2 feet) diameter manway (0.64 centimeters [0.25 inches] thick bolted steel plate cover) was located in the center of each tank. All piping associated with the tanks utilized welded joints with no threaded couplings. The piping and conduit associated with each tank was: 3 fuel oil pipelines -- 3.2 centimeters (1.25 inches) outside diameter by 3.7 meters approximately (12 feet) to the building; 1 fuel oil return pipeline -- 0.64 centimeters (3 inches) outside diameter by approximately 4.6 meters (15 feet) to the building (empty during normal operation); 1 centrifuge fuel oil pipeline -- 3.2 centimeters (1.25 inches) outside diameter by approximately 9.1 meters (30 feet) to the building; 1 vent pipeline - 0.64 centimeters (3 inches) outside diameter by approximately 6.1 meters (20 feet) (including above ground components); 1 vertical fill pipeline connection -- 10.2 centimeters (4 inches) outside diameter by 15.2 centimeters (6 inches) tall (empty during normal operation); 1 fuel oil cross tie pipeline -- 7.6 centimeters (3 inches) outside diameter by approximately 3.05 meters (10 feet) long (empty during normal operation); 1 fuel level indicator conduit -- electrical and did not contain product.

There was no history of repairs made to these tanks.

In about 1970, the tanks were pumped empty of product and abandoned.

The tanks were excavated on April 13, 1993 following the Site Assessment Process. The soil around where the tanks had been located was sampled, the results analyzed, and the site was backfilled to match the surrounding grade.

Location: The tanks were located (5 feet) north of the north wall of the 182-K, Emergency Water Pump House. They were 1.5 meters (5 feet) apart.

Release Description: Prior to the removal of these tanks, there were no known leaks (unplanned releases) associated with them.

Related Sites/Structures: The site was related to the 182-K Emergency Water Pump House (Coolant Backup System).

Waste Type: Construction Debris

Waste Description: The two tanks were used for storage of diesel oil (product).
Type: Septic Tank  Start Date: 1/1/1955
Status: Inactive  End Date: 

Description: The sanitary sewer system was properly abandoned and Closed Out in 1999. It is composed of a septic tank, two leaching trenches and associated piping. The septic tank and dosing chamber are composed of reinforced concrete per Hanford Standard E-5-11. There is a maximum of 1.5 meters (5 feet) of fill on the cover slab. There are 149 meters (150 + 238 + 102 feet) of 20 centimeter (8 inches) vitrified clay pipe to the septic tank, followed by 6.1 meters (20 feet) of 15 centimeter (6 inches) vitrified clay pipe to the larger leaching trench. There are an additional 68 meters (122 + 102 feet) of 15 centimeter (6 inches) of vitrified pipe connecting 1717-K to the system. The leaching trench contains 128 meters (420 feet) of 15 centimeters (6 inches) vitrified clay pipe laid with open joints. The second leaching trench is connected directly to the system piping with 6.1 meters (20 feet) of vitrified piping. The piping within the leach trench is a single 9.1 meters (30 feet) of vitrified piping. (also see 100-K-103)

Location: The system is north and northeast of 1704-K and 1717-K buildings.

Related Sites/Structures: 100-K-103 contains components of this septic system that may not have been addressed with the 1999 sewer abandonment. The system serviced 1704-K (Offices) and 1717-K (Maintenance Shop) buildings.

Waste Type: Equipment
Waste Description: This unit received sanitary sewage from the 1704-K Office Building and the 1717-K Maintenance Shop.

Closure Info: The septic system was abandoned in 1999 per the requirements of Washington Administrative Code 246-272-1851. All septage inside the tank was removed and the empty tank was filled to eliminate void spaces. The septic system lids were left in place, in accordance with an agreement with the Washington Department of Health. The reclassification is documented on form 99-103.

---

Type: Storage Tank  Start Date: 1/1/1955
Status: Inactive  End Date: 1/1/1997

Description: The site was an above ground vertical stainless steel storage tank mounted on a concrete base. The tank has been removed and disposed at ERDF. This tank is no longer in existence. The tank was part of a system called the Liquid Alum System that supplied liquid alum for water treatment. The liquid was supplied either by rail car or tank truck, as both connections are shown on the Liquid Alum System diagram in HW-24800-103. The piping and instrument identification diagram, H-1-16552, shows the pipelines, valves, and instrumentation related to the tank.

Location: The site was the eastern-most of two alum storage tanks located approximately 10.7 meters (35 feet) south of the southwest corner of the 183-KE Head House and 10.7 meters (35 feet) south of the 183-KE Chlorine Vault.

Related Sites/Structures: The tank was associated with the 183-KE Head House. The head house was the water quality center for the entire water treatment plant. In it were the facilities for metering raw water, for chemical injection into raw, filtered, and process water, and for effluent and influent control throughout the filter plant.
Process Description: Alum was used as a coagulant in water treatment. During the season of water high turbidity activated silica was added to aid in coagulation. Alum was fed from the storage tank and proportioned directly into the raw water line. The proportioning pump was paced by the flow of raw water in its 91-centimeter (36-inch) raw water pipeline and fed at 30 parts per million (ppm) at a maximum flow rate of 121,000 liters/minute (32,000 gallons/minute). During the winter, the liquid alum was pumped through heat exchangers for purpose of heating and agitating the chemicals.

Waste Type: Chemicals

Waste Description: The unit was used for storage of liquid alum (aluminum sulfate). Material Safety Data Sheet (MSDS) #040407 lists aluminum sulfate as an EPA hazardous substance. It is believed that this tank has been cleaned out.

Code: 100-N-7

Classification: Not Accepted

Names: 100-N-7; 182-N Facility Liquid Unplanned Release (Remediated)

Reclassification: None

Type: Unplanned Release

Start Date: 1/1/1987

End Date: 1/1/1987

Description: The release site consists of a concrete flume on the river bank that extends into the river. The release at this site was approximately 19 liters (5 gallon) of oil that was mixed with a continuous permitted water discharge. The oil was dispersed into the river with the rest of the permitted discharge from the flume. The flume is currently dry and there is no evidence of the release.

Location: The site is located on the Columbia River upstream of the 181-N Building, and extends from the 182-N Tank Farm into the river.

Release Description: On February 6, 1987, approximately 19 liters (5 gallons) of turbine oil was discharged to the Columbia River through the 182N tank farm raw water return line. A small (pin hole size) leak in a lube oil line in the No. 2 drive turbine allowed oil to enter the secondary steam system. Steam condensate from this system returns to the 100-N steam condensate system that drains to the river. The leak in the lube line was repaired.

Related Sites/Structures: This site is related to the 182-N Tank Farm Overflow Outfall (NPDES Permit Outfall #005).

Waste Type: Chemicals

Waste Description:

Code: 100-N-8

Classification: Accepted

Names: 100-N-8; 108-N CUF; 108-N Facility

Reclassification: Rejected (9/11/2000)

Type: Loading Dock

Start Date: 1/1/1963

End Date: 1/1/1990

Status: Inactive

Description: The 108-N Chemical Unloading Facility (CUF) was designed to remove liquids from railroad cars. The 108-N Building, metal structure used to offload chemicals, tank foundations, and tank pit are part of this site and remain at the location. The ground surface around these facilities is graveled.
**Location:** The 108-N CUF is located within the 100-N Exclusion Area perimeter fence near the southeast corner, and east of the 116-N-8, less than 90-day storage pad.

**Related Sites/Structures:** The 120-N-5 Acid/Caustic Transfer Trench and Neutralization Unit, the 120-N-6 Sulfuric Acid Tank trench drains, and the 120-N-7 Unloading Station french drain are associated with the unit.

**Process Description:** The unit was used for offloading, storage and transfer of 93% sulfuric acid and 50% sodium hydroxide solutions received by railroad car or tank truck. The 120-N-7 Unloading Station french drain was used for containment of small releases from the overhead transfer boom during offloading from railcar or truck. The facility had three 38,000 liter (10,000 gallon) above ground steel sulfuric acid tanks and one 290,000 liter (76,800 gallon) sodium hydroxide tank. Adjacent to the sulfuric acid tanks are five 120-N-6 sulfuric acid french drains where tank overflows were vented. The french drains are 0.6 meter (2 feet) in diameter and consist of a clay pipe packed with lime. The acid transfer system used a 3,800 liter (1,000 gallon) steel transfer tank located in a pit west of the 108-N Building. The tank filled with acid via gravity flow from the storage tanks. Air pressure was used to transfer acid by way of piping through the trench to the 163-N Day Tank. There are no french drains associated with the sodium hydroxide tank. Transfer pumps in the 108-N Building transferred the sodium hydroxide directly to the 163-N Day Tank from the storage tank.

**Waste Type:** Animal Waste

**Waste Description:** The site received 93% sulfuric acid, and 50% sodium hydroxide solutions.

Status: Inactive  
End Date: 1/1/1987

Description: The release occurred at the 120-N-5 Acid/Caustic Transfer Trench. There is no remaining evidence of the spill at the concrete-lined trench.

Location: The site is located within the 120-N-5 Acid/Caustic Transfer Trench. The transfer trench is a polymer lined concrete trench located between the 108-N Chemical Unloading Facility and the 163-N Demineralization Plant.

Release Description: On September 2, 1987 a leak was noted in the piping during a caustic transfer from the 108-N Storage Tank to the 163-N Caustic Day Tank. The caustic collected in the 120-N-5 Transfer Trench. When the leak was noticed, the transfer was stopped and the pipeline was repaired. There is no documentation to indicate the caustic reached the soil.

Related Sites/Structures: This site is related to the 108-N Chemical Unloading Facility, 163-N Demineralization Plant, and the 120-N-5 Acid/Caustic Transfer Trench.

Waste Type: Animal Waste

Waste Description: The site received caustic sodium hydroxide.
Description: The site is a leak of fuel oil found contained in a drain trench, inside the 184-N Facility. The oil was absorbed and the trench cleaned up immediately. The Auxiliary Operations Supervisor for N-Reactor at the time stated the spill did not reach the drain at the far end of the trench.

Location: The spill occurred inside the 184-N Building and accumulated in a drain trench.

Release Description: This spill was included in the 100-NR-1 Work Plan (DOE/RL-90-22 Draft E) and the 100-N Technical Baseline Report (WHC-SD-EN-TI-251). The work plan says "an unknown amount of fuel oil leaked from a loose pipe fitting at the 184-N Annex. Oil was being transferred from the day tank to the No. 2 Boiler. The oil was contained in the 184-N Annex drain trench and cleaned up.

As part of the WIDS site investigation in 1994, an interview was conducted with the former Auxiliary Operations Supervisor and remembered this particular spill. He said it was a very small spill contained within the trench and did not reach the drain at the far end of the trench. According to Fact Sheet No. 100N-87-95 the spill was cleaned up, and the probable cause listed as: "The most likely cause is the coupling was loosened to perform work on the transmitter, and upon recognizing that the transmitter was not isolated, an attempt was made to retighten the coupling." The spill date was October 14, 1987.

Related Sites/Structures: The spill occurred in the 184-N annex building.

Waste Type: Equipment

Code: 100-N-19 Classification: Accepted
Names: 100-N-19; HGP Construction Debris Dump Solid Waste Site; SWMU #11 Reclassification: Rejected (6/30/2004)
Type: Dumping Area Start Date: 
Status: Inactive End Date: 
Description: The site is a large area consisting of a series of pits and depressions containing soil, rock, concrete, metal, wood, and asphalt that have been dumped in the area over time. The site is relatively long [more than 1000 meters (3000 feet) long] and narrow [about 150 meters (500 feet) wide] in shape.

Location: The Hanford Generating Plant (HGP) Construction Debris Dump is located south and east of the Bonneville Power Administration (BPA) Hanford Substation along a dirt road.

Related Sites/Structures: The site is associated with 600-32 and 100-N-39 which are duplicate codes for the same site, a dumping are contained within the larger 100-N-19 Dumping Area.

Process Description: The site was used to dispose of non hazardous construction debris from 100-N and the Hanford Generating Plant.

Waste Type: Equipment

Code: 100-N-21 Classification: Accepted
Names: The site contains mounds of soil, rock, concrete, metal, wood, and asphalt that have been dumped in the area.
### Names: 100-N-21; 1143-N Blast Yard; Blast Yard Solid Waste Site

**Reclassification:** Rejected (9/11/2000)

### Type: Dumping Area

**Start Date:**

### Status: Inactive

**End Date:**

#### Description:
The area has thin, scattered patches of red garnet sandblasting material. Paint chips, reported in 1994 as being mixed in with the garnet (Cote 1994), are no longer visible. The site is in use as a parking lot.

#### Location:
The site is located in the southeast portion of the 100-N Area, southwest of MO-535 and MO-229 and east-southeast of the 1143-N Paint Shop.

#### Related Sites/Structures:
The 1143-N Paint Shop is related to this site.

**Waste Type:** Asbestos (friable)

**Waste Description:** The area has scattered patches of red garnet sandblasting material.

---

### Names: 100-N-27; 108-N Neutralization Pit; 108-N Sump

**Reclassification:** Rejected (9/11/2000)

### Type: Sump

**Start Date:** 1/1/1963

**End Date:** 1/1/1990

#### Description:
The acid neutralization pit is constructed of concrete with a brick lining, and is covered with a steel lid.

#### Location:
The unit is located west of the 108-N Building.

#### Release Description:
No known leaks occurred in the system.

#### Related Sites/Structures:
This facility received drainage from the 108-N floor drains and from the acid transfer tank. Neutralized waste was sent from the 108-N Neutralization Unit by the water jet pump to the 183-N Facility where it was then discharged to the river through the 259-centimeter (102 inch) outfall line.

#### Process Description:
The pit was used to manually neutralize waste acid. This site received drainage from the 108-N floor drains and from the acid transfer tank. The neutralized waste was sent via a water jet pump to the 183-N facility where it was then discharged to the river through the 260 centimeter (102 inch) outfall line. Sufficient quantities of 50% sodium hydroxide were used to neutralize the 93% sulfuric acid waste. The brick lining was replaced at least once.

#### Waste Type: Animal Waste

**Waste Description:** The pit was used to neutralize waste sulfuric acid before eventual release to the river. Chemicals received by the pit included 93% sulfuric acid and 50% sodium hydroxide.

---

### Names: 100-N-39; Hanford Substation Construction

**Reclassification:** Rejected (7/14/2005)

---

*Hanford Site Waste Management Units Report*

February 2015
Dump Area; SWMU #11

**Type:** Dumping Area

**Status:** Inactive

**Description:** This site should be rejected because it is a duplicate of 600-32 and contained within the larger dumping area 100-N-19. There is no similar dump near the area originally mapped (in Arcview) as the site location, inside the BPA Substation fence. The site is a construction dump with evidence of burning activity. The Hanford Generating Plant RCRA Facility Assessment Report states "The site is a large, irregular shaped burn pit and a large borrow pit covering 5 to 10 acres. The site contains large blocks of concrete and miscellaneous debris."

**Location:** The site is approximately 305 meters (1000 feet) south of the Hanford Generating Plant property fence.

**Related Sites/Structures:** This site is a duplicate of 600-32 and 100-N-19.

**Waste Type:** Process Effluent

**Waste Description:** The waste includes construction debris and combustible construction waste that was burned. The site contains large blocks of concrete, miscellaneous debris, one empty drum and one pile of sand blast grit

**This Site Was Consolidated With:**

**Code:** 600-32

**Names:** 600-32; N Area Landfill

---

**Code:** 100-N-40

**Classification:** Accepted

**Names:** 100-N-40; Unplanned Release at 108-N

**Reclassification:** Rejected (9/11/2000)

**Type:** Unplanned Release

**Start Date:** 1/1/1987

**End Date:** 1/1/1987

**Description:** The site is a graveled field at the 108-N Chemical Unloading Facility.

**Location:** The site is located at the railcar unloading station at the 100-N-8 (108-N Chemical Unloading Facility) and 120-N-6.

**Release Description:** Approximately 38 liters (10 gallons) of sodium hydroxide was spilled to the ground on December 26, 1987. Difficulties during the transfer of sodium hydroxide from a rail car to the caustic storage tank prompted the operator to disconnect the transfer line and set it on the ground.

**Related Sites/Structures:** This release occurred at the 100-N-8 (108-N) Chemical Unloading Facility.

**Waste Type:** Process Effluent

**Waste Description:** The waste is sodium hydroxide spilled to the ground.

---

**Code:** 100-N-56

**Classification:** Accepted

**Names:** 100-N-56; 181-N Building Drywell

**Reclassification:** Rejected (9/11/2000)

**Type:** French Drain

**Start Date:**
**Status:** Inactive  
**End Date:**

**Description:** The drywell is not visible from ground surface and is apparently located underground. The drywell, judging by the site drawing, is adjacent to the fenceline north of the 181-N Building. The ground surface is graveled. Another drywell, 100-N-73 (Miscellaneous Stream 395) is in this area, but it drains a parking lot north of the 107-N Building via a concrete trench.

**Location:** The site is located in the 100-N Area, north of the 181-N Building and between the double security exclusion area fences.

**Related Sites/Structures:** The 181-N Building is associated with this waste site.

**Process Description:** The site received waste water from the 181-N River Pumphouse Building. According to Don Eckert of 100-N Operations, only river water entered the pipeline leading to the drywell.

**Waste Type:** Process Effluent

**Waste Description:** River water from inside the 181-N Pumphouse is the only source of waste water to this site.

**Location:** This stormwater runoff is in the area east of the 107-N Building.
Process Description: This Miscellaneous Stream is stormwater runoff.

Waste Type: Water

Waste Description:

---

Code: 100-N-73

Names: 100-N-73; 107-N Building West Area

Reclassification: None

Stormwater Runoff; Miscellaneous Stream #395

Type: Injection/Reverse Well

Status: Inactive

Classification: Not Accepted

Start Date: End Date:

Description: The drain is a concrete structure with a steel lid, fed by a concrete trough running from north of the 107-N Building, along the base of the security fence.

Location: This Miscellaneous Stream is a drywell on the north side of the 181-N Pumphouse.

Related Sites/Structures: This drywell drains the security exclusion area from north of the 107-N Building south to the French drain.

Process Description: This Miscellaneous Stream drains stormwater from the area north and west of the 107-N Building and flows via a concrete trench to a drywell on the north side of the 181-N Pumphouse. It is designed to prevent erosion on the river bank that could otherwise be caused by stormwater.

Waste Type: Water

Waste Description:

---

Code: 100-N-74

Names: 100-N-74; 183-N Building Fire System Drain; Miscellaneous Stream #492

Reclassification: Rejected (9/11/2000)

Type: Injection/Reverse Well

Status: Active

Classification: Accepted

Start Date: End Date:

Description: The site is in a graveled lot on the north side of the 183-N Building. A fire system relief valve (site 100-N-75) extends about 1 meter (3 feet) above the ground, and is surrounded by six steel barrier poles to protect it from vehicles. Two metal 10 centimeter (4 inch) pipes with handles for turning valves are next to the relief valve, but no pit is visible.

Location: The Miscellaneous Stream is in a valve pit on the north side of the 183-N Building.

Related Sites/Structures: The Miscellaneous Stream is for the 183-N Building fire system.

Process Description: When fire system piping is opened at the valve pit for repair, untreated water from the Columbia River (via the Hanford Site export water system) drains from pipes into the pit.

Waste Type: Process Effluent
Recrense:

100-N-75; 183-N Building Fire System Relief Valve; Miscellaneous Stream #493

Type: French Drain
Status: Active

Description: The relief valve is visible in a large graveled area north of the 183-N Building. It is surrounded by 6 metal posts that protect it from vehicles. The relief valve is just under 1 meter (3 feet) high, and painted red. The entire area is marked "Underground Radioactive Materials."

Location: This Miscellaneous Stream is north of the 183-N Building, adjacent to the valve pit.

Process Description: This stream is a relief valve that releases during upset conditions in the plant fire system. Released water flows into a container, and overflows onto the ground. The water is from the Columbia River, via the Hanford Site export water line.

Waste Type: Construction Debris

Code: 100-N-75
Classification: Accepted
Reclassification: Rejected (9/11/2000)

Names: 100-N-75; 183-N Building Fire System Relief Valve; Miscellaneous Stream #493

Start Date:
End Date:

Description: The two french drains were plugged with grout and can no longer receive steam condensate or stormwater drainage. The drains were plugged with grout on June 13, 2001. The french drains were connected to each other underground, and provided steam condensate and stormwater drainage just east of the 181-N Pumphouse. These drains are believed to have been built to receive steam condensate blowdown. However, when the steam line was removed the drains were left behind, and drained excess stormwater.

Both drains are about 46 centimeters (18 inches) in diameter and constructed of concrete. A 10 centimeter (4 inch) pipe connects them; this pipe is about 20 centimeters below the lip in the southern drain and about 1 meter (3 feet) below the lip of the northern drain. Because the northern drain is noticeable higher than the southern drain, it is difficult to tell if the pipe is level or drains preferentially toward either side. The drains are about 16 meters (52 feet) apart.

Location: The drains are on the east side of the paved and graveled road that is east of the 181-N Pumphouse.

Process Description: These drains originally were built to drain steam condensate, but later drained excess stormwater.

Waste Type: Sanitary Sewage

Code: 100-N-76
Classification: Accepted
Reclassification: Rejected (4/12/2004)

Names: 100-N-76; 181-N Pumphouse French Drains

Start Date: 1/1/2001
End Date:

Waste Type: Sanitary Sewage
Reclassification: 116-N-8; 116-N-8 Storage Pad; 1330-N; 163-N Mixed Waste and Hazardous Waste Container Storage Pad

Type: Storage Pad (<90 day)  Start Date: 12/1/1986

Status: Inactive  End Date:

Description: The site status was changed to inactive since the hazardous materials were removed and the above-grade structure and concrete pad were demolished in June 2008 (per document D4-100N-0018).

Containers were stored on a curbed and fenced concrete pad. The pad was covered by an open metal shed, divided into three storage areas each with its own locked gate. The entire unit was approximately 45 by 18 meters (150 by 60 feet). A small cabinet in front held personal protective equipment and spill response materials. The front of the unit was an asphalt parking/driving area; the sides and back were gravel.

Location: The site is located south of the 163-N Building.

Release Description: No spills have been recorded at this site. No stains are visible on the concrete.

Waste Type: Misc. Trash and Debris

Waste Description: This site receives radioactively contaminated oil and miscellaneous hazardous process chemicals in drums and containers. The amounts received are variable based on operations.

---

Reclassification: 120-N-5; 108-N/163-N Transfer Line and Neutralization Pit Product Piping

Start Date: 1/1/1963  End Date: 1/1/1990

Description: The Transfer Line and Neutralization Pit is a 220-meter (720-foot) long polymer lined concrete pipe trench (encasement) that contains two transfer lines that run between the 108-N and the 163-N Buildings. The trench has concrete bottom and sides and a metal plate cover. The enclosed lines are one 6.4-centimeter (2.5-inch) sodium hydroxide line and one 10.2-centimeter (4-inch) sulfuric acid line. The trench runs 50 meters (154 feet) south from the 163-N Building to a neutralization pit, east for 132 meters (433 feet), and then north for 26 meters (85 feet) to the 108-N Building. The 1.22-meter (4-foot) by 3.05-meter (10-foot) concrete neutralization pit, located at coordinates N149307 and E571120, is designed to receive waste spills from within the encasement. Its upper surface is a few inches above grade. The neutralization pit has two 61-centimeter (24-inch) steel manhole covers, one marked "acid" and the other "caustic", that provide pit access. DOE/RL-90-22 describes its internal dimensions as two vaults, each measuring 1.8 by 1.8 by 3.1 meters (6 by 6 by 10 feet) deep.

Location: The site is a pipe trench that is located between the 108-N and the 163-N Buildings.

The site transfers sulfuric acid and sodium hydroxide from the 108-N Chemical Unloading Facility to the 163-N Demineralization Plant for use in water treatment.

**Waste Type:** Misc. Trash and Debris

The unit transferred sodium hydroxide and sulfuric acid reagents from a chemical unloading facility to the point-of-use at the 163-N Demineralization Plant via transfer pipes contained in a concrete trench. Several leaks to the soil resulted from corrosion of the transfer pipes and concrete trench by the concentrated solutions.

**Code:** 120-N-6

**Names:** 120-N-6; 108-N Acid Tank Vent French Drains

**Type:** French Drain

**Status:** Inactive

**Description:** This site consisted of five french drains which were removed in 1988. No evidence of the former french drains remains. The area is surrounded by posts, chain, and a sign stating "Controlled Area - Authorized Personnel Only" and "108-N/ WIDS Site 120-N-6".

**Location:** The site is located on the south side of the 108-N Building and south of the 105-N Reactor Building.

**Release Description:** Unknown quantities of sulfuric acid tank overflows and condensate were discharged to the drains. An unplanned release of an unknown quantity of soda ash (soda ash is purified sodium carbonate) sufficient to cover a 6.1 by 9.2-meter (20 by 30-foot) area occurred in 1981. Soda ash was used to neutralize acid spills. Hanford Drawings H-1-45007, Sheets 1, 14, and 15, and H-1-29247 show the location of this release. Any remaining amounts of this material would have been removed with the french drains and the surrounding soil in 1988.

**Process Description:** Three french drains were designed to receive inadvertent overflows and condensate from the three sulfuric acid storage tanks located south of the 108-N Building. Two other french drains were designed to receive tank vent overflows and condensate from the transfer tank which was located in a concrete pit just west of the 108-N building. The drains were packed with limestone to neutralize the acid before entering the soil column.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** The drains received unknown quantities of sulfuric acid overflows from the acid storage tanks and transfer lines in intermittent discharges. Each discharge is estimated to have averaged less than 3.8 liters (1 gallon) of liquid.

**Code:** 120-N-8

**Names:** 120-N-8; 163-N Sulfuric Acid Tank Vent French Drain

**Type:** French Drain

**Status:** Inactive

**Description:** The french drain was removed in 1988 and the site has been covered with gravel. There is currently no evidence of the former french drain at the site.

**Location:** The site is located approximately 1 meter (3 feet) west of the west wall of the 163-N Building at
a point approximately 5 meters (16 feet) south of its northwest corner.

**Release Description:** The releases are described as intermittent small discharges of sulfuric acid from 163-N Demineralized Water Treatment Plant day storage tank. The average amount of each discharge is estimated to be less than 3.8 liters (1 gallon). There are no documented unplanned releases associated with the unit.

**Related Sites/Structures:** The drain received sulfuric acid from the 163-N Demineralized Water Treatment Plant sulfuric acid day storage tank.

**Process Description:** The unit is a french drain used to receive overflow of sulfuric acid from the 163-N demineralization plant sulfuric acid day tank. The unit was constructed of clay pipe filled with limestone to neutralize the sulfuric acid releases.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The unit received unknown amounts of sulfuric acid in intermittent discharges. Each discharge is estimated to have averaged less than 3.8 liters (1 gallon) of corrosive liquid.

---

**Code:** 124-N-5  
**Classification:** Accepted

**Names:** 124-N-5; 124-N-5 Septic Tank; 1607-N5; 100-N Sanitary Sewer System No. 5

**Type:** Septic Tank  
**Start Date:** 1/1/1981  
**End Date:** 1/1/1987

**Description:** The site is in the middle of a large graveled lot, free of vegetation. When the tank was deactivated, it was covered with a layer of parking lot gravel and is no longer visible.

**Location:** The unit is located south of 1115N (MO050) and west of 1135N (MO352).

**Related Sites/Structures:** This sewer system served office buildings 1111-N, 1116-N, 1117-N 1118-N, 1123-N 1124-N, and 1131-N.

**Process Description:** Untreated sanitary sewage enters the septic tank where the heavy solids settle to the bottom of the tank. The lighter solids, fats and greases partially decompose and rise to the surface and form a layer of scum. The solids that have settled to the bottom are attacked by bacteria and form sludge. The clear sewage then enters a system of properly sized and constructed narrow trenches partially filled with a bed of washed gravel or crushed stone into which perforated or open joint pipe is placed. The discharge from the septic tank is distributed through these pipes into trenches and surrounding soil.

**Waste Type:** Construction Debris

**Waste Description:** This unit received approximately 14,000 liters/day (3,800 gallons/day) of sanitary sewage.

---

**Code:** 124-N-6  
**Classification:** Accepted

**Names:** 124-N-6; 124-N-6 Septic Tank; 1607-N6; 100-N Sanitary Sewer System No. 6

**Type:** Septic Tank  
**Start Date:** 1/1/1979  
**End Date:** 1/1/1987

**Description:** A site visit in July 1999 was unable to visually locate this site. The site was covered with parking lot gravel and the exact location cannot be visually identified.
Location: The unit is located south of the 1113-N Trailer.

Related Sites/Structures: The septic system received sanitary sewage from office trailers 1113-N, 1114-N, and 1115-N. This septic system was directly hooked up to Sanitary Sewer System No.7, (124-N-7).

Process Description: Untreated sanitary sewage enters the septic tank where the heavy solids settle to the bottom of the tank. The lighter solids, fats and greases partially decompose and rise to the surface and form a layer of scum. The solids that have settled to the bottom are attacked by bacteria and form sludge. The clear sewage then enters a system of properly sized and constructed narrow trenches partially filled with a bed of washed gravel or crushed stone into which perforated or open joint pipe is placed. The discharge from the septic tank is distributed through these pipes into trenches and surrounding soil.

Waste Type: Asbestos (friable)

Waste Description: This unit received an unknown amount of sanitary sewage.

Code: 124-N-7

Names: 124-N-7; 124-N-7 Septic Tank; 1607-N7; 100-N Sanitary Sewer System No. 7

Type: Septic Tank

Start Date: 1/1/1984

End Date: 1/1/1987

Classification: Accepted

Reclassification: Rejected (9/11/2000)

Location: The unit is located southwest of the 1115-N Trailer.

Related Sites/Structures: The system received sanitary sewage from office trailers 1103-N, 1104-N, and 1145-N and after modifications received sanitary sewage from 124-N-6 Sanitary Sewer System and the 1145-N Building.

Process Description: Untreated sanitary sewage enters the septic tank where the heavy solids settle to the bottom of the tank. The lighter solids, fats and greases partially decompose and rise to the surface and form a layer of scum. The solids that have settled to the bottom are attacked by bacteria and form sludge. The clear sewage then enters a system of properly sized and constructed narrow trenches partially filled with a bed of washed gravel or crushed stone into which perforated or open joint pipe is placed. The discharge from the septic tank is distributed through these pipes into trenches and surrounding soil.

Waste Type: Oil

Waste Description: This unit received approximately 19,700 liters/day (5,200 gallons/day) of sanitary sewage from office trailers.

Code: 124-N-8

Names: 124-N-8; 124-N-8 Septic Tank; 1607-N8; 100-N Sanitary Sewer System No. 8

Type: Septic Tank

Start Date: 1/1/1983

Classification: Accepted

Reclassification: Rejected (9/11/2000)
A site visit in July 1999 found two concrete pads (0.6 meters by 0.6 meters [2 X 2 feet]) with 19.6 centimeter (8 inch) lids marked "Sewer" in the general location of this site. It is not known if one of the markers is from the old system (124-N-8) or the replacement sewage system (124-N-10).

The unit is located southwest of 1135N (MO352).

The system received sanitary sewage from office trailers 1132-N, 1133-N, 1134-N and 1135-N.

This unit received approximately 3,400 liters/day (900 gallons/day) of sanitary sewage from office trailers.

The Effluent Treatment Facility contains several tanks and process systems that make up the primary and secondary treatment trains for the treatment of dilute waste water generated at the Hanford Facility. The primary treatment train receives waste water in the surge tank, located outside the Effluent Treatment Facility Building on the south side. The secondary treatment train collects, concentrates, dries and packages the waste (generated by the primary treatment train systems) in lined steel containers.

The Effluent Treatment Facility lies north of the Liquid Effluent Retention Facility an east of Canton Avenue in the 200 East Area.

The Effluent Treatment Facility is associated with the 242-A Evaporator and the Liquid Effluent Retention Facility.

Mixed waste stored in the double-shell tank system is transferred to the 242-A Evaporator, where the waste is concentrated through an evaporation process. The concentrated slurry waste is returned to the double-shell tank system, and the evaporated constituents are re-condensed, collected, and transferred to the Liquid Effluent Retention Facility until they are transferred to the Effluent Treatment Facility for additional treatment. The facility consists of a primary and a secondary treatment train. The primary treatment train removes or destroys dangerous and mixed waste components from the waste water. The primary treatment train consists of the following treatment operations: pH adjustment, filtration, ultraviolet oxidation, hydrogen peroxide decomposition, fine filtration, de-gasification, reverse osmosis, polishing (ion exchange column) and final pH adjustment and verification. The secondary treatment train processes the waste byproducts removed by the primary treatment train. The secondary waste
is dried to a powder, containerized and transferred to a mixed waste treatment, storage and/or disposal unit. The secondary treatment train includes the following treatment components: secondary waste receiving tanks, Effluent Treatment Facility Evaporator (forced circulation evaporator), concentrate tank, thin film dryer, container handling, and support systems. Treated effluent meets delisting requirements and is discharged as nonhazardous waste to the State-Approved Land Disposal System.

**Waste Type:** Soil

**Waste Description:** The unit treats process condensate containing small amounts of volatile and semivolatile organic constituents, inorganic constituents and radionuclides.

**Description:** The 357 meter by 192 meter (1172 ft by 629 ft) fenced area contains two adjacent five acre gravel disposal basins and a metal sampling building (#6653). Pond B is north of Pond A. The 6653 metal sampling building is 4.2 meters by 6.1 meters (14 ft by 20 ft) and is located near the east fence line and gate.

**Location:** Pond A (216-E-43A - South Pond) and B (216-E-43B - North Pond) and 6653 are located about 660 meters east of 216-B-3C, which is east of and outside the 200 East security fence.

**Related Sites/Structures:** Liquid waste from seven Hanford facilities (Plutonium Finishing Plant, 222-S Complex, T-Plant Complex, 284-W Power Plant, PUREX Plant, B-Plant, and 242-A-81 Water Services Building) is transported via eleven miles of pipe to the two evaporation/infiltration ponds (Pond A and Pond B). There are two pumping stations associated with the pipeline (one in 200 E and one in 200 W). The pipeline is WIDS sitecode 600-291.

**Waste Type:** Misc. Trash and Debris

**Waste Description:** Liquid waste is discharged to TEDF from the Plutonium Finishing Plant, 222-S Complex, T-Plant Complex, 284-W Power Plant, PUREX Plant, B-Plant, and 242-A-81 Water Services Building. Examples of waste include non-contact process cooling water, lab waste, steam condensate, air conditioning condensate, housekeeping water, outdoor sumps (rain water), reservoir overflow, boiler blowdown, sanitary sources (water softener, safety shower/eye wash, etc), floor drains, HVAC sanitary water, raw water, storm water, strainer backflush.

</table>
Description: All remaining 90 day storage areas were removed when PUREX was closed down and cleaned to meet the deactivation end point criteria prior to transition from Westinghouse Hanford Co. to Bechtel Hanford Inc. (BHI).

Location: The site was located north of the 202-A Building and east of the 2714-A Chemical Warehouse in the 200-East Area.

Release Description: There were no known releases from this site.

Related Sites/Structures: This pad was related to the PUREX facility.

Waste Type: Equipment

Waste Description: When this unit was active, typical wastes contained in the staging area over a 1-year period included approximately 1,000 kilograms (2,205 pounds) of flammable waste oils, 1,900 kilograms (4,190 pounds) of combustible waste oils, and 1,600 kilograms (3,530 pounds) of wastes unidentified prior to receipt of analysis.

Code: 202-A NU

Classification: Accepted

Names: 202-A NU; Elementary Neutralization Unit/202-A Building; PUREX; 202-A Neutralization Unit

Reclassification: Rejected (6/18/2014)

Type: Neutralization Tank

Start Date: 7/1/1986

End Date: 

Description: The waste site has been evaluated and reclassified to Rejected. The site had been defined as an elementary neutralization unit, that was an "in-line" waste treatment process occurring inside the PUREX facility (202-A). Potassium hydroxide was added to the waste stream to reduce the pH before discharging to cribs, ponds or ditches.

TPA-MP-14, Rev. 2, Section 2.0 states that WIDS does not document buildings or facilities that do not contain TSD units. It further states that, after buildings are demolished, the footprint will be evaluated for potential soil contamination. If present, the soil contamination will be added to WIDS as a Discovery Site.

Location: The in-line neutralization process was located inside the PUREX (202-A) Building. A neutralization tank (WIDS sitecode 200-E-58) was placed underground, outside 202-A, near the 216-A-45 Crib.

Waste Type: Process Effluent

Waste Description: The system treats process condensate. A nominal flow 2.7E+05 liters (72,000 gallons) per day, is neutralized in line from a pH of between 1 and 2 to a pH of approximately 4 by addition of potassium hydroxide. This stream then passes through a 26,500-liter (7,000-gallon) underground tank containing 27 metric tons (30 tons) of calcium carbonate rock (installed January 1987) for neutralization to a final pH of between 6 and 7. It is then discharged to the 216-A-45 Crib.

**Description:** This site is located in the PUREX Building on the canyon deck and F-Cell canyon floor.  
**Location:** The pile of material is located inside the 202-A building.  
**Waste Type:** Barrels/Drums/Buckets/Cans  
**Waste Description:** The PUREX Containment Building is permitted for the storage of waste designated TCLP toxic for lead (D008), cadmium (D006), and chromium (D007) and toxic (WT01). Discarded process equipment removed from service in the PUREX Plant and known to have shielding, weights, and or counterweights containing elemental cadmium or lead was stored on the canyon deck within the containment building. However, this waste has been removed and placed on a burial box inside the PUREX Storage Tunnel 2. In November 1996, chromium contaminated concrete solids from the E-Cell floor were stored in F-Cell within the containment building as well as a lead-lined remote camera assembly on the West Crane Maintenance Platform.

---

**Code:** 205-A  
**Classification:** Accepted  
**Names:** 205-A; 205-A Silica Gel Facility  
**Reclassification:** Rejected (6/18/2014)  
**Type:** Process Unit/Plant  
**Start Date:** 1/1/1956  
**End Date:** 1/1/1976  
**Status:** Inactive  
**Description:** The waste site has been evaluated and Reclassified to Rejected. The site is a small building constructed of transite. It contains lead lined silica gel beds, made from lead shielded 55 gallon drums. The structure is 3.6 meters by 3 meters by 2.4 meters (12 feet long, 10 feet wide and 8 feet high). It sits on a concrete pad inside the 203-A tank farm enclosure.

TPA-MP-14, Rev. 2, Section 2.0 states that WIDS does not document buildings or facilities that
do not contain TSD units. It further states that, after buildings are demolished, the footprint will be evaluated for potential soil contamination. If present, the soil contamination will be added to WIDS as a Discovery Site.

Location: The building is located within the 203-A Basin, north of the PUREX canyon building. It is inside the PUREX facility fence.

Process Description: The Silica Gel facility was a prototype unit, placed in service in 1956 to prove process feasibility. The uranium solution from the solvent extraction systems often required further treatment to meet product specifications. Silica gel absorbed the zirconium and niobium contaminants, without significant loss of uranium. After successfully demonstrating the process, the 205-A unit was converted to product use. Another silica gel facility was also built at REDOX. Since the PUREX unit was not designed for continuous operation, uranium solutions from PUREX were often transferred to REDOX of treatment.

Waste Type: Process Effluent
Waste Description: The unit contains silica gel and process and flush solutions. The amount of radionuclides present is not known. There is less than 2,000 counts/minute smearable beta/gamma; 5 millirad/hour nonpenetrating, 1 millirem/hour penetrating and detectable alpha. The tanks are assumed to contain silica gel and may contain either process or flush solutions.

The pipelines from 242-A Evaporator to the 207-A basins are sitecode 200-E-234-PL. The south basin distribution lines are sitecode 200-E-236-PL.</td>
<td>When operating, the three cells of the 207-A South Basins were filled alternately, sampled, and discharged to the 216-A-37-1 Crib after meeting release specifications. The 242-A Evaporator could retrieve the liquid waste for reprocessing or storage in the tank farm, via line 300, if discharge specifications were not met. After the 207-A North and South basins ceased to operate, the effluent was diverted to the 200 Area Treated Effluent Disposal Facility.</td>

The Following Sites Were Consolidated With This Site:
Names: 200-E-236-PL; 207-A South Basin Distribution Lines; Lines 557, 558, 559, 560, 562, and 563

Code: 211-A NU
Names: 211-A NU; Elementary Neutralization Unit/211-A Building; PUREX; 211-A Neutralization Unit
Type: Neutralization Tank
Status: Inactive
Start Date: 1/1/1986
End Date: 1/1/1990
Description: The site has been evaluated and reclassified to Rejected. The 211-A Neutralization Unit was located inside the 211-A Building.

TPA-MP-14, Rev. 2, Section 2.0 states that WIDS does not document buildings or facilities that do not contain TSD units. It further states that, after buildings are demolished, the footprint will be evaluated for potential soil contamination. If present, the soil contamination will be added to WIDS as a Discovery Site.

Location: The 211-A building is located adjacent to the north side of 202-A.

Process Description: PUREX process water was required to be very pure. The 211-A building contained the demineralizer columns (deionizer units). When the deionizers became loaded, they were recharged with acidic and basic solutions. The spent acid and basic solutions were combined in the 211-A Neutralization Unit. The pH was tested and adjusted until it was 7.0 pH. Then the solution was discharged to the chemical process sewer.

Waste Type: Animal Waste

Waste Description: Approximately 318 kilograms (700 pounds) per year of 9% sulfuric acid is combined with 272 kilograms (600 pound) per year of sodium hydroxide within the water demineralizer columns during regeneration.

Code: 216-A-39
Type: Crib
Status: Inactive
Start Date: 1/1/1966
End Date: 1/1/1966
Description: The site consists of a crib and two trenches dug from the north door of the 241-AX-801-A Building. The trenches extended to the brow of the north hill, then over the hill to the flat ground below. The trenches continued eastward 27 meters (90 feet). Later, a pipeline was added that connected the 241-AX-801-B building to the 216-A-39 crib.

Drawing H-2-33295 shows the crib structures. Each crib has three SCH 40 pipes. The drawing also states the crib was covered with approximately 6 meters (20 feet) of dirt in 1973. The risers were extended above the new grade in May 1973.

Location: Site is located near the southeast corner of the 241-AZ tank farm, inside the tank farm fence.

Release Description: This crib was built in 1966 to accommodate a liquid release that contaminated the 241-AX-801-A building. A team was changing out a valve on the 241-AX-103 tank recirculator line. The radioactive line pressurized and resulted in a release to the floor of the instrument (241-AX-801-A) building. Dose rates from the release were greater than 5 rad per hour at a distance of 3 meters (10 feet). A trench, 0.9 meters (3 feet deep), was dug to receive the liquid. The trench extended from the north side of the 241-A-801-A building to the brow if the north hill, then
Process Description: The 216-A-39 originally consisted of two trenches that received liquid from a spill of radioactive material in June 1966. In 1969, a pipeline was added to connect the 241-AX-801B building to the crib.

Waste Type: Equipment

Waste Description: The site originally received waste from a radioactive spill in the 241-AX-801-A Building (June 1966). The maximum dose rate from this release was 5 rad per hour at a distance of 3 meters (10 feet). Later, the crib received floor drainage via a pipeline from the 241-AX-801-B building.

Related Sites/Structures: The crib is associated with the 241-AX-801-A and 241-AX-801-B buildings.

Recycling: 242-A; 242-A Evaporator

Active Names: 242-A

Type: Evaporator

Status: Active

Classification: Accepted

Reclassification: None

Start Date: 1/1/1977

End Date: 

Description: The 242-A Building contains the evaporator vessel, supporting process equipment, and the principal process components of the evaporator-crystallizer system. The building comprises two adjoining, structurally independent structures, designated A and B. Structure A houses the processing and service areas while structure B houses operating and personnel support areas.

Location: This Evaporator building is located adjacent to the south side of the 241-A Tank Farm, outside the tank farm fence. It is near the corner of 4th Street and Canton Ave.

Related Sites/Structures: The structures associated with the unit include: the 241-AN, the 241-AP, and the 241-AW Tank Farms, and the 207-A Retention Basins. The pipelines from 242-A to the 207-A basins are sitecode 200-E-234-PL.

Process Description: The 242-A Evaporator is used to treat mixed waste from the Double-Shell Tank System by removing water and most volatile organics. Two waste streams leave the 242-A Evaporator following the treatment process. The first waste stream, the concentrated slurry, is pumped back into the Double-Shell Tank System (Tank Farms AN, AW, and/or AP). The second waste stream, process condensate, is routed through condensate filters for treatment before release to the Liquid Effluent Retention Facility and receives final treatment at the Effluent Treatment Facility.

Waste Type: Steam Condensate

Waste Description: Waste types include: dilute non-complexed radioactive waste, PUREX dilute miscellaneous waste, PUREX cladding removal waste, and complexed radioactive waste. Hazardous chemicals used include: sodium nitrate used to regenerate ion exchange column, sodium hydroxide used for decontamination applications, and the antifoam agent used in the evaporator.
vessel.

Code: 296-A-13  Classification: Accepted
Names: 296-A-13; 291-AR Filter Building Stack  Reclassification: None
Type: Stack  Start Date: 1/1/1997
Status: Inactive  End Date: 

Description: The site is a process effluent stack that was part of the 244-AR Canyon Exhaust Ventilation System (K-3). The stack is mounted on a buried concrete stand. The stack is equipped with a galvanized steel ladder, a stainless steel breech, a cleanout access, two stainless steel monitoring holes, 7.6 centimeters (3 inches) and 20.3 centimeters (8 inches), and spray rings. When the stack is operating, the exit temperature is 25.6 degrees Centigrade (78 degrees Fahrenheit) and exit velocity is 5 meters per second (16.4 feet per second). The stack has been plugged with grout and has not operated since 1997.

Location: The site is located due north of 291-AR Filter Building about 8.7 meters (28.5 feet) and 23 meters (75 feet) north of 244-AR Vault Building. The Washington State Plane coordinates listed in the Hanford Site Air Operating Permit Application are E575220 and N136090.

Related Sites/Structures: The site is related to the 291-AR Filter Building, 244-AR Vault Building, 291-AR Filter Building Extension and 216-A-41 Crib.

Process Description: The purpose of the ventilation system, identified as K-3, is to filter radiological contaminants from the canyon exhaust air prior to exhausting it to the atmosphere. Ventilation air exits Cell 1 (within 244-AR Vault) through a concrete air duct. The main duct terminates at a concrete gate and the branch turns left running south of the existing 291-AR Building where it connects to the east wall of the 291-AR Filter Vault Extension.

Two concrete exhaust ducts, each 3.5 meters (11.4 feet) wide by 2 meters (6.4 feet) deep, are located on the east and west corners of the ceiling at the north end of the filter building. These exhaust ducts extend 3.05 (10 feet) above the ceiling and are connected to the canyon exhaust ventilation fans (K3-9-1 and K3-9-2) located between the exhaust ducts. These fans draw the ventilation air from the canyon through the filters and exhaust to the canyon ventilation stack (296-A-13) located north of the 291-AR Filter Building. The ventilation system has been taken out of service and the suction fans have been blanked from the filter system.

Waste Type: Soil
Waste Description: The site received condensate and air exhaust from the 291-AR Filter Building. According to RHO-CD-673 (reference to 216-A-41 Crib), the waste was potentially slightly acidic and contained less than 1 curie total beta activity. Potential contaminants of concern (Stenner) may be tritium, cobalt-60, strontium-90, and cesium-137. WHC-SD-EN-RPT-007 states that radionuclide inventory is based on levels for "very high removable contamination" (WHC-CM-1-6) assuming worst case alpha (americium-241) and beta (strontium-90/yttrium-90) as representative nuclides. The level of contamination is assumed to be uniformly distributed over all ventilated surface areas. For americium-241 the contamination is 2,000 disintegrations per 100 square centimeters (dpm/100^2) and total activity of 0.00021 curies. For strontium-90 the contamination is 100,000 disintegrations per 100 square centimeters (dpm/100^2) and total activity of 0.0105 curies. For yttrium-90 the contamination is 100,000 disintegrations per 100 square centimeters (dpm/100^2) and total activity of 0.0105 curies. DOE/RL-94-51 lists the total alpha as 0.000000023 curies. Total beta is listed as 0.00000036 curies.
### Valve Pit

**Names:** 241-AN-A; 241-AN-A Diversion Box  
**Reclassification:** None

**Type:** Valve Pit  
**Start Date:** 1/1/1981

**Status:** Active  
**End Date:**

**Description:** This valve pit is fabricated of reinforced concrete. This valve pit accommodates pipes and jumpers and nozzles that go to different tanks. The valve pit is below grade with the cover block a few inches above grade.

**Location:** The unit is located inside the 241-AN Tank Farm fence, between the 241-AN-105 and 241-AN-106 tanks.

**Related Sites/Structures:** This unit is associated with the 241-A Tank Farm, the 241-AN-104 Tank, and the 242-A Evaporator.

**Process Description:** The valve pit has two functions. It routes slurry from the 242-A Evaporator to the designated 241-AN tanks and routes supernate from other tank farms to the 241-AN tanks.

**Waste Type:** Oil

**Waste Description:** This unit contains non-complexed waste, double-shell slurry waste, B Plant low-level waste, and PUREX low-level waste.

---

### Valve Pit

**Names:** 241-AN-B; 241-AN-B Diversion Box  
**Reclassification:** None

**Type:** Valve Pit  
**Start Date:** 1/1/1981

**Status:** Active  
**End Date:**

**Description:** This valve pit is fabricated of reinforced concrete. This valve pit accommodates pipes and jumpers and nozzles that go to different tanks. The valve pit is below grade with the cover block a few inches above grade.

**Location:** The unit is located inside the 241-AN Tank Farm fence, between the 241-AN-102 and 241-AN-103 tanks.

**Related Sites/Structures:** The unit is associated with the 241-A Tank Farm and the 241-AN-101 Tank.

**Process Description:** The valve pit has two functions. It routes slurry from the 242-A Evaporator to the designated 241-AN tanks and routes supernate from other tank farms to the 241-AN tanks. Waste material is routed through the 241-AN-B Valve Pit and then to the designated double-shell tanks. The 241-AN-B Valve Pit is connected by slurry lines and supernatant lines to the 241-AN-101, 241-AN-102, 241-AN-103 Double-Shell Tanks and the 241-AN-A Valve Pit.

**Waste Type:** Equipment

**Waste Description:** The unit contains non-complexed waste, double-shell slurry waste, B Plant low level waste, and PUREX low level waste.

---

### Double-Shell Tank

**Names:** 241-AN-101; 241-AN-TK-101  
**Reclassification:** None

**Type:** Double-Shell Tank  
**Start Date:** 9/1/1981

**Status:** Active  
**End Date:**

**Description:** This unit contains non-complexed waste, double-shell slurry waste, B Plant low level waste, and PUREX low level waste.
**Description:** The unit is comprised of a heat-treated, stress-relieved primary steel liner and a nonstress-relieved outer steel liner, both inside the reinforced concrete shell. The top of the dome was placed below grade for shielding.

**Location:** The 241-AN-101 Tank is located in the eastern portion of the 241-AN Tank Farm.

**Process Description:** The Double-Shell Tank System is used for the interim storage of liquid mixed waste generated on the Hanford Facility.

**Waste Type:** Oil

**Waste Description:** Tank 241-AN-101 began service by receiving non-complexed waste from PUREX in September 1981. Non-complexed waste was received and transferred through this tank until September 1990 when it began receiving dilute non-complexed waste. During this time, the tank also received low-level waste from B Plant, decontamination waste from N Reactor, and dilute non-complexed waste from the 200 East Area Single-Shell Tanks. As of March 1994, the tank was receiving only dilute non-complexed waste. The tank is an active dilute receiver tank which receives non-complexed salt well waste.

**Description:** Tank 241-AN-102 began service by receiving non-complexed waste from Tank 241-SY-102 in September 1981. The tank received non-complexed waste until December 1982. The tank received complexant concentrate waste from January 1983 until October 1983. From November 1983 until June 1984, the tank again received non-complexed waste. During 1984, the tank received low-level waste from PUREX. The tank received complexant concentrate waste from Tank 241-AW-101 from July 1984 until 1992 and has not received any waste since 1992. The tank is considered a concentrated waste holding tank.

**Description:** The unit is comprised of a heat-treated, stress-relieved, primary steel liner and a nonstress-relieved outer steel liner, both inside the reinforced concrete shell. The top of the dome was placed below grade for shielding.

**Location:** The 241-AN-103 Tank is located in the western portion of the 241-AN Tank Farm.
Process Description:

The Double-shell Tank System is used for the interim storage of liquid mixed waste generated on the Hanford facility.

Waste Type: Sanitary Sewage

Waste Description:

Tank 241-AN-103 began service by receiving non-complexed waste from Tank 241-SY-102 in September 1981. The tank received non-complexed waste until February 1984. During 1983, the tank received low-level waste from B Plant and dilute non-complexed waste from the 200-East Area single shell tanks. The tank received double-shell slurry feed waste from March 1984 until April 1986. Since May 1986, the tank has contained double-shell slurry waste. The tank has not received any waste, other than wash water, since 1986. The tank is considered a concentrated waste holding tank.

Recategorization:

241-AN-104; 241-AN-TK-104

Double-Shell Tank Active Names:

Type: Double-Shell Tank

Status: Active

Description: The unit is comprised of a heat-treated, stress-relieved primary steel liner and a nonstress-relieved outer steel liner, both inside the reinforced concrete shell. The top of the dome was placed below grade for shielding.

Location: The 241-AN-104 Tank is located in the eastern portion of the 241-AN Tank Farm.

Process Description:

The Double-Shell Tank System is used for the interim storage of liquid mixed waste generated on the Hanford facility.

Waste Type: Process Effluent

Waste Description:

Tank 241-AN-104 began service by receiving non-complexed waste in September 1981. The majority of the waste was sent from Tank 241-AW-102 during 1982. The tank continued to receive non-complexed waste until November 1982. The tank has contained double-shell slurry feed waste from December 1982 until the present. During 1983, the tank also received low-level waste from PUREX. The tank has not received waste since 1985. The tank is considered a concentrated waste holding tank.

Recategorization:

241-AN-105; 241-AN-TK-105

Double-Shell Tank Active Names:

Type: Double-Shell Tank

Status: Active

Description: The unit is comprised of a heat-treated, stress-relieved primary steel liner and a nonstress-relieved outer steel liner, both inside the reinforced concrete shell. The top of the dome was placed below grade for shielding.

Location: The 241-AN-105 Tank is located in the central portion of the 241-AN Tank Farm.

Process Description:

The Double-Shell Tank System is used for the interim storage of liquid mixed waste generated on the Hanford Facility.

Waste Type: Sanitary Sewage
Waste Description: Tank 241-AN-105 began service by receiving non-complexed waste in September 1981. The tank continued to receive non-complexed waste until November 1982. The tank received double-shell slurry feed waste from Tanks 241-AW-102 and 241-AN-104 from December 1982 until 1985, when waste reception ceased. The tank is considered a concentrated waste holding tank.

Description: The unit is comprised of a heat-treated, stress-relieved primary steel liner and a nonstress-relieved outer steel liner, both inside the reinforced concrete shell. The top of the dome was placed below grade for shielding.

Location: The 241-AN-106 Tank is located in the western portion of the 241-AN Tank Farm.

Process Description: The Double-Shell Tank System is used for the interim storage of liquid mixed waste generated on the Hanford Facility.

Waste Type: Chemicals

Waste Description: Tank 241-AN-106 began service by receiving non-complexed waste in September 1981. The tank continued to receive non-complexed waste until January 1983. From February 1983 until February 1984, the tank received concentrated customer waste. The tank contained Hanford facility waste from March 1984 until May 1990. From June 1990 until the present, the waste contained in the tank has been designated as phosphate waste. The tank has not received any waste, other than wash water, since 1984. The supernatant was pumped to Tank 241-AP-102 during 1992. The tank is considered a concentrated waste holding tank.

Description: The unit is comprised of a heat-treated, stress-relieved primary steel liner and a nonstress-relieved outer steel liner, both inside the reinforced concrete shell. The top of the dome was placed below grade for shielding.

Location: The 241-AN-107 Tank is located in the northwestern portion of the 241-AN Tank Farm.

Process Description: The Double-Shell Tank system is used for the interim storage of liquid mixed waste generated on the Hanford Facility.

Waste Type: Soil

Waste Description: Tank 241-AN-107 began service by receiving non-complexed waste in September 1981 from Tank 241-AN-102. The tank continued to receive non-complexed waste until June 1983. From July 1983 until the present, the tank has contained complexant concentrate waste, most of which was received from Tank 241-AZ-102 during 1983. The tank has not received any waste since 1986. The tank is considered a concentrated waste holding tank.
The cover block is made in two sections. The valve pit has a floor drain that empties to tank 241-AP-103. On the east end of the pit is a jumper storage area separated from the process side by a wall. The jumper storage area has 10 gage stainless steel liner on the floors and walls. The floor drain is in both the process and storage sides of the valve pit. It is not initially encased from the floor, but is encased as it leaves the valve pit area. All concrete and ferrous materials are treated with protective coating.

Location: The valve pit is located on the west side of the 241-AP Tank Farm, between tanks 241-AP-103 and 241-AP-105.

Related Sites/Structures: The valve pit is associated with the 241-AP Tank Farm and 241-AP-103 Tank.

Process Description: The unit is used for the transfer of liquid mixed waste within the tank farm.

Waste Type: Steam Condensate

Waste Description: The AP Tank Farm began receiving waste in July 1986. The waste consisted of non-complexed waste, Hanford Site facilities waste, double-shell slurry waste, low-level waste from PUREX, and N Reactor decontamination waste.

The tank is a double-shell tank with an outer structure of reinforced concrete lined with carbon steel. The primary tank is carbon steel located within the secondary liner. The tanks are separated by an annular space. The tank is placed on a concrete foundation. The dome is below grade for shielding.

Location: The 241-AP-101 tank is located in the northwest corner of the 241-AP Tank Farm.

Process Description: The Double-Shell tank system is used for the interim storage of liquid mixed waste generated on the Hanford Facility.

Waste Type: Steam Condensate

Waste Description: Tank 241-AP-101 began service by receiving non-complexed waste in July 1986. During 1987, 1988, and 1989, the tank received waste from PUREX. The tank received non-complexed waste until May 1990. From June 1990 until the present, the tank has contained dilute non-complexed waste. The tank has not received any waste since the fourth quarter of 1989. The tank is currently an active dilute receiver tank containing waste that is being concentrated by the 242-A Evaporator.
### Double-Shell Tank

**Type:** Double-Shell Tank  
**Start Date:** 1/1/1986  
**Status:** Active  
**End Date:**

**Description:** The tank is a double-shell tank with an outer structure of reinforced concrete lined with carbon steel. The primary tank is carbon steel located within the secondary liner. The tanks are separated by an annular space. The tank is placed on a concrete foundation. The dome is below grade for shielding.

**Location:** The 241-AP-102 tank is located in the northeast corner of the 241-AP Tank Farm.

**Process Description:** The Double-Shell Tank System is used for the interim storage of liquid mixed waste generated on the Hanford Facility.

**Waste Type:** Steam Condensate

**Waste Description:** Tank 241-AP-201 began service by receiving Hanford facility waste in July 1986. The tank received Hanford facility waste until May 1990. During 1988 and 1989, waste was transferred from the tank to the grout vaults. The tank received waste from PUREX during the third and fourth quarters of 1989. The tank has contained dilute non-complexed waste since June 1990. The tank has not received any waste since 1992. The tank is currently an inactive, grout feed tank containing excess water from the grout facility.

### Additional Information

**Code:** 241-AP-103  
**Classification:** Accepted

**Names:** 241-AP-103; 241-AP-TK-103  
**Reclassification:** None

**Type:** Double-Shell Tank

**Status:** Active  
**End Date:**

**Description:** The tank is a double-shell tank with an outer structure of reinforced concrete lined with carbon steel. The primary tank is carbon steel located within the secondary liner. The tanks are separated by an annular space. The tank is placed on a concrete foundation. The dome is below grade for shielding.

**Location:** The 241-AP-106 tank is located in the southwest portion of the 241-AP Tank Farm.

**Process Description:** The Double-Shell Tank System is used for the interim storage of liquid mixed waste generated on the Hanford Facility.

<td>The facility is includes four chemical storage/makeup tanks and a catch tank (204-AR-TK-1).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The 204-AR Facility receives railroad tank cars of liquid radioactive waste to be remotely unloaded inside a fully enclosed, heated, and ventilated building. The structure is a versatile facility that allows the pumping, sampling, and sluicing of the tank cars. Sluicing removes sludge buildup from the tanks and is done during or after the material is pumped out. When samples results show the contents of the railroad car or the catch tank do not meet tank farm specifications, chemical adjustments are made inside the rail car or catch tank. Liquids in the catch tank is periodically to the tank farm on a batch basis. Liquid in excess of the catch tank capacity overflows into the sump pit, that can be pumped to the 241-A-A valve pit.</td>
<td></td>

Waste Type: Steam Condensate

Waste Description: Low-level PUREX waste, complexant concentrate waste, complexed waste and dilute non-complexed, double-shell slurry waste, and non-complexed waste was received and distributed to all tanks via this diversion box.

Code: 241-AW-101
Type: Double-Shell Tank
Status: Active
Start Date: 1/1/1980

Description: The unit is comprised of a heat-treated, stress-relieved primary steel liner and a nonstress-relieved outer steel liner, both inside the reinforced concrete shell. The top of the dome is below grade for shielding.

Location: The 241-AW-101 tank is located in the northwest corner of the 241-AW Tank Farm.

Process Description: The Double-Shell Tank System is used for the interim storage of liquid mixed waste generated on the Hanford Facility.

Waste Type: Animal Waste
Waste Description: Tank 241-AW-101 began service by receiving non-complexed waste in July 1980. The tank continued to receive non-complexed waste until November 1981, and again from December 1982 until March 1983. From December 1981 until November 1982, the tank received dilute double-shell slurry feed waste. The tank received complexant concentrate waste from April 1982 until June 1984. From July 1984 until April 1986, the tank again received non-complexed waste. The tank received waste from PUREX and dilute non-complexed waste from the 200-East Area Single-Shell Tanks from 1984 until 1986. The tank contained double-shell slurry feed waste from May 1986 until the present. The tank has not received waste since 1986. The tank is currently an inactive concentrated waste holding tank.

The catch tank is a 41,640 liter (11,000 gallon) stainless steel lined catch tank located below the four diverter tanks inside the 241-AX-151 Diverter Station. The catch tank received drainage from the diverter tanks, cells and pump pit. The contents of the catch tank could be jetted to diverter tank E or F. The catch tank contains 11,150 liters (2946 gallons) of supernate waste that is anticipated to consist of waste similar to that contained in AX tank farm. The capacity of the catch tank is approximately 12,200 gallons (per RPP-RPT-31102).

Classification: Accepted
Reclassification: None
Start Date: 1/1/1971
End Date:

Description: The unit is composed of a heat-treated, stress-relieved primary steel liner and a nonstressed-relieved secondary steel liner, both inside a reinforced concrete shell. The dome is located below grade for shielding purposes.

Location: The 241-AY-101 tank is located on the north end of the 241-AY Tank Farm.

Related Sites/Structures: Structures associated with this tank include leak detection, monitoring and radiation instrumentation, ventilation systems, and risers.

Process Description: The tank is used for interim storage of waste generation on the Hanford Facility.

Waste Type: Misc. Trash and Debris
Waste Description: Dilute complexed waste is characterized by a high content of organic carbon including organic complexants, including: ethylenediaminetetra-acetic acid, citric acid, and hydroxyethyl-ethylenediaminetriacetic acid, being the major complexants used. Main sources of dilute complexed waste in the double shell tank system are saltwell liquid inventory.

Related Sites/Structures: Structures associated with this tank include leak detection monitoring and radiation instrumentation, ventilation systems and risers.
**Process Description:**
The tank is used for interim storage of liquid mixed waste generated on the Hanford Site.

**Waste Description:**
The unit has received neutralized high-level waste and double-shell slurry feed and is currently a dilute noncomplexed waste receiver tank. Prior to evaporator processing, samples are taken and analyzed for parameters such as visual appearance; percent solids; exotherms or endotherms; total organic carbon; gamma energy spectrum; weight percent water; pH; specific gravity; viscosity; and for the specific ions Al, OH, Cl, CO3, F, Na, NO2, NO3, Pm, PO4, Pu, SO4, Sr, Am, and Np. The unit received supernatant consisting of double-shell slurry feed and noncomplexed waste from A and BX tank farms.

**Code:** 241-AY-151  
**Classification:** Accepted

**Names:** 241-AY-151; 241-AY-151 Diversion Box; 241-AY-151 Pump Out Pit  
**Reclassification:** None

**Type:** Diversion Box  
**Start Date:** 1/1/1975

**Status:** Inactive  
**End Date:**

**Description:** This unit is an underground, reinforced concrete structure. It contains four PUREX style nozzles.

**Location:** The 241-AY-151 is located in the southern portion of the 241-AY Tank Farm.

**Related Sites/Structures:**
The unit is associated with single shell Tank Farms 241-A and 241-AX.

**Process Description:** This unit was used to transport radioactive waste solutions between storage and process facilities.

**Waste Type:** Process Effluent

**Waste Description:** The diversion box transferred liquid process waste between the processing plants and the tank farms. Lead shielding may also be contained inside the diversion box.

**Code:** 241-AZ VP  
**Classification:** Accepted

**Names:** 241-AZ VP; 241-AZ Valve Pit  
**Reclassification:** None

**Type:** Valve Pit  
**Start Date:**

**Status:** Active  
**End Date:**

**Description:** The valve pit surface features include a cement structure extending a few inches above the ground, with white cover blocks. T-handles and instrumentation extend through the cover blocks.

**Location:** The valve pit is located east of 241-AZ-101, inside the tank farm fence.

**Process Description:** The 241-AZ Valve Pit distributes waste between the 200 East Area double shell tank farms.

**Process Description:** The AZ valve pit has transfer lines internal to the AY and AZ Tank Farms (line SN-633 to 241-A-
AY-02A pump pit, Floor Drain to AZ-101, and line SN-632 to 241-AZ-01A pump pit) and external transfer lines (line SN-630 to 241-AN-01A pump pit and line SN-637 to 241-AP-A valve pit). This AZ valve pit is RCRA compliant and is active.

**Process Description:** The double-shell tank system is used for the interim storage of liquid mixed waste generated on the Hanford Facility.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The tank is currently an inactive, dilute receiver tank that receives only condensate from other aging waste tanks. From April 1986 until the present, the tank has contained aging waste.
The tank received waste from PUREX from 1986 until 1990. From February 1984 until February 1986, the tank received non-complexed waste. The tank received complexant concentrate waste from 1978 until November 1983. During December 1983 and January 1984, the tank received complexed waste. During 1977, the tank received residual liquor waste. Tank 241-AZ-102 began service by receiving water in 1976 and was labeled as a spare. The tank received evaporator waste from 1976 until 1977.

---

**Code:** 241-AZ-151CT  
**Classification:** Accepted

**Names:** 241-AZ-151CT; 241-AZ-151 Catch Tank  
**Reclassification:** Consolidated (5/3/2006)

**Type:** Catch Tank  
**Start Date:** 1/1/1977

**Status:** Inactive  
**End Date:**

**Description:** The catch tank is not visible from the surface. The catch tank portion is constructed below the diverter station.

**Location:** The 241-AZ-151 diverter station and catch tank are located southwest of 241-AZ-102 tank, inside the 241-AZ Tank Farm fence.

**Related Sites/Structures:** The 241-AZ-151 Diverter Station structure, which includes the diverter station and the catch tank, is associated with the 241-AZ Tank Farm tanks and facilities. The catch tank portion is constructed below the diverter station.

**Process Description:** The 241-AZ-151 Diverter Station structure transfers radioactive solutions, from various processing and decontamination operations, to tank farm tanks and facilities. Multiple transfer lines enter a 189 liter (50 gallon) tank in the diverter station. A spigot from the tank is rotated to engage in one of several pipe terminal openings to complete a desired routing. Containment is provided by the concrete walls, floor and cover blocks. The 241-AZ-151 Catch Tank is located directly below the receiving tank to contain transfer leakage. The catch tank (catch basin) has a concrete floor that slopes to a sump an collects leakage from both the pump pit and diverter room portions of the diverter station.

**Waste Type:** Water

**Waste Description:** This unit was used for transfer of mixed waste solutions from processing and decontamination operations. In 1994, it contained 15846 liters (4,170 gallons) of waste. In 2000, it contained 8037 liters (2115 gallons). The Tank Waste Summary documents indicate the diverter station and catch basin are active and the liquid volume changes daily. The liquid is pumped to the 241-AZ-102 tank as needed. Lead shielding may also be contained inside the diversion box.

**This Site Was Consolidated With:**

**Code:** 241-AZ-151DS  
**Names:** 241-AZ-151DS; 241-AZ-151-DS Diverter Station; 241-AZ-151 Diverter Station

---

**Code:** 241-AZ-151DS  
**Classification:** Accepted

**Names:** 241-AZ-151DS; 241-AZ-151-DS Diverter Station; 241-AZ-151 Diverter Station  
**Reclassification:** None

**Type:** Diversion Box  
**Start Date:** 1/1/1976

**Status:** Inactive  
**End Date:**

**Description:** The diverter station is an underground reinforced concrete structure. The catch tank is located under the 241-AZ-151DS Diverter Station (Drawing H-2-67256). It is part of the diverter station structure.
Location: 241-AZ-151 Diverter Station is located southwest of 241-AZ-102 tank, inside the 241-AZ Tank Farm fence.

Related Sites/Structures: The 241-AZ-151 Diverter Station and catch tank are associated with the 241-AZ Tank Farm, the AZ Loop Seal, and the 241-AZ-151 Catch Tank.

Process Description: The 241-AZ-151 Diverter Station transfers radioactive solutions, from processing and decontamination operations, to various tank farm tanks and facilities. Multiple transfer lines enter a small, 189 liters (50 gallons) tank. A spigot from the tank is rotated to engage in one of several pipe terminal openings to complete a desired routing. Containment is provided by the concrete walls, floor and cover blocks. The 241-AZ-151 Catch Tank is located directly below the receiving tank to contain transfer leakage. The catch tank is located under the 241-AZ-151DS Diverter Station (Drawing H-2-67256). It is part of the diverter station structure.

Waste Type: Demolition and Inert Waste

Waste Description: This unit was used to transfer of waste solutions from processing and decontamination operations. Volumes were variable according to specific plant operation. The types of waste received by this unit include: aging waste, concentrated complexant, double-shell slurry feed, and non-complexed waste. In 1994, it contained 15846 liters (4,170 gallons) of waste. In 2000, it contained 8037 liters (2115 gallons). The Tank Waste Summary documents indicate the diverter station and catch basin are active and the liquid volume changes daily.

The Following Sites Were Consolidated With This Site:

Code: 241-AZ-151CT
Names: 241-AZ-151CT; 241-AZ-151 Catch Tank

Code: 241-AZ-152 Classification: Accepted
Names: 241-AZ-152; 241-AZ-152 Diversion Box; 241-AZ-152 Sluice Transfer Box
Reclassification: None
Type: Diversion Box Start Date: 1/1/1977
Status: Inactive End Date:
Description: 241-AZ-152 is a reinforced concrete diversion box. All nozzles are 4 inch (10 centimeter) PUREX style.
Location: The 241-AZ-152 Diversion Box is located in the southwestern portion of the 241-AZ Tank Farm, east of the 241-AZ-151 Diverter Station.
Related Sites/Structures: The 241-AZ-152 interconnects the 241-AZ Tank Farm, the 241-AY Tank Farm, 241-AZ-151CT, and the 241-AY-152.
Process Description: The 241-AZ-152 diversion box transports radioactive waste solutions from processing and decontamination operations. Drainage is collected in the 241-AZ-151 Catch Tank.
Waste Type: Misc. Trash and Debris
Waste Description: 241-AX-152 contains high-level B Plant waste, aging waste, B Plant cesium feed waste, non-complexed waste, concentrated complex waste, cesium/strontium recovery waste, evaporator waste, double-shell tank slurry, low-level waste from B Plant, condensate (aging waste), residual liquor, and PUREX low-level waste. Lead shielding may also be contained inside the diversion box.

Code: 241-AZ-154 Classification: Accepted

Hanford Site Waste Management Units Report
February 2015
### Catch Tank

- **Names:** 241-AZ-154; 241-AZ-154 Catch Tank
- **Type:** Catch Tank
- **Status:** Inactive
- **Description:** The site is an underground carbon steel tank with a stainless steel liner.
- **Location:** The catch tank is located inside the 241-AZ tank farm, south of tank 241-AZ-101.
- **Process Description:** The 241-AZ-154 catch tank collected condensate from 241-AZ-101 and 241-AZ-102 in-tank steam heating coils. The catch tank was pumped into 241-A-417, but could also overflow into 241-AZ-102. The condensate passed through a radiation detector (241-F505) and then to a crib or to 241-A-417.
- **Waste Type:** Sanitary Sewage
- **Waste Description:** The catch tank received steam condensate from the 241-AZ-101 and 241-AZ-102 in-tank heating coils as well as precipitation and runoff. The only potential source of radioactive contamination was tank waste leaking into the steam coils that contaminated the condensate.

### Contaminated Storage Pit

- **Names:** 241-AZ-155; 241-AZ-155 Contaminated Storage Pit
- **Type:** Silo
- **Status:** Active
- **Location:** The pit is located inside the 241-AZ tank farm, southwest of the 241-AZ-102 tank.
- **Process Description:** The storage pit was and can be used to house failed long length contaminated equipment (e.g., transfer pumps, instrument trees). There are no jumpers or transfer lines that come into the pit. Should any liquid be found in the pit a jet pump could be installed in the pits sump to pump the liquid out.

### Expansion Ponds

- **Names:** 216-B-3A; B Pond First Expansion Lobe; B Pond Lobe A; West Expansion Lobe
- **Type:** Pond
- **Status:** Inactive
- **Location:** The site is located east of the 200 East Area perimeter fence. It is directly east of 216-B-3 Main Pond.
- **Description:** The 216-3-3A, 216-B-3B and 216-B-3C Expansion Ponds are considered a single RCRA TSD unit in the Hanford Facility Dangerous Waste Part A Permit Application (section 4.2.3.11). This RCRA TSD unit was clean closed on June 27, 1995. The waste site is RCRA constituent of a pond that was used for overflow from 216-B-3. The pond is roughly rectangular with approximately 4.5 hectares (11 acres) of surface area. It is inactive and dry. It was sampled and released from radiological controls with the exception of the percolation trench that is posted as a Soil Contamination Area. Radiological issues related to these expansion ponds will be addressed separately (see WIDS Sitecodes 216-B-3A RAD, 216-B-3B RAD, 216-B-3C RAD).
Related Sites/ Structures: The site is associated with the PUREX facility, the 216-B-3 Pond and UPR-200-E-14.

Process Description: The 216-B-3A was constructed to receive overflow from the 216-B-3 Main Pond due to the increased effluent discharge from the restart of the Plutonium Uranium Extraction (PUREX) plant (202-A). The 216-B-3A Overflow Pond was connected to the 216-B-3 Main Pond by the 216-B-351 Spillway. The spillway was designed with a manually operated slide gate in the headwall. The water flowed from the main pond, through the culvert, down a 0.61-meter (2-foot) wide, concrete-lined ditch, to a fiberglass reinforced 0.3-meter (1-foot) flume, to the overflow pond. The pond operated from October 1983 to January 1984, when the dike between the 216-B-3A and 216-B-3B ponds failed (Occurrence Report #84-02). Prior to the dike failure, the 216-B-3B Pond had never been used. All the discharge from the failed dike was contained in the 216-B-3B Pond. In response to the incident, the 216-B-3A and 216-B-3B Ponds were isolated. Effluent flow to the 216-B-3 Main Pond was reduced. A trench was dug in the 216-B-3A Pond to increase its infiltration rate. The trench measured 182 meters (600 feet) by 9 meters (30 feet) and was 2 meters (6 feet) deep. The debris from the dike failure was removed from the 216-B-3B Pond and a series of trenches were dug to increase its infiltration rate. Both 216-B-3A and 216-B-3B Ponds were fully operational by June 1984. In April 1994, discharges to the main pond and 216-B-3A lobe ceased and all effluent was rerouted to the 216-B-3C lobe via a pipeline.

Waste Type: Process Effluent

Waste Description: The site received overflow from the 216-B-3 Main Pond. Potential sources include 221-B steam condensate and process cooling water, 284-E Powerhouse water, 244-CR, 244-AR and 242-A cooling water, 202-A process, condenser, and air sampler vacuum pump cooling water, 202-A chemical sewer, fractionator condensate, and WESF cooling water.

Closure Info: A letter was issued by the Washington State Department of Ecology on June 27, 1995, accepting the TSD clean closure certification for the 216-B-3 Expansion Ponds in accordance with Washington State Administrative Code 173-303-610 (6).

Code: 216-B-3B  Classification: Accepted
Names: 216-B-3B; B Pond Lobe B; B Pond Second Expansion Lobe; East Expansion Lobe  Reclassification: Closed Out (6/27/1995)
Type: Pond  Start Date: 1/1/1983
Status: Inactive  End Date: 1/1/1995
Description: The 216-3-3A, 216-B-3B and 216-B-3C Expansion Ponds are considered a single RCRA TSD unit in the Hanford Facility Dangerous Waste Part A Permit Application (section 4.2.3.11). This RCRA TSD unit was clean closed on June 27, 1995. The waste site is RCRA constituent of a pond that was used for overflow from 216-B-3A pond. The pond is approximately 6.27 hectares (15.5 acres) of surface area. It is inactive and dry with a small posted radiological area in the northwest corner. Radiological issues related to these expansion ponds will be addressed separately (see WIDS Sitecodes 216-B-3A RAD, 216-B-3B RAD, 216-B-3C RAD).

Location: The site is located east of the 200 Area perimeter fence. It is southeast of 216-B-3 Main Pond, adjacent to the east side of the 216-B-3A overflow pond.

Process Description: The 216-B-3A and 216-B-3B Expansion Ponds were built in 1983 to receive overflow from the 216-B-3 Main Pond due to increased discharges of effluent from the restart of PUREX. In January 1984, the dike between the 216-B-3A and 216-B-3B ponds failed. Prior to the dike failure, the 216-B-3B Pond had never been used. All the discharge from the failed dike was contained in the 216-B-3B Pond. In response to the incident, the 216-B-3A and 216-B-3B
Ponds were isolated. Effluent flow to the 216-B-3 Main Pond was reduced. A trench was dug in the 216-B-3A Pond to increase its infiltration rate. The trench measured 182 meters (600 feet) by 9 meters (30 feet) and was 2 meters (6 feet) deep. The debris from the dike failure was removed from the 216-B-3B Pond and a series of trenches were dug to increase its infiltration rate. Both 216-B-3A and 216-B-3B Ponds were fully operational by June 1984. Although 216-B-3B was considered an active pond, it never received any effluent with the exception of the 216-B-3A dike failure incident.

Waste Type: Storage Tank
Waste Description: The 216-B-3A and 3B Expansion Lobes were constructed in 1983 to receive increased discharges from the 216-B-3 Main Pond due to the increased water volume from the restart of the PUREX Plant. A dike between the 216-B-3A and 3B ponds failed in January of 1984. The discharge from the failed dike was contained with the 216-B-3B lobe. Prior to the dike failure the 216-B-3B lobe had never received any effluent. In response to the incident, the 3A and 3B lobes were isolated and trenches were dug in the bottoms of the expansion ponds to increase infiltration rates. The 216-B-3B lobe was taken out of service in May of 1985. It remained potentially active until it was clean closed in June of 1995.

Closure Info: A letter was issued by the Washington State Department of Ecology on June 27, 1995, accepting the TSD clean closure certification for the 216-B-3 Expansion Ponds in accordance with Washington State Administrative Code 173-303-610 (6).

Code: 216-B-3C
Names: 216-B-3C; B Pond Lobe C; B Pond Third Expansion Lobe
Type: Pond
Status: Inactive
Start Date: 1/1/1985
End Date: 1/1/1997
Description: The 216-3-3A, 216-B-3B and 216-B-3C Expansion Ponds are considered a single RCRA TSD unit in the Hanford Facility Dangerous Waste Part A Permit Application (section 4.2.3.11). This RCRA TSD unit was clean closed on June 27, 1995. The waste site is RCRA constituent of a pond that was used for overflow from 216-B-3 and the 216-B-3-3 ditch. The pond is a rectangular shaped pond with approximately 17 hectares (41 acres) of surface area. It was excavated into a very coarse gravel layer with a very high percolation rate. It contained eight parallel trenches that ran in a north-south direction, extending the entire length of the pond. An area on the east side of the pond has been backfilled and surface stabilized. It is posted as an Underground Radioactive Material Area. The remaining of the pond is posted as a Contamination Area. Radiological issues related to these expansion ponds will be addressed separately (see WIDS Sitecodes 216-B-3A RAD, 216-B-3B RAD, 216-B-3C RAD).

Location: The site is located east of the 200 East Area perimeter fence and southeast of the 216-B-3 Main Pond.
Related Sites/Structures: The site is associated with the PUREX facility, 216-B-3 Main Pond, 216-B-3A Lobe, 200-E-126-PL pipeline and the 200 East Powerhouse Ditch.
Process Description: The 216-B-3C Lobe was constructed in 1985 to accommodate the increased effluent flow to the B Pond complex due to the decommissioning of the 216-A-25 (Gable Pond). From 1985 to 1994, the site received overflow form the 216-B-3 Main Pond. In 1994, when the 216-B-3-Ditch and the 216-B-3 Main Pond sites were decommissioned, effluent was routed directly to the 216-B-3C Pond via a pipeline. The pond received diminishing amounts of effluent until 1997, when the last remaining effluent was permanently diverted to the 200 Area Treated Effluent Disposal Facility.
**Waste Type:** Equipment

**Waste Description:** The site received non-RCRA regulated waste water consisting of steam condensate and cooling water.

**Closure Info:** A letter was issued by the Washington State Department of Ecology on June 27, 1995, accepting the TSD clean closure certification for the 216-B-3 Expansion Ponds in accordance with Washington State Administrative Code 173-303-610 (6).

---

**Code:** 216-B-56

**Names:** 216-B-56; 216-B-56 Crib

**Type:** Crib

**Status:** Inactive

**Description:** The site is enclosed with post and chain and labeled "crib". There are no radiological postings. A site visit on July 29, 1999, found the site surrounded by post and chain and labeled "CRIB". Three risers are visible in the center of the crib. Most of the site soil with some grasses and rabbit brush growing on the surface. There is no evidence that any stabilization has taken place. The pipeline connection to the unit was not installed. A pipe exits the ground south of the crib and extends vertically above grade approximately 0.9 meters (3 feet). The vertical pipe is labeled 'end of stub.' Well 299-E28-14 (well id A6792) is located northwest of the crib's southwest corner.

**Location:** The crib is located northeast of the 221-B Building, north of 7th Street and south of 216-B-59 and 216-B-59B Basins.

**Related Sites/Structures:** Within the crib structure, there are two 20.3 centimeter (8 inch) diameter liquid level gauge wells constructed of steel with galvanized metal caps. These wells are about 4.6 meters (15 feet) long and extend 0.9 meters (3 feet) above grade. These monitoring wells are located on each side of the pipe that runs the length of the crib. There is also a 10.2 centimeter (4 inch) vent pipe, 4.6 meters (15 feet) long rising from the north end of the distributor pipe and extending 1.2 meters (4 feet) above grade. The site was planned to be connected by a steel pipeline to 241-B-154 Diversion Box, but it never was. The crib was constructed with a side slope of 1:1.5. The crib was constructed with 1.2 meters (4 feet) of 1.9 - 3.8 centimeter (0.75 - 1.5 inch) gravel at the bottom of the crib, followed by 0.4 meters (1.25 feet) of 0.64 to 1.3 centimeter (0.25 to 0.5 inch) gravel, followed by a membrane barrier covered by sand. A membrane barrier was placed over the gravel and 0.61 meters (2 feet) up the sides of the crib. The site was then backfilled. A perforated 10.2 centimeter (4 inch) vitrified clay pipe runs the length of the crib 0.9 meters (3 feet) above the bottom. The site was associated with 221-B (B-Plant).

**Process Description:** Originally, the site was constructed to receive organic waste from 221-B (B-Plant). The pipeline connection to the site was never installed because of a change in disposal practices. Organic waste disposal to the ground was stopped, so this crib was never activated.

**Waste Type:** Storage Tank

**Waste Description:** The site was built but never used. No inventory is listed for the crib.

---

**Code:** 216-B-61

**Names:** 216-B-61; 216-B-61 Crib

**Type:** Crib

**Classification:** Accepted

**Reclassification:** Rejected (1/25/2000)

**Start Date:** 1/1/1968

---

Hanford Site Waste Management Units Report
February 2015

1783
The site is a backfilled crib that has never been used. It appears as a vegetated field. Boreholes, sampling, drawings, and process knowledge show that the crib was never used. The surface had been posted as a Contamination Area. The contamination is assumed to be the result of wind-blown contamination from adjacent areas (see sitecode 200-E-105). The contamination and the Contamination Area postings have been removed. The site is technically considered a Radiologically Controlled Area (RCA), because the 200 East Area perimeter fence is posted RCA. The crib is located inside the perimeter fence.

Location: The unit is 152 meters (500 feet) northwest of 241-BY Tank Farm and 61 meters (200 feet) south of 12th Street.

Process Description: The crib was built to receive intermediate level process condensate from the ITS #1 unit (located in the 241-BY Tank Farm) when the 216-B-50 Crib reached its radionuclide capacity. However, the 216-B-61 crib was never used. A 0.6 meter by 0.6 meter by 0.3 foot (2 foot by 2 foot by 1 foot) thick concrete pad was laid in the crib bottom. The crib was filled with 122 cubic meters (160 cubic yards) of 1.9 to 7.6 centimeter (0.75 to 3 inch) gravel. 279 square meters (3,000 square feet) of plastic membrane barrier were laid over the gravel. 22 cubic meters (30 cubic yards) of sand were laid over the membrane. A gage well constructed of vitrified clay 20 centimeters (8 inches) in diameter and 3.96 meters (13 feet long) extended from the crib bottom to 0.6 meters (2 feet) above grade. This vent pipe has a filter on top of the pipe. The bottom 0.6 meters (2 feet) of the pipe are perforated. A 10.2 centimeter (4 inch) diameter perforated pipe runs the length of the crib, 0.3 meters (1 foot) above the bottom of the crib.

Waste Type: Soil
Waste Description: This crib was built to receive condensate from the ITS (In Tank Solidification) unit, but never received any waste. It was never used.
**WIDS as a Discovery Site.**

**Location:** The 217-B Building is directly north of the 221-B Canyon and northeast of 271-B.

**Related Sites/Structures:** Structures associated with this site include supply and return water lines, blanked steam supplies, and the demineralizer equipment.

**Process Description:** The building is currently inactive because a new ion pure system was installed in 271-B during 1993. From 1985 to 1993, the building used an Illinois water treatment demineralizer system to provide demineralized water to the B Plant and Waste Encapsulation and Storage Facility. The systems resin was depleted in 1993. Sulfuric acid and nitric acid were used to regenerate the ion exchange columns.

**Waste Type:** Equipment

**Waste Description:** Demineralizer operations generated waste when the ion exchange columns were regenerated. Sodium hydroxide was used to regenerate the anion column, while sulfuric acid was used to regenerate the cation column. The sulfuric acid was neutralized with sodium carbonate, while the sodium hydroxide was neutralized with monosodium phosphate prior to discharge the 216-B-63 trench.

**Related Sites/Structures:**
The site was associated with the B Plant chemical sewer.

**Waste Type:** Process Effluent

**Waste Description:** Approximately 400 gallons (1,500 liters) per year of 1 Molar nitric acid is neutralized with 350 pounds (160 kilograms) per year of sodium carbonate.

**Code:** 221-B SDT

**Classification:** Accepted

**Names:** 221-B SDT; 221-B Settle and Decant Tank; 221-B-8-1 and 221-B-8-2; 221-B-TK-8-1 and 221-B-TK-8-2; B Plant Settle and Decant Tank

**Reclassification:** None
### Settling Tank

**Type:** Settling Tank  
**Status:** Inactive  
**Start Date:** 1/1/1945  
**End Date:**

**Description:** The 221-B Settle and Decant Tank consists of two cylindrical tanks in Cell 8: 221-B-8-1 and 221-B-8-2. The two tanks are isolated and decommissioned. The tanks were used in the neutralized current acid waste pretreated mission.

**Location:** The two tanks take up most of the spare Cell 8, near the east end of 221-B Building.

**Related Sites/Structures:** Structures associated with this site include the cell, the jumpers and transfer lines in this cell, the two tanks in the cell, and the rest of the neutralized current acid waste system.

**Process Description:** The unit was designed to operate as part of the neutralized current acid waste treatment process. The tanks were used as part of the primary solid/liquid separation process where solids were allowed to settle and the supernatant was decanted.

**Waste Type:** Equipment

**Waste Description:** The unit received neutralized current acid waste during the pretreatment mission, where the tanks acted as settling tanks. Prior to this, the tanks were used in the cesium and strontium recovery efforts.

---

### Related Sites/Structures

**Code:** 221-B SHNU  
**Classification:** Accepted  
**Reclassification:** Interim No Action (10/6/2005)

**Names:** 221-B SHNU; 221-B Sodium Hydroxide Neutralization Unit; 221-B Elementary Neutralization Unit for Sodium Hydroxide

**Type:** Neutralization Tank  
**Start Date:** 1/1/1984  
**End Date:** 1/1/1997

**Description:** This site had been a blue plastic, sodium hydroxide neutralization tank. The tank has been excessed.

**Location:** The tank was located inside the 211-BA building, north of 221-B.

**Related Sites/Structures:** The site is associated with the B Plant chemical sewer.

**Process Description:** Chemical waste from 221-B and 217-B flowed through underground chemical sewer lines to a lift station located near the southwest corner of 211-BA. The effluent was pumped out of the chemical sewer and into 211-BA building where it was diverted either to the acid neutralization tank or the sodium hydroxide neutralization tank to adjust the pH levels. The neutralized waste was released back into the underground chemical sewer line for disposal.

**Waste Type:** Process Effluent

**Waste Description:** Approximately 400 gallons (1,514 liters) per year of 2 Molar sodium hydroxide is neutralized with 800 pounds (360 kilograms) per year of monosodium phosphate.

### Storage

**Code:** 221-B-WS-1  
**Classification:** Accepted  
**Reclassification:** None

**Names:** 221-B-WS-1; B Plant Storage

**Type:** Storage  
**Start Date:**

**Status:** Inactive  
**End Date:**

**Description:** This cell is a heavy walled concrete pit with a concrete block cover. The cover is the only
means of entry. The cell is currently used for contained storage.

Location: Cell 4 is located near the west end of the B Plant Canyon, inside 221-B.

Related Sites/Structures: Structures associated with this cell include: the hoist and cover blocks, the canyon deck, and any equipment or piping which remains in the cell.

Process Description: This cell is now used to store drums of solid mixed waste (with no free liquids).

Waste Type: Process Effluent

Waste Description: Material stored in this area includes light bulbs with lead solder, and other solid mixed waste.

Description: The TPA and the RCRA Part A Permit Application classify this site as a waste pile that lies within a containment building. The site encompasses solid mixed waste (jumpers, counterweights, failed process equipment, and shielding) that is stored in cells and on the canyon deck.

Location: The location of the waste piles include the 221-B Canyon Deck and Cells, inside 221-B.

Related Sites/Structures: Since this storage site includes the canyon deck and most of the cells, there are many structures associated with the site. Associated structures include: piping, tanks, cells, overhead equipment, tools, instrumentation, and process materials.

Process Description: The designation of this area as a Treatment Storage or Disposal Unit is intended to satisfy requirements for the storage of solid/mixed waste within the canyon cells and on the canyon deck.

Waste Type: Equipment

Waste Description: This waste includes jumpers, and other failed or isolated process equipment which may have been contaminated with wastes from fuel processing.

Waste Type: Equipment

Waste Description: This waste includes lead shielding in the cells and on the canyon deck.

Description: This tank is a stainless steel cylindrical tank.

Location: The tank is located on the south side of cell 26.
Related Sites/Structures: Structures associated with the tank include piping and fittings, the other cell 26 tanks, equipment, and instrumentation.

Process Description: This tank was used to support the solvent extraction and organic treatment process that was performed at the B Plant to recover strontium from PUREX acidified sludge.

Waste Type: Process Effluent

Waste Description: This tank received organic mixed waste from the solvent extraction process of the strontium recovery program. The tank is maintained ready for use on an as needed basis.

Status: Inactive
Classification: Accepted

Description: The tank is only visible if the cell cover blocks are removed. The tank is a 7,571 liter (2000 gallon) stainless steel tank.

Location: The tank is located inside cell #27, inside the 221-B Plant canyon.

Process Description: The 221-B-27-2 tank is part of the organic mixed waste storage system that was contained in cells 26, 27, 28, 29 and 30 of the B Plant canyon. The organic waste was used in the recovery and purification of strontium and cesium.

Waste Type: Water

Waste Description: The tank contained organic mixed waste used in the recovery and purification of strontium and cesium.

<td></td>
</tr>
<tr>
<td>Location:</td>
<td>This building lies south of the 221-B Canyon, and west of 222-B Laboratory.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>Structures associated with this facility include tanks, agitators, process equipment, and instrumentation.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process Description:</td>
<td>The 224-B Concentration Facility received dilute plutonium nitrate solution that was the product of the 221-B Bismuth Phosphate process. This facility purified and reduced the volume of product. After concentration, the plutonium nitrate product was then shipped from 224-B to the 231-Z Isolation Building. The Plutonium Concentration Facility concentrated the liquid output from the plutonium separations plant from 1,249 liters to 30 liters. The concentration took place in six radiologically contaminated process cells (Cells A, B, C, D, E, &amp; F), located in the southeastern 1/3 of the 224-T building. The cells contained various tanks and piping. Cells A, B, D, and E contained a 40 inch centrifuge on a platform. Cell C is a pit that connects to the underground pipe tunnel from Sections 13 &amp; 14 of 221-T. Cell F was &quot;L&quot; shaped and included an office and a glass enclosure where partial finished product was collected for transfer to 231-W. The contaminated process cell equipment was flushed when the process was terminated (1960's). The amount of radiological or regulated material remaining within the process cells and piping is unknown. The plutonium concentration process was identical to the concentration process done at 224-T in 200 West Area. A thorough radiological characterization was done of the 224-B Hot Cells in 1985. An inventory of radioactive material remaining in the 224-B hot cells, based on average measurements, estimated 1.1 curies of cesium-137, 22 curies of strontium-90, 3.7 curies of cobalt-60, 5 curies of americium-241, 31 curies of plutonium-239 and 2 curies of other plutonium isotopes.</td>

</tr>
<tr>
<td>Description:</td>
<td>Documents dated 1987 and 1992 described the site known as the 226-B Hazardous Waste Storage Area (HWSA) as a concrete pad surrounded by a light chain barricade. It was posted with &quot;226-B Hazardous Waste 90-Day Staging Area&quot;, and &quot;PCB 30 Day Storage&quot; signs.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Additional information was provided by Ron Weissenfels (B-Plant Engineer) in 1998 that described the area as temporarily being three separate storage pads located north of B-Plant, and adjacent to the 211-BA and 219-B Buildings. However, a field visit in April 2000 found only one small, locked metal shed labeled "226-B<90 Day Storage - Dangerous/Hazardous Waste". Correspondence with the responsible contractor confirmed that the three pads were consolidated into one location prior to the area being turned over to WESF (Waste Encapsulation and Storage Facility).

Location: The pad is located north of B Plant, north of 211-BA and 219-B Buildings.

Related Sites/Structures: This storage pad is associated with B Plant activities and 200-E-32.

Process Description: This staging area provides temporary (less than 90 days) storage for hazardous wastes. The first waste receipt was on May 30, 1985.

Waste Type: Storage Tank

Waste Description: The staging areas temporarily store a wide variety of dangerous waste. Examples of waste previously stored here include: halogenated hydrocarbons, caustic liquids, acids, solvents, toxic chemicals and coolants and PBC's.

The Following Sites Were Consolidated With This Site:

<table>
<thead>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200-E-32</td>
<td>200-E-32; 226-B Pad East Side 90-Day Waste Accumulation Area</td>
<td>The WIDS site has been evaluated and reclassified to Rejected. TPA-MP-14, Rev. 2, Section 2.0 states that WIDS does not document buildings or facilities that do not contain TSD units. It further states that, after buildings are demolished, the footprint will be evaluated for potential soil contamination. If present, the soil contamination will be added to WIDS as a Discovery Site. The facility remains in a shutdown condition. The following sections describe as of September 1998. The 242-B Building was constructed in 1952 and used during the Hanford production plant era as a waste tank supernate evaporation facility. It is a twin to 242-T evaporator building. Originally, the building consisted of three sections. The north section contained the evaporator vessel (a steam-heated pot evaporator) along with the associated process components. The center section consisted of the control facilities (plutonium laboratory, storage room, change room, office area, and lunch room). Use of the building as an evaporation facility was terminated in 1962. At that time, Rooms 1 and 2 of 242-B were cleaned up to some extent and the waste evaporation equipment was removed and buried. The 242-B building became a research facility operated by PNL-BNW.</td>
</tr>
</tbody>
</table>

Location: 242-B Evaporator is located on the north side of the 200 East Area, north of the 221-B (B Plant) building. It is about 21.3 meters (70 feet) south of tank 241-B-104, south of the 241-B Tank Farm fence.

Related Sites/Structures: 242-B Evaporator interconnected with the following 242-B building components: cyclone stainless steel catch tank (75 gallons/284 L), cyclone separator, condenser, two catch tanks (4,185 gallons/15,840 L), feed tank (4,185 gallons/15,840 L), two pre-heaters (75 gallons/284...
**Process Description:**
The 242-B Facility was the former first cycle evaporator building and former control building. The evaporator was installed to evaporate cladding/first cycle waste and reduce the waste volume.

In the 1960's, PNL began using the facility as an Aerosol Research Facility. Studies such as free fall of powders and liquids and the burning of various types of materials were conducted. PNL also participated in tests on ruptured fuel, conducted in 242-B and 242-BL.

From 1970 through 1980s, the 242-B Building, except Rooms 1 and 2, was used for research on radioactive particles. This work consisted of simulating accidents related to airborne releases of radioactive material using depleted uranium as the particle. A wind tunnel and radioactive aerosol release tanks (RART) remain installed in Room 4 of the facility.

**Waste Type:** Equipment

**Waste Description:** Soil contamination exists external to the facility, a historical legacy because of diverter box failure from the tank farm operations in the nearby 241-B Tank Farm. Tank 241-B-103 historically would "burp" and contaminate the surroundings. The 207-B basin also was known to have "upsets' which led to field contamination in the general area.

**Code:** 215-C  
**Classification:** Not Accepted

**Names:** 215-C; 215-C Gas Preparation Building  
**Reclassification:** None

**Type:** Process Unit/Plant  
**Start Date:** 1/1/1949  
**End Date:** 1/1/1985

**Description:** The 215-C Gas Preparation Building is single-level concrete building that was within the radiation control area for the Semiworks Complex. The building has two rooms and a gas bottle storage area on the south side of the building. The building is now adjacent to the Hot Semi Works surface stabilized area, known as WIDS sitecode 200-E-41. Site visits in 2005 and 2007 found a Contamination Area posting is attached to the stairway to the 215-C roof, indicating contamination on the roof.

TPA-MP-14, Rev. 2, Section 2.0 states that WIDS does not document buildings or facilities that do not contain TSD units. Therefore, this has been classified as Not Accepted. It further states that, after buildings are demolished, the footprint will be evaluated for potential soil contamination. If present, the soil contamination will be added to WIDS as a Discovery Site.
Location: This building is located in the Semiworks Area, directly south of Seventh Street.

Related Sites/Structures: The associated structures for this site include other Semiworks facilities, and the equipment stored within the building.

Process Description: The 215-C Gas Preparation Building was constructed to support the 201-C Process Building. It provided compressed air for pneumatic equipment and instruments. It also supplied inert gas for use in the 201-C Building. In 1985, the unit was decontaminated and almost all equipment was removed from in and around the building. It has later been used for the storage of miscellaneous equipment. The building is currently empty, except for one or two pieces of original equipment. There are no active systems. The electricity to this facility was disconnected and removed from the pole in 1997.

Waste Type: Steam Condensate

Waste Description: The unit consists of a previously radioactively contaminated structure. The building was decontaminated in 1985, and was subsequently used to store equipment. The Semiworks Aggregate Area Management Study Report (DOE/RL-92-18) does not show any remaining radionuclide waste inventory for the 215-C Building.

<tr>
<td>Description</td>
<td>The ash pit is a large open depression located east of the 284-E Powerhouse. The Ash Disposal Pile is a large mound of material dredged, over years of operation, from the Ash Pit.</td>
</tr>
<tr>
<td>Location</td>
<td>The Ash Pit is located inside 200 East Area, south of 4th Street and 30 meters (100 feet) east of the 284-E Powerhouse. The Ash Disposal Pile is located east of the Ash Pit.</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>This pit received ash from the 284-E Powerhouse.</td>
</tr>
<tr>
<td>Process Description:</td>
<td>The site received ash from the 200 East Powerhouse. The powerhouse consisted of three coal fired boilers that were used to generate steam for the 200 East Area. An ash and water slurry was produced when the ash was sluiced from the powerhouse. The slurry was placed in the 200 East Powerhouse Ash Pit. When the ash pit became full, heavy equipment was used to remove the ash from the pit and place it in the Ash Disposal Pile, located east of the Ash Pit. The ash pit is a large basin divided into two parts by an earthen dam. Ash slurry could be directed to either compartment. The compartments were used alternately to allow one side to dry while the other was being filled. The rate of ash generation was approximately 9,480 cubic yards per year (7252 cubic meters per year) when the powerhouse was active. The pit capacity was approximately 81,020 cubic yards (61980 cubic meters) of ash. The dried ash was removed (pushed with bull dozers) periodically from the ash basins and placed in the eastern portion of the Ash Pit (known as the disposal pile). As of April 2000, the remaining ash in the pit and disposal pile is estimated to be less than a meter deep.</td>
</tr>
<tr>
<td>Waste Type:</td>
<td>Process Effluent</td>
</tr>
<tr>
<td>Waste Description:</td>
<td>A waste determination of the Hanford Site 200 Area steam plant ash was performed in the early 1990s. The coal ash waste stream was determined to be nondangerous. Samples were analyzed using the TCLP (Toxicity Characteristic Leaching Procedure), and all were below the regulatory limits. Eleven sample results were also reported for pH: the results ranged from 7.66 to 11.91, with an average of 9.27. The second and third highest pH results were 10.09 and</td>
</tr>
</tbody>
</table>
9.94. The rate of ash generation was approximately 9,480 cubic yards per year (7252 cubic meters per year) when the powerhouse was active. The pit held approximately 81,020 cubic yards (61980 cubic meters) of ash.

<td>200-E-8; 200 East Trench 94 Diesel Spill</td>
<td>Unplanned Release</td>
<td>1/1/1995</td>
<td></td>
</tr>
</tbody>
</table>

**Description:**
The spill occurred in the northwest portion of Trench 94. There is no longer any visible evidence of the spill. The spill site was remediated on June 15, 1995.

**Location:** Trench 94 is in the northeast corner of the 218-E-12B Burial Ground. The burial ground is in the northeast corner of 200 East Area.

**Release Description:** On May 1, 1995, the Westinghouse Solid Waste Management group was notified that discolored soil had been observed in the northwest corner of Trench 94. The spot measured 9.7 meters by 4.5 meters (32 feet by 15 feet). The spill was determined to be a release of approximately 37 to 40 liters (10 to 15 gallons) of diesel oil. The soil was discolored and had a diesel fuel odor. The soil was saturated, but there was no standing liquid. It appeared that the spill had occurred approximately one week previous to being reported.

**Related Sites/Structures:** The site is associated with the 218-E-12B burial ground.

**Waste Type:** Process Effluent

**Waste Description:** The spilled material consisted of 38 to 57 liters (10 to 15 gallons) of diesel oil to the soil.

**Description:**
The chemical demolition site is no longer marked or posted. A single event of thermal treatment of abandoned chemicals occurred in November 1984. The RCRA TSD was closed in 1995.

**Location:** The site was located in the northeast corner of 200 East Area, inside the 200-E Burn Pit. It is east of the 218-E-8 Burial Ground.

**Related Sites/Structures:** The site is associated with the 200 East Burn Pit (200-E BP).

**Process Description:** The site was used as a thermal treatment (detonation) pit for excess shock sensitive or potentially explosive chemical waste in 1984. A single event of thermal treatment of abandoned...
chemicals occurred in November 1984.

**Waste Type:** Process Effluent

**Waste Description:** This unit had detonations of the following chemicals: 1984: Isopropyl Ether 8 L (2.1 gal), 1,4-Dioxane 1,250 mL (0.33 gal), 2-Butoxyethanol 19 L (5.0 gal), Methyl Ethyl Ketone 177 mL (0.05 gal), Hydrogen Peroxide 11.36 L (3.0 gal), Dioxane 946 mL (0.25 gal), Sodium Azide 473 mL (0.12 gal), Phosphoric Acid 189 L (0.05 gal); 1985: None; 1986: None.

**Code:** 200-E-9

**Names:** 200-E-9; 2607-EN; 2607-EN Septic Tank/Pump Station; 2727-E Septic System

**Type:** Septic Tank

**Status:** Active

**Description:** The above ground area is posted "Septic Tank 2607-EN". The area is surrounded with metal fence posts and chain. Three concrete and one PVC cylinders (manholes) with covers protrude above grade in the underground tank area. The surface is disturbed and covered with Russian thistle, cheat grass, and other weedy species. Two "Sanitary Tile Field" signs are located south of the septic tank.

**Location:** The site is 75 feet south of the southwest corner of the 2727-E Safeguards and Security Building (which is in 200 East Area on 4th Street).

**Related Sites/Structures:** The 2727-E building was serviced by this septic system.

**Process Description:** Receives sanitary sewage from 2727-E Safeguards and Security Building.

**Waste Type:** Process Effluent

**Waste Description:** Sanitary sewage from 2727-E Safeguards and Security Building.

---

**Code:** 200-E-10

**Names:** 200-E-10; 200-E-3 Toluene Dump Site; Paint/Solvent Dump South of Sub Trenches

**Type:** Dumping Area

**Status:** Inactive

**Description:** A site visit in 1997 identified a large gravel depression north of 241-AN Tank Farm. The site consists of an area within this large depression. The bottom of the depression has hard pan type soil, while the sides are gravel and sand. Asphalt and other debris are on the sides of the road berm. Another site visit in May 2004 found the appearance has not changed. There is no definite visual evidence of liquid dumping. The actual dumping area is not marked or posted.

**Location:** The site is located north of 241-AN tank farm and west of Canton Avenue inside the 200 East Area.

**Release Description:** In 1991, it was reported that approximately 39 liters (10 gallons) of toluene was dumped inside the pit north of 241-AN Tank Farm during the summer of 1984 or 1985. In 1995, two ICF Kaiser painters reported disposing of liquid paint waste to the ground inside the pit north of 241-
AN Tank Farm. They recalled dumping approximately 95 liters (25 gallons) of liquid in one visit and another 95 liters (25 gallons) in a second visit. In 1996, a visit to the pit with one of the painters verified the pit north of 241-AN Tank Farm, just west of Canton Ave. as the dumping site location. He indicated the place in the southeast portion of the pit as the area affected by the dumping. It measured approximately 9 meters by 9 meters (30 feet by 30 feet).

**Waste Type:** Process Effluent  
**Waste Description:** The waste dumped into the pit included approximately 229 liters (60 gallons) of paint wastes like toluene, solvents, and methyl ethyl ketone. CERCLA reportable quantities are listed at 40 CFR 302, in Table 302.4. The RQ for toluene is 1000 lbs. There is no RQ listing for paint. The reported disposal at 200-E-10 was 25 gallons (twice) = 50 gallons, or about 400 pounds. Conservatively estimating the paint as 100% toluene, the disposal was less than the CERCLA RQ. Therefore, the release was not (is not) a threat to human health and the environment.

</table>

**Code:** 200-E-11  
**Names:** 200-E-11; Diesel Oil Spill at BX-BY Tank Farm  
**Type:** Unplanned Release  
**Status:** Inactive  
**Description:** The site is a spill of non-regulated diesel oil on August 7, 1995. The oil and soil were excavated and the site backfilled by September 7, 1995.  
**Location:** The incident occurred just outside the fence directly west of tanks BY-112 and BY-111.  
**Release Description:** A fuel truck driver on his daily refueling rounds discovered a leak of diesel oil from a generator. It was discovered that about 75 to 95 liters (20 to 25 gallons) had leaked out of the unit's two 57-liter (15-gallon) tanks. The oil had leaked out of a failed gasket on the fuel suction line between the tank and first fitting. The tanks were cascaded, and thus the fuel from the second tank was siphoned out. An analysis of the fuel was made, and it was determined that the fuel was non-regulated.  
**Waste Type:** Process Effluent  
**Waste Description:** The spill was diesel oil.

**Code:** 200-E-12  
**Names:** 200-E-12; Sand Piles from RCRA General Inspection #200EFY95 Item #5  
**Type:** Laboratory  
**Status:** Inactive  
**Description:** A 1995 site inspection discovered this site and described it as two sandy areas which are a different color sand than the surrounding sand. The two sand piles were approximately 27 meters (30 yards) apart. During a February 1997 visit, an empty, stainless steel tank and a nearby pit were also observed at the site. The tank, labeled "X-12," measured 1.47 meters (58 inches) high and 1.35 meters (53 inches) in diameter. The area has been roped off with steel posts and rope. The sandy areas were approximately 3.7 meters (4 yards) in diameter. The site
was visited again on August 26, 1998, for a GPS survey. The two sand piles appeared to have been removed; only traces of the piles remained. Between the remains of the two sand piles were equipment for some sort of experiment. A small pit with deteriorated clear plastic was observed by the "X-12" tank. The experiment equipment consisted of two large polypropylene water tanks, a large rectangular pit and a metal frame set up over the pit. One of the tanks was 2.7 to 3.0 meters (9-10 feet) tall with a 2840 liter (750 gallon) capacity. It was labeled "Non Hazardous River Water" and appeared to be approximately half full. The second water tank was only about 1.5 meters (5 feet) tall and had a larger diameter than the first tank. It was also labeled "Non Hazardous River Water" and appeared to be approximately three-quarters full. There were no volume markings on this tank. The shorter tank was also posted "Experiment in Process, Contact Ray Clayton @ 372-6037." The rectangular pit was approximately 4.6 meters (15 feet) long and 1.5 meters (5 feet) wide and 0.9 meters (3 feet) deep. The bottom of the pit was covered with a tarp and the sides appeared to be covered with plywood. Over the top of the pit was a metal frame suspending a spray device over the pit. The site was revisited on July 26, 1999, in order to confirm the current conditions of the site. The "X-12" tank is still there, sitting on a wooden pallet. The small pit with the deteriorated plastic is there and looks unchanged. The two large polypropylene tanks observed in 1998 are gone. The space where they had been located was occupied by wood debris and PVC pipe. The large rectangular pit has been filled in. What appears to have been the metal frame over the former pit is now lying on the ground to the north. A cylinder of compressed nitrogen is within 2 meters (6.6 feet) of the south sand pile remnant. The cylinder is labeled "For Research Use. Please do not move from this site. POC Fenton Khan 372-0426 or Janelle Downs 376-6641." The cylinder is resting on a metal plate and is secured to a metal post. This cylinder is the only material that is part of an ecological experiment for the vitrification project, and is separate from the other material found at the site.

Location: The site is located inside 200 East Area, southwest of PUREX. It is along a dirt road that runs north from First Street, approximately 0.8 kilometers (0.5 miles) west of the intersection of First Street and Canton Avenue. The site is approximately 0.5 kilometers (0.3 miles) north of First Street.

Process Description: After some research, it was discovered that the sand piles, identified in 1995, are actually the remains of several experiments in preparation for locating a suitable site for long term storage for vitrified material. The sand piles are evidence of seasonal soil infiltration tests, using water. The sand is not a waste site. Later, PNNL used the same area for water infiltration tests.

---

Code: 200-E-16  
Classification: Accepted  
Reclassification: None  
Names: 200-E-16; B Plant Waste Concentrator; Low Level Waste Concentrator; Single-Stage Thermal Siphon Reboiler  
Type: Evaporator  
Status: Inactive  
Start Date:  
End Date:  
Location: The low-level waste concentrator is located in cell #23 of building 221-B. Cell #23 is the first cell east of 221-BC.  
Process Description: The low-level waste concentrator was operated to concentrate the low-level waste in the low-level waste storage and treatment tank system. The low-level waste concentrator is a thermal siphon and shell and tube heat exchanger. This system has been used only for concentration of the B Plant Complex low-level waste stream. No NCAW waste has been concentrated with the B Plant low-level waste concentrator. This system currently is inactive with no intention of resuming operation and is included to reflect past operations. The low-level waste concentrator system includes the following equipment: the waste concentrator (E-23-3), the deentrainer (D-
Rev. 24
DOE/RL-88-30
23-2), the condenser (E-23-4), and receiving tank (TK-23-1). The maximum process design capacity for the low-level waste concentrator is 7,300 gallons (27,633 liters) per day.

**Waste Type:** Process Effluent

**Waste Description:**

**Description:** The 200 Area Liquid Effluent Retention Facility (LERF) is comprised of a group of surface impoundments. The site is surrounded by a fence (about 700 meters by 400 meters). The three LERF basins are located in the southern portion and are numbered from west to east as 242AL42, 242AL43, and 242AL44, respectively. Each basin is constructed with 2 liners; a leachate collection system; sampling and liquid level risers; and a floating cover. There are three metal buildings within the fence.

**Location:** The basins are located in the northeast corner of 200 East Area; about 300 meters south of the 2025E building and just east of Canton Ave.

**Related Sites/Structures:** Double Shell Tanks (DST), 242-A Evaporator, 2025E, 200 Area Effluent Treatment Facility (ETF), 600-211 (SALDS).

**Process Description:** Mixed waste from the Double-Shell Tank System is transferred to the 242-A Evaporator, where the waste is concentrated by evaporation. The evaporated constituents are recondensed, collected, and transferred to LERF. Other facility effluents may be added later. The effluent is stored in the basins until it is processed by the 200 Area Effluent Treatment Facility (ETF). Waste from the ETF may be recycled via the LERF for additional treatment.

**Waste Type:** Water

**Waste Description:** Process condensate from the evaporator contains small amounts of volatile and semivolatile organics; inorganics; and radionuclides. By permit, constituents may include spent halogenated and non-halogenated solvents and ammonia.

**Description:** The 216-B-3 Borrow Pit is a shallow, scarred gravel area adjacent to the northeast corner of the backfilled 216-B-3 Pond. It is slowly revegetating with native grasses and crested wheatgrass, but large areas of bare ground remain.

**Location:** The site is located east of the 200 East Area perimeter fence. It is northwest of the backfilled 216-B-3 Main Pond, and north of a posted Underground Radioactive Material Area (the 216-B-3 Ditches).
### Process Description:
Fill material was taken from this area in 1994 for 216-B-3 stabilization activities. No waste has been placed into the borrow pit.

### Related Sites/Structures:
The borrow pit is associated with the 216-B-3 Pond.

### Code: 200-E-20
**Classification:** Not Accepted  
**Names:** 200-E-20; 218-E-10 Annex; 218-E-10 Borrow Area; 218-E-10 Borrow Pit; Unused Portion of 218-E-10 Burial Ground

### Type: Depression/Pit (nonspecific)
**Start Date:** 1/1/1980

### Status: Inactive
**Description:** The area is posted with signs that read "Do Not Enter - 218-E-10 Burial Ground - Authorized Personnel Only." The area has revegetated naturally.

### Location:
The site is located inside the 200 East Area, north of the 218-E-10 burial trenches. It is near the corner of 12th Street and Akron Ave.

### Related Sites/Structures:
The borrow pit and unused designated trench area is associated with the 218-E-10 Burial Ground. The unused portion of the burial ground is associated with WIDS sitecode 200-E-292, which documents a small amount of debris.

### Process Description:
The area was originally reserved for additional 218-E-10 Burial Ground trenches. No additional burial trenches were placed in this area. In 1980, clean backfill material was taken from the east side of the unused Annex area to surface stabilize the eastern 10 hectares (25 acres) of the 218-E-10 burial ground trenches. No waste has been placed into the pit. Only clean backfill material has been removed.

### Code: 200-E-21
**Classification:** Not Accepted  
**Names:** 200-E-21; 218-E-12A and 218-E-12B Borrow Pit; 218-E-12A and 218-E-12B Soil Borrow Area; Pit 33

### Type: Depression/Pit (nonspecific)
**Start Date:** 1/1/1979

### Status: Active
**Description:** The 218-E-12A / 218-B-12B Burial Ground Borrow Pit is a large scraped area located west of the 218-E-12A Burial Ground and south of the 216-B-2 Covered Ditches. It is not marked or posted.

### Location:
The Borrow Pit is located west of the 218-E-12A Burial Ground and south of the 216-B-2 Covered Ditches.

### Related Sites/Structures:
The borrow pit is associated with 218-E-12A and 218-E-12B Burial Grounds.

### Process Description:
Clean backfill material from this borrow pit area was used on both the 218-E-12A and 218-E-12B Burial Grounds. The 218-E-12A Burial Ground was initially surface stabilized with material from this borrow pit in 1980. The southeast portion of the 218-E-12B Burial Ground was surface stabilized with material from this borrow pit in 1981. Additional backfill material was added to the burial grounds from this borrow pit in 1994. No waste has been placed into the borrow pit.

### Septic Tank

**Code:** 200-E-24  
**Classification:** Accepted  
**Reclassification:** None  
**Start Date:**

| Description: | The septic and dosing tank area (about 60 ft by 10 ft) has five manholes at grade and two 7-ft high 4-in diameter metal pipe air vents. The drain field is within a fenced area about 300 ft north of the septic tank area. The drain field fenced area is about 360 feet by 130 feet and has six valve boxes and a gate at the south end. The drain field consists of three trenches and one trench reserved for future use. |
| Location:    | The site is west of B-Plant and east of route 4 south. It is east of 2704-HV and west of the 216-B-62 crib. A GPS survey was done in August 1998. |
| Process Description: | This system receives sanitary sewer from 2704-HV, 2701-HV, MO723, MO850, MO046. |
| Waste Type:  | Sanitary Sewage |
| Waste Description: | This system receives sanitary sewage from 2704-HV, 2701-HV, MO723, MO850, MO046. |

### Septic Tank

**Code:** 200-E-28  
**Classification:** Accepted

---

_Hanford Site Waste Management Units Report_  
February 2015
Names: 200-E-28; 221-B Building Contaminated Steam Condensate Release
Reclassification: None
Type: Unplanned Release
Start Date: 1/1/1990
Status: Inactive
End Date: 
Description: The release occurred inside the 221-B building. Liquid was observed seeping through the 221-B Canyon wall expansion joint located between cells 38 and 39 in the electrical gallery. Visible portions of the expansion joint are 3/4" to 1" wide however, the actual point of release is below grade and is not visible. The expansion joint is located 40 feet from the west end of the building between cells 38 and 39.
Location: The release occurred at the 221-B Building (B Plant), 40 feet from the west end and under 221-B Building.
Release Description: On July 17, 1990, a nuclear process operator discovered a solution seeping from the expansion joint between cells 38 and 39, inside the electrical gallery. The seepage was collecting in the gallery floor sump. It was later determined that the release involved approximately 80,000 gallons to 230,000 gallons (over a one year time span) of radioactive steam condensate that could not be accounted for. The steam condensate contained Sr-90 and Cs-137. It is assumed to have been released to the soil column.
Related Sites/Structures: The release is associated with B Plant operations.
Waste Type: Steam Condensate
Waste Description: The waste was approximately 80,000 to 230,000 gallons of steam condensate contaminated with Cs-137 and Sr-90 that leaked through the expansion joint between cells 38 and 39 of the B Plant Canyon Building directly into the soil column.

Code: 200-E-32
Classification: Accepted
Names: 200-E-32; 226-B Pad East Side 90-Day Waste Accumulation Area
Reclassification: Consolidated (4/20/2000)
Type: Storage Pad (<90 day)
Start Date: 
Status: Inactive
End Date: 
Description: This site is a duplicate of 226-B HWSA, according to Fen Simmons, the Environmental Compliance Officer for the facility. It was entered into WIDS as a Discovery site in 1996 in error. In addition, it was entered at a time when WIDS was required to track<90 Day Storage Pads. WIDS is no longer required to track these areas per TPA-MP-14.
This Site Was Consolidated With:
Code: 226-B HWSA
Names: 226-B HWSA; 226-B Hazardous Waste Storage Area

Code: 200-E-33
Classification: Accepted
Names: 200-E-33; PUREX 214-A 90-Day Waste Accumulation Areas
Reclassification: Rejected (9/14/2000)
Type: Storage Pad (<90 day)
Start Date: 
Status: Inactive
End Date: 1/1/1996
Description: This 90 day storage area and any residual contamination were removed when PUREX was
closed down and cleaned to meet the deactivation end point criteria prior to transition from Westinghouse Hanford Co. to Bechtel Hanford Inc. (BHI).

**Location:**
The unit was the 214-A Bay Dangerous Waste Storage area in PUREX.

**Related Sites/Structures:**
This pad was one of the 90 day storage areas for PUREX.

<tr>
<td>Description: The site had been a concrete pad with a peaked roof supported by beams. The sides were fenced. The east side of the pad was the Hazardous Material storage area. The west side of the pad was the mixed waste storage area. In 2011, amended water was sprayed during the 209E building demolition activities. Post-demolition, three to six inches of surface material was removed from all areas affected by the amended water and prior to applying a gravel cap. The final gravel cap was expanded to cover all affected areas. The posted URMA was expanded to include the entire gravel cap. The gravel cap now covers several WIDS sites. The additional WIDS sites under the 209E gravel cap are 200-E-4, 200-E-35, 209-E-WS-1, 209-E-WS-2, 2718-E-WS-1 and 200-E-293 (2718E footprint). The 209-E-WS-3 (Tank 111), adjacent to the south side of the foundation, is within the URMA but was not covered or backfilled.</td>
<td></td>

</tbody>
</table>
### Storage Pad (<90 day) - Inactive

**Description:** This site has been inactive at least since 1993, according to the current (May 2000) manager of 90 Day Pads for the River Protection Program (RPP). Its previous location is unknown, but only enclosed conex boxes (self-contained with a spill berm) had been used for 90 Day Storage in the past in the tank farms. This 90 Day Area was moved to RPP's only remaining 90-Day Area, at 209-E (200-E-35) before 1993.

**Related Sites/Structures:** This site was associated with the 241AZ Tank Farm.

</thead>
</table>

**Description:** A release from the PUREX stack caused a ground surface contamination area adjacent to the
outside east of the PUREX perimeter fence measuring approximately 2.6 hectares (6.5 acres). The site is not currently marked or posted.

**Location:** The site was adjacent to the east side of the PUREX exclusion fence.

**Release Description:** On July 18, 1985 a radiation survey of the ground adjacent to the east PUREX fence and around Air Sampler #971 found contamination levels ranging from 300 counts per minute to 5,000 counts per minute. The area was posted as a Surface Contamination Area. On 8-6-86 the site was assigned the Unplanned Release number UN-216-E-34.

**Process Description:** During PUREX operations, ammonium nitrate would build up on the 291-A stack walls. Periodically the material build up would flake off and was blown out of the stack with the stack air flow. The flakes were distributed on the ground around the stack and the surrounding area, dependent on wind direction and velocity.

**Waste Type:** Process Effluent

**Waste Description:** Gamma Spectrum Analysis of ammonium nitrate flakes from the PUREX stack showed the flakes contained 2.53 microcuries of ruthenium-106, 0.05 microcuries of ruthenium-103, 2.56 microcuries of rhodium-106 and 0.01 microcuries of cesium-137.
Waste Description: The site is a 9 meter (30 foot) long steel I beam.

Code: 200-E-49
Names: 200-E-49; Borrow Pit North of BC Cribs and Trenches
Type: Depression/Pit (nonspecific)
Status: Inactive
Description: The site is a shallow, scraped area located north of the BC Trenches. The borrow pit is currently located inside the boundary of the posted BC Radiologically Controlled Area (WIDS sitecode UPR-200-E-83) and is considered part of the BC Controlled Area.

Location: The site is located south of 200 East Area on the south side of Route 4S.

Related Sites/Structures: The borrow pit is associated with the surface stabilization of the BC Cribs and Trenches (216-B-14 through 19 Cribs, and Trenches 216-B-21 through 34 and 216-B-52 through 58) and the BC Controlled Area (UPR-200-E-83).

Process Description: Because of recurring surface contamination problems, the surfaces of the backfilled 200 BC Cribs and Trenches were surface stabilized beginning in August of 1981. Clean backfill material was taken from the area north of and adjacent to the BC Trenches. No waste was placed into the borrow pit.

Code: 200-E-50
Names: 200-E-50; 284-E Brine Pit; 284-E Salt Dissolving Pit and Brine Pump Pit
Type: Sump
Status: Inactive
Description: The brine pit is no longer visible. It was cleaned out, demolished into itself, and backfilled with gravel in 1999. It is not marked or posted. The salt dissolving pits and brine pump pit were part of a single below-grade concrete structure that provided brine for the 284-E Powerhouse.

The two salt dissolving pits each had inner dimensions of 4.3 meters (14 feet) long by 2.4 meters (8 feet) wide by 2.8 meters (9.25 feet) tall. They had a designed high water line 2.4 meters (7.75 feet) from the pit bottom. An overflow slot connecting the two dissolving pits was located 0.3 meters (1 foot) above the high water line. The bottom of each pit was filled with a 12.7 centimeter (5 inch) layer of 1.3 to 2.6 centimeter (1/2 to 1 inch) gravel topped by a 17.8 centimeter (7 inch) layer of 0.3 to 0.6 centimeter (1/8 to 1/4 inch) gravel. The dissolving pits each had a 2.4 meter (8 foot) by 0.9 meter (3 feet) opening at the top for receiving salt. Each pit had a capacity of 23,600 kilograms (52,000 pounds) of salt.

The brine pump pit was located adjacent to the two salt dissolving pits. The pit was 3.3 meters (10.67 feet) long by 2.2 meters (7.33 feet) wide by 2.1 meters (7 feet) deep. It held two pumps and associated piping (all brass) for the brine system. The floor of the pump pit sloped toward a 46 by 46 by 46 centimeter (18 by 18 by 18 inch) sump in a corner.

Location: The brine pit was located south of the 282-E Water Reservoir near the railroad track.

Related Sites/Structures: The site is associated with the 284-E Powerhouse.
### Process Description:
The brine was used to regenerate the ion exchange demineralizers that were part of the powerhouse water treatment system. The brine was created by adding water to the salt in the dissolving pit. As the water passed through the salt, the solution became saturated. The brine passed through the layers of gravel which filtered out salt crystals and other particles. The filtered brine was then drawn off by a pipe connecting to the adjacent brine pump pit. A float valve was used to maintain the water/brine level.

**Waste Type:** Steam Condensate

**Waste Description:** The structure was cleaned out, demolished, and buried in place.

</tr>
<tr>
<td>Location</td>
<td>The washdown pit is south of the 200 East Powerhouse and coal ramp.</td>
</tr>
<tr>
<td>Related Sites/Structures:</td>
<td>The pit is associated with the 284-E Powerhouse.</td>
</tr>
<tr>
<td>Process Description:</td>
<td>The powerhouse coal ramp was washed down periodically. The washdown water was collected in three sumps. During the summer months, the sumps were pumped approximately two times per week, discharging the water into the washdown pit. During the winter months, the sumps were pumped two times per day. When the 284-E Powerhouse began shut down activities in December 1997, the pit became inactive. The process was eliminated from the Inventory of Miscellaneous Streams report in June 1998.</td>
</tr>
</tbody>
</table>

**Waste Type:** Steam Condensate

**Waste Description:** The pit received effluent pumped from sumps that held coal ramp wash water.

---

| Code: | 200-E-52 | Classification: Accepted |
| Names: | 200-E-52; 200 East Powerhouse Coal Pile |
| Type: | Depression/Pit (nonspecific) |
| Status: | Inactive |
| Description: | Only a shallow surface covering of coal remains at the site. On the east and south banks there are large pieces of metal debris (I-beam, metal grate). A coal-covered metal plate covers the chute to the conveyor belt. |
| Location: | The coal pile was located south of the 284 Powerhouse and east of the coal ramp. |
| Related Sites/Structures: | The site is associated with the 284-E Powerhouse. |
**Process Description:** Large piles of coal had been stored in this area to fuel the 284-E Powerhouse. The powerhouse was shut down in December 1997.

**Waste Type:** Steam Condensate Waste Description: A thin layer of coal and coal dust remains on the surface of the area. A few pieces of metal debris are located at the east end of the coal storage area. A waste determination for Anthracite (Anthrafilt) was performed in 1994. A waste determination for bituminous coal dust was performed in 1996. The waste streams for both types of coal were determined to be nondangerous.

</tr>
<tr>
<td>Type: Unplanned Release</td>
<td>Start Date: 1/1/1991</td>
</tr>
<tr>
<td>Status: Inactive</td>
<td>End Date:</td>
</tr>
</tbody>
</table>

**Location:** The release occurred south of the 202 A building, inside the PUREX facility fence.

**Release Description:** On January 13, 1991 (ref. occurrence report RL--WHC-PUREX-1991-035) a raw water line ruptured in the basement of the 293 A building, resulting in over 380,000 liters (100,000 gallons) of water flooding the basement and backing up into the PUREX Canyon exhaust ventilation ductwork, including the #1 deep bed fiberglass filter. At the time of the release, pumping the water to the tank farms was not possible due to limited available tank storage space. Disposing the water to a crib was ruled out due to the radionuclide content. While disposal options were being sought, the liquid remained in the ventilation ductwork for 21 months. Since the ductwork was not designed to retain liquids, the possibility of a release to the environment was reported in September 1992. Approval to transfer the liquid to the tank farms was given in September 1992. Based on the original release estimate of 380,000 liters (100,000 gallons), it is believed that 201,400 liters (53,000 gallons) leaked to the soil over the 21 months from the release date to the date the liquid was transferred.

**Waste Type:** Ash Waste Description: The water leaked into the soil over a period of 21 months.

**Description:** The site is a circular stormwater drain with a metal-grate cover. The drain is considered to be active.
### Location:
The site is located north of 202-A (PUREX Canyon), at the northwest corner of the asphalt walkway leading from the guard house to 202-A.

### Waste Type:
Oil

### Waste Description:
The site receives stormwater runoff from the north side of the PUREX facility.

#### Code: 200-E-62
#### Classification: Accepted
#### Names: 200-E-62; 202A Building Steam Condensate; Injection Well (Z); Miscellaneous Stream #71
#### Description: The drain has a portion of metal culvert extending above the surface. It has a metal cover with a rusty pipe going into it. The steam plant that fed the pipeline that drained condensate to this site has been shut down and could not be easily re-started.
#### Location: The site is located inside the PUREX fence, on the north side of 203-A, north of the containment dike for tank TK-P3. It is south of 275-EA.
#### Process Description:
Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.
#### Waste Type: Steam Condensate
#### Waste Description:
The site received non-contaminated steam condensate.

#### Code: 200-E-63
#### Classification: Accepted
#### Names: 200-E-63; Injection Well (AA); Line #8801 Steam Condensate; Miscellaneous Stream #72
#### Description: The drain is a 1.22 meter (4 foot) diameter, concrete drain with a metal cover.
#### Location: The site is located north of 202-A, on the northwest corner of the 211-A tanks, between tank TK-41 and the 211-A chemical access railroad tracks.
#### Process Description:
Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.

visible from the surface. The site received steam condensate.

**Location:** The site is located on the northeast side of 202A, next to the north wall of the 206-A fractionator.

**Process Description:** Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.

**Waste Type:** Demolition and Inert Waste

**Waste Description:** The site received non-contaminated steam condensate.

<td>Inactive</td>
</tr>
<tr>
<td>Description</td>
<td>A piece of 1/2 inch diameter PVC pipe extends approximately 0.6 meters (2 feet) out of the ground on the north side of the 2712-A building. No drain is visible at this location. It is assumed that a drain pipe from the 2712-A building may have been previously connected to this PVC pipe. It is also possible Stream ID #459 is a duplicate of 216-A-35, located west of the 2712-A building. 216-A-35 is a 1.5 meter (4 foot) diameter drain extending approximately 0.3 meters (1 foot) above ground and is painted yellow.</td>
</tr>
<tr>
<td>Location</td>
<td>The Inventory of Miscellaneous Streams Report states this drain is located on the southwest corner of the 202-A building. The coordinates in listed in the document place it in the same location as 216-A-35. A PVC drain pipe is located adjacent to the north wall of 2712-A Building, south of 202A. This is a possible location of Stream #459, since the building contained pumps.</td>
</tr>
</tbody>
</table>

**Process Description:** The site documented site description for stream #459 has created some confusion. In 1998, when the site walkdown was done, the 2712-A Building housed air sampling pumps. This building was considered the source of pump seal water drainage. The Inventory of Miscellaneous Streams Report states that Stream ID 459 received pump seal water, but indicated it was located near the southwest corner of 202-A. The coordinates in the document indicate it is in the same location as 216-A-35.

**Waste Type:** Process Effluent

**Waste Description:** The site received pump seal water.

*Hanford Site Waste Management Units Report*

February 2015
Status: Inactive  
End Date: 1/1/1997

Description: The site received steam condensate. It is now a pile of rust colored rocks and broken clay tile pipe.

Location: The site is located southeast of the 291-B Sand Filter, adjacent to the steam line.

Process Description: Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.

Waste Type: Process Effluent
Waste Description: The site received non-contaminated steam condensate.

---

Code: 200-E-89  
Classification: Accepted
Names: 200-E-89; B Plant Yard Steam Condensate; Miscellaneous Stream #4
Reclassification: None
Type: Injection/Reverse Well  
Start Date:
Status: Inactive  
End Date: 1/1/1997
Description: The site is a 0.9 meter (3 foot) diameter cement culvert with a rusted metal lid, used for draining steam condensate.

Location: The site is located south of the 292-B Building, adjacent to the steam line.

Process Description: Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.

Waste Type: Process Effluent
Waste Description: The site received non-contaminated steam condensate.

**Code:** 200-E-93  
**Classification:** Accepted

**Names:** 200-E-93; B Plant Yard Steam Condensate; Miscellaneous Stream #8

**Type:** Injection/Reverse Well  
**Start Date:**

**Status:** Inactive  
**End Date:** 1/1/1997

**Description:** The site is a 0.9 meter (3 foot) diameter concrete culvert with a metal cover. Approximately 0.3 meters (1 foot) of the structure is aboveground. The drain structure has been damaged. One side is broken.

**Location:** The site is located adjacent to the south side of the 292-B Building.

**Process Description:** Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.
DOE/RL-88-30
Rev. 24

Code: 200-E-95  Classification: Accepted
Names: 200-E-95; 222B Steam Condensate;  Reclassification: None
Quit: Miscellaneous Stream #308
Type: French Drain  Start Date:
Status: Inactive  End Date: 1/1/1994
Description: The site is a 0.4 meter (18 inch) diameter french drain with a blue metal cover. The drain received steam and air conditioner condensate originating from inside the 222-B Building. The place where the source pipe protruded from the concrete block wall above the drain is visible, but it was cut and capped inside the building.
Location: The site is located adjacent to the north wall of the 222-B building, near the northeast corner of the building.
Process Description: The drain received steam and air conditioner condensate. Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion. The air conditioner condensate was atmospheric moisture condensing on the cooling coils.
Waste Type: Process Effluent
Waste Description: The site received steam condensate and air conditioner condensate. The condensate was batch discharged during winter.

---

Code: 200-E-97  Classification: Accepted
Names: 200-E-97; 212B Building Steam Condensate;  Reclassification: None
Quit: Miscellaneous Stream #470
Type: French Drain  Start Date:
Status: Inactive  End Date: 1/1/1997
Description: The site is a 0.4 meter (18 inch) diameter cement french drain with no lid. The cement drain structure has a cement ring that rises 5 centimeters (2 inches) above the surrounding grade. It is filled with dirt and is dry.
Location: 212-B is located near the southwest corner of the canyon 221-B building. This drain is located adjacent to the north wall of the 212-B building, in between 212-B and 221-B.
Process Description: Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.
Waste Type: Process Effluent
Waste Description: The drain received steam condensate from the 212-B building.
Reclassification: 200-E-98; 271B Building Ice Machine Overflow; Miscellaneous Stream #490

French Drain

Status: Inactive

Start Date: 1/1/1997

End Date: 

Description: The drain is not visible. A sheet metal shroud and a guard rail have been placed over the area that included the drain to keep small animals from accessing the building where pipes were removed. A portion of the source pipe is visible protruding from the cement block wall above the shroud. The pipe has been cut and capped. The shroud was placed over the site to keep stormwater and animals out of the basement of the 271-B Building. When the pipe connecting the air compressors in the basement with the air tanks outside was disconnected (see attached photo, blue structure on right is the tank, blue pipe above is the air pipe), a potential entry point for stormwater and animal entry into the building remained. The steel cover protects the building.

Location: The site is located adjacent to the east wall of 271-B.

Related Sites/Structures: The site is associated with the 271-B building.

Process Description: The drain received overflow drainage from an ice machine in a second floor lunchroom, via a copper pipe through a cement block wall. The stream was eliminated as a Miscellaneous Stream in July 1997.

Waste Type: Process Effluent

Waste Description: The drain received overflow from an ice machine located inside 271-B.

---

Reclassification: 200-E-99; Miscellaneous Stream #570; Steam Trap 2P-Yard-MSS-TRP-017

French Drain

Status: Inactive

Start Date: 1/1/1998

End Date: 

Description: There is no drain structure. It is a low spot in the soil where the steam line discharged steam. The rocks and soil are stained with rust. There is a tag on the steam line that identifies it as MSS-TRP-017.

Location: The site is located adjacent to the steam line, east of the 291-B Sand Filter, near Baltimore Ave.

Process Description: Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.

Waste Type: Process Effluent

Waste Description: The site received non-contaminated steam condensate.
**Code:** 200-E-100  
**Classification:** Accepted  
**Names:** 200-E-100; Miscellaneous Stream #571; Steam Trap 2P-Yard-MSS-TRP-019  
**Reclassification:** None  
**Type:** French Drain  
**Status:** Inactive  
**Start Date:**  
**End Date:** 1/1/1998  
**Description:** The site is a low spot in the ground under the steam line where steam discharged. The rocks and soil are slightly stained with rust. There is a tag that identifies it as MSS-TRP-019.  
**Location:** The site is located east of the 291-B Sand Filter, near Baltimore Ave. It is 6 meters (20 feet) west of the steam trap MSS-TRP-017 (site code 200-E-99).  
**Process Description:** Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium). The treated water was introduced into boilers to produce steam. This steam was superheated before distribution to facilities for heating and process use. Disposal sites received steam condensate from the steam distribution lines. When used for heating purposes, this was a seasonal discharge. Non-regulated chemicals were added to dechlorinate the water, prevent scale, and control corrosion.  
**Waste Type:** Steam Condensate  
**Waste Description:** Steam was produced from sanitary water that had been sent through a water softener system to remove minerals (calcium and magnesium).

---

**Code:** 200-E-105  
**Classification:** Accepted  
**Names:** 200-E-105; Soil Contamination Area on the 216-B-61 Crib  
**Reclassification:** Rejected (7/28/2008)  
**Type:** Unplanned Release  
**Status:** Inactive  
**Start Date:**  
**End Date:**  
**Description:** This site had been a radiologically posted area located on top of the 216-B-61 Crib and also extended to an area where loose tumbleweeds had accumulated between the south edge of the crib and a soil berm. The posted areas had been designated as Soil Contamination Area (SCA) and Contamination Area (CA). Later, only a very small posted (1.2 by 1.2 meters) Contamination Area, located approximately 30 meters (100 feet) west of the 216-B-61 crib remained. In October 2003, the remaining area was also down posted. All the individual radiological postings have been removed. Since the 200 East Area perimeter fence is posted as a Radiologically Controlled Area (RCA), everything inside the fence is technically a RCA.  
**Location:** The site located in the northwest portion of 200-E Area, south of 12th Street. It is northwest of the Hanford Prototype Barrier that covers the 216-B-57 Crib.  
**Waste Type:** Process Effluent  
**Waste Description:** The contamination is a result of blown-in tumbleweeds.

---

**Code:** 200-E-106  
**Classification:** Discovery  
**Names:** 200-E-106; IDF Integrated Disposal Facility; IDWF; ILAW; Immobilized Low-Activity Tank Waste; Immobilized Low-Activity Waste  
**Reclassification:** None  
**Type:**  
**Status:**  
**Start Date:**  
**End Date:**  
**Description:**  
**Location:**  
**Waste Type:**  
**Waste Description:**
As of January 2002, the plans for this site are to construct trenches in the middle of the southern section of the 200 East Area.

The area designated for the trenches is between 1st and 4th Streets and between the coal plant and the PUREX facility in 200 East.

The tank waste remediation program will separate the wastes into two fractions. One fraction, consisting of high-activity wastes, will be vitrified and stored at Hanford until a national repository can be licensed. The low-activity wastes will also be vitrified, but permanently disposed at Hanford in the Immobilized Low-Activity Waste vaults.

The waste disposed in these trenches will be vitrified low-activity waste from the single and double-shelled tanks. More than 200,000 cubic meters (7,000,000 cubic feet) of waste is expected to be disposed at the site.

The site is located within a large chain link fenced area with a locked gate. It is an empty hole in the ground that has been covered with a piece of plywood.

This site is a discontinued 90 Day Storage Pad. Material had been stored in two, self-contained steel cabinets. When the 90 Day Storage Pad was no longer needed, the empty cabinets were moved to the 226-B laydown area. There is no visual evidence remaining at the location of where the cabinets had been located.

The pad was located near the southeast corner of the intersection of 7th and Atlanta Avenues, southwest of the 225-B Waste Encapsulation and Storage Facility (WESF).

This site was related to the 225-B Building.

The cabinets contained PCBs, solvents, and dangerous and mixed wastes.
Waste Type: Process Effluent
Waste Description:

Code: 200-E-122  Classification: Accepted
Names: 200-E-122; CF Bullpen; Construction Forces Bullpen; Equipment Storage Yard; Laydown Yard
Type: Storage  Start Date: 
Status: Inactive  End Date: 1/1/2004
Description: The site had been an equipment/material storage yard that was enclosed in a locked, chain link fence. The fence was marked Radiological Buffer Area. Inside the fence, several groups of material were surrounded with radiation rope and marked with Contamination Area signs. Some of the material inside the fence includes, scaffolding, barrels, wood, scrap metal, wooden crates, tables and cabinets. In 2004, the area was cleaned up. The chain link fence was removed. No posted contamination areas remain. A single post and WIDS sign marks the area.
Location: The site is located south of B Plant and south of 222-B.

Waste Type: Process Effluent
Waste Description: Radioactively contaminated material was stored inside the fenced area.

Code: 200-E-126-PL  Classification: Accepted
Names: 200-E-126-PL; Underground Pipeline from 207-B to 216-B-3 Ditch
Type: Radioactive Process Sewer  Start Date: 1/1/1987
Status: Inactive  End Date: 1/1/1997
Description: Due to the restructuring of Operable Units, as described in the Tentative Agreement for Central Plateau Cleanup, this pipeline has been split into segments (200-E-126-PL-A and 200-E-126-PL-B). The waste site was originally described as an underground pipeline from 207-B Retention Basin to the 216-B-3A, 216-B-3B and 216-B-3C Ponds. The portion of pipeline east of Canton Ave. (that fed the B Pond lobes) is being excluded from this site description because it is being re-used to feed the Treated Effluent Disposal Facility (TEDF) and is active (see 600-291-PL). The pipeline from 207-B to Diverter Station #2 is constructed of 56 centimeter (22 inch) diameter plastic pipe (subsite 1). The pipeline east of Diverter Station #2 splits into two pipelines. Southern part extends from Diverter Station #2 to the head end of the 216-B-3 ditches. It is constructed of 53 centimeter (21 inch) diameter vitrified clay pipe (subsite 2). The northern part extends from Diverter Station #2 to Diverter Station #3 and is constructed of 61 centimeter (24 inch) diameter corrugated metal pipe (subsite 3). The pipelines are marked with steel posts and Underground Radioactive Material - Pipeline signs. A piece of (30 inch) diameter corrugated Metal pipe that connects the southeast corner of 216-B-3A pond to the northeast corner of 216-B-3C pond. It is considered part of this waste site (subsite 4) because it is associated with pond effluent distribution and is not part of the TEDF system.
Location: The pipeline extends eastward from the 207-B Retention Basin, to Diverter Station #2. The pipeline splits into two branches east of Diverter Station #2. A portion of pipeline extends from Diverter #2 to the 216-B-3 ditches. A branch of pipeline extends eastward from Diverter Station #2 and runs to Diverter Station #3. A separate section of corrugated metal pipe
connects the southeast corner of the 216-B-3A Lobe to the northwest corner of the 216-B-3C lobe.

Related Sites/Structures: The site is associated with Diverter Stations #2 and Diverter Station #3 (see sitecode 200-E-118) as well as the 207-B Retention Basin, B Plant, PUREX and the 200 East Powerhouse. Portions of the original pipeline were re-used to feed the TEDF system (600-291-PL).

Process Description: The pipeline conveyed B Plant effluent to the 216-B-3 Pond and Ditch system. B Plant cooling water effluent was originally routed through the 207-B Retention Basin to the 216-B-2-1, 216-B-2-2 and 216-B-2-3 ditches. In 1987, the 216-B-2-3 ditch was closed and was replaced by this, 22 inch diameter plastic underground pipeline. It extended from the 207-B basin to Diverter Station #2. By 1994, all of the open ditches (216-B-2-1, 216-B-2-2, 216-B-2-3, 216-B-3-1, 216-B-3-2 and 216-B-3-3) had been backfilled and surface stabilized. After 1994, all the effluent was conveyed to the 216-B-3A and 216-B-3C pond lobes only through underground pipelines. In 1995 the ponds were closed. The remaining effluent was transferred the Treated Effluent Disposal Facility (TEDF). Parts of the pipelines east of 200 East Area, that had fed the ponds, were re-used to feed the TEDF disposal basin. The TEDF portion begins at Manhole #8 and extends to Pump Station #3. In the event of a failure at Pump Station #3, the effluent can be routed to 216-B-3C (C lobe). The section that connects the southeast corner of 216-B-3A to the northwest corner of 216-B-3C is constructed of 76 centimeter (30 inch) corrugated metal pipe.

Waste Type: Process Effluent

Waste Description: The pipeline transported 221-B Plant, PUREX, and 200 East Area Powerhouse effluent that included process cooling water, steam condensate and chemical sewer waste.

This Site has the Following SubSites:

Code: 200-E-126-PL:1
Names: 200-E-126-PL:1; 22-Inch Diameter Poly Pipe from 207-B to Diverter Station 2

Code: 200-E-126-PL:2
Names: 200-E-126-PL:2; 21 Inch Vitrified Clay Pipe from Diverter Station 2 to the Head End of 216-B-3 Ditches

Code: 200-E-126-PL:3
Names: 200-E-126-PL:3; 24-Inch Corrugated Metal Pipe from Diverter Station #2 to Diverter Station #3

Code: 200-E-126-PL:4
Names: 200-E-126-PL:4; 216-B-3B; 216-B-3C and 216-E-28 Contingency Pond; Pond Inlet Piping to 216-B-3A

Code: 200-E-126-PL:5
Names: 200-E-126-PL:5; 30-Inch Corrugated Metal Pipe Connecting 216-B-3A Pond to 216-B-3C Pond

Code: 200-E-126-PL:1 Classification: Accepted

Names: 200-E-126-PL:1; 22-Inch Diameter Poly Pipe from 207-B to Diverter Station 2 Reclassification: Rejected (10/19/2010)

Type: Radioactive Process Sewer Start Date:

Status: Inactive End Date:

Description: This subsite became part of 200-E-126-PL-B.

Location: The pipeline segments in this waste site are located inside 200 East Area, west of the Inner/Outer Area boundary. The waste site begins at the 207-B retention basin and terminates at the Inner/Outer Area boundary.
The SubSite is Part Of:
Code: 200-E-126-PL
Names: 200-E-126-PL; Underground Pipeline from 207-B to 216-B-3 Ditch
